### **B204 An Advanced Extraction Method for Cyanide Metabolite Using Magnetic Carbon Nanotubes Facilitated Dispersive Micro Solid Phase Extraction (Mag-CNT/d- $\mu$ SPE)**

*Sun Yi Li, BS\*, Sam Houston State University, Huntsville, TX 77341; Jorn Chi-Chung Yu, PhD, Sam Houston State University, Huntsville, TX 77341*

**Learning Overview:** After attending this presentation, attendees will better understand an advanced extraction process for the extraction of a cyanide metabolite from biological samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) reviewing the potential use of the cyanide metabolite 2-Aminothiazoline-4-Carboxylic Acid (ATCA) as a forensic marker in cyanide exposure and in medicolegal death investigation; and (2) demonstrating advancement of Mag-CNT/d- $\mu$ SPE in extracting ATCA from biological samples using a one-step derivatization approach.

Cyanide intoxication can occur due to accidental exposures in industrial settings, consumption of cyanide-containing foods, or by illegal uses of cyanide in suicide, homicide, or terrorist acts. Sensitive analytical techniques have been developed to detect cyanide from biological samples. However, due to the unstable nature and incomputable kinetics of cyanide in biological samples upon storage, the analysis of its metabolites is considered to be more feasible for the purpose of exposure confirmation. The detection of the minor metabolite of cyanide, ATCA, has been proposed as an alternative method to determine cyanide exposure because of its stability and specificity. Studies have been extensively published to extract ATCA using conventional Solid Phase Extraction (SPE) and Liquid-Liquid Extraction (LLE). This research of ATCA extraction based on d- $\mu$ SPE has also been demonstrated to be promising for biological samples. In this work, a brief review of studies on the potential use of ATCA as a forensic marker will be discussed, and the performance of an advanced Mag-CNT/d- $\mu$ SPE in extracting ATCA from biological samples will be presented.

The Mag-CNT used in this study were synthesized in the Sam Houston State University research laboratory. The application of Mag-CNT/d- $\mu$ SPE to extract ATCA from biological samples was found promising and has been published. In this work, the combination of desorption and derivatization steps of ATCA from the Mag-CNT surface into a one-step process was investigated. Deionized water was used in method development and synthetic urine was used in optimization steps. In a typical extraction process, 5mg of Mag-CNT was used to extract ATCA from 500uL of biological sample in a microcentrifuge tube, which was spiked with known amount of ATCA and its isotopic internal standard, ATCA-<sup>13</sup>C, <sup>15</sup>N. The samples were then acidified with hydrochloric acid, vortexed, and sonicated for d- $\mu$ SPE for 10min. After d- $\mu$ SPE, the Mag-CNT were isolated with the aid of a strong magnet and were dried at 65°C under vacuum. N-Methyl-N-(trimethylsilyl)trifluoroacetamide (MSTFA) was added to the dried Mag-CNT to derivatize and desorb ATCA, and the derivatized extracts were subjected to Gas Chromatography/Mass Spectroscopy (GC/MS) analysis. Optimization of the extraction parameters, including the amount of Mag-CNT, sample and derivatization volume, extraction and derivatization time, and dilution solvent systems was performed in triplicates.

The advanced Mag-CNT/d- $\mu$ SPE with the one-step derivatization approach was capable of reaching the detection limit of 5ng/mL and has a linear dynamic range between 10–1,000ng/mL, which is capable of detecting human endogenous level of ATCA in urine samples. The average extraction efficiency of 97.0% was obtained with a satisfactory bias and precision of  $\pm 20\%$  at the low, medium, and high level of quality control samples. It is envisioned that this advanced extraction platform will provide an additional tool for the quantitation of ATCA from biological samples with GC/MS analysis in forensic settings.

**Cyanide Metabolite, 2-Aminothiazoline-4-Carboxylic Acid, Magnetic Carbon Nanotubes**

### **B205 Direct Analysis in Real-Time Mass Spectrometry (DART®-MS) and Atmospheric Solids Analysis Probe/Mass Spectrometry (ASAP/MS) for the Detection and Analysis of Seed-Based Toxins**

*Edward Sisco, PhD\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Natalie Damaso, PhD, Oak Ridge Institute for Science and Education/FBI Laboratory, Woodbridge, VA 22191; Elizabeth Robinson, MS, National Institute of Standards and Technology, Gaithersburg, MD 20899; James M. Robertson, PhD, Reserve Support Unit, Quantico, VA 22135*

**Learning Overview:** After attending this presentation, attendees will have an understanding of how two ambient ionization MS systems could be used for the analysis of seed-based toxins in pure form or in the presence of the complex seed or seed mash matrices. This type of analysis could be crucial in suspected poisoning cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the necessary methods and capabilities for the detection of seed-based toxins in suspected poisoning cases through a rapid analysis that does not require any sample preparation.

Atmospheric Ionization Mass Spectrometry (AIMS) techniques (e.g., Direct Analysis in Real Time Mass Spectroscopy [DART®-MS] and Atmospheric Solid Analysis Probe/Mass Spectrometry [ASAP/MS]) have demonstrated utility for varying applications, such as psychoactive plant drug analysis and plant seed species identifications. These methods have been shown to be significantly faster than conventional methods without the need for sample pre-processing or derivatization steps. In cases in which poisonous plant evidence is to be identified, morphological characteristics are typically used in the initial presumptive identification. However, when there are no morphological characteristics, such as the case of seed mash, techniques such as DART®-MS or ASAP/MS may be helpful to presumptively identify possible poisons associated with the evidence. The chemical information from this type of presumptive analysis would aid toxicologists in deciding which extraction protocol (e.g., organic, acidic, or alkaline) to use for the isolation of the toxin from the mash. This would streamline the process of identification of the toxin present in the evidence.

This work provides the foundation to demonstrate the use of AIMS techniques (namely DART®-MS and ASAP/MS) for chemical analysis of seed-based toxins. In this project, a total of seven different toxins from five different seed species were targeted. Development of optimized methods for analysis required the ability to detect a large range of molecular weights and volatilities, necessitating some modifications from traditional analysis, specifically for DART®-MS. The use of techniques such as Infrared Thermal Desorption (IRTD) DART®-MS were employed to heat the sample to temperatures necessary for analyte desorption. From the optimal methods, instrument limits of detection of sub-nanogram to tens of nanograms was exhibited for DART®-MS, along with single to tens of micrograms per milliliter for ASAP/MS.

Analysis of actual seeds and seed mashes highlighted the rapid and sensitive analysis of these techniques for a presumptive test such as this. Detection of the toxin or toxins in the seeds was readily achievable, in most instances. For DART®-MS, samples were able to be analyzed as either an intact seed, dry seed mash, or extracted seed mash. For ASAP/MS, both the dry seed mash and extracted seed mash were capable of being analyzed, though for both techniques, the use of the extracted mash was superior.

The chemical information produced by these techniques also may allow for species identification. The mass spectral profile produced from all seeds analyzed, which included seeds from the same genus (i.e., *D. innoxia* and *D. stramonium*) and seeds of the same type (i.e., oleander) were compared using linear discriminant analysis. Differentiation of the species based on the chemical signatures was readily achievable in this instance, highlighting the ability to provide more information than just the toxin present. Current work is focusing on additional evaluations of this capability and on the use of random forest analysis to identify the most discriminative peaks for targeting purposes.

The use of AIMS techniques in the detection of seed mashes for the presumptive identification of toxins has not been demonstrated before. However, given the successful results of this work and the increasing usage of AIMS techniques, especially DART®-MS, in forensic laboratories, this offers a unique opportunity to deliver rapid presumptive information to toxicologists and investigators. The ability to also be able to obtain species-specific information using these tools could provide crucial information in these investigations.

#### **Toxins, Mass Spectrometry, Toxicology**

### **B206 The Determination of Total Tetrahydrocannabinol (THC) Concentration in Plant Material Via High Performance Liquid Chromatography With Ultraviolet Visible Diode Array Detection (HPLC-UV DAD)**

*Stephanie Olofson, MS\*, Arvada, CO 80002; Kaitlin A. Schroeder, MS, Colorado Bureau of Investigation, Arvada, CO 80002*

**Learning Overview:** After attending this presentation, attendees will understand the process of quantitative method development and validation, the extraction of THC's from plant material for quantitation, and examples of practical application involving casework performed by the Colorado Bureau of Investigation (CBI) Forensic Science Laboratory.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a guide for laboratories seeking to develop and implement a THC quantitation procedure for plant material.

The State of Colorado, per the Colorado Revised Statutes (CRS) 35-61-101, defines industrial hemp as “a plant of the genus *cannabis* and any part of the plant, whether growing or not, containing a delta-9-tetrahydrocannabinol (THC) concentration of no more than three-tenths of one percent (0.3%) on a dry weight basis”. Colorado statute SB17-090 indicates that the delta-9-THC concentration is determined by measuring the combined concentration of delta-9-THC and delta-9-Tetrahydrocannabinolic Acid (THCA). Colorado’s legalization of medical and recreational marijuana, as well as a thriving hemp industry, has created a need for the development and utilization of scientific methods to distinguish hemp from marijuana. Primarily focused on the critical value of 0.3% THC as defined by the CRS, an HPLC-UV DAD method was developed and validated by the CBI to evaluate plant materials with total THC concentrations between 0.1% and 10%.

Samples are initially analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) prior to quantitation. The quantitative method involves the concurrent preparation of a six-point calibration curve, three positive aqueous controls, two plant process controls, and case samples (prepared in duplicate). Sample preparation consists of an initial drying step, grinding of the plant material, thermal decarboxylation of THCA to THC, and extraction in methanol. Androstenedione is used as an internal standard. Additionally, samples undergo a profiling step *prior* to decarboxylation by HPLC-UV DAD. This step allows the analyst to understand the components of the sample and, when compared with the quantitated samples, demonstrates that complete thermal decarboxylation of THCA was achieved.

Analysis of case samples utilizing this method has produced a surprising variety of results. The laboratory has analyzed samples that were quantitated below the lower quantitative limit of the method (0.1% total THC's) as well as samples above 10% THC. Perhaps most surprising has been the number of *true* hemp samples received by the CBI for analysis and the variation observed in terms of their overall cannabinoid profiles and physical appearance.

The precision of the method was determined using ten replicate injections of six THC solutions with concentrations ranging from 5 to 250 $\mu$ g/mL ( $n=60$ ). The Relative Standard Deviation (RSD) was calculated at each concentration and all were less than 3%. The accuracy was determined by comparing one set of six calibrators with the corresponding target concentrations ( $n=6$ ). Again, the RSD was calculated for each level and determined to be less than 3%. The measurement of uncertainty for the method is 8.31%, reported as a relative percentage of the total THC concentration, and was determined using replicate samplings ( $n=32$ ) of a known plant sample (0.32% THC) obtained from the Colorado Department of Agriculture. The CBI has created a robust method for the determination of total THC concentration in plant material.

---

#### **Tetrahydrocannabinol, Quantitation, HPLC-UV DAD**

### **B207 High-Performance Thin-Layer Chromatography (HPTLC) Densitometric Analysis of Cannabinoids in *Cannabis sativa* L.**

Yifan Liu\*, Allentown, PA 18104-6132; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104; Matthew R. Wood, PhD, Ocean County Sheriff's Department, Toms River, NJ 08753; Marianne E. Staretz, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** The goal of this presentation is to report the results of the evaluation of different mobile phase systems for the analysis of cannabinoids in *Cannabis sativa* L. using HPTLC, as well as a method to differentiate marijuana samples from hemp samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reporting the results of the evaluation of ten mobile phase systems used in the HPTLC analysis of cannabis products. The most useful HPTLC systems for the analysis of cannabinoids in *Cannabis sativa* L. in forensic casework will be presented.

TLC is a planar chromatographic method that has been used as a routine, quick-and-easy tool for screening seized drugs in forensic casework. However, historically, traditional TLC has resulted in poor resolution due to systematic errors from hand-spotting, temperature/humidity control, and measurement of the Retardation factor ( $R_f$ ). HPTLC has been applied in the pharmaceutical field for years, yet it is not widely used in forensic science field. HPTLC has the potential to provide better resolution of forensic samples and to generate reports for more convenient documentation for peer review of casework.

There has been a variety of methods used to analyze cannabinoids by TLC, but the literature is void of a critical review of the different mobile phase systems. This presentation will report the results of the evaluation of ten different mobile phase systems for the analysis of cannabinoids in *Cannabis sativa* L. using HPTLC. All systems were run in triplicate.  $R_f$  were recorded and the resolution was calculated for 11 different cannabinoid certified standards. A CAMAG® HPTLC instrument setup was used for all analyses. The setup included an Automatic TLC Sampler 4, an Automatic Development Chamber 2, a TLC visualizer, and a TLC Scanner 3. HPTLC silica gel 60 F<sub>254</sub> 20 x 10cm plates were used for nine systems and an RP-18 WF 10 x 10cm plate was used for one additional system. Parameters for plate development included 30 seconds pre-drying, 20 minutes of humidity control and tank saturation with mobile phase, 70mm migration distance, and 5 minutes of drying after development. Samples were visualized on the plate under white light and at 254nm and 366nm wavelengths. A CAMAG® Chromatogram Immersion Device III was used to dip the developed plate into 0.5% Fast Blue B salt solution for five seconds. visionCATS CAMAG® HPTLC software (version 2.5) was used to control, document, and analyze all results from experiments. Two systems, xylene-hexane-diethylamine (25:10:1) and 6% diethylamine in toluene gave the best results in separating the three major cannabinoids,  $\Delta^9$ -*trans*-tetrahydrocannabinol ( $\Delta^9$ -THC), Cannabidiol (CBD), and Cannabinol (CBN). The results of the analysis of various cannabis products from casework will be presented.

The xylene:hexane:diethylamine (25:10:1) system was used to develop a calibration method for  $\Delta^9$ -THC. Regression analysis showed a linear relationship ( $R^2 > 0.99$ ) with a range of quantitation between 50–500ng. Marijuana samples and suspected hemp samples were able to be differentiated based on color intensity of sample when compared to standard calibrators of  $\Delta^9$ -THC and CBD.

HPTLC is a superior method to lower-resolution traditional TLC systems for qualitative identification of the common cannabinoids in cannabis products submitted to crime laboratories. It can also be used for quantitative analysis of THC in cannabis products when necessary. Using the proper mobile phase system with HPTLC can eliminate systematic errors from lower-resolution TLC, increase resolution, and make documentation easier. It is possible to differentiate hemp from marijuana, which could be very useful in cannabis casework, given recent legislative changes.

#### **HPTLC, Cannabinoids, Mobile Phase**

### B208 A New Analytical Scheme for the Analysis of Cannabis Plant Material: Marijuana or Hemp?

Sandra E. Rodriguez-Cruz, PhD\*, Drug Enforcement Administration, Dulles, VA 20166

**Learning Overview:** The goal of this presentation is to provide an overview of the new Drug Enforcement Administration's (DEA's) scheme for the analysis of cannabis submissions and the distinction between marijuana and hemp materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing a new analytical scheme for the analysis of cannabis.

Prior to December 2018, DEA laboratories used a three-tier analytical scheme for the analysis of cannabis submissions. This scheme consisted of macro and microscopical tests, the Duquenois-Levine (DL) color test, and separation analysis using either Thin-Layer Chromatography (TLC), Gas Chromatography/Flame Ionization Detector (GC/FID), or Gas Chromatography/Mass Spectrometry (GC/MS). For many years, this protocol for analysis provided the scientific foundation for reporting cannabis conclusions.

On December 20, 2018, the President of the United States signed into law the Agriculture Improvement Act of 2018 (Farm Bill), and with it, two significant changes were introduced. The new law includes an explanation of the term "hemp," now defined as "the plant *Cannabis sativa* L. and any part of that plant, including the seeds thereof and all derivatives, extracts, cannabinoids, isomers, acids, salts, and salts of isomers, whether growing or not, with a delta-9 tetrahydrocannabinol (THC) concentration of not more than 0.3 percent on a dry weight basis." As a second significant change, the new law also excluded the term "hemp" from the definition of marijuana in the Controlled Substances Act. These federal law changes directly affected the manner in which suspected cannabis submissions are analyzed by forensic chemists because the previously established analytical testing requirements—albeit sufficient for cannabis identification—were not fit for the purpose of assessing the level of THC present in a sample and, therefore, fell short of distinguishing between marijuana and hemp. In other words, unlike many other routine drugs encountered by analysts, the new "Farm Bill" requires the assessment of a quantitative property in order to provide a qualitative conclusion regarding the identification of marijuana submissions.

As a result of the federal law changes described above, a new analytical scheme was designed for the analysis of suspected cannabis materials submitted to DEA laboratories. In this presentation, this new testing protocol will be discussed. The new scheme includes macro and microscopical analysis, a new "typification" color test, and GC/MS analysis. The new color test allows differentiation between the two main chemotypes of cannabis by producing a pink color when the CBD concentration in the material is greater than THC (CBD > THC) or a blue color when THC > CBD. The GC/MS test is a limited-purpose method used to assess if the level of THC in a sample is above or below a decision limit of 1% (w/w). This presentation will include information on the background and validation of the new "typification" color test and on the scope, design, and validation of the GC/MS method. The discussion will also describe implementation of the new analytical scheme throughout DEA laboratories, as well as sampling and reporting requirements.

#### Cannabis, Marijuana, Hemp

## B209 Forty-Plus Ways Not to Analyze Beverages for Cannabinoids

Carl E. Wolf II, PhD\*, Virginia Commonwealth University, Health-Pathology Department, Richmond, VA 23298; Hedi L. Brightman, BS, Virginia Commonwealth University, Richmond, VA 23298; Justin L. Poklis, BS, Virginia Commonwealth University, Richmond, VA 23219-0613; William J. Korzun, PhD, Virginia Commonwealth University, Richmond, VA 23298

**Learning Overview:** After attending this presentation, attendees will understand the factors involved in selecting a method for the analysis of cannabinoids in beverages.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting approaches to determining acceptable methods for analyzing marijuana-infused beverages.

**Background/Introduction:** In the past decade, use of cannabinoids in the United States has increased tremendously. This increase has been primarily in marijuana-infused products, initially as food products and now as beverages. These products contain the psychoactive drugs delta-9-Tetrahydrocannabinol (THC) and/or Cannabidiol (CBD), and other cannabinoids. They are marketed and sold for their reputed medical and recreational properties. Regulation of these beverages exists only in the states in which they are legal. Federally, the United States Drug Enforcement Administration (DEA) has classified marijuana as a Schedule 1 substance. There is only one each United States Food and Drug Administration (FDA)-approved formulations of THC and CBD. In 2018, the Agriculture Improvement Act (Farm Bill) legalized hemp. This legislation does not address the formulation of marijuana-infused beverages, nor does it address the standardization of methods for potency analysis of these beverages. There is an increased need for accurate methods to determine THC and CBD content in these beverages. The three most common beverage matrices involve fermented (beer/ale), brewed (tea/coffee), and high sugar (soft drinks). Each of these matrices creates its own analytical challenges. Simple dilution methods with an aqueous or organic solvent are not plausible options for all beverages due to the potential for varying complex matrices (i.e., plant material, pulp, sugar, etc.), and the low solubility of cannabinoids in aqueous solvents.

**Objective:** To develop a method for the forensic analysis of cannabinoid-infused beverages.

**Methods:** More than 40 different methods were evaluated for Process Efficiency (%PE). These included simple dilutions, rapid solid Phase Extraction (SPE), and Quick, Easy, Cheap, Effective, Rugged, Safe (QuEChERS) methods, in which the aqueous and organic solvents were substituted or buffered in each method. To account for the low solubility of cannabinoids in aqueous solvents, the beverage was prepared by solubilizing the cannabinoids in an emulsion (surfactant [2% fruit pectin], carrier oil [12.6 % canola oil]), then adding the beverage (85.40%). %PE was determined at 14mcg/mL (5mg serving [ $n=3$ ]) in two different sets of samples for each extraction method. The before set was fortified before the extraction method, and the Non-Extracted External (NEET) standards were prepared in methanol. The %PE was determined using the post-extraction addition method. The %PE was calculated by using the average peak area of the before-fortified samples and dividing by the average peak area of the NEET samples, then multiplying by 100. An extraction method had an ideal %PE if the determined %PEs were within 75%–125% for all three matrices evaluated. A method had an acceptable %PE if determined %PE variations in all three matrices was  $<\pm 15\%$ . Samples analysis was performed using a previously presented and published high-performance liquid chromatography/tandem mass spectrometry cannabinoid method.

**Results:** In most extraction methods, %PE was similar between the fermented and brewed matrices, but the high sugar matrix was more than 20%–50% higher. The %PEs for the United Chemical Technologies Clean Screen FAST/THC 200mg/3mL (UCT THC) column for fermented, brewed, and sugar matrices were 40, 45, and 54%, respectively. Sample preparation involved 25mL of beverage, 225mL water, and 250mL acetonitrile, which was added to the UCT THC column and eluted with 80psi of air. The eluate was collected and analyzed.

**Conclusion:** No extraction method was determined to be ideal, but the UCT THC column was acceptable.

*This project was supported by a grant from the National Institute of Justice Research and Development in Forensic Science for Criminal Justice Purposes.*

### Cannabinoids, Beverage, THC

### **B210 An Analysis of Illicit Drugs by Portable Ion-Trap Gas Chromatography/Mass Spectrometry (GC/MS)**

*Leah Rynearson, BS, University of New Haven, West Haven, CT 06516; Zachary Lawton, MS, PerkinElmer, Inc, Shelton, CT 06484-4794; Meghann McMahon, MS, Wisconsin Department of Justice, Milwaukee, WI 53204; Pauline E. Leary, PhD\*, Federal Resources, Stanfordville, NY 12581; Koby Kizzire, PhD, University of New Haven, West Haven, CT 06516; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT 06516*

**Learning Overview:** After attending this presentation, attendees will understand the value of portable ion-trap GC/MS for the on-scene analysis of illicit drugs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and law enforcement community by examining the benefits and limitations of field deployable ion-trap GC/MS for the analysis of illicit drugs.

False positive results from on-scene illicit-drug analysis using presumptive color tests have caused numerous wrongful arrests. In many states, forensic laboratories do not ever receive evidence for confirmatory identification of the illegal substance unless the defendant goes to trial, which makes it impossible to know the severity of this problem. Additionally, some defendants take a plea deal, which can result in these defendants spending months or years in prison for a crime they did not commit. Improving the reliability of on-scene illicit-drug testing by incorporating confirmatory methods capable of achieving very low limits of detection, GC/MS into the field could help reduce these wrongful arrests.

The purpose of this research was to build a GC/MS spectral library of illicit drugs and some common additives for a commercially available portable ion-trap GC/MS. The instrument uses a toroidal ion trap, which has three major advantages over other portable GC/MS systems: (1) its small size, which is essential when designing an instrument optimized for portability; (2) its durability due to having no components that require the highly precise alignment of the standard quadrupole system; and (3) its higher operating pressure, which lowers pumping requirements. Due to the potential for space charge and other ion-ion interactions in ion-trap MS, a customized library for this type of field application is critical. Space charge occurs when too many ions are trapped in a small volume causing problematic ion-ion repulsions that can result in a shift in observed  $m/z$  values. Other ion-ion interactions can occur inside the trap, such as when ion fragments complex with each other, resulting in observed  $m/z$  values that are greater than those expected from the initial fragmentation that occurs during the ionization process. Since space charge and other ion-ion interactions may potentially occur with ion-trap systems, an electronic GC/MS library created using data collected from an ion-trap GC/MS is a necessary supplement to the National Institute of Standards and Technology (NIST) MS database because the NIST MS database is primarily comprised of quadrupole mass spectra. If the potential of space charge and ion-ion interactions is not accounted for during the library-search process, this behavior may result in a missed identification (e.g., false negative).

In this research, more than 50 common illicit drugs and 15 additives were used to create an ion-trap GC/MS library after repeated testing. Many of the tested compounds had mass spectra different from that of the NIST MS database due to the presence of space charge and/or other ion-ion interactions. The ion-trap GC/MS library was then used to test the ability to detect and identify illicit substances and their additives in seized drug samples. In addition, results were compared with data generated from the same samples using a field-portable quadrupole GC/MS. It was concluded that with additional library development, portable ion-trap GC/MS is a viable choice for the confirmatory identification of seized drugs in the field.

#### **Illicit Drugs, Portable GC/MS, Ion-Trap GC/MS**

### **B211 New Psychoactive Substances in Forensic Drug Cases: Crossing the Borders of Gas Chromatography/Mass Spectrometry (GC/MS) Selectivity**

*Ruben F. Kranenburg, MS\**, Dutch National Police, Amsterdam, NH 1014BA, NETHERLANDS; *Arian C. Van Asten, PhD*, University of Amsterdam, Amsterdam 1098XH, NETHERLANDS

**Learning Overview:** After attending this presentation, attendees will understand the limitations of traditional techniques for drug identification in the current market comprised of many isomeric substances; gain insight into novel tools to add complementary selectivity to GC/MS, such as Gas Chromatography-Vacuum Ultraviolet (GC-VUV); learn about strategies of “crossing borders” of traditional GC/MS selectivity; and get more out of current available data using chemometric tools and Likelihood Ratio (LR) calculations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, specifically drug experts, by enabling them to identify and overcome possible isomeric challenges in drug isomer analysis, reducing the risks for false positive or false negative results in case reports.

The global drugs-of-abuse market is facing major changes over the past decade. New Psychoactive Substances (NPS) form an emerging group of more than 700 synthetic drugs and are comprised of many closely related and isomeric classes of compounds. Most of these compounds are not legally controlled and are sold as “legal highs,” while others are banned substances in various countries. When a “legal high” is put under judicial control, other closely related yet uncontrolled compounds often increase in popularity and occurrence. This fuels a perpetual cycle in which increasingly diverse NPSs are continuously being developed.

This transformation of the drugs-of-abuse market changes the needs of forensic drug analysis laboratories. Established methods, such as GC/MS, fall short in terms of selectivity, as isomeric NPS have identical masses, very similar fragmentation spectra, and can co-elute in fast screening methods. Traditional spectroscopic measurements using Fourier Transform Infrared (FTIR) or Raman find limitations in multicomponent mixtures, as is often the case in adulterated samples or tablet formulations. Thus, in forensic laboratories, a need has arisen for analytical methods capable of distinguishing known, as well as identifying yet unknown, NPS isomers.

Three new strategies have been investigated in the Dutch National Police and University of Amsterdam groups to tackle the isomeric NPS dilemma: (1) VUV spectroscopy provides distinctive and very reproducible spectra for various ring-isomers. Selectivity-wise, GC-VUV is complementary to GC/MS for certain NPS classes consisting of both ring- and aliphatic chain isomers; (2) low-energy Electron Ionization (EI) on a Gas Chromatography/quadrupole Time-Of-Flight (GC/qTOF) system produces less fragmented, more information-rich, mass spectra for NPS isomers. Multivariate statistics were applied to discriminate among ring-isomers; and (3) Infrared Ion Spectroscopy (IRIS) at the FELIX laboratory successfully differentiated ring-isomeric forms of NPSs and correctly identified an NPS directly from a complex case sample. Finally, IRIS presents a promising approach for the identification of unknown NPSs for which reference standard compounds are not available when combined with quantum chemical prediction of IR spectra for candidate molecular structures.

#### **GC-VUV, NPS, Isomers**

### **B212 Implementing Raman Spectroscopy as a Tool to Characterize Sexual Assault Lubricants**

*Santana A.L. Thomas, PhD\**, National Center for Forensic Science, Orlando, FL 32816-2367; *Nicholas Andersen*, University of Central Florida, Orlando, FL 32816; *Mark Maric, PhD*, Orlando, FL 32816; *Candice Bridge, PhD*, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816

**Learning Overview:** This project is an extension of the National Center for Forensic Science Sexual Assault (NCFS SAL) database. The database provides analytical data of sexual lubricants obtained from Direct Analysis in Real Time-Time-of-Flight/Mass Spectrometer (DART®-TOF/MS), Gas Chromatography/Mass Spectrometer (GC/MS), and Fourier Transform Infrared Spectroscopy (FTIR). After attending this presentation, attendees will understand the significance of Raman spectroscopy for screening sexual assault lubricants and its ability to classify unknown lubricants.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a supplemental method to identify trace lubricant residue based on its distinct “chemical fingerprints.”

More than 10 % of sexual assault cases reported involve condom use. In these instances, the chance of retrieving DNA evidence becomes minimal, and, therefore, other pertinent evidence, such as trace lubricant, can assist with justification. Previous research of the NCFS lab demonstrates the confidence of identifying and classifying trace lubricant based on its chemical constituents. Protocols were established using DART®-MS, GC/MS, and FTIR to distinctly associate various types of lubricants produced by multiple manufacturers. Further investigation elaborates on the ability to use chemical components as a bias to confidently classify lubricants into distinctive groups (e.g., flavored water-based, anesthetic water-based).

Raman spectroscopy provides molecular identification based on inelastic scattering from a monochromatic light (laser source). The change in frequency of a photon after interacting with the sample defines Raman scattering. Raman spectroscopy is non-destructive, highly sensitive, and reproducible with the appropriate parameters. These advantages appeal to forensic labs, which increases its use in identifying trace evidence, including textile fibers, paint, polymers, pigments and dyes, cosmetics, and explosives. Raman spectroscopy has presented itself as a useful tool in criminalistics, especially in the analysis of polymers, such as lubricants. Therefore, expanding the SAL database with spectral analysis of lubricants using Raman spectroscopy can prove beneficial.

Fifty samples inclusive of 21 Personal Hygiene Products (PHPs), 12 bottled lubricants, and 17 condoms were analyzed using Raman spectroscopy. The PHPs included body washes and soaps, whereas the lubricants were representative of two types: water-based and oil-based. Spectra were obtained on neat lubricants and extracts in triplicates via Raman spectroscopy with a laser beam at 785nm. Statistical analyses were performed using Principal Component Analysis (PCA), Hierarchical Cluster Analysis (HCA), and Linear Discriminant Analysis (LDA) to classify the samples into groups based on shared components. After assessment of the neat samples, ten groups were established with 10% similarity based on the HCA dendrogram. Most of the samples clustered into groups could be identified by their obvious classes (lubricants vs. personal hygiene products); however, overlap was found, which will be discussed in the presentation.

#### **Raman Spectroscopy, Lubricants, Personal Hygiene Products**

### **B213 Assessing the Value of a Physical End Match in Trace Evidence: A Comparison of Human-Based and Computational-Based Approaches**

*Meghan Prusinowski, MS\*, Morgantown, WV 26505; Evie K. Brooks, BS, Statesville, NC 28625-9298; Pedram Tavadze, MS, West Virginia University, Morgantown, WV 26506; Aldo Romero, PhD, West Virginia University, Morgantown, WV 26506; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506*

**Learning Overview:** After attending this presentation, attendees will be informed regarding a developed systematic method for reporting the quality of a physical fit of duct tape edges, the results for inter- and intra-examiner variation in the reporting of a quantitative similarity score, and the comparison of human-based and computational-based approaches.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the value of physical fits in trace evidence. This presentation will also demonstrate the development of a systematic method on duct tape and highlight future research that aims to expand the materials and methodologies applied to the analysis of edges to offer additional support to inform the examiner's expert opinion.

Physical match examinations have played a critical role in forensic science for many years and extend across many forensic disciplines. The analysis of a potential physical fit involves an examination of separated edges to determine if the compared items re-align with distinctive features. In trace evidence, physical fits represent the highest degree of association between two items of evidence. As such, many examinations end once a fit is discovered and documented. Currently, physical fit examinations are being appraised to introduce a more standard and systematic methodology to support the opinions of examiners.

This work expands on the research presented by the West Virginia University group at the 2019 American Academy of Forensic Science conference regarding the comparison of duct tape edges using a systematic and quantitative method through an increased sample set, additional methods of interpreting the data, and assessment of intra-examiner and inter-examiner variation. In this study, edge similarity scores were utilized to assess 2,500 duct tape edges of varying grade, separation method, and degree of stretching. Edge similarity scores were calculated as a relative ratio of observed matching sections per scrim area. The performance rates of the method were calculated, and the distributions of scores were assessed to interpret the quality of a fit between edges. Overall, the method produced accuracies of between 84.9%–99.8% for the different tapes sets, with no false positives reported. It was found that the grade of the tape had a substantial impact on the quality of a fit between edges.

The distributions of edges were assessed utilizing Receiver Operator Curves (ROCs), boxplots, kernel density functions, beta distributions, and score likelihood ratios, demonstrating that a score of 80% or higher indicates strong support for a match, while scores below 25% indicate strong support for a non-match. Intra-examiner and inter-examiner variation were evaluated on blind sets of tape ends and agreement better than 15% was observed between reported edge similarity scores. Additionally, a machine learning algorithm was developed to predict if images of two pieces of duct tape coincide. The algorithm is based on Artificial Neural Networks (ANN) using the open-source python package scikit-learn. To train and use the ANN, first, the connectivity pattern of the network was defined. The architecture is defined by the number of initial input nodes, number of hidden layers with their corresponding neurons, and, finally, the number of output neurons. In the preliminary architecture of the network, five hidden layers with 200 nodes in each layer were chosen, using a constant learning rate; 200 matched the torn images, and 200 images were classified as not matched. The training step used 80% of this data and the rest was used to evaluate the accuracy of the model. Within these parameters, accuracy of ~85% was achieved, which was comparable to the examiner's performance.

**B214 A Survey of Elements Detected in Automotive Paint Layers by Scanning Electron Microscope/Energy Dispersive X-Ray Spectrometry (SEM/EDS)**

*Christopher S. Palenik, PhD\*, Microtrace, Elgin, IL 60123-4755; Ethan Groves, BS, Microtrace, LLC, Elgin, IL 60123; Lina Michely, PhD, Microtrace, LLC, Elgin, IL 60123; Yu Chen Lim, MS, Université de Lausanne, Lausanne, Vaud 1015, SWITZERLAND; Skip Palenik, BS, Microtrace, Elgin, IL 60123-4755*

---

**Learning Overview:** After attending this presentation, attendees will develop an understanding of the major, minor, and trace elements commonly detectable in automotive paint samples by EDS in an SEM.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community and, in particular, trace evidence analysts by providing an increased context by which to assess the significance of elemental data collected from automotive paint samples.

The elemental analysis of paint layers by SEM/EDS is a distinct step in the forensic comparison of automotive paint as defined by the American Society for Testing and Materials (ASTM) Guide E2809. While the elemental analysis of paint by SEM/EDS is utilized by many laboratories conducting paint analysis, case reviews and a review of several crime laboratory Standard Operating Procedures (SOPs) show that various stages of this process, from sample preparation through interpretation, could be better defined. A set of 300 automotive paint samples (i.e., street samples), comprising 1,203 individual layers, was employed to investigate each step of this process. Here, data on the elements that were detected in each layer of this automotive paint sample set are presented. While this is nominally a trivial process for major elements, the impact of closely spaced layers, the choice of analytical variables, and the challenges of objectively processing spectra demonstrate that this is not a trivial process for the determination of minor and trace elements.

Layers in each paint sample were delineated and identified as a clear coat, tinted clear coat, base coat, or primer by a combination of light microscopy and backscatter electron imaging. Using a thick section, each of the 1,203 layers (356 clear coats, 79 tinted clear coats, 347 color coats, and 421 primer layers) was then analyzed by EDS twice, first using livetimes of 20s and 200s. In both cases, analyses were performed from a manually drawn raster area within each layer. The resulting spectra were evaluated to determine which elements were detected in each layer. To avoid the subjectivity of manual peak assignments, this work evaluated several objective criteria for peak detection. Various combinations of the following approaches were compared: (1) a fixed element list, (2) an automated peak identification algorithm, (3) a 3-sigma detection limit threshold (based on the EDS counting error), and (4) fixed weight percent detection limit thresholds. Through iterative processing of the data, a fixed list of 24 elements was developed, which included every element detected in at least one of the 1,200 layers. Spectra from both the 20s and 200s livetime runs were then processed using three detection limits: 3-sigma (representing the lowest detection limit), 0.25wt-% fixed, and 0.50wt-% fixed (representing the highest detection limit). Using the highest detection limit (0.5wt-%) and a 20s analysis time, four elements (carbon [C], nitrogen [N], oxygen [O], and silicon [Si]) were detected in at least 40% of the clearcoats. Seventeen elements were detected in at least 1% of the color coats (C, N, O, magnesium [Mg], aluminum [Al], Si, phosphorus [P], sulphur [S], chlorine [Cl], potassium [K], calcium [Ca], titanium [Ti], chromium [Cr], iron [Fe], copper [Cu], zinc [Zn], and barium [Ba]). Seventeen elements were detected in at least 1% of the primer layers (C, N, O, Mg, Al, Si, P, S, Cl, Ca, Ti, Fe, Zn, tin [Sn], Ba, bismuth [Bi], and strontium [Sr]). The average number of elements detected in a given layer increased from the clear coat (four) to the color coat (seven) to the primer (nine). The 200s analyses increased the number of elements detected; however, this impacted only elements detected at low concentrations (i.e., near the detection limit).

These results have numerous practical applications: (1) each of the detected elements can be associated with an expected component in the paint (e.g., a binder, filler, pigment, or additive); (2) this data provides information about the frequency of particular elements in each layer of paint, as well as their anticipated concentration range in the paint; and (3) this dataset provides new insight into the significance of the suite of elements detected in a questioned automotive paint layer and sample, which may ultimately improve the value of elemental data obtained from paint samples.

### B215 Parameter Optimization and Validation for Qualitative Elemental Analysis of Electrical Tape Backings by X-Ray Fluorescence (XRF)

Evie K. Brooks, BS\*, Statesville, NC 28625-9298; Andria H. Mehlretter, MSFS, FBI Laboratory, Quantico, VA 22135; Susan M. Marvin, PhD, FBI Laboratory, Quantico, VA 22135; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506

**Learning Overview:** After attending this presentation, attendees will have learned of the benefit of implementing XRF in the analysis of electrical tape backings due to the rapid and non-destructive nature of the method. Attendees will gain an understanding of the key factors and potential interferences to assess when attempting to adapt this method for use in their respective laboratories while learning of the relevant figures of merit reported for the method on an XRF instrument.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the validation process of a rapid and non-destructive method for increased sample discrimination of electrical tape backings beyond traditional Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS) analysis.

Electrical tape becomes relevant forensic evidence in high-profile casework involving homicides or explosive devices. As such, it is critical that practitioners have access to rapid, minimally invasive techniques of analysis to best support these investigations. The characterization of electrical tape backings through XRF spectroscopy has been shown to be a highly discriminatory, non-destructive method of analysis requiring limited sample preparation. In a previous study by Prusinowski et al., XRF analysis of electrical tape backings exhibited increased discrimination from traditional SEM/EDS methodology from 78.8% up to 91.0%, making the method desirable for implementation in a forensic laboratory.<sup>1</sup>

This study describes the process of parameter optimization and validation of the method on an XRF spectrometer for casework use. This work expands upon the previous discrimination study by broadening the total sample set of characterized tapes from 40 to 90 samples. Replicate measurements on different locations of the tape sample were analyzed ( $n=3$ ) to assess the within-sample variability. XRF provided superior discrimination to SEM/EDS on the expanded dataset and a more comprehensive elemental characterization (17 elements by XRF vs. 8 by SEM/EDS). Duplicate controls and tape fragments from the same roll were also analyzed to assess inter-day, intra-day, and intra-roll variability. Parameter optimization included comparison of atmospheric conditions, collection times, and instrumental filters. A study of the effects of adhesive and backing thickness on spectrum collection revealed key implications to the method that required modification to the sample substrate. As an electrical tape standard reference material does not currently exist, the National Institute of Standards and Technology (NIST) Standard Reference Material (SRM) 1831, a standard soda-lime glass, was found to be an adequate reference material for tuning the instrument.

In addition to the parameter optimization, figures of merit assessed during the validation portion of this study included accuracy, precision, sensitivity, selectivity, and processed sample stability. By optimizing this technique for use on an XRF instrument, a new tool for rapid, highly informative elemental analysis of electrical tape backings was provided to expand examiners' casework capabilities.

### B216 A Quantitative Trace Elemental Analysis of Aluminum Materials for Forensic Discrimination

Michelle Jordan\*, Woodbridge, VA 22191; Christopher P. Saunders, PhD, Brookings, SD 57006; JoAnn Buscaglia, PhD, FBI Laboratory, Counterterrorism and Forensic Science Research Unit, Quantico, VA 22135

**Learning Overview:** After attending this presentation, attendees will understand how trace elemental analysis of aluminum (Al) materials by Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) can be used for source discrimination of Al samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a method to measure the trace elemental composition of Al samples, which can be used to discriminate among various sources of aluminum.

**Hypothesis Statement:** Quantitative measurement of trace elemental concentrations in Al materials by ICP/MS can discriminate between sources and provide valuable information regarding the exclusion or potential association of two compared samples.

Al is commonly used as a metallic fuel in the chemical mixtures of Improvised Explosive Devices (IEDs) to increase the heat of explosion. Various types of Al-rich products, including foil, paste, powder, cans, spray paint, pyrotechnics, and binary exploding targets are easily accessible to the general public and can provide the starting material for production of IEDs. Al powder from these sources can be produced inexpensively using simple, available techniques. This research developed a method to accurately and precisely measure the trace elemental concentrations of Al materials and aims to evaluate its discrimination potential for various sources of Al through the comparison of their trace elemental profiles.

Koons et al. measured trace element compositions for 30 rolls of Al foil and determined that there were quantifiable differences among rolls from 12 discrete manufacturers.<sup>1</sup> In addition to being able to differentiate between manufacturers, different lots from the same manufacturer also displayed distinct compositions. This study builds on these initial results and develops a more robust determination of the discriminatory power of comparisons of Al trace element compositions. This will be achieved through increased sampling, sample diversity, and more sensitive instrumentation. The total number of samples included in the present study is larger (~350 sources, currently) and sample variability is greater in terms of source material and region. The instrumentation allows for greater precision and lower detection limits, potentially yielding additional elements for comparison.

Concentrations of trace elements are determined from solutions using High-Resolution-Inductively-Coupled Plasma-Mass Spectrometry (HR-ICP-MS). For sample types that necessitate separation, the Al component is isolated from the other components of the product. Approximately 50mg of purified Al is dissolved using high-purity hydrochloric and nitric acids. Three aliquots of these concentrated sample digestions are removed and diluted to ~500ppm of dissolved Al for analysis on a HR-ICP-MS. Measurements were obtained using external calibration and internal standardization. The calibration standards reflect a wide range of elemental concentrations that may be observed in Al samples. A multielement internal standard is used in order to correct for instrumental drift, signal suppression, and matrix effects resulting from the high Al matrix of the samples. National Institute of Standards and Technology (NIST) and International Analytical Reference Materials (IARM) Al alloy reference materials are used as external standards and are regularly measured to verify the accuracy of the method. Quantitative data for all analyte elements certified in the external reference materials are collected; non-certified analytes are also measured, though the accuracy of these measurements cannot be verified.

An initial test was conducted to determine the homogeneity within a roll of Al foil for the measured element concentrations. This test provides a means to assess the degree of sampling necessary for Al foil rolls measured in this study. Three samples were taken across the width of a roll at approximately every ten feet for the entire length of the roll (250ft), totaling 78 samples from a single roll of Al foil. These samples were digested and analyzed according to the established procedure.

Statistical analysis will be used in order to determine which elements will have the greatest effect on the discriminating power (which is equal to one minus the random match probability) when attempting to distinguish between Al sources. Within- and between-source distributions of trace elemental concentrations will be used to develop criteria to compare Al samples from two sources: one from the Al material recovered from a crime scene and the other from a specified known Al source. Further, a method to assess the evidential support for an association between materials recovered from a crime scene and a specified Al source versus an alternative source will be explored.

### B217 Vibrational Spectroscopic Analysis of 3D-Printed Polymers Pre- and Post- Manufacturing

Ryan G. Zdenek\*, West Babylon, NY 11704; April Bowen, BS, University of New Haven, West Haven, CT 06516; John A. Reffner, PhD, John Jay College of Criminal Justice, New York, NY 10019; Maria-Isabel Carnasciali, PhD, University of New Haven, West Haven, CT 06516; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will understand the value of vibrational spectroscopy for the analysis of polymers used in the manufacturing of 3D-printed objects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the chemistry of polymers used in 3D printing, pre- and post-manufacturing, and how that information can be obtained through vibrational spectroscopy, thus informing criminalists about the significance of vibrational spectra of 3D-printed objects.

Additive manufacturing, commonly known as 3D printing, is becoming increasingly common in today's society. The ease of use and decreasing cost make this technology accessible to a wide range of individuals. 3D printing has been used to manufacture a range of legal items, including airplane and automobile parts, footwear, medical prosthetics, and even models for forensic reconstructions and court presentations. Unfortunately, it is also readily available for individuals to manufacture items that can be used in criminal activity, such as firearm components, knuckle dusters, pipe bomb components and ATM skimmers. In an investigation in which 3D-printed parts are recovered and a 3D printer is found, it would be valuable to be able to associate the printed object with an unused spool of polymer. Thus, there is a need for forensic-focused research to evaluate whether an association can be made between 3D-printed objects and their raw material (i.e., the polymer filament) as well as the discrimination potential of polymers produced from different batches and different manufacturers. It is the focus of this research to be able to understand the chemical nature of the polymers used in 3D printing, including changes in their crystallinity via the manufacturing process, in addition to methods for their classification and discrimination.

Polymer crystallinity refers to the degree of structural order or alignment of the molecular chains in a solid composed of repeating structural units. Different polymers have various ranges of degrees of crystallinity, which refers to the percentage of order within the solid. Polymers can crystallize upon cooling from the melt; thus, it is possible for there to be a change in polymer crystallinity as a result of the 3D manufacturing process. In order to associate a 3D-printed object with its polymer filament, it is imperative to understand any changes to the crystallinity of a polymer as a result of the 3D-printing process.

Infrared (IR) and Raman spectroscopy are common instruments used in forensic laboratories and are well known and validated analytical methods for polymer characterization and analysis. In addition to identifying the components of the polymer, such as the main chemical, additives, and pigments, vibrational spectroscopy has been used for analyzing polymer crystallinity. Changes in polymer crystallinity can result in peak splitting and changes in peak shape, which may result in a shift in the computer-selected peak position.

This research focused on the vibrational spectroscopic analysis of two common polymers used in 3D printing: Polylactic Acid (PLA) and Acrylonitrile Butadiene Styrene (ABS). For each polymer type, filament spools of different colors within the same brand and also different brands were analyzed. Pre-manufactured samples were analyzed from each spool at increments of 24in for a total of five pre-manufactured measurements per spool. Additionally, for all polymer filament spools, three items were manufactured at three different temperatures for a total of nine 3D-printed objects per spool.

IR and Raman spectral analysis resulted in the identification of the major and minor components (e.g., additives and pigment) of the polymers for classification as well as lot and brand comparisons. It was concluded that different brands and colors of polymers were able to be discriminated based on their vibrational spectra. Within a spool of polymer, there were no meaningful detectable differences, indicating that the polymers within a spool are homogeneous. Last, statistical comparisons of the peak positions, splitting and Full Width Half Max (FWHM) values of the pre- and post-manufactured polymers indicated that there were no consistent differences over the range of melting temperatures to indicate a measurable change in crystallinity via the 3D-printing process. Overall, vibrational spectroscopy was shown to be a valuable tool for 3D-printed polymer identification, which can be used to associate a 3D-printed object with a specific manufacturer's polymer filament.

#### 3D-Printed Polymers, Infrared Spectroscopy, Raman Spectroscopy

### **B218 Non-Destructive Separation of Pollen Grain Constituents for Biochemical Analysis**

*Bryan McCullough\*, Orlando, FL 32826; Luz J. Kelley, MS, National Center for Forensic Science, Orlando, FL 32816; Gerardo Sibaha, BS, Orlando, FL 32826; Kayley Jenks, BS, Orlando, FL 32826; Matthieu Baudelet, PhD, National Center for Forensic Science, Orlando, FL 32826; Mauro Martinez Labrador, MPh, National Center of Forensic Science, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will understand a comprehensive separation protocol that furthers the use of pollen grain beyond microscopy (i.e., DNA and chemical analysis).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing additional avenues for the analysis of pollen grains in forensic laboratories at the state or local levels.

Forensic palynology, the study of pollen grain morphology, has been used in a variety of cases around the globe. Pollen grain evidence provides the ability to determine the location where people or objects have been by the unique assemblage that gets transferred onto them. This deposition can occur from direct contact with a plant or dirt samples and/or by airborne pollen. Current analysis in the field of forensic palynology relies on the use of visual microscopic analysis (optical microscopy or scanning electron microscopy) to determine the plant species a single grain originates from via its morphological features. Pollen grains are a multi-component structure consisting of an external pollen coat over a decay-resistant shell, containing its genetic material. To visualize the unique morphology of pollen grains, the coating and other external material must be removed. The most common technique is acetolysis. It uses a mixture of acetic anhydride and sulfuric acid to dissolve any organic and/or inorganic material from the grain surface. It also dyes the grain a dark brown hue for visual microscopic analysis. The removal of organic material from the pollen also destroys the pollen coat and DNA (via infiltration through the pollen apertures), leaving only the shell (more explicitly, exine and intine) of the pollen grain for microscopic analysis. This procedure prevents any additional analysis.

In recent studies, it has been known that analytical methods such as Inductively Coupled Plasma/Mass Spectrometry (ICP/MS), Raman, and Infrared (IR) absorption, as well as DNA analysis, can provide additional information for the identification of pollen species. But as mentioned above, current cleaning methods prevent any additional analysis due to the chemical destruction of the coating and the genetic material. Reciprocally, any DNA analysis has been done by crushing the grains, preventing microscopic and chemical analysis.

This presentation will show a simple cleaning method that maintains the pollen grain morphology while also providing material for additional spectroscopic and DNA information. Soxhlet extraction using ethanol as a solvent will be shown to be a method that allows for DNA and coating to be removed without damaging or altering the chemical integrity of both components. This presentation will show the complementary analyses obtained from every constituent of pollen grains from nine different species. Molecular information (from Raman and IR absorption), elemental analysis (from ICP/MS), DNA analysis (via quantitative Polymerase Chain Reaction [qPCR]) and microscopic analysis (via Scanning Electron Microscopy [SEM] and digital microscopy) can be combined for the classification of pollen species.

Such a simple and versatile preparation of pollen grains will indubitably bring the use of pollen as a forensic evidence back to the light and provide forensic examiners with new options for geolocation and association.

### **B219 Thanatochemistry at the Crime Scene: A Microfluidic Paper-Based Device for Ammonium Analysis in the Vitreous Humor**

Giacomo Musile, PhD\*, Università Di Verona, Forensic Medicine, Verona 37134, ITALY; Yvane Agard, MS, Unit of Forensic Medicine, Verona 37129, ITALY; Elio De Palo, Unit of Forensic Medicine, Verona 37134, ITALY; Ksenia Shestakova, MS, Sechenov University, Moscow, RUSSIA; Federica Bortolotti, PhD, MD, Department of Medicine & Public Health, Verona 37134, ITALY; Franco Tagliaro, PhD, MD, Department of Medicine & Public Health, Verona 37134, ITALY

**Learning Overview:** After attending this presentation, attendees will be informed about the advantages of the use of paper-based microfluidic technology for inferring the Postmortem Interval (PMI).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new tool for estimating the time since death. Thanks to the low cost and portability of the developed devices, this method has the potential of offering a real breakthrough at the crime scene, offering, for the first time, the possibility of a rapid and objective estimation of the time since death after the equilibration of the body temperature with the environment (approximately 18–20 hours).

The estimation of the time since death is a crucial question that forensic experts need to answer directly at the crime scene to effectively address the investigations.

Notwithstanding a large number of studies regarding the PMI estimation, this problem is still faced using body examination. To obtain more accurate and objective data, after the first 20 hours during which body cooling is typically used, most of the literature is based on the analysis of the postmortem changes occurring in the vitreous humor, such as potassium estimation. Recently, the correlation between the concentration of the ammonium ion in the vitreous humor and the time since death was demonstrated.<sup>1</sup> Although the analytical methods offer sensitivity and specificity, at the moment, thanatochemistry analyses require the application of expensive and complex separative instruments.

Since the first introduction by Whitesides et al., the use of Paper-Based Microfluidic Devices ( $\mu$ PADs) for the development of chemical sensors has been extensively reported.<sup>2,3</sup> Among several approaches for producing  $\mu$ PADs, the use of commercial wax printers proved to be inexpensive and straightforward in the fabrication process. The procedure is based on two steps: (1) patterning chromatography paper into hydrophilic channels by fabricating hydrophobic barriers, and (2) the addition of the reagent to the hydrophilic portion of the paper support. The sample is driven through the reagent zone as results of the wicking capacity of the paper without external assistance. This paper-based technology proved to be rapid and easy-to-use. This approach does not require highly qualified personnel nor expensive instrumentation. Also, it can be performed onsite, also enabling a prompt analytical response in less-equipped environments. The advantages of  $\mu$ PADs have provided forensic science with reliable tools to face different forensic issues.

On the grounds of the above considerations, the goal of this presentation is to show the use of a low-cost device able to provide a rapid and sensitive colorimetric detection of the ammonium in vitreous humor. The developed procedure is conceived to obtain a first-line response for inferring the PMI before samples are sent to an equipped laboratory for further analysis. The preliminary results could be used to prioritize investigative directions.

The proposed microfluidic devices were designed as a single spot pattern. The test was based on a specific reaction for the detection of ammonium, which uses the Nessler's reagent. The vitreous humor sample is transferred without any treatment directly onto the hydrophilic portion of the paper, and a colorimetric reaction is developed in a few minutes. The color change is measured in terms of "Red, Green, Blue [RGB] distance" by using a simple and free application for smart phone cameras. The device was optimized to accurately and precisely quantify the ammonium concentration. The selectivity of the Nessler's reaction was tested toward the main vitreous humor components, and the stability over ten days was tested. The optimized device was used for the determination of ammonium ion in vitreous humor samples from forensic autopsies ( $n=25$ ). The results obtained with the proposed method were compared with the data obtained with an instrumental analysis based on capillary electrophoresis.

In conclusion, the results of the use of a paper-based microfluidic approach and the advantages of the device as an additional tool to the traditional methods for an objective, although still presumptive, estimation of the time of death directly at the crime scene will be shown during the presentation.

### C1 The Development of a Cleaning Protocol for Mobile Devices Damaged by Fire

Caige McCabe, BS\*, Marshall University, Huntington, WV 25701-2709; Josh Brunty, MS, Marshall University, Huntington, WV 25701; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701; Dale Mosley, West Virginia State Police Digital Forensics Unit, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand the cleaning protocols developed to aid in handling mobile devices following fire damage and extinguishment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a best practice for evidence collection to safely handle, clean, store, and acquire data from mobile devices following fire damage and extinguishment.

Mobile devices damaged by fire can be problematic for forensic investigators. If the inner components of the mobile device are damaged or melted, the probability of collecting a successful cable acquisition decreases. In many cases, the outer shell and components of the device are easily destroyed, while the inner components of the mobile devices remain mostly intact, but blackened and soiled. In these cases, mobile devices may need to be cleaned utilizing a forensically sound protocol before they are sent to a forensic analyst.

Many fire marshals and fire departments do not have cleaning protocols for mobile and/or digital devices. Once collected and submitted to the forensic laboratory, digital devices may sit untouched for months due to backlog. Residue from extinguishers can be corrosive to devices and can damage the inner components. The goal for this project was to determine an appropriate, low-cost cleaning methodology and protocol for mobile devices damaged by fire that evidence collection teams, fire departments, and fire marshals can implement before forwarding the devices to the forensic laboratory for analysis.

The three most common ignition modalities are commercial gasoline, commercial diesel, and combustibles. Fire departments typically utilize water as the primary extinguishment method, while class A foam and dry chemical fire extinguishers are often the extinguishers used in a workplace setting. The ignition and extinguishment outlined were used during experimentation.

A total of 60 Blackberry® 8330 Curve and 9330 Curve 3 mobile devices were used during this experiment. All devices were initially imaged via traditional cable acquisition with Cellebrite® Universal Forensic Extraction Device (UFED) 4PC® version 7.18.0.199 and total file sizes were collected for the acquired physical image. The devices were then introduced to each of the methods of ignition, burned in a controlled setting, then extinguished. The devices were collected and cleaned utilizing various predetermined cleaning protocols. A Gas Chromatography/Mass Spectrometer (GC/MS) equipped with a Restek Rtx®-5MS column (30.0m x 250µm x 0.25µm) was utilized before and after cleaning each phone to confirm that there was no remaining residue from ignitable liquids or the extinguishers. Previous research determined a 15-minute cleaning cycle with 5% Elma Ultrasonics® Elma Tec® Clean A1 Solution followed by a 24-hour drying cycle is the ideal cleaning procedure for mobile devices that have been submerged in ignitable liquids.<sup>1</sup> Scrubbing Bubbles® was used as the second cleaning method for departments that do not have access to an ultrasonic cleaner. The third cleaning method used was a 95% solution of isopropyl alcohol because it is currently used in laboratories to clean water from the boards of mobile devices.

To determine that the data on the mobile devices remained intact after cleaning, the devices were re-imaged using cable acquisition as previously outlined or advanced acquisition methods (chip-off or JTAG) where cable acquisitions failed. For devices where acquisition was not possible, the conditions of the logic board and internal components were examined to determine whether it was fire/heat damage or the extinguishing chemical that prevented a successful acquisition. Using Cellebrite® UFED Physical Analyzer® version 7.7.0.93, the file sizes collected after cleaning were compared to the file size collected prior to damage to show that the data on the mobile device had not been changed.

### C2 Ear Asymmetry—A Preliminary Evaluation of Identification Accuracy for Forensic Purposes

*Laura Donato\**, Rome 00199, ITALY; *Al Ozonoff*, PhD, Boston Children's Hospital, Boston, MA 02115-5724; *Alessandro Di Luca*, MD, Roma 00197, ITALY

---

**Learning Overview:** After attending this presentation, attendees will have important updates about the correlation between measures of the ear and will have the opportunity to appreciate how these can be useful for personal identification in the forensic field.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by considering the possibility of a correlation between the measures relating to the ear and its application in the context of personal identification in the forensic field.

In the modern age, the identification of the living has become a major challenge in the field of forensic science. To achieve this goal, forensic sciences have focused on biometrics, a method to classify and identify the physiological and behavioral traits of an individual. The study of biometric parameters was focused for forensic purposes to ensure an accurate assessment in the identification process.

Facial features, such as the eyebrows, nose, lips, ears, or details, such as scars or tattoos, are useful parameters to identify a person of interest in the forensic context. These features are considered important because of their rarity in form, position, and size across different individuals.

Among these parameters, the ear has attracted much interest given its inter- and intra-individual uniqueness. The main challenge is regulated by defining how the uniqueness of this biometric parameter is distinctive for each individual. Forensic sciences have been studying this anatomical element for many years thanks to the non-intrusiveness of the methodologies provided. The analysis of the external ear makes it possible to observe and record its characteristics by simple observation and scanning. The uniqueness and permanence of the ear characteristics have been made into a biometric identifier. It has been observed that the shape and structure of the ear remain permanent from about 8 to 70 years of age.

The morphological and metric study of this body component demonstrates a high degree of individual uniqueness. However, the ear is often partially covered and thus difficult to visualize and measure. Furthermore, the resolution of surveillance video may not allow accurate measurement of some key components. This limits the use of the ear in some cases of video surveillance identification.

The present study aims to quantify intra- and inter-individual variability in metrics associated with the ear. By subjecting the ear to nine measurements, the goal is to study the extent to which these metrics differ between individuals and to quantify variation in the same individual between the right and left ears.

Nine ear measurements from 35 individuals with ages ranging from 4 to 76 years (mean=32.9, SD=15.9) were studied. For each measurement, the difference between left and right ears, the Coefficient of Variation (CV) across all individuals, and the correlation between each measurement were calculated. The association between each measurement and sex, age, height, and history of boxing or rugby was also examined.

Pearsonian correlation among the nine measurements ranged from 0.48 to 0.91, indicating the nine metrics are highly correlated within each individual. CVs ranging from 12.1% to 31.5% were found, suggesting some measures are more suitable for identification because of greater inter-individual variation. These data will help to develop these measures for the purposes of identification and differentiation among individuals.

### C3 An Investigation Into the Encoding and Encryption of Black Box Data on a DJI Spark

Elijah A. Vela\*, Laredo, TX 78043; Josh Brunty, MS, Marshall University, Huntington, WV 25701; Dale Mosley, West Virginia State Police Digital Forensics Unit, Huntington, WV 25701; Rob Attoe, BS, Spyderforensics LLC, Masontown, WV 26542

**Learning Overview:** After this presentation, attendees will have a better understanding of the black box files obtained from a drone and the formatting of their encoding or encryption.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by attempting to identify patterns of obfuscation and encryption within black box files of a DJI Spark. In addition, several open source tools will be used to acquire, parse, and compare data to ascertain which tool or combination of tools provides the most amount of usable data.

With the increased use of Unmanned Aerial Vehicles (UAV), new methods of forensic data collection and analysis of UAVs and their associated devices have been developed. In an attempt to combat the unwanted access to sensitive device data by outside third parties, such as law enforcement, companies who make these UAVs have increased their security. This increased security requires new methods and techniques to be employed in order for information to be gleaned.

DJI, a Chinese technology company, is one of the most prominent suppliers of drones to the world. The drones sold by DJI range from professional drones aimed at experienced flyers to smaller user-friendly amateur drones. The specific type of drone used during this study was the DJI Spark, a small drone primarily made for taking short flights while capturing pictures and videos. This drone has the capability of being controlled by a remote control, cellular device, or motion control. For the purposes of this study, the Spark was connected to a Samsung™ SM-G9001® mobile device.

The cellular device was imaged using Magnet® ACQUIRE™ version 2.13.0.15121. Files from this device and the drone's on-board microSD card were imaged using AccessData® FTK Imager® version 4.2.0.13. The DJI Spark flight logs were obtained using DJI Assistant 2® version 1.2.5. This free DJI app provided files from the internal memory of the drone. Flight logs were exported in a single .DAT file while black box data was exported in series of .log files. The DJI .DAT file was then extracted using DatCon's ExtractDJI® version 1.4.2, which provided a series of FLYxxx.DAT files. These individualized files provided a three-digit number, in place of "xxx," that corresponded to a recorded flight on the drone.

The .DAT files were parsed through using various open source tools, including DatCon®, Airdata™, and DROP.<sup>1</sup> Using these programs, readable .txt, .log, and .csv files were created where information about a drone's systems and flight parameters were displayed. The amount of information displayed across the applications varied. Common information among the tools used included the time of flight, battery percentage in relation to the time, and the mode of flight the drone was using.

Files pertaining to the black box consisted of mostly text documents that displayed information in WidChar when opened in Notepad® version 6.1. The hex values of these files were observed using FTK Imager® and HxD Hex Editor® version 2.3.0.0.

Log files obtained from the companion cellular device contained information about the flights extracted from the drone. In addition to the flights pulled from the drone directly, the companion cellular device included information about previous flights that were inaccessible from the drone. Located in a folder for the DJI Go 4® application, a flight error propagation log was found containing error notifications and time stamps.

The results of this research will provide a better understanding of the obfuscation and encryption techniques employed by DJI. In addition, this study aims to obtain a greater insight of which open source tools may retrieve usable forensic data from a DJI Spark and its associated products.

## Digital & Multimedia Sciences—2020

---

### C4 The Organization of Scientific Area Committees (OSAC) Digital/Multimedia Scientific Area Committee Standards Work—Part 1: Digital Evidence and Video/Imaging Technology and Analysis (VITAL)

*Julie A. Carnes\**, Target, Brooklyn Park, MN 55445; *Steven B. Watson, BA\**, VTO Labs, Broomfield, CO 80021-8042; *Christina A. Malone, MSFS*, Defense Forensic Science Center, Forest Park, GA 30305; *Richard Vorder Bruegge, PhD*, Federal Bureau of Investigation, Quantico, VA 22135

---

**Learning Overview:** After attending this presentation, attendees will have learned about the latest work in developing OSAC Standards for the Digital and Multimedia Sciences disciplines of Digital Evidence and VITAL.

**Impact on the Forensic Science Community:** Standards are vital to ensuring the sound practice of forensic science across all disciplines. In order to implement these standards, community members must know of their existence and scope. This presentation will impact the forensic science community by offering newcomers an introduction to such standards, while offering more experienced practitioners with an opportunity to probe the finer details of the current work and shape the direction of future work.

The OSAC for Forensic Science works to strengthen the nation's use of forensic science by facilitating the development of technically sound forensic science standards and by promoting the adoption of those standards by the forensic science community. These standards are written documents that define minimum requirements, best practices, standard protocols, and other guidance to help ensure that the results of forensic analysis are reliable and reproducible.

The OSAC forensic science disciplines are spread across five major "Scientific Area Committees" or "SACs." The SAC most relevant to the American Academy of Forensic Sciences (AAFS) Digital & Multimedia Sciences Section is the "Digital/Multimedia SAC" (DMSAC). The DMSAC incorporates four subcommittees that address the following disciplines: Digital Evidence, Video/Imaging Technology & Analysis, Facial Identification, and Speaker Recognition. This presentation will focus on the work of the first two, while a companion presentation addresses the second two.

Recently, the Forensic Science Standards Board (FSSB), which oversees the work of the various SACs and Subcommittees, directed each subcommittee to establish a "roadmap" of standards for their discipline. Each roadmap would identify the individual standards considered to be of the highest priority for placement on the OSAC Registry of Standards.

It should be noted that only standards that have been published by an acknowledged Standards Development Organization (SDO) are eligible for publication on the OSAC Registry. While many standards within OSAC disciplines have been published through SDOs, the work of OSAC has revealed that most of these require some modification to reflect the latest advances in forensic science. Likewise, OSAC subcommittees have identified a number of additional standards that have not yet been published through an SDO and, therefore, have begun to develop these standards themselves. Once prepared by an OSAC subcommittee, these documents are passed on to an SDO to ensure transparent input by the broadest possible community of stakeholders. As a result, individuals interested in actively developing standards have at least two opportunities to do so—either through participation in the OSAC or through an SDO. The SDOs with which the OSAC Facial Identification and Speaker Recognition subcommittees are currently engaged include: the American Society for Testing and Materials (ASTM), the Acoustical Society of America, and the American National Standards Institute (ANSI).

In order to facilitate the process by which standards are reviewed and validated through the OSAC, the FSSB has established an ontology to define the categories and subcategories of standards that may be included in the roadmaps. The major categories of standards as defined in this ontology are as follows: Competency; Method Validation; Examination & Analysis; Reporting & Testimony; Quality Assurance; Terminology; and Conclusions, Interpretation, & Opinion. It is expected that individual standards may span more than one of these categories.

During this presentation, attendees will learn about various efforts to develop standards within the disciplines of digital evidence and video/imaging technology and analysis with such topics as: Standard Terminology for Digital and Multimedia Evidence; Examining Magnetic Card Readers; Forensic Audio Laboratory Setup and Maintenance; Data Acquisition from Digital CCTV Systems; Training Guidelines for Video Analysis, Image Analysis & Photography; Latent Print Evidence Imaging Resolution; and Establishing Confidence in Digital and Multimedia Evidence Forensic Results by Error Mitigation Analysis.

## C6 On Generic Digital Forensic Readiness

Martin S. Olivier, PhD\*, University of Pretoria, Pretoria, GP 0028, SOUTH AFRICA

**Learning Overview:** The goal of this presentation is to move the discourse on digital forensic readiness from how such information may be collected to a deeper discussion of the cost/benefit trade-offs required (where cost also refers to the privacy of the innocent).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a simple, generic, digital forensic readiness model that allows researchers to propose specific readiness models more concisely. More importantly, the concise description facilitates comparison. In particular, it encourages deeper reflection on the nature, utility, and impact of proactive traces collected.

In digital forensics the phrase “forensic readiness” refers to information that needs to be collected during day-to-day operations of IT systems, such that the evidence required to examine a specific case at some stage will be available and known to be reliable. This presentation provides a generic model of the notion. The intention is to move the discourse from *how* such information may be collected to a deeper discussion of the cost/benefit trade-offs required (where cost also refers to the privacy of the innocent).

Had the phrase “forensic readiness” occurred in other forensic science disciplines, it would probably have referred to the availability of data and samples to facilitate a laboratory’s (or analyst’s) ability to examine a variety of cases. Examples that come to mind are databases of fingerprints, fiber characteristics, and chemical compositions of drugs, to name but a few. The hashes of known software maintained as part of the United States National Software Reference Library is arguably the best-known example of such preparation in the digital forensics discipline.<sup>1</sup>

Note that such “readiness” is not entirely foreign to forensic science. Cockpit voice and data recorders are of immense value when the causes of aviation accidents are examined (and they are present solely for such investigations). In many contexts a (manual or digital) log of activities is maintained that, again, is very useful during an investigation that involves those activities. However, a more abstract (and more formal) description of typical forensic readiness not only serves to better distinguish such work from the examples mentioned above, but also enables one to present a generic forensic readiness model.

In papers on forensic readiness, such readiness is typically engineered for some system  $S$ . The readiness often prepares for some irregularity (such as specific crimes or contraventions of corporate policy). Let  $i$  be some irregular activity (such as spoofing of an email or some specific form of fraud). The set of activities  $A_i$  that would be sufficient to perform  $i$  is then determined. To be ready to examine whether  $i$  occurred, it is posited that each activity in  $A_i$  should leave a trace. Such a trace is recorded in a logging facility, with the nature of the log entry dependent on the information required to prove  $i$ . Let, for any set of traces,  $T$ , the proposition  $\rho(T,i)$  denote that  $T$  is sufficient to prove  $i$ . If  $\rho(T,i)$ , then it follows that  $\rho(T,-i)$ .

This study contends that a simple model based on this notation simplifies the description of a forensic readiness model. The papers explore this for several published readiness models.

Based on the simple model, important questions come to the fore, such as whether the space required for storing traces is warranted by the prevalence (or impact) of any given inappropriate action  $i$ . Questions about the size of the generated traces naturally raise the question of whether the size for any proposed mechanism is minimal. It may be possible to offset the costs of being ready for  $i$  if  $i$ -readiness also implies  $j$ -readiness for an irregular activity  $j$ ; expressed formally, that is when  $\rho(T,i) \Rightarrow \rho(T,j)$ .

A major concern about readiness models is the fact that they collect “evidence” about innocent people even before an irregular activity is performed. It is possible to consider privacy metrics for a set of traces  $T$ . If two equivalent readiness models lead to the collection of traces  $T$  and  $T^0$ , respectively, then the one with the better privacy score is obviously the better choice. However, the nature of such privacy metrics requires further research.

In summary, this presentation presents a simple generic digital forensic readiness model that allows researchers to propose specific readiness models more concisely. More importantly, the concise description facilitates comparison. In particular, does it encourage deeper reflection on the nature, utility, and impact of proactive traces collected?

### C7 The National Institute of Standards and Technology (NIST) Scientific Foundation Study for Digital Examiners

*Barbara Guttman, BA\*, National Institute of Standards and Technology, Gaithersburg, MD 20899-8970; Mary T. Laamanen, MS\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Craig Russell, MS, National Institute of Standards and Technology, Gaithersburg, MD 20899*

---

**Learning Overview:** After attending this presentation, attendees will be aware of: (1) the NIST's efforts to develop scientific foundation reviews for various forensic disciplines, and (2) specifically, the development of a scientific foundation study for digital forensics examiners.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the trust in the use of current forensic methods for digital investigations based on solid scientific underpinning and provide a strategic direction for future research in areas that need further strengthening.

"A scientific foundation review is a study that seeks to identify and evaluate the body of scientific evidence that underlies a forensic method or practice".<sup>1</sup> Working with the forensic community, NIST researchers developed a concise method for testing the accuracy of results that could be from a digital forensic examination. This method included collecting metadata related to an examiner's work environment and experience and developing tests targeting digital discovery from hard drives and mobile devices as part of a forensic examination. The goal of this study is to achieve a comprehensive evaluation of outcomes from digital forensic practices used by investigators in both the public and private sector. Protections will be in place to protect the confidentiality and privacy of participants.

To date, there are no major known inter-laboratory studies for digital examiners, prompting the need for this scientific foundational study. This study will attempt to identify differences in work environments (i.e., number of employees, training opportunities, investigator's experience) that could possibly impact laboratories reaching different results. Participants will provide background information describing their current work affiliation, followed by a set of questions related to their acquired skill set, and an electronic discovery test designed for a hard drive or mobile device. The tests are developed with a minimum amount of multiple-choice questions that will focus on forensic artifacts common to any investigation. All responses will be collected in a survey format created for analysis of results. This study is designed as a black box study focusing on the results and not on the methods and practices used by participants to reach their conclusions. Participation in this study is voluntary and open to individuals who conduct digital discovery as part of their official work duties. Upon completion of this study, NIST will publish a report detailing the results.

### C8 Attitudes of Citizens of the United States, the United Kingdom, and Turkey in Permits Requested by Mobile Apps

*Burak Oclu, MS\*, Istanbul Kultur University, Istanbul, Bakirkoy, TURKEY; Dilara Oner, MS, Istanbul University, Cerrahpasa, Istanbul, Fatih 34098, TURKEY; Hande Ermis, MS, Istanbul University, Istanbul, TURKEY; Gursel Cetin, PhD, Istanbul University, Cerrahpasa, Istanbul, Fatih 34100, TURKEY*

**Learning Overview:** After attending this presentation, attendees will be able to understand the relationship between risk, privacy, and mobile risk attitudes of citizens of different countries and interpret this in terms of mobile application permissions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the difference between attitudes in daily life and the actual situations that occur according to the data security risks that may arise.

How to secure information has become an important problem as application-maker firms have increased their access to personal data. In this context, this research aims to establish the relationship between risk, privacy, and mobile risk attitudes of people living in different countries. For this purpose, a survey of 26 questions was conducted for citizens living in the United States, United Kingdom, and Turkey, provided that there were 150 people from each country (in total 450 people). Surveys of their native languages were conducted for participants in all countries. The survey consists of multiple-choice questions with questions consisting of a Likert scale of 5s.

Hypotheses in the study are “H<sub>0a</sub>: there is no relationship between the risk attitude and the privacy attitude”; “H<sub>0b</sub>: there is no relationship between the privacy attitude and mobile risk attitude”; and “H<sub>0c</sub>: there is no relationship between risk attitude and mobile risk attitude.”

Within the scope of this research, “H<sub>0a</sub>” and “H<sub>0b</sub>” were rejected and a strong positive relationship in the United States, a weak positive relationship in the United Kingdom, and a moderate positive relationship in Turkey were identified. “H<sub>0c</sub>” was also rejected and a moderate positive relationship in the United States and United Kingdom and a weak positive relationship in Turkey were found. Participants were asked which of the nine different types of mobile application permission request options they would not want to grant access to. As a result of the research, the most unwanted permission given in the United States was “location information,” “access to SMS records” in the United Kingdom, and “phone call records” in Turkey.

According to the results of the research, 55.33%, 48%, and 87.39% of respondents in the United States, United Kingdom, and Turkey stated that they are using an Instagram™ app, while, respectively, 54.21%, 68.05%, and 46.56% of users have declared that they will not allow downloads for the application if they see the permissions requested by the application without specifying the application name.

Respectively, 19.33%, 70%, and 95.30% of respondents in the United States, United Kingdom, and Turkey stated that they are using the WhatsApp app, while, respectively, 34.48%, 63.80%, and 46.85% declared that they would not download the app with current permissions.

Respectively, 28.67%, 39.33%, and 22% of respondents in the United States, United Kingdom, and Turkey stated that they are using the Spotify® app, while, respectively, 55.81%, 55.93%, and 42.42% declared that they would not download the app with current permissions. Although the real estate app is different in each country, respectively, 12%, 10%, and 16% of the respondents in the United States, United Kingdom, and Turkey said they are using the real estate application, while, respectively, 50%, 80%, and 70.80% of these users have declared that they will not download the current permissions.

When the results are examined, all hypotheses are rejected for all countries and this means that there was a positive relationship between “risk, privacy, and mobile risk attitude.” In addition, the permissions that the participants do not want to allow are different between the countries. In comparison to the already downloaded applications and declarations against the permits requested without naming the application, it is understood that citizens living in the United Kingdom are more likely to avoid taking risks than citizens living in the United States and Turkey. This has also emerged as an important finding of denial of application permit request at a high rate seen in all countries. Because people avoid reading individual permissions, and because the requested permissions become routine after a certain period of time, differences can arise during the course of the activities with the risk attitudes of people in daily life. This can lead to questions about the sharing and protection of personal information.

#### Mobile Application Permission, Risk Attitude, Data Security

### C9 Apple® iCloud® Message Sync Forensic Investigations and Artifacts

Andrew N. Crouse, BA\*, Epiq Systems, Inc, Washington, DC 20006; Kaylee A. Schoepe, BS\*, Huntington, WV 25701; Brian Smith, BS, Epiq Systems, Inc, Atlanta, GA 85034; Wesley Wong, BA, Epiq Systems, Inc, Los Angeles, CA 90071

**Learning Overview:** After attending this presentation, attendees will better understand Apple's® iCloud® Message Sync functionality and its impact on Apple® device forensic examinations of property lists and SQLite databases. Studies of relevant artifacts will be discussed and the changes observed when different user actions occur on an iOS® device in regard to native text messaging and message synchronization to the Apple® iCloud®.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting Apple® iOS® artifact differences relating to user activity surrounding Apple's® iCloud® Message Sync functionality and usage on iOS® devices.

Apple® iCloud® Message Sync has introduced a natively new way for users to sync and store Apple® iMessages®, Short Message Service (SMS), and Multimedia Messaging Service (MMS) (native Apple®) messages. Prior to the introduction of iCloud® Message Sync, an examiner would expect the native Apple® messages to be extracted through an iTunes® backup or using a variety of third-party forensic tools. With the new option for users to store native Apple® messages in their iCloud® account, Apple® no longer needed to include messages in iTunes® and iCloud® backups for disaster recovery or “new device data transfer” purposes.<sup>1</sup> Due to forensic methods and tools relying on iTunes® and iCloud® backup technology to perform extractions, this presented an issue whereby data could potentially be overlooked. This presentation will discuss the forensic analysis of iCloud® message sync artifacts on Apple® iOS® devices that would be potentially relevant to findings in both civil and criminal cases.

Mobile devices, particularly Apple® iOS® devices, have become a common occurrence in both the worlds of digital forensics and e-discovery. Obtaining data from these devices is critical, and oftentimes text messages, such as iMessages®, SMS messages, and MMS messages, contain valuable information relevant to cases. Text messages are typically extracted from Apple® mobile devices through two methods: (1) direct-device collections using a forensic tool or Apple® iTunes®, and (2) analysis of Apple® iTunes® backup files stored via backups to either a local computer or the Apple® iCloud®. In researching these methods, the native Apple® messaging database (sms.db) was collected and parsed by the examiner's tool of choice.

Apple® iCloud® storage services allow users to sync and store data, such as photos, contacts, notes, keychain information, health data, map data, reminders, and more, in their online account. In 2018, Apple® released an iCloud® service called Apple® iCloud® Message Sync, which allowed native Apple® text messages to be stored in a user's iCloud® account and synced to all Apple® iDevices® connected to that iCloud® account.<sup>2</sup> The synchronization of this data from a local device to a user's iCloud® account is controlled from options in the settings of the device. Some of this data, such as photos, notes, and reminders, are set up to sync by default once iCloud® is initially turned on; however, Apple® iCloud® Message Sync data is not turned on by default and must be manually turned on by the user.

The addition of this iCloud® Message Sync service to Apple® devices complicated standard Apple® device collections when native messaging needed to be analyzed. The utilization of iCloud® Message Sync on an Apple® mobile device can lead to the possibility of some data being stored on both the iCloud® and the device or only in the iCloud®. Additionally, when a user has enabled iCloud® Message Sync, traditional iCloud® backups may not contain native Apple® text messages when collected with third-party forensic tools.

Through research, it was able to be determined that the above can affect the conclusions digital examiners make upon collecting text messages from a device. The enabling of the Apple® iCloud® Message Sync option on the device does make changes to both the sms.db database and property list (.plist) files on the device. If examiners do not observe specific data, they may incorrectly conclude it does not exist, when in reality it may be stored solely in the iCloud®.

This presentation will focus on a comparison of Apple® iOS® artifacts to show where examiners can find evidence of iCloud® Message Sync activity. Studies of devices with and without iCloud® message sync turned on will be analyzed and compared, as well as time stamp variances in the sms.db database that may reflect the originating device when multiple iOS® mobile devices are logged into the same iCloud® account. Additionally, a comparison of identified artifact differences in the sms.db tables and property list files will be presented.

### C10 Joint Task Action Group (JTAG) and Chip-Off Data Analysis and Testing

*Jenise Reyes-Rodriguez, BS\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Richard Ayers, MS, Gaithersburg, MD 20899-8970*

---

**Learning Overview:** After attending this presentation, attendees will better understand the capabilities and limitations of a variety of digital forensic tools that provide support for the analysis of JTAG and Chip-Off binaries from mobile devices operating over the Android™ operating system. The Computer Forensic Tool Testing (CFTT) project at the National Institute of Standards and Technology (NIST) has performed testing across classic digital forensic tools, as well as tools tailored specifically for the data extraction and analysis from mobile devices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview on analysis across multiple JTAG and Chip-Off binaries imported within a variety of digital forensic tools.

As mobile device usage and sophistication continue to grow, the need for rigorous research and testing conducted across a variety of forensic tools and techniques is critical. JTAG and Chip-Off data extraction provide forensic examiners with the ability to often recover additional data in comparison to a logical or file system data extraction. JTAG is a non-destructive method that returns a byte-for-byte memory dump of accessible data from supported mobile devices. Chip-Off is a destructive technique that entails removing the flash memory chip from the Printed Circuit Board (PCB). Removing the flash memory entails cutting and grinding the PCB, allowing the chip contacts to be exposed. Once the chip has been prepared, the memory registers of the chip are read utilizing the correct adapter and by running a programmer application.

The JTAG and Chip-Off research and testing conducted within the CFTT lab includes JTAG and Chip-off binaries from a variety of mobile devices. Each mobile device was populated with a defined dataset, including active and deleted data across numerous types of data elements. In addition to binaries collected using either the JTAG or Chip-Off data extraction technique, data for supported devices were extracted using both JTAG and Chip-Off. Analysis across multiple devices and techniques provides insight into advantages of one technique versus another. Additionally, performing both data extractions on supported devices illustrates any differences between JTAG and Chip-Off extractions for a unique mobile device.

The goal of this research and testing within the CFTT program is aimed at providing the forensic community with an understanding of the capabilities and limitations of various digital forensic tools that support analysis of JTAG and Chip-Off binary files. These results provide insight into any pros and cons across a combination of supported techniques and tools.

The presentation gives a summary of findings and lessons learned during the research and testing process of tools capable of extracting and analyzing memory contents from numerous JTAG and Chip-Off binaries.

*Certain trade names and company products are mentioned in the text or identified. In no case does such identification imply recommendation or endorsement by the author or the author's employer, nor does it imply that the products are necessarily the best available for the purpose.*

#### Mobile Forensics, JTAG, Chip-Off

### C11 Forensic Gait Analysis: A Strength of Evidence Evaluation From Closed-Circuit Television (CCTV) Footage

*Dilan Seckiner\**, University of Technology Sydney, Blacktown, NSW 2148, AUSTRALIA; *Claude Roux, PhD*, University of Technology Sydney, Broadway, NSW 2007, AUSTRALIA; *Xanthe Mallett, PhD*, University of Newcastle, Callaghan, NSW 2308, AUSTRALIA; *Philip Maynard, PhD*, University of Technology Sydney, Ultimo 2007, AUSTRALIA; *Didier Meuwly, PhD*, University of Twente, Enschede 7522, NETHERLANDS

---

**Learning Overview:** After attending this presentation, attendees will better understand the application of a morphometric technique for analysis and the subsequent approach to evaluate the strength of the evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing a gap within research that was addressed via a method of evaluating forensic gait examination through assessing the strength of evidence that was successfully applied to the research, thus highlighting both competence and performance.

**Introduction:** The ubiquitous nature of surveillance cameras allows continuous monitoring of an area where footage can be obtained for later use, if criminal or other activity of interest occurs, for investigative and evaluative purposes. In the process, gait is often important, as facial analysis is not always possible due to obstruction of the face. Subsequently, a photo-comparative analysis of the footage and of a Person of Interest (POI) may be required. Such examination involves evaluation of the strength of evidence at both activity (relates to activity undertaken by the individual within the footage) and source level (alludes to features observed within the anatomy and gait of an individual), thus underlining its importance.

**Goals:** The goals of this research are to develop a standardized method for morphometric body and gait analysis that incorporates the quantification of image distortion and to determine distinct features of the body during gait (stance, walk, run).

**Hypothesis and Specific Objectives:** The hypothesis and specific objectives include the development of an analytical model that shows distinctive features of gait in a forensic context while determining features of the body during stance and gait (walk and run) and determining the frequency, distinguishability, and dependency of the features within subpopulations while viewing correlations of age/ethnicity/sex and examining the robustness of gait to different conditions (person, accessories, and environment) observed in forensic scenarios.

**Method:** The method includes a morphometric assessment of 18 anthropometric measurements (static, dynamic, and angle), 25 morphological features for stance, and 52 morphological features for gait of both male and female volunteers.

**Results:** As a result, a standardized protocol was produced, and population databases established from which frequency statistics are attained. Moreover, features were observed as either common or distinct, once compared to all age, race, and sex categories for correlation determination. These components were then applied to assess the strength of evidence between the trace and the reference materials, resulting in a likelihood ratio value.

**Conclusion:** As a forensic tool, the forensic gait analysis method often lacks validation, and its evaluation misses empirical substantiation. Nevertheless, the availability of trace material in numerous cases and the potential for development of the method suggests that research on this topic cannot be overlooked. The broader purpose of this study established a method of evaluating gait analysis that offers valuable information to the criminal justice system while being scientifically robust and highlighting its limitations.

**Forensic Gait Analysis, CCTV, Morphometric**

### **C12 An Acceptable Resolution for the Identification of Knives Captured Within Closed-Circuit Television (CCTV) Imagery**

*James Zjalic, MSc\*, Verden Forensics, Edgbaston, England B15 1TH, UNITED KINGDOM*

---

**Learning Overview:** After attending this presentation, attendees will better understand the reliability issues surrounding the identification of knives within CCTV imagery and will be presented with findings from research into this area.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing research pertaining to the minimum acceptable resolution for the analysis of a purported knife within CCTV imagery, thus increasing reliability of said analysis.

Previous research has been conducted to define thresholds for the face in terms of facial width in resolution and pixels as well as bit-rates, and it is the recent spike in knife crimes within the United Kingdom that has driven the need for research into these measurements in relation to knives.

The increase in knife crime over the past few years within the United Kingdom has led to a substantial increase in the purported identification of knives from CCTV imagery to provide evidential support in criminal trials. As no weapon is recovered in the majority of cases, a precedent appears to have developed for both forensic image examiners and police officers to render opinions such as “appears to be a knife as it is shiny” without the application of any form of methodology. It is also common for those accused to claim the object is an e-cigarette, further confusing the analysis. Imagery from real casework will be shared to allow attendees to gain an understanding of the issue and why research into this area is essential.

The ability to render an opinion, and the reliability of such, is in direct correlation with the quality of the imagery and the features that an examiner believes are consistent with an object.

To address the above, the research presented tests the following hypothesis: the minimum dimensions required for a reliable opinion to be given in relation to an object purported to be a knife can be defined.

To test the proposed hypothesis, CCTV imagery of both knives and e-cigarettes of similar dimensions, colors, and materials were captured at decreasing resolutions in conditions mimicking real casework. These included differing encoding algorithms, environments, perspectives, and lighting. Analysis was then performed using a morphological analysis methodology until it was deemed of insufficient quality to draw a reliable opinion. Attendees will be presented with the detailed methodology and subsequent findings.

It is of the utmost importance that analysis of objects purported to be knives is as reliable as possible, since in a large number of these cases, the defendant is facing extended periods of imprisonment, especially if the alleged crime is murder. The research presented aims to go some way in increasing the reliability of any analysis performed in relation to such through an initial analysis suitability triage through the use of an acceptable object resolution threshold that can be utilized in casework.

### C13 Unlocking Apple® Mobile Devices: A Forensic Practitioner's Perspective and Lessons Learned

Christina A. Malone, MSFS\*, Defense Forensic Science Center, Forest Park, GA 30305; Joseph Levi White, MS\*, Defense Forensic Science Center, Forest Park, GA 30297

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of the current capabilities of GrayKey as it applies to specific case examples at the Defense Forensic Science Center (DFSC).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the benefits and limitations of GrayKey as it pertains to the unlocking and extraction of data from mobile devices in a digital forensics laboratory.

Smart phones are becoming increasingly important in digital evidence investigations. Obtaining data from a smart phone may assist in cases dealing with any number of criminal activities, including theft, sexual assault, and homicide. Evidence extracted from mobile devices may include pictures, call logs, text messages, e-mails, videos, and documents. While this evidence may be critical to a case, accessing the information may prove difficult, especially if the device is locked with enhanced security methods (Personal Identification Number [PIN]/passcode lock, pattern lock, fingerprint, facial recognition, etc.) or utilizes data encryption.

The Apple® iPhone® is one of the most popular smart phones within the United States. Bypassing the security features of Apple® mobile devices to gain access to any maintained data is of great importance to law enforcement and digital forensic examiners. One primary tool used for gaining access to locked Apple® mobile devices is the topic of this presentation.

The tool is a device that allows users to attempt to access locked Apple® iOS® devices within their own facilities. Apple® mobile devices are connected one at a time to the unit, which uses proprietary software to gain access to the device. Once access is gained, the tool performs two actions. First, software designed to determine the unknown passcode is introduced to the mobile device. Second, data is extracted from the device, with accessibility to certain types of data dependent on the security status of the device. When an iOS® device is first powered on, it is in Before First Unlock (BFU) mode. Once the passcode has been entered on the device, it switches into After First Unlock (AFU) mode. Prior to determining the passcode of the mobile device, the tool can perform both BFU and AFU partial file system extractions. After the unknown passcode is determined, the full contents of the file system may be obtained.

The tool has been used in numerous cases at the DFSC since the fall of 2018. In addition to completing routine data extractions from mobile devices, many lessons and unique scenarios have been encountered since the introduction of this capability at the DFSC. During this presentation, insight will be given into the types of scenarios that have been encountered, as well how obstacles have been addressed. Several unique case examples will be highlighted by both an experienced digital forensic examiner and an examiner new to mobile forensics. The experiences and lessons learned will demonstrate how the tool has been implemented in a forensic laboratory setting.

### C14 2D/3D Imaging for Forensic Ballistics Comparison Assessment

*Sebastiano Battiato, PhD\*, Università di Catania, Catania 95125, ITALY; Oliver Giudice, PhD\*, Roma 00044, ITALY; Luca Guarnera, MS\*, Università di Catania, Catania 95125, ITALY; Antonino Barbaro Paratore, MS\*, Carabinieri Scientific Investigation Department, Messina 98122, ITALY; Angelo Salici\*, Carabinieri Scientific Investigation Department, Messina, ITALY*

**Learning Overview:** After attending this presentation, attendees will be familiar with various comparison techniques used in the field of forensics firearm examination that are currently based on analysis of 2D and 3D imaging of cartridge cases and bullets. This presentation will attempt to standardize all the existing solutions by presenting a simple but schematic view. All the techniques will be presented, organized in various categories, and the pros and cons will be exposed considering the practical application scenarios.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing attention to innovative techniques in support of forensic ballistics analysts.

The main steps of a firing process of a self-automatic gun are: loading a round of ammunition into the chamber, shooting the bullet through the barrel, and ejecting the spent cartridge case. During this process, the class and individual characteristics of the gun are transferred from the hard surface of the weapon to the softer surface of the bullets and cartridge cases as a unique fingerprint. When a firearm is used to perpetrate a crime, bullets and cartridge cases will be found in the collected evidence on the scene; it is possible to then identify both the class (make and model) and the individual weapon that was fired. Currently, the collected bullets and cartridge cases on the crime scene are analyzed using an optical comparison microscope. The main limitation of this method is that the overall forensic evaluation made by experts, in some cases, could make it difficult to report the value of the scientific findings in terms of balance, logic, robustness, and transparency.<sup>1</sup>

The possibility of representing cartridge cases in 2D images, topography images, or in 3D point clouds has opened up new research challenges as well as the opportunity to move from manual optical comparison techniques to more sophisticated semi-automatic digital techniques, with the aim of obtaining objective assessments.

In 2015, the National Institute of Standards and Technology (NIST) standardized the forensic ballistics comparison analysis by introducing the Congruent Matching Cells (CMC).<sup>2</sup> Exploiting this method, based on the principle of discretization of cartridge case images, it is possible to obtain an accurate identification process and, consequently, an estimation of the error. In late 2016, the NIST Ballistics Toolmark Research Database (NBTRD) was published as an open-access dataset containing 2D and 3D acquisitions of bullets and cartridge cases fired by different guns.<sup>3</sup>

The ballistic comparison based on 2D images is very sensitive to lighting conditions and, consequently, some important details for the comparisons could be lost. These anomalies do not occur if one considers a representation of cartridge cases and/or bullets as point clouds in 3D space. In this way, it is possible to reconstruct the geometrical structure of the element itself and obtain a more accurate ballistic comparison.

This presentation will show techniques based on 2D images up to those that work on 3D point clouds.

Taking advantage of 3D representations of cartridge cases, in recent years, several very useful solutions have been implemented to obtain an accurate result. Giudice presents a technique that identifies the primary keypoints in order to perform a good alignment operation between the 3D point clouds.<sup>4</sup> Excellent results have been obtained exploiting the neural networks as described in Giudice et al.<sup>5</sup> By means of Siamese Neural Network, the distance between point clouds in 3D space is calculated for classification tasks (type and gun identification). Finally, a new “immersive 3D technology” will be presented, aimed at supporting the operator during the analysis phase.

### C15 A Morphometric Analysis of Ears in Twins: An Aid to Forensic Personal Identification

Greta Cena, MD\*, University of Torino, Torino 10126, ITALY; Francesco Lupariello, MD\*, University of Torino, Torino 10126, ITALY; Niccolò D. Melloni, MD, University of Torino, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the uniqueness of morphological and biometric features of ears from one individual to another and in the same subject.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the importance of evaluating morphological characteristics and dimensions of the auricle as a tool for forensic identification of living or deceased individuals.

The idea of using ears for identification purposes dates back to the late 19<sup>th</sup> century when Bertillon included it as one of 11 anthropometric measurements in his manual system for identifying individuals.<sup>1</sup> In fact, although the primary function of the pinna is to collect sound waves and transmit them to ear drum through the external auditory meatus, the ear is an under-recognized defining feature of the physiognomy of the face.<sup>2</sup>

Since the morphological characteristics of the external ear stay fixed in the same person after completion in development until death, while they vary from one individual to another according to age, sex, and ethnicity, comparative analysis of ear biometrics represents a useful tool in forensics for positive identification of living or deceased people.<sup>2,3</sup> As the morphology of ears tends to be hereditary, the present twin study was undertaken to determine morphological and biometric variations of both ears within pairs for individualization purposes.<sup>4</sup>

The study was conducted on four pairs of homozygotic twins: two males and six females, aged 18 to 45 years. Each pair underwent facial 3D laser scanning using a Head and Face Color 3D Scanner, with the subjects' heads in Frankfurt Horizontal plane. Acquired facial surface reconstructions were obtained through Cyberware Echo software. Reference vertical (Y, midline through glabella) and horizontal (X, through right and left endocanthion) planes were constructed on the models. For each patient, the following standardized measurements of both ears were recorded twice by a single investigator using landmark points defined by Farkas and colleagues: Total Ear Length (TEL), Ear Breadth (EB), Distance Preaurale-Glabella (P-G), Preaurale-Subnasion (P-Se), Preaurale-Exocanthion (P-Ex), and Preaurale-Pogonion (P-Pg).<sup>5</sup> The Ear Index (TEL/EB X100) was calculated for both ears. Morphological ear shapes and lobule attachment were also noted. Intra-individual and intra-pair comparisons of those parameters were conducted. Data were analyzed using an Excel<sup>®</sup> statistical analysis program.

When comparing both sides in the same individual, complete symmetry was noted regarding the shape of the auricles and lobule attachment, with 100% intra-pair concordance. Triangular shape was the most common (50%), followed by the oval (25%) and round ones (25%). The lobule was attached in 25% of individuals, while it was free in 75% of individuals.

The mean value of TEL was 60.8±9.4mm (right ear R: 61.14±9.31mm; left ear L: 60.46±10.13mm). An average Intra-Individual Discrepancy (IID) of 2±1.72mm was found comparing R and L. A mean Intra-Pair Discrepancy (IPD) of 2.19±1.85mm for R and of 1.59±1.63mm for L was noted. The mean value EB was 33.79±4.35mm (R: 34.28±4.43mm; L: 33.3±4.51mm). The mean IID of breadth was 1.32±0.63mm and IPD of 0.85±0.63mm in R and of 0.96±1.03mm in L was noted. The mean total Ear index was 55.57% (R: 56.08% and L: 55.08%) with a mean IPD of 2.97% and a mean IID of 0.63% and of 2.73% for R and L, respectively. All ear anthropometric dimensions were found to be significantly higher in males. TEL and P-Ex distance were the only two parameters showing higher values on L. As far as EB and P-Pg distance were concerned, there seemed to be a higher variability when comparing the two ears of the same individual than when considering the auricles on the same side of the twins in each pair. On the other hand, TEL, P-G, and P-Se showed higher IPDs, especially when considering the right ears. P-Ex was the only parameter showing comparable IID and IPD.

The results of this pilot study on variations of ears morphology between homozygous twins can be used as supportive evidence that ear biometrics could represent a helpful tool in forensic issues since auricles showed measurable variations even between individuals sharing the same genetic heritage.

### C16 The Development of a Cleaning Protocol for Mobile Devices Contaminated With Controlled Substances

Rachel Valerio\*, Marshall University, Huntington, WV 25701; Josh Brunty, MS, Marshall University, Huntington, WV 25701; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701; Dale Mosley, West Virginia State Police Digital Forensics Unit, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand the dangers digital forensics analysts face with regard to drug exposure and will learn decontamination protocols that will protect analysts while allowing for digital data acquisition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing protocols that support both the digital forensic analyst's safety and digital data acquisition when cleaning digital devices contaminated with controlled substances. The focus of this presentation is on the decontamination of mobile devices from various illegal and potentially dangerous drugs, such as heroin, cocaine, methamphetamine, and fentanyl/carfentanil. In addition, this presentation will recommend appropriate Personal Protective Equipment (PPE) that is vital to the safety of the digital analysts.

Digital evidence submitted with potentially undetected dangerous illicit substances has become a huge concern in the digital forensics community. While there are suggested protocols and best practices to collect liquid, structurally, and thermally damaged devices, there is little-to-no accepted protocol within the forensics community to effectively clean drug-contaminated devices that ensures both the safety of the analyst and a complete data acquisition from the mobile device.<sup>1</sup>

A set of 60 Blackberry® 8330 Curves and Blackberry® 9330 Curve 3s were utilized for this research. Initial hash values and total size from file system and physical acquisitions were obtained using Cellebrite® UFED 4PC version 7.18.0.199 for all of the devices used. Both industrial and household cleaners were used as decontamination cleaners. The industrial cleaners tested include: Apple® Environmental® Meth Remover Parts 1 and 2, First Line Technology® FiberTect Polyester Pads/Wipes, First Line Technology® Dahlgren Decon 200mL Ready-to Use Configuration, and Intelgard® EasyDECON Parts 1 and 2. The household cleaners included Lysol® Fresh & Clean Multi-Surface Cleaner, Formula 409® Multi-Surface Cleaner, Alconox, Inc.® Liquinox 1232 Critical-Cleaning Liquid Detergent, Fiberlock Technologies® Shockwave-Concentrate, and Scrubbing Bubbles®. Each controlled substance was diluted in methanol and run on a Gas Chromatograph/Mass Spectrometer (GC/MS) equipped with a Restek® DB-5 column (30.0m x 250µm id x 0.25µm particle size) to obtain reference data. The devices were then systematically exposed to each drug, and the presence of the drug was confirmed using the GC/MS. Each cleaner was used to attempt to clean the controlled substance from the device to the point of no detection. Cleaning steps were repeated if the drug remained detectable.

Data acquisitions from each digital device were obtained both immediately after the cleaning process and one week after to simulate the environment of a working digital forensics laboratory. Advanced data extraction techniques such as chip-off or JTAG were attempted if a traditional cable acquisition was unsuccessful. The data acquired after cleaning was compared to the initial hash values and flash.bin file sizes. The success of each data acquisition was then used to create a list of recommended decontamination methods for digital devices contaminated with the tested controlled substances.

### C17 The Application of Artificial Intelligence (AI) in Digital Forensic Science

*Zeno J. Geradts, PhD\*, Netherlands Forensic Institute, Den Haag, SH 2497 GB, NETHERLANDS*

---

**Learning Overview:** The goal of this presentation is to learn from different possibilities in AI and know the limitations and possibilities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a brief statement on how AI impacts digital forensic science; however, validation is always needed.

AI tools that work like humans and learn from examples are often integrated into many different software tools, such as object detection tools, Automated Fingerprint Identification Systems (AFIS), face recognition, speaker recognition, author recognition, and many more. We see many different tools that are combined and used in pipelines to extract evidence from big data.

AI is included in many search engines and many products, and we are used to having them. Now, smart phones often include much AI for recognizing the user and predicting the information someone is interested in. Speech recognition works well enough to use for searching the internet. People are sometimes not aware that their digital devices, such as tablets and smart phones, are listening to their conversation if they have not turned the privacy modes on. Later, the user might get advertisements related to some words they were discussing, such as, for example, a vacation to Corsica if they were discussing that part of the world. In criminal settings, using certain phrases may later be used as supporting evidence in court.

For facial comparison, it is well known that bias exists, depending on the training sets. There are cities, such as San Francisco, that abandoned the use of this technology by the government due to bias and other privacy concerns. However, since facial comparison algorithms have proven to be much better, and in many cases outperform humans, the use of an algorithm to assist the forensic scientist is used more often. Sometimes, we have patterns, such as the Photo Response Uniformity (PRNU) to identify cameras, that a user cannot really see, and an algorithm can compare better. In practice, we see that AI is used to make faces that never existed, based on training material, such as the deep fakes.

For image and video manipulation detection, more algorithms are developed that also use deep learning techniques to detect the manipulation. It is very important that we can explain in court how these algorithms work, and that the results are validated. Also, we need to be aware that once a method for detection has been published, it is possible to attack the detection method. For this reason, it is necessary to perform continuing research on the application of methods in AI, without seeing it as a complete black box. The reproducibility of results with AI is another issue that should be addressed, since based on the starting point of a dataset, different results may be obtained.

### C18 Cloth Classification With a Semi-Supervised Generative Adversarial Network (SGAN)

*Jette Korthals Altes, BS, Netherlands Forensic Institute, Den Haag 2497GB, NETHERLANDS; Andrea Macarulla, MSc, Netherlands Forensic Institute and University of Amsterdam, Den Haag 2497GB, NETHERLANDS; Owen Corrigan, PhD, Dublin City University, Dublin, IRELAND; Zeno J. Geradts, PhD\*, Netherlands Forensic Institute, Den Haag, SH 2497 GB, NETHERLANDS*

---

**Learning Overview:** After attending this presentation, attendees will be aware of new possibilities for tracking persons based on a description of clothing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing novel ways of searching for certain clothing items on video based on machine learning.

If large amounts of video are collected from different camera systems, often it is necessary to track a person based on clothing, especially if the face is not visible in the images. With that information, investigators can look for the person on Closed-Circuit Television (CCTV) and recordings from other sources in the relevant area. This is a simple task in theory, but tedious in practice, since there may be many hours of video footage with a high number of people in them. The goal of this presentation is to automate this task using machine learning methods.

One practical obstacle to achieving this goal is a lack of labeled training data. A semi-supervised learning method was applied to circumvent the lack of relevant, available datasets. A semi-supervised SGAN was used. This SGAN consists of two networks, a generator, which generates images, and a discriminator, which classifies images into the different classes or as being a generated image. The generator receives feedback from the discriminator, and will thus create more real looking images, and the discriminator will learn to correctly classify the images. The idea is that the discriminator will also learn from the generated images, even though they are not labeled as one of the classes.

New annotations were provided for 280 images of an existing dataset of surveillance footage (CUHK Person Re-identification Data Set). These annotations consist of manually tagged clothing items. New images were created, where each image contained only one clothing item. This was to simplify the task, instead of making it a multi-label classification problem. The ten classes consisting of the most images were selected. These were: a backpack, a bag, boots, a coat, jeans, oxfords, sneakers, a sweater, trousers, and a T-shirt. The SGAN was trained using 25, 50, or 100 images per class. The performance of the SGAN was compared to that of a baseline model, where the generator never got updated, so the generated images do not resemble the real image. As expected, the baseline performed better the more images it had to train with. However, the SGAN performed worse than the baseline, regardless of the amount of images it had to train with. Visual inspection of the generated images showed that these did not look like the real images; this could be an explanation for the worse performance of the SGAN. With the SGAN, training on 100 images per class, with ten classes, an accuracy of 64% was achieved. This paves the way to classification of clothing in the field of multimedia forensics.

---

### C19 A Wild Manhunt for Stego Images Created by Mobile Apps

*Li Lin\**, Iowa State University, Department of Mathematics, Ames, IA 50010; *Wenhao Chen, BS*, Iowa State University, Coover Hall, Ames, IA 50011; *Stephanie Reinders, BA\**, Iowa State University, Dept of Mathematics, Ames, IA 50011; *Yong Guan, PhD*, Iowa State University, Ames, IA 50011; *Min Wu, PhD*, University of Maryland, Electrical & Computer Engineering Department, College Park, MD 20742; *Jennifer Newman, PhD\**, Iowa State University, Department of Mathematics, Ames, IA 50011

**Learning Overview:** The goal of this presentation is to describe the challenge of detecting images with secretly embedded information by mobile apps. This presentation will evaluate academic algorithms and commercial software for this problem and make great progress with the proposed methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the realization of the situation of wide-spread usage of stego apps for illegal purposes and the possibility of detecting them. This presentation will also introduce some fast and high-accuracy tools aimed at some specific photo editing apps.

Digital image forensics is a young but maturing field, encompassing areas such as camera identification, forgery detection, and steganalysis. Steganalysis is the analysis of image data to discover if hidden content is contained within the image, and, if so, to uncover further information about the hidden content. Most of the academic research on steganalysis has focused on identifying or classifying an image as cover (innocent) or stego (with hidden content). However, large gaps exist between academic results and applications used by practicing forensic analysts.

To move academic discoveries closer to real-world implementations, it is necessary to use data that represent “in the wild” scenarios. This project looks at stego images created by mobile apps. For the past three years, research has been conducted on collecting stego images from different phones and different stego apps. One of the main contributions is a procedure for generating a large image database by using Android® emulators and reverse engineering techniques. In 2019, StegoAppDB, the first database consisting of stego images produced from mobile apps, was built and put online.<sup>1</sup> With the large amount of data from the StegoAppDB, for the first time, the performance of software that is designed for stego detection can be tested. Although most stego apps implement some classical embedding algorithms, none of those commercial programs have successfully detected images from apps. One main reason is that those old detection programs rely on the hidden fixed patterns, such as signatures or watermarking, for the algorithm developers, which are completely erased by the app developers.

In the December of 2019, another work was presented to discuss steg detection on images from mobile apps by using two different approaches: “signature” detection and Machine Learning (ML) methods.<sup>2</sup> This study analyzed Android® apps that implement steganography algorithms by applying reverse-engineering techniques to the binary code. In analyzing the code, it was determined that most algorithms used to hide the message are far from the advanced algorithms published in academic research papers. Some apps provide little security, even if a complicated embedding method was used but strangely had a unique “signature” embedded, and make the stego image and its app easily identifiable as such. Moreover, the extraction of hidden information for those app can be achieved. This study developed detection tools for all images with well-defined “signature” patterns and achieved nearly 100% accuracy. For the apps that do not have the “signature”, the study applied the ML-based detection methods to identify stego images. ML has been widely used in the academic community. However, applying those ML algorithms to the real-world data is not trivial. First, the real-world data has more variance in exposure settings and embedding rates, which is not the typical case in the academic world. Second, an input image provided by the user is processed before the embedding step by the app, and, therefore, an input image is not necessarily the cover image in the traditional definition. This study summarized most pre-processing methods and output the post-processed images as cover images for training the classifiers. This study used instrumentation techniques to perform the non-trivial task to batch-generate cover-stego image pairs for ML steganalysis. These proposed ML methods can detect both spatial domain and JPEG domain stego images with a decent accuracy. Per research, this is the first time an ML detection algorithm was applied to identify stego images generated by mobile stego apps.

### C20 Control Point Selection for Analysis and Height Measurement From Closed-Circuit Television (CCTV) Images

*Angela Savva, BS, University of Technology, Sydney, Broadway 2007, AUSTRALIA; Domenic Raneri, BS, University of Technology Sydney, Broadway 2007, AUSTRALIA; Sebastien Moret, PhD, University of Technology Sydney, Sydney 2007, AUSTRALIA; Philip Maynard, PhD\*, University of Technology Sydney, Ultimo 2007, AUSTRALIA*

**Learning Overview:** The goal of this presentation is to illustrate the effects of control point selection on precision and accuracy in the analysis of CCTV footage. The hypothesis of precise and accurate measurements in the absence of control points is also presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining that validation of the control point selection process and parameters, such as camera resolution, is an important step in presenting photogrammetric evidence with known error rates. The hypothesis that natural image landmarks can be just as robust when substituted in the place of purpose-built control point markers may significantly reduce the time and resources police are required to spend in the field, and it may enhance the analysis of CCTV evidence where measurements are involved by improving the calibration process.

Agencies may use CCTV footage to extract meaningful information about the movements, activities, and characteristics of a person of interest. One such characteristic is height, and as a class characteristic it is a powerful exclusionary tool. In addition to the capabilities of laser scanning and photogrammetry to create 3D photo-realistic reconstructions of crime scenes, there is keen interest in applying these techniques to ascertaining height measurements from recorded traces left on CCTV footage. Control point selection has shown promise in a number of studies focused on obtaining height from single-image surveillance video. Control point selection as a photogrammetric tool in crime scenes currently has limited literature—especially when it comes to establishing precision and accuracy and assessing the impact of image variables on precision and accuracy.

In this work, experiments were designed to test the variability of photogrammetric errors with image resolution. A calibration set-up with 50 purpose-made control point targets was filmed and scanned. Using a photogrammetric package, control point selection was used to achieve camera calibration, followed by derived height measurement of a physical object of known height placed in the field of view of the footage. The resolution of the original footage was digitally down-sampled in 5% increments and the measurements repeated. It was hypothesized that image resolution would be inversely proportional to precision, with an unknown effect on accuracy. The effect of uneven control point distribution within the space was also investigated. The accuracy of the measurements was externally validated using Light Detection And Ranging (LIDAR).

It was found that image resolution did systematically impact the precision of the results for height measurement and calculation of the camera location. It was observed that the greatest error range in calculated camera position and measured height was in the lowest-resolution image.

It was found that the accuracy was impacted by the nominated location of the control point in the image, which is a manual and subjective process. Concern was raised as to subjectivity of manual point selection, and the question is posed as to whether relying on automated target detection or shape-matching algorithms (which are already commercially available), would be a better option.

Follow-up experiments were conducted to investigate whether purpose-made control points could be replaced by immovable existing features within the field of view of the camera, an area of research that has limited/no existing literature. Precision and accuracy analysis using landmarks was conducted in a similar manner to the earlier height measurement, noting that existing fixed features may not be evenly distributed in the field of view.

#### Photogrammetry, Control Points, CCTV

### C21 Using an Orthogonal Fingerprint Matcher to Boost Recognition of Contactless Fingerprints

Mark A. Walch, MArch, MPH\*, *Sciometrics LLC, Chantilly, VA 22150*

**Learning Overview:** After attending this presentation, attendees will better understand the capabilities and possibilities as well as the current status of off-the-shelf smart phone technology as a fingerprint-capture device in support of identity matching. Technical details will be provided regarding the process of capturing accurate photographs with a smart phone camera, rendering these images into high contrast fingerprints and automatically matching these fingerprints to identities. A new concept will be presented that contactless fingerprints should be handled as latent fingerprints for matching purposes with final adjudication of results performed by an orthogonal matcher.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a new idea that contactless fingerprints be treated as latent prints and discussing the steps for implementing this concept. Specific reporting will be provided on the development and testing of techniques for capturing contactless prints using a mobile device and submitting these prints to an Automated Fingerprint Identification System (AFIS) as latents against legacy “rolled” or “flat” prints. Once the AFIS results are returned, this presentation will discuss the adjudication of the matching results using orthogonal recognition technology originally developed by the Federal Bureau of Investigation (FBI) Laboratory (Project GRAFF) as an “Afterburner” and generating an objective score that makes a statistical statement regarding the results.

Fingerprints are truly the “human barcode” and among the best measures of human identity available. Conventional fingerprint sensors require a person to touch the device platen or sensor. Disadvantages to this mode of acquisition include the time required to collect (particularly rolled) prints, as well as hygiene concerns. Recently, technologies have been developed to use smart phones as fingerprinting devices. Since capturing fingerprints with the camera on a phone does not require physical contact, this method of collection has been labeled “contactless fingerprinting.” Contactless fingerprinting can be performed by the “rear” phone camera with no additional hardware. A 12-megapixel camera can produce high-resolution images (from 500 to 1,000ppi) that capture sufficient ridge detail to support fingerprint matching. A typical strategy for contactless fingerprinting is to capture ten fingers in three pictures: two “slaps” (four fingers each) plus two thumbs held together. Once captured, the images are processed into high-contrast prints; features are extracted from these prints and placed into an AFIS query format. Matching can either be performed on the mobile device or the fingerprint images can be set to a remote server for matching.

Images produced by contactless devices are fundamentally different from conventional scanned ink and livescan fingerprints, supporting the concept that they be treated as latents. Contactless and contact prints differ in both distortion characteristics and image sensor characteristics. New pathways for device certification are being developed for contactless fingerprinting to ensure these new contactless fingerprint images are matchable to conventional fingerprints captured through inking or contact scanning. For example, through funding from the FBI’s Biometric Center for Excellence, the National Institute of Standards and Technology (NIST) has been developing standards for certifying contactless scanning so images obtained in this manner can be submitted for matching against the FBI’s databases. However, the body of current research focuses on what can be done on the mobile device to create contactless images that are most compatible with legacy collections. This presentation discusses a different approach in terms of technology that can be employed to handle the contactless fingerprint transaction. The content of the presentation focuses on a specific approach for submitting limited sets of prints (such as would be the case for latents) and introducing orthogonal matching technology that will modify the matching process without fundamentally changing the nature of how existing AFIS systems work. The outcome of the modified process is improved performance for matching contactless prints submitted against collections of prints obtained through contact methods.

This presentation of treating contactless prints as latents will be supported by actual data obtained through contact fingerprinting and matched against an AFIS with contact reference prints taken from the same and different individuals. These results will show original accuracy scores for contactless images against legacy contact prints using a commercial AFIS. In contrast to these original scores, results incorporating the orthogonal technology as an Afterburner are also shown to demonstrate its impact on scoring and ensuring data from all ten fingers can be reliably collected using contactless methods.

#### Contactless, Fingerprints, Orthogonal

### C22 Machine Learning in Data From Crime-Related Mobile Devices: Bidirectional Recurrent Neural Networks for Named-Entity Recognition (NER) in WhatsApp, Instagram™, and Facebook® Messenger Text Conversations

Matheus S. Oliveira\*, Universidade de Brasília, Brasília 70910-900, BRAZIL; Daniel M. Caldas, MS, Polícia Civil do Distrito Federal, Brasília, Distrito Federal 70297-400, BRAZIL; Thiago P. Faleiros, Universidade de Brasília, Brasília 70910-900, BRAZIL

**Learning Overview:** This presentation summarizes the initial efforts of a Brazilian Federal District Police forensic research team to use the huge amount of text data extracted from crime-related mobile devices to shed light on the general crime panorama of the Brazilian Federal District and to develop tools that can help the digital forensic investigator in his casework. Attendees will have a chance to see the nature and format of the text data extracted from mobile devices in Brazil, the path chosen by the research team to retrieve drug-related information from this data, the difficulties encountered, and the solutions developed by the team.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing how recently developed Bidirectional Long Short-Term Memory (LSTM) Neural Networks can be used to extract information from text data retrieved from crime-related mobile devices. This presentation will show the strategy developed by the forensic research team to perform drug-related named-entity recognition on WhatsApp, Instagram™, and Facebook® Messenger Text Conversations.

It is notable that in recent years there was a significant increase in the volume and variety of data in the hands of corporations and institutions. Most of this data is represented in the form of unstructured text. Many are examples situations in which huge quantities of text data can be used to achieve valuable insight.

The Digital Forensics Department of the Brazilian Federal District Police works as a hub to a huge amount of data retrieved from mobile devices owned by crime perpetrators and victims. This data group represents an untapped potential. The correct interpretation of this data can bring valuable information on the general panorama of criminal offenses in the Federal District.

In order to start exploring this data group, the forensic research team considered the development of a tool to extract drug-related information from text conversations. Machine learning techniques have already been successfully employed to identify crime-related images on police databases, but content-sensitive text analyses are yet to be used in this context.<sup>1</sup>

NER is an information extraction technique that aims at locating and classifying named-entity mentions in unstructured text into predefined categories, such as person names, organizations, quantities, etc. Recently published research used a Recurrent Neural Network to perform NER in Brazilian legal texts, obtaining satisfactory results.<sup>2</sup>

A Bidirectional LSTM Neural Networks was chosen to perform drug-related NER in text conversations retrieved from mobile devices seized by police officers in the Federal District. The researchers identified a similarity between these text messages and tweets made by Brazilian users, so public tweets were used as a complementary source to the database.

After a pre-processing stage, the database was manually labeled. The entities were assigned the values B-DRUG, for terms that represent names of drugs, and B-DRUG\_RELATED, for terms that represent activities related to drug abuse. The final base was made up of 102,325 words, of which 7,356 refer to drugs and 2,148 correspond to drug-related activities. After the construction of the database, a Bidirectional LSTM Neural Network was implemented and trained with the database.

The model was then tested. The base was randomly divided, using 80% of its data for training, and 20% for testing. Experiments revealed that the model was able to satisfactorily classify the test data, obtaining a precision rating of 0.99 for B-DRUG terms and 0.97 for B-DRUG\_RELATED terms. The F1-Scores were 0.99 and 0.98, respectively. A validation test was performed using only data from the mobile devices, resulting in a precision rating of 0.91 for B-DRUG terms and 1.00 for B-DRUG\_RELATED terms. The F1-Scores were 0.74 and 0.93, respectively. These results are promising. Content-sensitive text classification in text messages is a difficult task, so named-entity recognition can be used in machine learning applications to aid in the fight against crime.

### C23 Steganography Detection Using Machine Learning (ML)

*Joshua Ralls\*, Eastern Kentucky University, Richmond, KY 40475; Shuangteng Zhang, PhD\*, Eastern Kentucky University, Richmond, KY 40475*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of steganography, steganalysis, and ML technologies. Specifically, attendees will gain an understanding about the features of the F5 steganography algorithm and how the hidden message embedded in a JPEG image by F5 algorithm can be detected.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, specifically the digital forensics and cybersecurity community, by introducing a possible ML-based approach for detecting steganography generated by using the F5 algorithm. This will help digital forensic as well as the cybersecurity investigators in their case investigations, and the experiences with ML for steganography detection gained in this research will also help researchers in their process of designing and developing the new steganography detection methods.

Steganography is a technology of hiding secret messages by embedding them into the cover media, such as audio, image, video, or text files. Because of its characteristics of detection avoidance and tamper resistance, steganography technology is widely used for secret message communication for both good and bad purposes, and it is increasingly used by cyber criminals for carrying malicious software and launching attacks. Therefore, it is very important for the digital forensics investigators and cybersecurity professionals to have methods to detect the steganography and thwart the cybercrimes.

F5 is a steganographic algorithm of hiding data into JPEG images. It works by changing the Discrete Cosine Transform (DCT) coefficients of a JPEG image. What makes F5 popular for JPEG image steganography is that it is quite strong against both visual and statistical attacks and, therefore, is difficult to detect. Most of the existing F5 steganography detection technologies use the traditional mathematical and statistical approaches to tackle the problem. These technologies possess a higher detection accuracy when the F5 steganography images carry a higher volume of messages. When the hidden message volume is not exceeding the F5 optimum capacity, the accuracy of those technologies is significantly lower.

In the past decade, with the advancement of the computing technology, ML, especially the deep learning technology, has become feasible, and this has opened the door for the numerous applications of these technologies in various fields. With the F5 steganography detection challenge in mind, this research took advantage of the deep learning capability of the Convolutional Neural Network (CNN) to design an ML-based approach to attack this difficult steganography detection problem.

This presentation will provide an overview about steganography, steganalysis, and ML technologies. Focusing on ML for steganography detection, this presentation will discuss the design of the CNN, feature selection and extraction, and training and testing of the developed CNN. The experiences and lessons gained in the design, training, and testing of the CNN for F5 steganography detection will also be discussed.

### C24 Digital Forensic Evidence Cracking an Ingenious Murder Cover-Up: Lochner's Principle Re-Validated

Mohit Chauhan, MBBS, MD, DHM\*, Government Medical College & Hospital, Chandigarh 160030, INDIA

**Learning Overview:** The goals of this presentation are to emphasize the importance of digital evidence at autopsy, to spread awareness about the mechanisms and technicalities of the mobile phone as an aid to solving crimes, to critically validate Lochner's Principle by the exemplar case, and by elucidating the importance of mobile phone device/Subscriber Identity Module (SIM) cards as useful sources of digital forensic trace evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating that by exploring the exchange of trace evidence, Lochner's principle utilizing non-contact theory may be used as an adjunct to Locard's principle, which propounded on the contact theory. Additionally, the basic working mechanism of digital mobile devices will be introduced.

The increasing usage of mobile cellular devices in daily life, with their inherent functioning technology, has been highly instrumental in death investigations in the recent past. The information stored in mobile devices can ascertain the movement and location of an individual with his contact and communications. There are some unique considerations about mobile phones and associated devices if found as a source of evidence. A major advantage of mobile devices from the forensic perspective is that even deleted information can be recovered from mobile devices in criminal investigations. This is because of the utilization in these devices of flash memory chips, which are physically durable against impact, high temperature, and pressure. Secondly, flash memory has a limited number of writes and can only be erased block-by-block, and mobile devices generally wait until a block is full before erasing data. Furthermore, mobile devices use proprietary wear-leveling algorithms to spread write/erase across flash memory blocks, which can result in deleted data remaining for some time while new data are written to less-used portions of memory. Keeping in mind all the collection, extraction, and analysis-related issues regarding trace evidence, digital evidence serves as excellent sources of information akin in specificity of 100% to fingerprinting when compared to other trace evidence. Nonetheless, the personal nature of these devices makes them easy to establish the last mile evidence required to fix the liability of a device to an individual. There are a growing number of mobile devices for personal organization and communication, many with access to the internet. These devices can be a source of digital evidence in any crime revealing personal information about an individual, including photographs, passwords, and other data. The information they contain can also be instrumental to a crime when they are used to steal intellectual property or create and disseminate child pornography. It has become routine for investigators to collect mobile devices, if available, as evidence in recent years. By far the most obvious trend is that mobile devices will continue to be important in forensic analysis and have large roles in both civil and criminal investigations. Currently, tools and training in this area are limited but, given the rapid increase in their use, this is likely to become one of the largest growth areas in the field of digital evidence examination.

Presented here is an unusual case of the homicide of an unidentified adult female who had been strangled, body tied up, and disposed of by an ingenious means of body sacking. At autopsy, a dead body of an adult female of Asian origin was brought to the mortuary for postmortem examination. One intact red Vodafone SIM card was found perfectly sticking against the back of the body, prevented from falling off or displacement by the brassiere. The cause of death was opined to be asphyxia and venous congestion consequent upon ligature strangulation in a homicidal manner by the ligature material (neck scarf) found *in situ*.

The recovered SIM card was provided to the investigating authorities for conducting prompt investigative operations to nab the suspect. Police tracked the suspect by the International Mobile Subscriber Identity (IMSI) method of phone tapping, thereby directly validating Lochner's principle and proving exclusively important in tracing the accused by temporal, relational, and functional analysis. The recovery of the SIM card played a key role in the identification of the victim, the assailant, and the motive of the homicide.

#### SIM Card, GSM, Digital Evidence

### C25 Quantum Digital Forensics: The Applications of Digital Forensics in a Quantum World

Suzanne I. Myers\*, Silicon Valley Bank, Tempe, AZ 85281

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how quantum computers are poised to impact the future of digital forensic work. Attendees will gain an understanding of how quantum computers function and insight into both the advantages and disadvantages of their application to the digital forensic landscape.

**Impact on the Forensic Science Community:** As with any new technology, digital forensic examiners need to understand how it works and what the impact is to the data they sift through daily to best anticipate both the case applications and the security needs of their industry. This presentation will impact the forensic science community by encouraging discussion on the applications of quantum computers and better preparing the digital forensic community for the anticipated challenges and opportunities of working in a quantum world.

Digital forensic analysts are on the cusp of needing to fight a battle against exponentially more powerful cyber threats. What was once only considered science fiction is now reality, and quantum computers in the wrong hands present a significant problem for those trying to protect individuals and organizations from attackers. The applications for a quantum computer—such as the expansion of cloud computing, a faster internet, unbreakable encryption, and new channels of communication—are also rapidly generating interest in the security industry.<sup>1</sup>

There are significant differences between quantum and classical computers, and some of the problems forensic examiners will face are extracting live data from a system when that data can be in multiple states at the same time, creating exact forensic copies when the state of a bit can change with each observation, capturing data in a transmission when the packet doesn't ever traverse a network, and breaking encryption in a post-quantum environment.<sup>2-4,7,8,10,12-14</sup>

With these challenges also come opportunities. Digital forensic analysts will be able to use quantum encryption to crack old cases that classical computers simply couldn't solve.<sup>5,6</sup> They'll be able to use quantum's pattern-matching technology to scan large databases for matches on faces, locations, and objects of interest.<sup>9</sup> Finally, quantum computers will very likely facilitate the transmission of classical information, making it imperative for examiners to know and understand the architecture they are dealing with.<sup>11,15</sup>

This presentation examines the above questions and discusses the types of forensic needs necessary in a quantum world. This presentation will review how data will be transmitted in a quantum environment, advantages and disadvantages versus classical forensics, the potential for live forensics, pattern recognition for law enforcement applications, and discuss the code-breaking implications for today's current forensic encryption challenges.

### C26 Applications of a Convolutional Neural Network (CNN) for Automatic Classification of Outsole Features

*Miranda R. Tilton, MS\*, Iowa State University, Ames, IA 50011; Susan VanderPlas, PhD, Iowa State University, Ames, IA 50011*

---

**Learning Overview:** After attending this presentation, attendees will be familiar with the ways that CNNs can be applied to classify forensic pattern evidence, specifically with shoe outsole features.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a powerful machine learning method to automatically classify shoe outsoles with the goal of improving the reliability of pattern evidence analysis. Results of this research can be used to automate and speed up shoe print database searches and provide valuable information about the relative frequency of specific characteristics found on outsoles within and across local populations.

The improvement of modern computing has led to the widespread implementation of machine learning, in which computers “learn” about data without being explicitly programmed. CNNs are a form of deep learning that mimics the human brain by using complex networks of hidden layers to learn patterns and make decisions about the contents of an image. For example, we may see an image that contains features such as “eyes” and “nose” and conclude that the image contains a “face.” Similarly, CNNs learn and combine local patterns in a set of training images to learn to detect the presence of a desired set of features in new images.

In forensic applications, images of shoe prints and outsoles are well-suited to classification using CNNs. This is because outsoles often contain distinct and well-defined shapes (e.g., circles, triangles, and text) that can be easily classified by a CNN. Once the shapes contained in a print are detected and classified, the resulting labels can be combined to determine the shoe’s category (e.g., athletic, formal) and brand, and labels for different outsoles can be compared to assess similarity between different designs.

A classification scheme was modified from sets of geometric features currently used by forensic footwear examiners, and thousands of outsole images were obtained and manually labeled according to the new scheme. These images were used to train a new classifier for the convolutional base of VGG16, a pre-trained CNN that is commonly adapted for novel image classification tasks.

One potential application of this new model is to automate and/or speed up database searches that examiners perform when searching for candidate shoe models which may match a questioned print. Another application, which is currently underway, is to collect a large amount of outsole data through sidewalk-embedded scanners, then utilize statistical methods to determine the relative frequency with which certain characteristics appear in shoes that are commonly worn within specific populations.

This presentation will include discussion of the process and challenges of developing a classification scheme and training a CNN for outsole recognition, summarize the performance of the current model, and present preliminary results for the determination of feature frequency in local populations.

---

#### Machine Learning, Shoe Outsole, Pattern Evidence

### C27 An Effective Security Assessment Framework for Drone as a Service (DaaS): A Digital Forensic Technique

Fahad Salamh, PhD\*, Kokomo, IN 46901-5879; Umit Karabiyik, PhD, Purdue University, Knoy Hall, Lafayette, IN 47907-2021; Marcus Rogers, PhD, Purdue University, West Lafayette, IN 47907

---

**Learning Overview:** After attending this presentation, attendees will be able to clarify security risks of drones, determine the best practices of security assessment, and make decisions related to the security of drones during operation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring the best practice techniques related to drone penetration testing, including an effective methodology to keep continuity of risk-free drone operation, especially drones used for emergency purposes, such as safety and rescue.

This presentation will raise awareness in the forensic science community as it draws the importance of securely operated drones for first responders. This presentation will cover various aspects of security, including data transmission, software restrictions, and embedded system-related events. In order to propose a security assessment for drones, they incorporate digital forensics and penetration testing techniques to suggest secure methods related to drone operations. Therefore, this research enhances the security level of flying devices and the overall digital forensics procedure in case of a disruption incident.

Firmware analysis and penetration testing on embedded devices is crucial today. Firmware is used in most emerging technologies, which make them an important factor in securing these embedded devices, such as drones. This presentation will cover aspects of security assessment conducted on three different types of drones used by safety and rescue organizations. The presenters focus on the analysis of firmware to determine both security vulnerabilities that could expose threats to the activity of drones, software restrictions that could limit the operation of drones, such as No Fly Zone (NFA), and operational communication commands. The use of DaaS is rapidly increasing, and risk assessment of software-related issues is important to support the adoption of DaaS in a secure operational manner.

The analysis in this work will be performed based on well-known security measures, such as the Open Web Application Security Project (OWASP) Internet of Things (IoT) top 10, the National Fire Protection Association (NFPA) 2400, standard for Small Unmanned Aircraft Systems (sUAS) used for public safety operations, and the National Institute of Standards and Technology (NIST) security guidelines, and develop a recommendation on the attack resistance based on conducted security auditing of the firmware.<sup>1</sup> Finally, this work will be conducted on DJI Matric, DJI Mavic, and Parrot Bebop, which are currently used by most of the safety and rescue organizations.

### C28 The Forensic Utility of Smart Doorbells

*Christina A. Malone, MSFS\*, Defense Forensic Science Center, Forest Park, GA 30305; Carl R. Kriigel, MA\*, United States Army Criminal Investigation Laboratory, Forest Park, GA 30297; Seth M. Eisenberg, Army Educational Outreach Program, Forest Park, GA 30297; Hillary Lathrop, PhD, Defense Forensic Science Center, Forest Park, GA 30297*

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of the current forensic utility of smart doorbells in regard to data extraction and image quality.

**Impact on the Forensic Science Community:** This presentation, a research project conducted by the Office of the Chief Scientist (the Research, Development, Testing, and Evaluation arm of the Defense Forensic Science Center), will impact the forensic science community by demonstrating how and what types of data may be extracted from smart doorbells, as well as demonstrating if the image quality is sufficient for image analysis.

There are numerous SmartHome devices currently available to the consumer, from home automation hubs to function-specific items. Valuable data can be recovered from such devices that may be useful to forensic investigations. Smart doorbells are devices with cameras, microphones, speakers, and motion-sensing abilities that operate via a mobile device or through Wi-Fi. Through their normal use, smart doorbells may capture visual information about a suspect, timeline, or series of actions during, before, and/or after the commission of a crime. Such information could impact the investigation of a crime where breaking and entering through a doorway occurred.

With the increased use of smart video doorbells, there is a need to determine appropriate data extraction methods, the extent to which data can be recovered, and the image quality of the recovered data. The current research examines two smart doorbells with video-recording capabilities to examine their potential for future forensic applications. Both an Amazon® Ring® and Google® Nest Hello™ video doorbells were used in the course of this research. These two devices were chosen based on availability to the researchers. Both devices offer live video-streaming and motion-sensing abilities.

Each device was installed on the doorframe at a traditional doorbell height. Placement was viewed to ensure the area being captured would properly capture people in proximity to the door. Researchers used each device over the course of several months in order to collect recordings from various times of the day and weather conditions. During this time, each doorbell was in continuous use; however, recording only took place when there was motion to activate the doorbell. At the completion of this timeframe, an extraction was conducted on each mobile device used to access the doorbells (iPhone® 7 Plus and iPhone® 6) using standard computer forensic methods. The two methods of extraction employed a Physical Analyzer. First, a physical extraction was performed. Second, a logical extraction was completed. Results of the extractions were compared to determine what type of data was retrievable and what affects the extraction had, if any, on image quality. The image quality was further assessed through an analysis of the metadata (e.g., resolution and file size) and visual analysis of the details present (e.g., scars, facial features, hats, and shirt tags).

#### SmartHome, Doorbells, Image Analysis

### C29 Counterfeit Drug Detection Using Multi-Spectral Imaging

*Brady Carter, PhD\*, Neutec Group, Farmingdale, NY 11735*

---

**Learning Overview:** The goal of this presentation is to: (1) provide instruction on multi-spectral imaging theory and measurement; (2) describe how multi-spectral imaging can be used to detect counterfeit drug products and packaging; and (3) provide case study examples of counterfeit drug detection using the Variable Magnification Lens (VML).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing multi-spectral imaging as an effective tool to help forensic teams identify counterfeit products or packaging in a fast, non-destructive manner.

Counterfeit pharmaceutical products are an increasing threat to patients and pose severe challenges to the pharmaceutical industry. The challenge for forensics teams searching for counterfeits is that the counterfeiters are becoming more sophisticated, making it increasingly difficult to distinguish authentic products from replicas. These teams need superior detection techniques. Multi-spectral imaging has been utilized in the field of satellite and airborne sensing for many years but is now available in a powerful benchtop laboratory analyzer. The system consists of a high-resolution camera that takes a series of images at wavelength bands ranging from ultraviolet to near-infrared light. Because a unique image is taken at each wavelength band, the images can be viewed individually or in combination. In addition, specific layers within the image can be isolated and compared. Multivariate analysis can then be utilized to identify differences between the spectra of each layer over the entire wavelength range.

The objective of this study was to utilize multi-spectral imaging to identify counterfeit pharmaceutical products. Three different tablet types consisting of both genuine and counterfeit samples were analyzed using multi-spectral imaging. A color image of the products did not reveal any differences, nor were differences detectable by the naked eye. However, by observing the entire spectra, it became clear that while distinguishable differences did not exist in the visual band, differences could be observed in the near-infrared region. Authentic and counterfeit samples were then compared using normalized Canonical Discriminant Analysis (nCDA) to identify the best way to differentiate between the samples. Once trained by nCDA with the correct combination of bands to use, the system was able to provide a spectral fingerprint to correctly identify genuine product from counterfeit in blind samples. Multi-spectral imaging was able to identify counterfeit tablets in blind samples with 100% accuracy and could even detect counterfeit tablets while still in the package, eliminating the need to remove the tablets for analysis. In addition, multi-spectral imaging was able to distinguish counterfeit packaging from authentic with full accuracy. Multi-spectral imaging was concluded to be an effective tool for forensics teams to identify counterfeit products in a fast, non-destructive, and versatile manner.

**Counterfeit, Imaging, Fast**

### C30 Pathways to the Identification of Multinational Victims of Mass Disasters: The Role of Blockchain Technology

*Shada Alsalamah, PhD\**, King Saud University, Riyadh 11545, SAUDI ARABIA; *Emilio Nuzzolese, PhD*, DSSPP, Sez. Medicina Legale, Università di Torino, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will have learned, using real-world cases, how blockchain technology adoption can achieve an automated archiving system to fully manage the identification of medical and dental data for comparison and data mining that should promote novel solutions for forensic human identification and Disaster Victim Identification (DVI).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how blockchain technology adoption should revolutionize the human identification and disaster management processes worldwide, improving the management of missing persons, Antemortem (AM) data repositories of living people, Postmortem (PM) data repositories of recovered unidentified human remains, interactions with electronic medical and dental records, and helping to facilitate the comparison of compatible biological profiles for definitive identification. The possible applications presented in this study promise enormous benefits to authorities, victims, their families, and society in general. This presentation should create a trusted ecosystem to help forensic science practitioners advance beyond traditional methods and stimulate innovative collaborations with computer scientists in order to improve procedures, especially in the area of forensic dental identification.

In mass disasters with multinational victims, it is critical to identify the deceased for judicial, ethical, religious, and human rights reasons, as well as to allow the next of kin to complete the grieving process. The DVI process is a complex procedure in which PM identifying data, essentially fingerprints, DNA, and dental, is collected, then compared with equivalent AM data related to the missing person's list. Although there are solutions used in the field of human identification, they all fall short of equipping practitioners with the tools needed for achieving human identification in a timely manner. Initially, it is significantly challenging to manage missing person's lists containing years, and sometimes decades, of family AM data resources' updates. Furthermore, there is currently no record of any holistic and decentralized technical solutions for managing both AM and PM data for human identification to support collaborative multinational and interjurisdictional processes. Blockchain technology provides the tools to facilitate building trustworthy, secure, and holistic ecosystems, and it can disseminate siloed AM and PM data across systems, protecting data breaches, redundancies, inconsistencies, and errors. As such, blockchain technology can revolutionize the human identification process worldwide in terms of managing missing person's lists, AM data repositories for living people, PM data repositories of recovered unidentified victims, and contribute to the comparison of compatible biological profiles for definitive identification.

This study presents real-world use cases that examine how this technology facilitates multi-jurisdictional data information-sharing in conjunction with the forthcoming circulation of patients' electronic medical and dental records. This study encourages openness and interjurisdictional victim information-sharing to paint a full picture that would allow each team to perform their tasks. However, this raises information security and privacy concerns that could hinder its adoption by some DVI teams that have to comply with tighter jurisdiction-specific data protection laws and regulations that are not applicable elsewhere, such as the General Data Protection Regulation (GDPR), considered the toughest privacy and security law applied today.

#### **Blockchain Technology, Disaster Victim Identification, Forensic Odontology**

### C31 A Proposed Framework for Digital Video Authentication

*Gregory S. Wales, MS\*, United States Department of Interior, Office of Inspector General, Lakewood, CO 80228; Catalin Grigoras, PhD, Denver, CO 80202; Jeff M. Smith, MS, National Center for Media Forensic, Colorado University-Denver, Denver, CO 80204*

---

**Learning Overview:** After attending this presentation, attendees will understand the proposed authentication process for digital video using methods based upon scientific research and publication in which various analyses may be combined into a framework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a logical and scientifically sound process for digital video authentication.

Digital video authentication is a complex process of establishing the provenance of a questioned recording to determine whether it is consistent with an original recording or if there is evidence of alteration. One simply has to look at news outlets or social media to see that our society video records events from births to deaths and everything in between. A trial court's acceptance of videos supporting administrative hearings, civil litigation, and criminal cases is based on a foundation that the videos offered into evidence are authentic; however, technological advancements in video editing capabilities provide an easy method to edit digital videos.

The proposed framework offers a structured approach to evaluate and incorporate methods, existing and new, that come from scientific research and publication. The proposed framework incorporates methods or techniques that are evaluated for reproducibility, repeatability, accuracy, and precision while meeting the general legal requirements (a general application of the *Daubert* standard) recognized by courts in the international community, United States, and many countries around the world.

This presentation offers a quick overview of digital video file creation chain. This also includes factors that influence the final digital media streams and a general description of camera sensor noises for both Complementary Metal-Oxide-Semiconductor, and Charge Couple Device type sensors.

This presentation addresses the overall development and proposed use of the framework, previous research of analysis methods/techniques, testing of the methods/techniques, and an overview of the testing results. The framework provides the forensic video examiner a structured approach to subjecting the questioned video file to a series of smaller tests while using previously published and forensic community-recognized methods/techniques. The proposed framework also has a proposed workflow optimization option for use by management in an effort to manage resources and personnel. The framework has a built-in methodology evaluation tool based upon a general application of the *Daubert* standard. The methodology evaluation tool includes a methodology validation assessment and a legal assessment to aid the forensic video examiner in determining if a proposed method should be included or excluded from use as part of the specific framework protocol for each video file considered for authentication. Also, the proposed framework offers the forensic video examiner a methodology to assess published video and audio authentication techniques recognized in the forensic science community while using generally accepted criteria to test and evaluate the techniques as expected by the courts.

This presentation will also note some limitations to the use of the proposed framework for digital video authentication. The limitations include the following: acceptance of the proposed framework for video authentication by the courts will always be based upon a case-by-case basis dependent upon each case's facts, proper use of the scientific methods, and the overall experience, training, and knowledge of the forensic video examiner who testifies as an expert; the proposed framework is intended for digital video and is not applicable to analog video; and no scientific inquiry, including those in media forensics, produce results of absolute certainty—this includes digital video authentication. The proposed framework uses a philosophy that avoids implying 100% certainty with the exception of known alterations or deletions applied in the underlying testing/experiments for the development of the proposed framework.

This presentation will also note that the framework is designed for incorporation of new digital video authentication methods that are developed in the forensic science community, as they are proven to be based upon scientific research and publication and are accepted in the forensic science community.

#### Digital Video, Authentication, Camera Sensor Noise

### C32 Automated Standards-Based Normalization and Correlation of Mobile Device Evidence

Eoghan Casey, PhD\*, University of Lausanne, Lausanne, Vaud 1015, SWITZERLAND; Martina Reif, MS\*, University of Lausanne, Lausanne, SWITZERLAND; Quentin Rossy, PhD, School of Criminal Justice, University of Lausanne, Lausanne 1015, SWITZERLAND

**Learning Overview:** This presentation will provide attendees with a more efficient, reliable, standards-based approach to automatically normalize, combine, and correlate digital and multimedia evidence. This presentation provides a fit-for-purpose solution using the evolving Cyber-investigation Analysis Standard Expression (CASE) standard to represent information extracted using mobile device forensic tools and to combine this information into correlation analysis tools. This work concentrates on treating the following categories of information: (1) communications (Short Message Service [SMS], chat messages, email); (2) identifiers (telephone numbers, email addresses, social media accounts, Internet Provider [IP] addresses); (3) temporal indicators (timestamps, call durations); and (4) spatial indicators (Global Positioning System [GPS] coordinates, addresses).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) saving time correlating and analyzing digital/multimedia evidence from mobile devices; (2) reducing risk of errors and omissions combining and correlating digital/multimedia evidence from mobile devices; (3) increasing completeness of forensic analysis of digital/multimedia evidence; and (4) tracking chain of evidence throughout the export and combination process to allow forensic analysts to track findings back to their origin.

Increasingly, mobile devices contain large amounts of digital evidence relevant to criminal investigations.<sup>1</sup> This digital evidence can be analyzed to make inferences about identities, locations, chronologies, and relationships between relevant entities to address critical questions in criminal investigations.<sup>2</sup> However, there are severe limitations in current capabilities to combine and correlate all available digital evidence. First, no single mobile device forensic tool can extract all types of digital evidence. Second, tools export data in different formats, without consideration for interoperability. Third, it is necessary to combine the results from multiple tools to obtain comprehensive visibility across all digital evidence. Fourth, mobile device forensic tools do not maintain chain of evidence throughout the export and combination process, making it difficult to track forensic findings back to their source. Dealing with these problems, forensic practitioners reformat and combine information from different sources by hand, which is a laborious and time-consuming process that can result in errors and omissions.<sup>3</sup> For example, using spreadsheet software or database applications to import and format data from various sources can result in items such as date-time stamps being altered, entries not being imported, and other problems that negatively impact forensic analysis. There is a need for automated combination and correlation between datasets processed by mobile device forensic tools.<sup>4</sup>

The specific educational objectives of this presentation are to: (1) raise attendee awareness of current limitations in mobile forensic tools and how to address these limitations; (2) teach the attendees how digital/multimedia evidence extracted using mobile forensic tools is automatically translated into the CASE standard; (3) inform attendees about open source resources for implementing CASE in existing tools and systems; (4) demonstrate the value of importing normalized digital/multimedia evidence from mobile forensic tools into a platform for correlation and analysis; and (5) provide a roadmap of work to strengthen and expand CASE adoption across the digital forensic community.

This work addresses challenges in the way different tools represent extracted data, including missing information, only displaying one party in communications, and variations in the format of common information (e.g., timestamps, phone numbers).

By implementing the CASE standard, this solution does not require tool developers to alter their data model. Instead, it is necessary to translate their data model into a community-developed ontology for representing cyber-investigation information. This approach allows visualization tools, such as Cellebrite® and Analyst's Notebook®, to automatically (rapidly) import data from all sources into a cohesive and comprehensive picture to support selection, correlation, and analysis.

#### Digital/Multimedia Evidence, Standards-Based Correlation, Chain of Evidence

### C33 Known Source Artifacts Examination With Digital Forensic Tools

*Hayden A. Hendrickson, BS, Eastern Kentucky University, Computer Science, Richmond, KY 40475; Amanda A. Moses, BS\*, Kentucky State Police, Frankfort, KY 40601; Kimberly Bradley, MS\*, Kentucky State Police, Electronic Crime, Frankfort, KY 40601; Shuangteng Zhang, PhD, Eastern Kentucky University, Richmond, KY 40475*

---

**Learning Overview:** After attending this presentation, attendees will understand the capability of various digital forensic tools when used to examine devices with known, documented activities. Recovery of artifacts related to activity is attempted by using each tool. Each tool's data extraction will be reviewed for the tool's ability and accuracy of locating the artifact.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing knowledge regarding how forensic tools extract known expected artifacts. This knowledge will help examiners validate examination results and know which tool could be used to get a more precise representation of what has occurred on a device. This presentation will not only give examiners knowledge on forensic tools for Windows® computers, but also for mobile devices.

In the field of digital forensics, forensic software plays a major role in obtaining the evidence used in convicting or excluding someone of a crime. Multiple different digital forensic tools have come to the market in recent years and all these tools are claimed to be the best for all the examiner's needs for extracting and reporting digital evidence. However, because these tools process the data using different methods and present the recovered evidence in various ways, it is very challenging for the examiners to know how each tool behaves. In order to overcome this challenge, it is important for digital forensic investigators to have the knowledge of what tools are best at doing certain tasks they want the tools to do. This presentation is designed to provide digital forensic practitioners with that knowledge.

Digital forensic examiners must prepare every examination as if it were to be presented in court. Having confidence in the tools and methods used for data extraction is a critical element for testimony. This presentation will provide attendees with information about effectively comparing the forensic tools and how the results can vary depending on the software used. Windows® computers and mobile device technology change at a rapid rate and the amount of people who use mobile devices grows every year. With more devices that are constantly changing, it has become increasingly important that examiners be aware of the differences in examination results and know how to validate their findings.

This presentation will provide an overview of methods to validate different forensic software tools and their capabilities for discovering related digital evidence on Windows® computers and mobile devices.

---

### Digital Forensics, Artifacts, Digital Forensic Tools

### C34 Teaching Digital Forensics to Young Women and Underserved Youth

*Eoghan Casey, PhD\*, University of Lausanne, Lausanne, Vaud 1015, SWITZERLAND; Daryl Pfeif, BA, Digital Forensics Solutions, New Orleans, LA 70130*

---

**Learning Overview:** After attending this presentation, attendees will better understand: (1) the overarching design principles and research underpinning this innovative educational initiative; (2) practical lessons learned throughout the development and implementation of the Digital Forensic Science Learning Environment (DFSLE) and related activities; and (3) educational and infrastructure challenges and resulting solutions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) bringing more women and underserved populations into traditionally underrepresented computer science-related fields; (2) enhancing Science, Technology, Engineering, and Math plus Computing (STEM+C) education at out-of-school settings; (3) increasing the number of qualified candidates for a rapidly growing number of digital forensic science positions; (4) providing a robust instructional framework for teaching science inquiry-based subjects; and (5) promoting responsible online behavior and cyber street smarts.

Attendees will learn about an initiative to address the growing demand for qualified candidates in digital forensics, particularly young women and men from underrepresented populations. This presentation explains the design, development, implementation, and future of the DFSLE, an innovative educational program and supporting virtual learning laboratory created to provide youth with digital forensic knowledge, skills, and career pathways. This program combines online and in-person classroom elements that challenge students to become cyber sleuths solving real-world problems, applying methods and tools in digital forensics, and exploring complex social and technical issues associated with cybercrime. The DFSLE extends the Investigate and Decide Learning Environment (IDLE) framework from learning sciences, teaching technical and problem-solving skills through goal-based investigative scenarios. By immersing students in real-world problem-solving situations, this initiative strives to motivate students to develop scientific reasoning, technical knowledge, practical skills, and pursue related careers while improving their cyber street smarts. This initiative has included students from grades 9-12 in Baltimore, MD, New Orleans, LA, and Seattle, WA. The project connects with aspects of expectancy-value theory and Social Cognitive Career Theory (SCCT) to encourage students to pursue educational or career pathways related to computer science and STEM. In particular, this focuses on the community and relationship-building elements of the mentor network and collaborative peer-learning activities to provide strong social and environmental supports. The practical curriculum has been augmented with teacher training, classroom dashboard, lesson plans, and a pathway resource guide. Classroom activities introduce students to experts in the domain as role models and career mapping. In this manner, this initiative guides students along pathways that can lead to community college and university degree programs and, ultimately, into the workforce.

**Sustainability:** The Computer Science Study Lab (CSSL) is being promoted in partnership with the National Girls Collaborative. Further work on teaching training and open source training datasets is underway to ensure long-term sustainability of this initiative.

**Digital/Multimedia Evidence, Forensic Science Education, Computer-Assisted Training**

### C35 iOS® Photo Vault Forensics

Siddharth S. Chowdhury, MS\*, Purdue University, West Lafayette, IN 47907; Kayla Rux, Mishawaka, IN 46545; Kathryn C. Seigfried-Spellar, PhD\*, Purdue University, West Lafayette, IN 47907

---

**Learning Overview:** After attending this presentation, attendees will be aware of what artifacts may be forensically recovered from photo vault applications using iOS®.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing relevant information for digital forensic investigators who may need to identify and recover relevant artifacts from a vault application on the iOS®.

Modern digital devices, such as laptops, personal computers, mobile phones, and tablets, have vault apps—applications that hide photos, videos, and texts in a secure “vault.”<sup>1</sup> These vault applications allow the user to securely store their personal data, which makes it difficult for anyone except the device’s owner to view the files, even if they have access to the device.<sup>2</sup> These mobile vault applications often disguise themselves by pretending to look like other applications, such as a calculator, or only display information when the user enters a valid password.

From a law enforcement investigation perspective, offenders may use vault apps to hide illegal images, such as child sexual exploitation materials or illicit text messages with minors. In cases such as these, vault applications may serve as a hindrance to law enforcement. While traditional digital forensic tools may be able to recover photos directly stored on the phone, they may not be able to find those secured by photo vaults.<sup>3</sup>

While studies have examined vault applications on Android® operating systems, limited research exists using the iPhone® or iOS® ecosystem. The current study had four aims: determine what information can be forensically recovered from vault applications, examine implications for user privacy, document the methods for forensically extracting information from vault apps, and compare the results from different digital forensic tools. The five most popular vault applications in 2019 on the iOS® store were analyzed. Various types of photos were uploaded to the vault applications using the following techniques: creating a photo by taking a screenshot, saving a photo from a text message, saving a photo from a browser, and using the phone’s camera to create the photo. This study also compared the results of various digital forensic tools (e.g., Cellebrite®, Axiom®). The results will be fully discussed and recommendations for the digital forensic examination of photo vault apps on the iOS® ecosystem will be provided.

#### Photo Vault, Digital Forensics, Mobile Forensics

### C36 A Constantly Moving Target: Best Practices for Apple® iOS® Device Seizure, Access, and Extraction

*Joseph Levi White, MS\*, Defense Forensic Science Center, Forest Park, GA 30297*

**Learning Overview:** After attending this presentation, attendees will have an understanding of the current best practices for seizing Apple® iOS® devices to ensure a higher probability of obtaining access to any valuable maintained data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the current best practices for seizing and processing various Apple® iOS® mobile devices. This presentation will demonstrate how the methods used during seizure and submission to a laboratory may dictate the potential unlocking capabilities, extraction capabilities, and types of data that can be obtained.

Evidence maintained on mobile devices, such as the Apple® iPhone®, may be critical to a case, but the advanced security measures (encryption, Personal Identification Number (PIN)/passcode lock, pattern lock, fingerprint, facial recognition, etc.) enabled on the majority of newer mobile devices to protect the owner from unauthorized access to their personal device also stands in the way of the digital forensic examiner. The actions taken by the first responder, the initial person to seize and/or interact with the mobile device, the evidence custodian, any triage personnel, etc., all may have a drastic impact on what can be done to obtain data from that device later in a laboratory setting.

Many, if not most/all, law enforcement/crime scene agencies and forensic science laboratories adhere to strict methods and/or policies and procedures for seizing evidence, conducting an inventory, photographing the evidence, processing the evidence through the laboratory, and issuing reports. These policies and procedures are required for obtaining and maintaining agency/laboratory accreditation. The problem lies within the fact that many of these policies and procedures, if adhered to, will result in either the loss of digital data or the loss of access to digital data maintained on locked iOS® devices.

This presentation will highlight multiple current typical mobile device seizure/processing methodologies and their potential impact on casework. As specific actions are taken with an iOS® device, access and security features utilized by laboratory personnel to gain access to the device may be altered. Something as simple as removing the Subscriber Identity Module (SIM) card from the device for evidence inventory can disable future biometric (facial identification or fingerprint) access to the device. Powering off mobile devices at seizure is a typical practice for evidence storage and transfer, but this action changes the lock state on iOS® devices from After First Unlock (AFU) to Before First Unlock (BFU) mode. This change from one of the device's least secure states (AFU) to one of the most protected states (BFU) causes an iOS® device to block access to various types of data maintained on the device. The timeline from device seizure to obtaining access to maintained data has become very critical. With each passing second, there is a greater potential for evidentiary data to be deleted from the device or blocked from future access.

Due to seemingly constant security and feature updates to the Apple® iOS® operating system, best practices for iOS® device seizure and processing are constantly evolving. With each new software release, digital forensic examiners must be willing to adjust and implement changes to methods and/or policies and procedures quickly to remain steady on the moving target of defeating advanced mobile device security.

### C37 Unlocking Fingerprint Scanner-Enabled Mobile Phones

*Christina A. Malone, MSFS\*, Defense Forensic Science Center, Forest Park, GA 30305; Anthony Koertner, MS, United States Army Criminal Investigation Laboratory, Forest Park, GA 30297; Seth M. Eisenberg, Army Educational Outreach Program, Forest Park, GA 30297; Hillary Lathrop, PhD, Defense Forensic Science Center, Forest Park, GA 30297*

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of the efficiency and effectiveness of using recorded fingerprints to unlock fingerprint scanner-enabled mobile phones.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the benefits and limitations of a novel technique of using recorded fingerprints to unlock fingerprint scanner-enabled mobile phones.

This presentation, a research project conducted by the Office of the Chief Scientist (the Research, Development, Testing, and Evaluation arm of the Defense Forensic Science Center [DFSC]), focuses on the benefits and limitations of a novel technique of using recorded fingerprints to unlock fingerprint-scanner-enabled mobile phones.

Mobile devices are frequently submitted as evidence in digital forensic examinations. While law enforcement officials are required to secure a search warrant prior to the examination of mobile devices, there are often issues accessing locked phones even after a search warrant is obtained. While suspects may willingly provide a passcode to a locked mobile phone, there are also numerous occasions when a passcode is not provided (e.g., death, uncooperative suspect or victim, etc.). A suspect cannot be required to provide a passcode; however, to conduct a thorough digital forensic examination, it is imperative that examiners are able to access the mobile device's data in a timely fashion. While there are technologies that may assist an examiner in cracking the passcode, often such solutions are expensive and time-intensive. Furthermore, security features of mobile phones may erase data after failed passcode unlock attempts, so it is essential that an alternate method of unlocking a mobile phone is available.

Recently, several articles have demonstrated the possibility of unlocking fingerprint scanner-enabled mobile phones using printed images of fingerprints. A process using a standard inkjet printer combined with silver, conductive inks, and specialty paper can be used to generate a fingerprint capable of unlocking a mobile phone. While a technique has been roughly outlined and has been demonstrated, the success of this process requires further investigation in order to be standardized and employed with commercially available products for practical applications in a crime laboratory setting.

While the articles cite specific instances where mobile phones have been unlocked, recorded prints have not been used as a part of this process. Furthermore, the mobile phone itself may be host to a latent fingerprint, which could be imaged and used to unlock the phone. Within a criminal investigation laboratory, both of these sources of fingerprints have potential for assisting in a digital forensic examination.

Three fingerprint scanner-enabled mobile phones (Samsung™ S6 Edge+, Samsung™ Galaxy S7, and iPhone® 5S) were selected, based on their availability within the Documents & Digital Evidence Branch at the DFSC. A total of six subjects provided record prints (inked and LiveScan), and each participant enrolled his or her right and left thumb and index fingers in each of the mobile phones. Enrolled fingerprints were removed from each phone between participants. Three male and three female subjects were used to produce a sample set of fingerprints that varied in subtle differences in the ridges (e.g., thickness, widths, etc.). The variation among the donors was used to demonstrate the feasibility of the approach across multiple individuals in the general population.

The recorded prints were scanned and enhanced. An inkjet printer with silver, conductive inks was used to print the fingerprints on the appropriate specialty paper. Each printed fingerprint was used to attempt to unlock the mobile phones using various methods. Multiple image enhancements were also made to test the efficacy of the printed fingerprints. Each print was tested multiple times in a systematic manner to determine the repeatability of the technique. The results of each process were recorded and compared to illustrate the differences between participants, mobile devices, image enhancements, and application of the fingerprint to the scanner (heat and/or pressure).

### C38 A Forensic Comparative Analysis of a Fitness Tracking Application on Mobile Devices Assigned

*Christina A. Malone, MSFS\*, Defense Forensic Science Center, Forest Park, GA 30305; Carl R. Kriigel, MA\*, United States Army Criminal Investigation Laboratory, Forest Park, GA 30297; Seth M. Eisenberg, Army Educational Outreach Program, Forest Park, GA 30297; Hillary Lathrop, PhD, Defense Forensic Science Center, Forest Park, GA 30297*

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of the current capabilities of extracting the mobile app, STRAVA™, Global Positioning System (GPS) data from mobile devices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the benefits and limitations of the extraction techniques used for obtaining GPS data that is recorded through the STRAVA™ app.

This presentation, a research project conducted by the Office of the Chief Scientist (the Research, Development, Testing, and Evaluation arm of the Defense Forensic Science Center), focuses on the benefits and limitations of the extraction techniques used for obtaining GPS data that is recorded through the discussed mobile fitness-tracking app.

Digital Forensic Examiners (DFEs) are responsible for extracting data from various electronic devices and performing analyses on different data types. It is the responsibility of the Digital and Multimedia Evidence (DME) community, including DFEs and researchers, to determine how to extract and interpret the data as well as discover if the data may be a potentially useful source of information. With the expansion of body-worn, fitness-tracker devices, the DME community searches for potentially pertinent data stored within fitness-tracking devices and the companion client devices that store the data.

The example body-worn, fitness-tracking app is used to track athletic activity via satellite navigation. It also works with GPS-enabled watches and head units. Tracking the user's activity may be forensically useful in establishing a suspect's location on a specific date and time. As such, understanding the data and establishing an extraction procedure will enable DFEs to successfully extract physical activity pattern data in cases where a suspect's or victim's location or activity may be important to establish.

Two companion client devices (iPhone® 7 Plus and iPhone® 6) were used for this research based on their availability to the researchers. The premium version of the mobile fitness-tracking app was loaded to the iPhone® 7 Plus. The basic version was loaded to the iPhone® 6. The companion clients were used to record a number of activities (e.g., running, walking, cycling, etc.) to generate data. Generated data included distances, locations, times, and dates to show each user's activity pattern. Recording only occurred when the app was activated. A manual log of each user's activities was kept for post-extraction data comparison. Data was collected over several months to establish the user's activity patterns and to collect various fitness activities. After several months, physical (full, including deleted data) and logical (partial) extractions were conducted on each device using standard computer forensic methods. Results were analyzed for accuracy by comparing the app's data to the user's manual log, as well as comparing the data recovered through the different extraction techniques. Through the evaluation of the app and the data extracted, investigators and examiners will be provided with relevant information on the steps to take when recovering and examining mobile devices and the GPS data that could be associated with a crime.

#### Mobile Device Forensics, Cell Phone Forensics, Digital Extraction

### C39 Android™ App Forensic Evidence Database (AndroidAED)

Chen Shi, MS\*, Iowa State University, Ames, IA 50011; Chao-Chun Cheng, Iowa State University, Ames, IA 50011; Connor Kocolowski, Iowa State University, Ames, IA ; Emmett Kozlowski, BS, Iowa State University, Ames, IA 50014; Justin Kuennen, BS, Iowa State University, Ames, IA 50014; Matthew Lawlor, BS, Iowa State University, Ames, IA 50014; Mitchell Kerr, BS, Iowa State University, Ames, IA 50014; Jacob Stair, BS, Iowa State University, Ames, IA 50014; Zhonghao Liao, PhD, Iowa State University, Ames, IA 50011-1153; Zhenqiang Gong, PhD, Iowa State University, Ames, IA 50011; Yong Guan, PhD, Iowa State University, Ames, IA 50011

**Learning Overview:** After attending this presentation, attendees will better understand how AndroidAED will be beneficial for academic researchers whose studies relate to mobile applications that grant them the ability to search through many of the available applications across various third-party app stores.

**Impact on the Forensic Science Community:** AndroidAED, per this study's research, is the first Android™ app forensic evidence database with the highest precision and the most comprehensive coverage in discovering evidence generated from Android™ apps. This presentation will impact the forensic science community by illustrating how digital forensic investigators can significantly improve the process of investigation of evidence from mobile devices.

With more than 2.7 billion smart phone users across the world, it is no surprise that the mobile app industry is thriving.<sup>1</sup> Android's™ smart phone share increased to 86.7% in 2019 and has remained at more than 75% in the past ten years. A recent study of globally available apps by AndroZoo shows that the number of apps has exceeded eight million and is still rapidly growing.<sup>2</sup> Current digital forensic practices for finding data on these apps is limited, time consuming, and error prone. As an example, Cellebrite® UFED, a commercial mobile device forensic tool, only supports the profiles of 6,000 apps.<sup>3</sup> If mobile devices contain apps that are not included in the 6,000 apps, it cannot work properly. Therefore, an up-to-date, real-world evidence database of Android™ apps from multiple app stores—AndroidAED—is being built employing two analyzing tools developed by this study, namely static and dynamic EviHunter, respectively.<sup>5,6</sup> Web crawlers are created to traverse app stores to collect metadata and download application files. Since each site has a different design and functions, a crawler tailored to each store to collect data was created. The crawlers utilize BeautifulSoup to scrape each webpage and the Selenium driver for webpage interactions. Currently, seven crawlers have been completed and 40 more are under development. The currently supported app markets include: Google® Play Store, APKPure, Uptodown, APKMirror, Aptoide, and F-Droid.<sup>4,7-11</sup> After collecting the file, it will be processed using the forensic analysis tools, collecting where the application is storing the evidentiary information. The information about the application that is collected from each store webpage gets stored into a MongoDB instance. The actual APK files of the applications are stored in a separate file system, and the path to the file is linked to the app entry in MongoDB. In this way, digital forensic investigators can simply query the database to find all the possible evidence data (e.g., locations, photos, call logs, time, etc.) generated by the app and corresponding evidentiary file path. Moreover, considering that the apps installed on the suspect's device can vary on the app's version and source of installation (app store), AndroidAED hosts all the available versions of apps that have been collected from various app markets.

The main contributions of AndroidAED are summarized as follows: (1) AndroidAED, per research, is the first Android™ app forensic evidence database with the highest precision and the most comprehensive coverage in discovering evidence generated from Android™ apps; (2) AndroidAED will be accessible for digital forensic investigators and significantly improves the investigation of evidence from mobile devices; (3) AndroidAED will be available for academic researchers whose studies relate to mobile applications that grant them the ability to search through many of the available applications across various third-party app stores; and (4) AndroidAED will keep updating to provide the most up-to-date evidentiary data for real-world apps, ranging from very popular to very unpopular, available from app stores around the world.

### C40 The Use of the On-Screen Time Display for Authentication of Body-Worn Video

*Gretchel Lomboy, MSc\*, Seattle, WA 98115; James Zjalic, MSc, Verden Forensics, Edgbaston, England B15 1TH, UNITED KINGDOM*

---

**Learning Overview:** After attending this presentation, attendees will better understand the need for the development of methods for the authentication of Body-Worn Camera (BWC) recordings and will be presented with the results from research performed in relation to such.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing one method of authenticating body-worn video in a matter that can be utilized in casework with immediate effect.

The proposed method takes advantage of the on-screen time display of BWC video recordings, which is superimposed onto video frames during encoding. It is based on the assumption that as this is added during the encoding stage, factors relating to the capture environment, such as lighting, time of day, camera movement, and recording length, have no influence on parameters such as the pixel values used to represent it and the resolution of both its digits and the display in its entirety. It, therefore, stands to reason that its representation should be consistent across recordings captured with a device of the same make and model. As transcoding decodes and re-encodes the visual content in a different format, it can also be inferred that this embedded trace will be changed when a conversion occurs, as would be the case when editing and uploading to social media.

The increase in the use of BWCs by law enforcement, combined with the recent trend for videos from such to be shared on both social media and by news and media outlets, has made the authentication of these recordings of more importance than ever before.

To address the above, the following hypotheses were proposed, in sequential order: (1) the on-screen time display within BWC video streams from a specific make and model of device is consistent regardless of all other factors; (2) the on-screen time display within BWC video streams changes when the video is transcoded from the original recording; therefore (3) the on-screen time display within BWC video streams can be used to determine the authenticity of a recording.

To test the proposed hypotheses, a dataset of original recordings was developed through the capture of videos in different environmental conditions, under differing light sources, and of varying lengths. Various parameters of the onscreen time display related to resolution and pixel values were then measured to allow the intra-variability (between captures from the same device) and inter-variability (between captures of differing devices) to be determined. The video data was then transcoded to new formats and comparisons made between the measurements from parameters of the original recordings and their transcoded versions was performed.

This research aims to provide a stepping stone for further developments in methods of authentication of body-worn video.

---

#### **Body-Worn, Video, Authentication**

### C41 Narrative Use Cases for Harmonizing Forensic Science Practices and Digital/Multimedia Evidence

Mark Pollitt, PhD, Ellicott City, MD 21043; Eoghan Casey, PhD\*, University of Lausanne, Lausanne, Vaud 1015, SWITZERLAND

**Learning Overview:** Attendees of this presentation will learn to apply core forensic science processes to cases involving digital/multimedia evidence. After attending this presentation, attendees will have a clearer understanding of how to integrate digital/multimedia evidence and forensic science by: (1) learning how to apply core forensic concepts and principles (as defined in the Organization of Scientific Area Committees [OSAC] technical publication 002) to digital/multimedia evidence; (2) comprehending the use of narrative to understand and explain forensic treatment and interpretation of digital/multimedia evidence; (3) emphasizing the importance of narrative in forensic science; and (4) raising the awareness of judges, attorneys, and juries of the uses and value of digital/multimedia evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) strengthening scientific foundations of digital/multimedia evidence; (2) increasing the practical application of core forensic concepts in digital/multimedia evidence; (3) clarifying the importance of narrative in conveying forensic science concepts and results; (4) increasing participation in generating and refining use cases for digital/multimedia evidence in forensic science; and (5) raising awareness of judges, attorneys, and juries as to the uses and value of digital/multimedia evidence.

There is a need for increased integration of digital/multimedia evidence into forensic science.<sup>1</sup> At the same time, there is a need for digital transformations in forensic science.<sup>2</sup> The National Institute of Standards and Technology Organization of Scientific Area Committees (NIST OSAC) process has encouraged all forensic science disciplines to explore their foundations and practices; it has also revealed the commonalities between them.<sup>3</sup>

Narrative theory plays an important role in forensic science in clearly conveying concepts and findings using a framework and context that people can easily comprehend.<sup>4</sup> Taking this approach, this presentation will guide forensic practitioners through the practice of applying core forensic processes to actual digital forensic investigations. Specifically, this presentation introduces a project out of the NIST OSAC that is creating a reference database of narrative use cases involving digital/multimedia evidence that capture the methods and outcomes in relation to underlying core forensic questions and processes. Narrative use cases in this reference database cover forensic analysis of digital/multimedia evidence, including speaker comparison and facial comparison.

This work is part of the OSAC Digital/Multimedia Scientific Area Committee (SAC).

### C42 Digital Evidence in the United States Courts of Appeal

Martin Novak, MPA\*, National Institute of Justice, Washington, DC 20531

**Learning Overview:** After attending this presentation, attendees will understand: (1) the most common legal basis for appeals related to digital evidence, (2) the most frequent outcomes for those appeals, (3) the most prevalent challenges to digital forensics, and (4) which appeals are the most likely to result in a affirmed or reversed decision for the defendant. Overall, attendees of this presentation will be well informed as to how digital evidence has performed in the United States Courts of Appeal and how the United States Courts of Appeal generally view the science behind computer forensics.

**Impact on the Forensic Science Community:** Though the use of computer forensics in criminal investigations has expanded in recent years, there is limited empirical evidence about the prevalence of the use of digital evidence in the court system and its impact on prosecutorial outcomes. One case review from Losavio and Losavio examined cases that involved ineffective assistance of counsel with regard to computers as the basis for appeal from 2015–2016.<sup>1</sup> In addition, Cole, Gupta, Gurugubelli, and Rogers examined 100 appeal cases that involved digital forensics, and results revealed search and seizure was the main reason for appeal.<sup>2</sup> The current study aimed at further examining digital forensics in the United States Courts of Appeals. Specifically, this presentation will impact the forensic science community by an examination of cases from the United States Courts of Appeals in which legal issues were related to digital evidence. The purpose of this research was to determine the most common legal basis for appeals relating to the introduction or exclusion of digital evidence, the frequency with which cases involving an appeal regarding digital evidence affirmed or reversed for the defense, whether certain challenges to digital evidence are more prevalent than others, and whether there are trends or areas of the law as applied to computer forensics and digital evidence needing further attention by the criminal justice system.

This analysis was based on a review of cases in the United States Circuit Courts of Appeals from 2010 through 2015. Cases were identified via LexisNexis, using the following search terms: Computer, Computer Forensics, Chat Log, Electronic Evidence, Cell Phone, Sexting, iPhone, Child Pornography, Digital Evidence, Computer Investigation, GPS, and Encryption. The United States Circuit Courts of Appeals were an ideal venue for this study for two principal reasons. First, the 11 Circuit Courts of Appeal and the associated 94 United States District Courts cover the nation. There is at least one court in each state and the District of Columbia. Second, the 11 Circuit Courts of Appeal and the 94 District Courts adhere to the same rules of evidence—the Federal Rules of Evidence.

Probable Cause was the most frequently occurring legal issue encountered as a basis for appeal at 30.61%, followed by Sufficiency of Evidence at 28.57%; Defective Warrants at 12.24%; and Warrantless Seizures at 6.12%. Other legal issues less frequently encountered included Scope of the Warrant, Probative Value, Expectation of Privacy, Scientific Merit, Exclusionary Rule, Relevancy, Authenticity, and Hearsay.

Of the 147 cases included in this study, only 22 appeals were based on the science of computer forensics, including probative value, authenticity, hearsay, relevancy, and scientific merit. In each of those cases, previous rulings were affirmed. Out of the ten reversals for the defense, five were based on sufficiency of evidence. In the two cases where judgement was affirmed for the defense, one was based on a defective warrant, while the other was based on the scope of the warrant. Results will be compared to previous literature regarding digital evidence in the courts.

The majority of challenges seen in this study were based on Search and Seizure issues, rather than the science of computer forensics. This study only examined cases heard by the United States Courts of Appeals. Future research may involve an in-depth look at cases at the federal district court level to examine this issue.

One area of concern is particularity in regard to the scope of search warrants. Particularity governs how far the government can search, based on a factual predicate. Several important cases with regard to particularity have been decided by the courts recently (*Riley v. California* and *United States v. Ganas*).<sup>3,4</sup> This issue will likely continue to be central to appeals based on the Search and Seizure of digital evidence.

#### Digital Evidence, United States Courts of Appeal, Appeals

## D1 Amusement Park Accidents Caused by Fatigue Failure

*Chan-Seong Park, PhD\**, Division of Forensic Safety, Wonju-si, Gangwon-do 220-170, SOUTH KOREA; *Honh-Pil Jeon*, Division of Forensic Safety, Wonju 26460, SOUTH KOREA; *Kwangsoo Choi, MA*, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Jae-mo Goh, PhD*, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Nam-Kyu Park, PhD*, National Forensic Service, Wonju, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will understand the mechanism underlying two amusement park accidents caused by fatigue failure of mechanical parts of the rides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing failure mechanisms of amusement park rides.<sup>1</sup>

This presentation introduces two cases of amusement park accidents. One is a bungee drop accident caused by the fatigue failure of rolling bearings. The other is the “Crazy Clown” accident caused by fatigue failure of fastening bolts. In the bungee drop accident, a moving frame with 15 passengers stopped abruptly in the middle of the main structure at a height of 27m. While the rescue team was trying to rescue the passengers from the moving frame, it suddenly dropped, causing one rescue worker to fall to his death. A second accident happened nine years after the first accident. The moving frame with 12 passengers dropped abruptly as it was moving upward. It stopped at a height of 53cm due to the operation of the emergency brake system. Some passengers suffered spinal fractures. After an investigation, this study concluded that the moving frame was in an unstable equilibrium that would be broken with a small disturbance load while the rescue team was in operation. The unstable equilibrium state was maintained by the weight of the passengers and the frictional forces caused by the urethane wheels and poor lubrication of the pneumatic rod. The urethane wheels were severely worn out, and some were octagonal as a result. The rolling bearings of urethane wheels failed by flaking and corrosion that added frictional force. The moving frame was tested by varying the compressed air pressure as well, and all of the test cases were recorded by a video camera to analyze the time difference of the moving frame at each operation step. It was also concluded that the moving frame dropped because only one air compressor was operating while the other air compressor was not operating at the time of the second incident. It was recommended that a control system for the bungee drop should be installed to prevent the start-up of the moving frame, given the poor state of the compressed air system.

In the Crazy Clown accident, the fastening bolts of the rotating arm were broken abruptly when it turned around the central axis. The passenger was injured by the dropped cabin that was attached to the arm. After an investigation, the broken bolt was determined to have failed by fatigue as beach marks were commonly shown on the broken surface; however, the mechanical properties satisfied the requirements. From this, it was concluded that the fatigue was caused by external factors, such as improper fastening.

### Amusement Park Accident, Fatigue Failure, Flaking

### D2 The Role of the Dynamometer in the Analysis of Manner of Death by Asphyxia: A Case Report and Review of the Literature

Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Francesco Sicilia, MD\*, Università Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Orazio Malfa, MD, Università "Magna Graecia" of Catanzaro, Catanzaro, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Gionata Fragomeni, PhD, Campus S Venuta, Catanzaro 88100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of the dynamometer in the study of cases of asphyxia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the applicability of the dynamometer for studying the entity of the force and for the correct analysis of dynamics in cases of asphyxia.

Asphyxia is the respiratory failure caused by stopping the passage of air in the respiratory tract. It includes ligature strangulation that requires the use of a tool such as a cord applied around the neck. The strangulation includes the application of a force, a vector with a point of application, direction, and intensity. These characteristics can be measured by using the dynamometer, a device consisting of a spring and a graduated scale. In forensic literature, studies concerning the dynamometer are not reported. In this work, the dynamometer was used to reproduce an experimental model useful for studying the manner of death in cases of asphyxia.

In this case, a woman reported her husband for trying to strangle her by using an electric cable. The woman said she had placed her hands between the cable and her neck in an attempt to defend herself. From the statements, it emerged that during the struggle, both fell on the floor. The man confessed what had happened, but declared that he had never intended to kill her and that he had not exercised intense traction on her neck. The investigators collected the testimonies and carried out the analysis of the scene. The cable was seized and examined. The victim was analyzed with an examination of anthropometric measurements. The investigators reproduced an experimental model using a cable similar to the one seized. The cable was configured by reproducing a knot with a rope. The circumference was inserted around the neck of a dummy with characteristics similar to human skin. The free end of the cable was attached to a Crane Scale® digital dynamometer, capable of measuring the force in kilos (kg) on the display. The operators (both male and female) proceeded to: (1) tensile tests of the dynamometer at increasing intensity until maximum individual strength was reached; (2) evaluate the interaction between the cable and the surface of the dummy; (3) vary the application force both in intensity and in direction; (4) pull the cable, placing the knot on the lateral side of the neck (both anteriorly and posteriorly, then laterally to the right and left); and (5) simulate the tight constriction of the loop by interposing the hands of the dummy between the rope and the neck, according to the dynamics reported by the woman.

The cable had a diameter of 8mm and a rope with a knot showing blood stains. The inspection of the victim revealed some ecchymosis only on the left and back side of the neck. The victim had no other injuries except for bruising on her wrists.

The model showed that by pulling the cable, it was possible to restrict the circumference of the loop and compress the neck, easily reaching 5kg of force (minimum 2kg, max 25kg).<sup>1</sup> The cable caused a blunt tangential action on the tissue. The position of the knot on the lateral side of the neck caused a tight constriction mechanism of the loop on the posterior area of the neck, compatible with the victim's injuries. The experimental study showed that, even with the hands below the cable, it was possible to cause an intense traction. Finally, the position of the victim lying on the floor increased the negative effects of tight constriction. The manner was therefore compatible with a strangulation occurring by tightening the cable with the knot on the left neck area. In literature, four variables have been identified that have an interaction with the outcome of a strangulation: position, direction, force intensity, and surface of application.<sup>1-3</sup> In this case, the dynamometer allowed the estimation of the force applied on the neck and the study of the injuries caused on the tissue by analyzing potential measurable combinations in relation to the testimony and to the injuries analyzed. The data were used in court as scientific support to demonstrate the homicidal intent of the perpetrator and the reliability of the victim's statements.

The dynamometer offers the advantage of: creating reproducible models at low cost; studying the effects of forces pre-established by the operator; reproducing different dynamics; and verifying the witnesses.

It would not be applicable in suffocation and strangulation by the hands in which there is not a tool on which to apply a traction and, therefore, to measure the force.

### D3 Railway Fatalities: The Importance of the Autopsy for the Reconstruction of Railway Accidents

*Claudia Perrone, MD\*, Legal Medicine, Department of Public Health Sciences, Bari 70124, ITALY; Ilaria Santoemma, Bari 70124, ITALY; Alessandra Stellacci, Bari, Puglia 70124, ITALY; Salvatore Moliterno, MD, Section of Legal Medicine University of Bari, Bari 70124, ITALY; Lucia Nardelli, Francavilla Fontana, Provincia Brindisi-Regione Puglia 72021, ITALY; Alessio Ostuni, MD, Sections of Legal Medicine and Criminology, Bari 70124, ITALY; Francesco Vinci, MD, Bari 70124, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will better understand the possibility of reconstructing the dynamics of a railway accident through a multidisciplinary approach.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining the multidisciplinary approach of reconstructing a railway accident, in particular by observing and studying, during the external examination of the cadaver, the specific physical imprint abrasions, by inspecting the railway vehicle and the areas surrounding the railway track and, in some cases, through autopsy, which can reveal multiple lesions and injuries not found only by external examination of the cadaver. This presentation, showing two unusual railway accidents, will also impact the forensic science community by enhancing knowledge of the reconstruction of a train accident (rail accident or train crash).

The train accidents involved heavy vehicles with metal wheels and prescribed tracks on rails (trains, subway, or underground, tram, etc.), which cause serious and complicated injuries achieved during the phases of impact from knocking down and sometimes running over a person, almost always having fatal detrimental effects.

**Method:** Two railway accident cases are presented here. The first deals with a 30-year-old man, found in a prone position, along the ballast of the inter-track section of the Bari-Lecce railway route. During the cadaverous external examination of the victim, a circular ecchymotic-excoriate with a diameter of 13.5cm was observed in the left posterior dorsal region that corresponded in morphology and dimensions to the right buffer of the railway locomotive, previously examined during the inspection. The injury was characterized by a large laceration caused by the skin being stretched as a result of the full-scale impact. That was sufficient to establish that the victim, at the moment of the adverse event, had his back toward the locomotive.

The second case deals with a 39-year-old man, found in a supine position along the ballast adjacent to the railway track of the Bari-Lecce route who, while fleeing from a robbery, jumped over a protective wall of the Ferrovie dello Stato Italiano (Railroad of the Italian State), and fatally collided with a railway convoy, causing injuries that at the first external examination appeared to be caused solely by falling from the top of the wall. Later, however, the autopsy showed very serious injuries to the head, characterized by a wide fracture and complete detachment of the brain from the brain stem, the ribs, including several rib fractures, and lesions of the left lung, the abdominal, with right hepatic and renal laceration, and the limbs, including a fracture of the head of the left humerus and multi-fragmentary fracture of the left femur. This injury could be caused by a violent impact against protruding parts of the convoy and by the body being thrown toward fixed surrounding structures as can be seen from the frontal part of the cranium where the presence of an ecchymotic and excoriate rectangular lesion of 10 x 16cm with a series of imprint abrasions close together inside it was identified, with thin even dots like a “barcode,” all attributable to the morphology and size of a bump against the stem of an old track located on the ballast where the body of the victim was found.

For a reconstruction of the dynamics, a careful external examination of the cadaver and an inspection of the railways were insufficient in the first case; in the second case, it was necessary to consider the autopsy assessment.

This study revealed the significant impact of the multiple injuries related to the rail accidents. The goal of this presentation is to show that linking together the inspection of the railway vehicle, the surrounding areas, the external examination of the cadaver, the observation of typical imprint abrasions to the body, and the autopsy is extremely important for reconstructing the dynamics of the train accident.

#### Rail Accidents, Physical Imprint Abrasions, Train Collision

### D4 A Comparison of Scientifically Valid and Traditional Firearm Trigger Mechanism Evaluation Techniques

*John Nixon, MBA\*, ARC, Bippus, IN 46713*

**Learning Overview:** After attending this presentation, attendees will have gained an appreciation of the basic science and technology behind firearms trigger mechanism evaluation, current trigger mechanism evaluation techniques, the influence that test techniques and their results have on final conclusions drawn, and the ultimate impact of those conclusions within the criminal and civil justice systems. Attendees will learn that widely applied crime laboratory trigger examination techniques generate inaccurate and incomplete data, and that they frequently result in misleading conclusions being drawn with regard to firearm safety. Attendees will be introduced to a scientifically valid trigger mechanism evaluation technique that has been adopted by many crime laboratories and firearms manufacturers worldwide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of a scientifically valid trigger testing technique and associated data analyses. The implications for civil and criminal litigation, where accidental or negligent discharge of a firearm is an issue, will be discussed.

The effort required to discharge a firearm is a function of both the force applied to and the distance traveled by the trigger. Engineers have long been able to design trigger mechanisms and calculate the travel, peak force, and total effort required to discharge a firearm. Engineers have had the capability to scientifically test trigger mechanisms to determine the force-travel profile, and calculate the effort required to actuate the mechanism. However, until relatively recently, the techniques involved were labor intensive and required a laboratory. Analysis and interpretation of the test data required appropriate engineering and mathematical education and training.

In the absence of an engineer and a laboratory, firearms users and armorers wanted a simple way to evaluate “trigger pull” and, historically, the arsenal weight and spring gauge techniques have been used to determine the peak force required to actuate a trigger. These peak force techniques generate minimal and inconsistent data that are misleading when used to quantify the relative ease of firearm discharge.

A purpose-built electro-mechanical trigger testing device linked to a computer, and utilizing analytical software, makes relatively easy work of scientifically valid trigger mechanism testing and evaluation. The technique, equipment, and data analyses are described and explained with the aid of practical examples and case studies. Specifically, the firearm is secured in a test rig, and an electrically driven mechanical arm moves the trigger rearward at constant velocity. The force range is from 0 to 20 pounds, with a resolution of 0.007 pounds, and the travel range is from 0 to 1.4 inches. Every 0.005 inches, the electro-mechanical test apparatus software records the force exerted on the trigger face, and these data are downloaded to a computer where the software plots a chart and utilizes integral calculus to determine the total effort required to actuate the trigger mechanism. The software displays key trigger characteristics, such as energy to actuate and trigger travel to actuation. A suitably qualified person can use the chart to visually identify potential defects, modifications, and/or design deficiencies in the trigger mechanism, and the captured data may be exported and analyzed in greater detail. The equipment can be further modified with the addition of an electrical circuit that enables the determination of lock time (illustrated). Another advantage of this system is that, for practical purposes, the effort required to actuate the trigger mechanism is independent of the position of the test arm on the trigger face.

It is concluded that widely employed “traditional” peak force methods of firearms trigger evaluation should be phased out and replaced by electro-mechanical trigger evaluation, with the measure of ease of discharge expressed in terms of the effort required to actuate the trigger mechanism, thereby providing a scientifically valid method of comparison between firearms.

#### Trigger Pull, Trigger Actuation Energy, Accidental Discharge

## D5 Defect Investigation of a Gun Rack

*Darren Franck, MSME\*, Advanced Engineering Associates, Inc, Charleston, WV 25304; Harold Franck, MSEE, Advanced Engineering Associates, Inc, Charleston, WV 25304*

---

**Learning Overview:** The purpose of this presentation is to highlight investigative methods to address untested hypotheses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting investigative methods to assess the validity of a defect claim. These methods will be compared to untested hypotheses promulgated by opposing experts, which highlights the need for ethical standards.

This case study presents a defect investigation involving a manufacturer of a gun rack used in a police cruiser. Civil actions were brought against numerous parties, including the installer of the gun rack, manufacturers of components used in the gun rack design, and the owner of the cruiser. The defect allegations were supported by multiple experts, who opined that the design and installation of the gun rack was defective.

The incident occurred during a training course for members of a local police department. The plaintiff was seated in the right front passenger seat of a police cruiser during braking tests. It was alleged that the gun became dislodged from the rack as the vehicle decelerated, which caused the butt end of the gun to strike the plaintiff's head. Severe and lasting injuries were claimed, which formed the bases of the lawsuit.

The plaintiff's experts presented various hypotheses to explain the alleged failure of the gun rack. The rack includes a pocket to secure the butt end of the gun, a trigger guard to prevent accidental discharge of the weapon, and a locking mechanism at the barrel end. The installation did not include the trigger guard at the request of the vehicle owner. One expert hypothesized that the absence of the trigger guard caused or contributed to the dislodgement of the gun. Another expert claimed that the unsecured mount of the timer module produced a current spike that unlocked the mechanism and allowed the gun to detach from the mount.

None of these experts performed pertinent testing of the gun rack assembly. The failure to test their hypotheses represents a disregard for the scientific method and a violation of ethical standards. Experts were hired by one of the defendants to assess the validity of the defect claims. Numerous tests were conducted by the experts involving exemplar gun racks subject to inertial loads, vehicle decelerations, vibrations, and impact loads. Measurements were gathered to document loading on the locking mechanism, decelerations on the timer module, as well as data culled from current and voltage probes.

None of the tests resulted in failure of the locking mechanism. Vehicle decelerations and impact loads did not cause a current spike sufficient to open the lock. Moreover, manual depression of the push button on the timer module during hard braking did not yield detachment of the gun from the locking mechanism. Static testing confirmed that a significant inertial load would be required to open the lock spring even after depressing the push button. These loads were not achieved by the deceleration forces and weight of the gun. Moreover, the allegations are not consistent with the movement of the gun resulting from collapse of the butt stock. Similarly, the installation of the trigger guard would not have affected the detachment of the gun from the rack. However, the alleged movement of the gun to the front dashboard would have been highly unlikely in the absence of the trigger guard.

The experts' work allowed their clients to be released from this lawsuit. However, the suit involving the remaining defendants continued, resulting in unnecessary legal and expert fees. This presentation highlights the need for ethical standards in forensic sciences.

---

### Locking Mechanism, Non-Destructive Testing, Ethics

## D6 The Effect of Fabric Tension on Knife and Tool Damage

Patrick H. Geoghegan, PhD\*, Aston University, Birmingham B4 7ET, UNITED KINGDOM; Debra J. Carr, PhD, Aston University, Birmingham B4 7ET, UNITED KINGDOM; Sarah V. Hainsworth, PhD, Aston University, Birmingham B4 7RT, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand how fabric tension can affect the damage caused by the penetration of knives during stabbing and slashing events.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new data that can be used to better understand the effect of fabric tension on the damage patterns left during a knife attack.

Knife crime continues to be a major challenge in the United Kingdom where access to guns is heavily reduced compared to the United States. In 2019, by May 14 there had already been 100 fatal stabbings in the United Kingdom, not counting the events that caused life-changing injuries.<sup>1</sup> However, this issue is not solely a problem affecting the United Kingdom. The United States has a higher homicide rate “due to knives or cutting instruments” per every million of population; in 2016, this was at 4.96 for every million of population compared to the United Kingdom’s 3.26 per million.<sup>2</sup>

Damage to clothing regularly occurs during a sharp-force fatality. Karlsson reported that 79% of 145 victims had damage to clothing after being subjected to a sharp-force event.<sup>3</sup> Examination of the resultant size and appearance of the severance in the fabric post-impact can provide information about the characteristics of the weapon used, the dynamics of the assault, and the post-impact conditions to which the fabric was exposed.<sup>4</sup> The tension applied to a fabric is affected by clothing fit (i.e., ranges from ill-fitting clothing that is oversized or to purposely undersized such as athletic sportswear). Tension applied to a fabric reportedly influences the severance profile; however, there is very little experimental data available to provide confidence in the analysis of what the severity of the influence might be. Cowper et al. provides one of the few studies in this area.<sup>5</sup>

The goal of this research was to investigate whether fabric tension affects the resulting severance due to stab and slash events. A range of commonly worn fabrics were pre-tensioned over silicone skin-simulant resin. The pre-tensioning ranged from loose fit to tight. Several sharp implements, including kitchen knives and sharpened screwdrivers, were used to perform stabbing events that were recorded using high-speed imaging. The forces generated during the stab events were recorded using an instrumented knife and a dynamometer. The fabric was examined post-test to determine the effect of tension on the severance. The results are presented in a way that provides insights that can be used to inform future analysis of fabric damage.

## D7 The Effectiveness of Overt and Covert Protection Against Attacks by Sharp Implements

*Sarah V. Hainsworth, PhD\**, Aston University, Birmingham B4 7RT, UNITED KINGDOM; *Patrick H. Geoghegan, PhD*, Aston University, Birmingham B4 7ET, UNITED KINGDOM

---

**Learning Overview:** After attending this presentation, attendees will understand how weapon profile affects the penetration ability of knives and spikes in stabbing and slashing attacks against body armor and slash hoodies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how overt and covert protection performs against attacks from knives, shivs or spikes, and other sharp implements.

Kevlar® is commonly used in body armor to protect against stab, slash, and spike attacks. Unlike ballistic attacks, attacks with edged and spiked weapons usually occur with the assailant and intended victim in close proximity to each other (unless the weapon is thrown). Stab/slash vests and clothing are therefore commonly worn by police officers, prison officers, security guards, and doormen. Kevlar® armors are typically lightweight in comparison to other body armors so the vests can be worn for long periods without undue fatigue or drop-off in performance of the wearer. Kevlar® vests can have both stab and spike ratings and protect against weapons such as knives, broken bottles, and syringes, for example. In prisons for example, protection is required from homemade weapons or “shivs.”

Protection for individuals can be in the form of stab-resistant protection worn over clothing (overt protection) or panels worn under normal clothing (covert protection). A range of different types of clothing with Kevlar® in the weave of the clothing is also available from hoodies to sweaters and T-shirts. There are a number of standards available for body armor. Commercially available clothing usually complies to the National Institute of Justice (NIJ) Level 1 stab and spike resistance (CAST/HOSDB KR1 and SP1). However, composite manufacturers and other protective materials are continuously developing new materials that offer new protection mechanisms.

The goal of this research is to show how weapon geometry interacts with stab-proof materials using high-speed video testing of attacks by sharp implements and subsequent analysis of fabric damage using microscopy. The outcomes will be used in collaboration with manufacturers of anti-stab clothing to show how performance of these materials and clothing can be improved. The stab-resistant clothing and protection will be contrasted with tests against ordinary fabrics. The tests show for a range of weapon types how a stab vest worn over clothing, a covert anti-stab panel, a slash hoodie, and a long-sleeve T-shirt perform in response to penetration by a weapon. The forces generated during the stab attacks will be recorded using an instrumented knife and a dynamometer. By understanding the exact mechanisms of damage to the materials and how the implements penetrate through the material, this study will be able to inform the development of stab-proof vests and clothing and allow improved personal protective equipment to be developed.

The results show that knives generally penetrate the fiber network by cutting through the individual fibers but that shivs and other pointed instruments penetrate through the fiber network and, therefore, differing strategies are required for providing protection for different weapons.

The results are discussed in terms of the way in which these insights can inform the future development of body armor.

---

### Stabbing, Body Armor, Knives

### D8 The Impact of Ventilation on Fire Patterns in Full-Scale Structures: Experiments, Analysis, and Education

*Daniel Madrzykowski, PhD\*, UL Firefighter Safety Research Institute, Columbia, MD 21045-5887; Craig G. Weinschenk, PhD, UL Firefighter Safety Research Institute, Columbia, MD 21045*

---

**Learning Overview:** The goals of this presentation are to: (1) develop a better understanding of the relationship to the availability of oxygen in a structure fire and how that impacts the fire damage; and (2) learn how to access the data and video results from the study via a freely available, interactive web portal.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the report, the time histories of the data, and the videos from this study that provide foundational documentation for the understanding of ventilation-controlled fires and the resulting fire patterns. Lack of knowledge of post-flashover and ventilation-controlled fire damage by fire investigators has resulted in unwarranted prosecutions and incarcerations for arson. This study supports the understanding of separate and distinct fire patterns that are generated by ventilation-controlled burning conditions in a structure. In past criminal cases, fire investigators have misunderstood ventilation-generated patterns and incorrectly identified them as evidence of arson.

Residential fires tend to be ventilation limited. Understanding ventilation-limited fires can aid fire investigators in analyzing fire patterns and locating the area of origin. When and where the fire receives oxygen impacts the fire and subsequent fire patterns. With the support of the National Institute of Justice, a series of full-scale fire experiments were conducted to: (1) examine how differences in ventilation to full-scale structure fires result in changes to the fire damage and fire patterns within the structure; (2) measure the fire environment within the structures and compare the data with the fire damage in the structures; and (3) document the repeatability or lack thereof of the fire conditions and fire patterns within a structure based on the available ventilation. The experiments were planned with the assistance of a technical panel that included members of the American Academy of Forensic Sciences, Bureau of Alcohol Tobacco and Firearms, International Association of Arson Investigators, National Association of Fire Investigators, National Association of State Fire Marshals, National Institute of Standards and Technology (NIST), NIST Organization of Scientific Area Committees for Forensic Science, and the National Fire Protection Association.

The test structures included a 1,200 sq. ft. one-story ranch structure and a 3,200 sq. ft. two-story colonial structure. The colonial had an open floor plan with a two-story family room and open foyer. The test scenarios ranged from fires in the structures with no exterior ventilation to room fires with flow paths that connected the fires with remote intake and exhaust vents throughout the structures. Elevated fires originating in the kitchens were also examined.

The structures were photographed before and after each fire experiment. Instrumentation was installed to measure gas temperature, gas pressure, and gas movement within the structures. In addition, oxygen sensors were installed to determine when a sufficient level of oxygen was available for flaming combustion in a given area. Standard video and firefighting thermal imaging cameras were also installed inside the structures to capture information about the fire dynamics of the experiments. Video cameras were also positioned outside the structures to monitor the flow of smoke, flames, and air at the exterior vents.

The results from a series of full-scale house experiments examining the impact that changes in ventilation had on the fire patterns are available for reference and further study on the free UL Firefighter Safety Research Institute (FSRI) web portal, [fireinvestigation.ulfirefightersafety.org](http://fireinvestigation.ulfirefightersafety.org).

This presentation will highlight key findings of the study using photos, data, videos, and fire flow graphics. The use of the fire investigation portal to access the report, data, videos, and free on-line training will also be demonstrated.

#### Fire Pattern, Ventilation-Limited Fire, Flashover

### D9 The Explosive Destruction of a Horse Trailer With Integrated Living Quarters

*David R. Bosch, PhD\*, Forensic Engineering Inc, Phoenix, AZ 85008; Mark C. Pozzi, MS\*, Sandia Safety Sciences, Edgewood, NM 87015*

---

**Learning Overview:** The goal of this presentation is to share with the forensic science community the detailed methodology used to determine the root cause of an explosion and flash fire within a recreational vehicle that severely burned two victims.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a detailed discussion regarding the unusual failure mode of a sewer system commonly used in recreational vehicles. An example of the risks and costs associated with expectation bias will also be discussed.

The incident to be presented and discussed involved a horse trailer with integrated living quarters that was involved in a gas explosion, which resulted in two severely burned occupants. The trailer with living quarters was being used to attend an equine event by two female enthusiasts. At the time of the explosion, the two occupants were within the living quarters of the horse trailer when a fugitive gas ignited, causing the severe explosion and flash fire. The two occupants were able to self-extricate themselves from the burning trailer. Upon exiting the trailer, one of the occupants was on fire. Witnesses quickly placed her on the ground and extinguished the flames. Both of the occupants suffered serious burn injuries.

The trailer and living quarters were severely damaged by the explosion and flash fire, resulting in significant investigative challenges. A team of experts with specialized skills in fire/explosion origin and cause, gas migration and gas explosion energy, mechanical and materials engineering, Recreational Vehicle (RV) codes and standards, and gas detection technology were quickly retained. The initial investigation revealed that the trailer was equipped with Liquefied Petroleum Gas (LPG) -fired appliances, which included a gas refrigerator, gas furnace, gas stove top, and a gas water heater. The entire LPG system, including all piping, fittings, controls, and appliances, were inspected and tested for leaks multiple times. After failing to find the source of the fugitive gas in the LPG components, the investigative team chose to consider the possibility that sewer gas from the onboard sewer system could have been the source of gas that exploded. After obtaining additional discovery and completing additional investigation, interviews (including the finding that there had never been a case involving a sewer gas explosion in a RV), and testing, the investigation ultimately revealed that the explosion and resulting conflagration were the result of errant sewer gas (i.e., methane). This finding was consistent with the discovery documents, which revealed that the black water holding tank had been replaced after having been torn from the trailer during an accident. The cause of the sewer gas leak was determined to be the failure to properly install the black water holding system, which allowed sewer gas to migrate into the living quarters of the trailer where the sewer gas mixed with air, ignited, and exploded. If the black water holding system had been properly installed, there would not have been an explosion and flash fire and the two female occupants would not have been seriously burned.

---

#### Gas Fire/Explosion, Recreational Vehicle Fire/Explosion, Sewer Gas

### D10 An Investigation Into the Cause of a Fire Engulfing Two Collided Buses

*Qiang Chen, PhD\**, Chinese Automotive Technology Research Centre, Beijing 100070, CHINA; *Xiao Hu\**, Beijing 100070, CHINA

**Learning Overview:** After attending this presentation, attendees will understand how a fire started and its origin after two buses collided accidentally. Attendees also will get a better view of a magnetic-steel remanence detecting method and metallographic method as applied to the research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of a magnetic-steel remanence detecting method and metallographic method as a combined technique when carrying out vehicle-fire analysis.

**Background:** This case involves two urban buses both packed with more than ten passengers. When the two buses were traveling along a side road in the opposite direction, they had a head-on collision when passing each other. Only a few of the passengers were evacuated promptly and a dozen people got stuck between distorted seats. Within minutes, both buses burst into flames. Eventually, the buses were burned down to the bare metal frames, causing heavy casualties. Considering its social impact, the local government administrative departments required a forensic investigation into what had started the fire.

**Methods:** First, the overall appearance of the two buses' remains were checked to determine the approximate areas of the worst burning. In this operation, forensic engineers should pay particular attention to the colors of residual metal parts, which would tell the developmental trail of the fire. Second, electrical wires, fuel pipelines, and other combustibles around the possible epicenter of the fire were analyzed. As the previous analysis shows that the earliest flame started near one of the drivers' dashboards other than its mid-tank or rear-engine, forensic engineers should focus on examination of cables. Third, residual cables were tested with total coverage by magnetic remanence detector, and circuit melted beads were looked for. Fourth, samples of circuit melted beads were examined through metallographic analysis apparatus, then these microstructure images were compared to find the primary short-circuited melted mark.

**Results:** A magnetic remanence detector revealed that the highest test value is 6.3mT, compared with the rest of the area of no more than 0.3mT. Two circuit melted samples were collected from the residual cables nearby. In the lab, two samples were carefully observed under metallographic microscope respectively. The microstructure images indicated that one sample has distinct characteristics of primary short-circuited melted mark. Thus it is concluded that the deadly fire was caused by a primary short circuit that would ignite a fire around combustible materials.

**Conclusions:** Electrical circuits in all vehicles have become more and more complex. In cases of head-on collision, a primary short circuit actually has caused a number of fire accidents without obvious traces. The results of this study confirm that metallographic analysis combined with magnetic remanence detecting could help forensic engineers investigate and locate the fire point efficiently and accurately.

#### Fire Investigation, Metallographic Analysis, Magnetic Remanence Detecting

## D11 Understanding and Controlling the Potential Risk of Jobsite Construction Hazards

*Daniel M. Honig, PE\*, Structures Consulting Engineers, Swarthmore, PA 19081*

---

**Learning Overview:** After attending this presentation, attendees will understand the significant safety factors required to avoid and/or minimize jobsite construction hazards. The work hazards presented by preexisting subsurface site utilities in direct proximity to the installation of new equipment and related foundation construction will be identified and evaluated. The accurate field measurement and documentation tolerance requirements for the installation of new foundation work relative to existing subsurface conditions requires ongoing careful and redundant engineering and field supervision tolerances and back checks. Forensic engineering requires recognition of these hazards and taking appropriate precautionary measures since this is incumbent to prevention, work safety, and identifying related issues should an incident occur.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees of the inherent jobsite hazards and risks when altering and/or upgrading existing electrical substations with new adjacent foundations. Given the limited timeframe needed to complete this type of industrial construction project, ongoing field engineering oversight, documentation, and quality control are critical to the successful and safe completion of this work.

In the summer of 2012 in an eastern Pennsylvania metropolitan area, a pharmaceutical company undertook a fast-track construction program for the replacement of existing switchgear equipment, including alterations to an adjacent electrical substation at one of their manufacturing facilities. For this work, they entered into a design/build fast-track agreement with an energy management company. Due to a large number of existing underground electrical ductbanks and related utilities within the foundation footprint of this project site, the designer/builder elected to proceed with the installation of a micropile foundation system. A general contractor was subsequently engaged in order to complete this overall substation and utility upgrade. The special and complex foundation system for support of this new building project and the civil/structural scope of work needed for completion of this project required the engagement and coordination of multiple subcontractors/subconsultants. This included the engagement of a consulting engineering firm for the field quality control of the new structural foundation system and building superstructure elements. During the exploratory excavation and installation phase of micropile drilling, the drill rig contacted and penetrated a ductbank containing an energized, high-voltage feeder cable. This incident caused a jobsite explosion resulting in the electric shock and serious injury of the drill operator.

This case study provides an engineering analysis of causal factors in this professional negligence case on behalf of the plaintiff (the drill rig operator). The significance of the resultant failure of this case illustrates how crucial diligent engineering analysis is for jobsite construction safety. Specifically, within the forensic community, recognition of these hazards is essential for identifying causal engineering factors for the prevention of construction failures.

### D12 Improving the Accuracy of the Quantitative Method for Evaluating Fracture Load by Blunt Force: A Proposal for the Fracture Load Analysis Method Using a Victim's Bone Shape, Bone Mineral Density Distribution, and Soft Tissue Thickness

Tatsuya Fukuoka, ME\*, University of Yamanashi, Kofu, Yamanashi 400-8511, JAPAN; Yasumi Ito, PhD, University of Yamanashi, Kofu 400-8511, JAPAN; Ryuichi Yamada, University of Yamanashi, Kofu, Yamanashi 400-8511, JAPAN; Yoshiyuki Kagiya, PhD, University of Yamanashi, Kofu-shi 400-0001, JAPAN; Tomotaka Matsubara, University of Yamanashi, Kofu, Yamanashi 400-8511, JAPAN; Sonoka Okura, University of Yamanashi, Kofu, Yamanashi 400-8511, JAPAN; Tetsuya Nemoto, PhD, Obu 474-8522, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand the advanced fracture risk evaluation method.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an advanced fracture risk evaluation method.

Restrictions on guns are strict in Japan, so many weapons used in murder cases are blunt weapons or knives. In the cases of murder and domestic violence using a blunt weapon, such as a hammer or hand, it is necessary to quantitatively evaluate the external load received by the human body and to objectively show the killing ability of the blunt weapon in court.<sup>1</sup> However, although there are established evaluation methods, such as head injury criterion for brain damage, there is no quantitative method for evaluating the fracture risk using a blunt weapon. Therefore, this study accurately calculated the load on the bone by striking the load cell covered with dummy skin with the blunt weapon, and the method for evaluating the fracture risk was established by comparing with the literature the value for the fracture load in every body part.<sup>2</sup> In addition, bone strength evaluation technology that accurately reflects bone characteristics, such as individual bone shape and Bone Mineral Density (BMD) distribution using computer simulation, has been developed and used in the medical field. It is considered that this technology could be used as an effective tool in fracture risk evaluation, and a quantitative method for evaluating fracture risk by static load, such as nursing care, has been developed. However, in the above two cases, it is not possible to quantitatively evaluate the fracture load by blunt force, such as the impact of the blunt weapon, considering the individual bone characteristics and the soft tissue thickness.

In this presentation, a quantitative method for evaluating fracture load by blunt force was designed and the method is reported. The outline of the method is shown below. The blunt force was applied to the load cell covered with dummy skin, and was converted to energy by measuring the propagation load with the load cell: the energy input to the dummy skin was calculated.<sup>2</sup> Then, the relationship between the input energy and the load that the bone received in each soft tissue thickness was clarified in advance: this is the logistic line of the load that bone received. The load that bone received was calculated by applying it to the input energy calculated for this logistic line. In the past, fractures were evaluated by comparing this load and the literature values for the fracture load, and the effects of bone characteristics in individuals have not been taken into consideration. On the other hand, fractures can be evaluated using the human bone model that reproduces the victim's bone characteristics in bone strength evaluation based on Finite Element Analysis (FEA). However, the buffer property of soft tissue cannot be reproduced during analysis. Therefore, this study combined these experimental and analytical methods. As a result, it was possible to analyze the fracture load by accurately calculating the load received by the bone using the above method and applying this load to the load condition in FEA for human bone model. The proposed method enabled fracture analysis using the victim's bone characteristics and soft tissue thickness.

Super soft urethane resin (EXSEAL) was used for dummy skin, and CLM-10KNS (TML) was used for load cell. As soft tissue, porcine soft tissue, which is a human substitute, was used. MECHANICAL FINDER (RCCM) was used for bone strength evaluation software using the finite element method. With this software, a bone model that accurately reflects BMD can be created by the quantitative computed tomography method.

A prototype has been completed to quantitatively evaluate fracture load by blunt force using the flow and equipment described above. Also, the fracture load  $F$  [N] is given by the following formula when a load is applied to the infant skull in the area  $A=100$  to  $1,000$  [mm<sup>2</sup>] in this study.<sup>3</sup>  $F=7.7615 A + 1786$ . Thus, it was clarified that the load loading area greatly affects the fracture risk. Therefore, aiming at the application of the load area to the load condition in FEA, the load area that the bone receives is measured experimentally. In addition to experimental verification using this protocol, it is applied to the actual appraisal.

### D13 Physical Properties of Additive Manufacturing to Combat the Illicit Use of 3D Printing Technology

*April Bowen, BS\*, University of New Haven, West Haven, CT 06516; Ryan G. Zdenek, West Babylon, NY 11704; Brooke W. Kamrath, PhD, University of New Haven, West Haven, CT 06516; Maria-Isabel Carnasciali, PhD, University of New Haven, West Haven, CT 06516*

---

**Learning Overview:** After attending this presentation, attendees will understand what physical factors of a 3D-printed object are significant for their forensic discrimination and classification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying systematic differences in the overall dimensions of a 3D-manufactured part due to the brand/type of printing machine, polymer filament material, software used to generate the printed file, and orientation of the printed part.

3D printing is becoming easily affordable and readily available. Available since the 1980s, 3D printers are used to create a range of objects, such as airplane and automotive parts, footwear, and medical prosthetics. The easiest way to begin the process of 3D printing is by using an existing computer model, which are available through open-source file-sharing sites. Criminals who take advantage of this technology can manufacture counterfeit parts, Automated Teller Machine (ATM) skimmers, firearms or their parts, and improvised weapons by the modification or replication of open source files. Additionally, there is little regulation for the manufacturing and ownership of 3D guns, which creates challenges in identifying parts and materials. The ability to associate a 3D-printed part to the printer that made it or the polymer from which it was made has the potential to be valuable in a forensic investigation. However, forensic research in additive manufacturing is lacking and, therefore, there are insufficiently validated test procedures.

The long-term goal for this research is to be able to associate a printed part with its source (e.g., the printer or the polymer). The potential for this type of association is based on the reproducible differences between different printers combined with consistency in the manufacturing of parts from a single printer. This research specifically evaluated the effect that different manufacturing parameters have on the physical dimensions of the resulting 3D-printed object. The manufacturing parameters that were tested included using different printers (same and different brands), polymer filament material, software used to generate the printed file, and orientation of the printed part. The hypothesis is that there are systematic differences at the macro scale that would enable differentiation of printed parts manufactured using different printers and parameters.

The MakerBot Replicator 5<sup>th</sup> Generation, MakerBot Replicator Plus, Stratasys Dimension Soluble Support Technology (SST) 1200es, and Sincor 3Dwox were used to create rectangles, cylinders, and wedges using Acrylonitrile Butadiene Styrene (ABS), Polylactic Acid (PLA), and Tough PLA Material. Programs such as SolidWorks, and Fusion 360, AutoCAD were also tested on the 5<sup>th</sup> Gen, Plus, and Dimension. Measurements of mass and dimensions (x, y, z, inner and outer diameter) were taken of each generated part. The Analysis Of Variance (ANOVA) of the measured physical measurements indicated there are statistically significant differences (p-value less than 0.05) between 3D-printed parts that are manufactured with different printers, software, orientation, and material. As the database increases in size, there is a possibility of determining the discriminating potential of physical measurements for the identification and categorization of 3D printing characteristics, which ultimately has the potential to help trace a printed part to its source.

## D14 Hot-Air Ballooning—Rare as Disastrous Incidents: An Italian Case Report

Eloisa Maselli, MD, Bari 70122, ITALY; Aldo Di Fazio, Matera, ITALY; Gianni De Giorgio\*, Section of Legal Medicine, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the characteristic injury patterns of hot-air balloon crashes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that identification of patterned lesions by the forensic pathologist can help the understanding of the dynamics of events.

Hot-air ballooning incidents are relatively rare; however, when they do occur, they are likely to result in a fatality or serious injury.<sup>1</sup> Human error is commonly attributed as the cause of hot-air ballooning incidents.

Hot-air balloon baskets are not enclosed and serious injuries may result from blunt trauma as a result of a fall or burns/electrocution resulting from collision with power lines of fuel leaks, so the nature itself of hot-air ballooning means that there is high potential for serious injury during ballooning incidents.<sup>2,3</sup>

In October 2015, during the Matera Balloon Festival, a hot-air ballooning pilot (72-year-old man) and two high school students (18 and 20 years old) crashed with a powerline while flying over a hill. A small onboard fire started after the impact and the vehicle lost altitude. The young men jumped from the basket. Their bodies were found 500 meters apart. The pilot remained on the basket and survived with some burns.

Computed Tomography (CT) scan examinations, autopsies, and histological analyses were performed on the two decedents. In the older student, the CT scan exam showed multiple fracturing (skull, cervical, chest, sacrum, hip, heels). The external examination revealed burns on the vest (anterior surface). Hair, eyebrows, beard, and mustache were burnt and there were multiple skin abrasions and lacerations on the entire body. Some skin blisters were found on the upper limbs. The autopsy revealed the presence of fracturing complexes of skull and chest with hemorrhagic infarction of soft tissue. There was hemothorax and the lungs were lacerated. In the abdomen, there were about 300cc of blood. Liver, spleen, and kidneys were lacerated and the hip was fractured. The histological analysis confirmed the burn lesions on the upper limbs' skin and tissue damages in the other organs.

The younger student's CT exam showed fractures of the skull, facial bones, chest, cervical-dorsal-lumbar-sacral rachis, and hip. The vest and the T-shirt of the student were burnt on the right lateral surface. The hair was burnt and the face had a large contusion area with some skin lacerations. The entire body had multiple abrasions and lacerations. The cadaveric section demonstrated complex fracturing of the skull and chest with lacerations of the lungs, heart, liver, and spleen. The histological studies confirmed the damage of the organs and the burn damage on the skin of the right upper limb and hip.

The cause of death of both young men was a traumatic-hemorrhagic shock by precipitation.

In conclusion, this case provides many topics for thought. First, the hot-air balloon crashed with a powerline and this event agrees with many international studies that show how the causes of hot-air balloon incidents are commonly associated with the human error of the pilot. Second, multiple patients with severe injuries can result from a single balloon crash. In this case, all three passengers suffered the consequences of the incident, although in different measures. Third, the severity of injuries may vary widely, from contusions to burns and death. In the crash at the Matera Balloon Festival, the only survivor exhibited only some burns while the deceased passengers were found to have burns, multiple fracturing, several organ lacerations, and both died from traumatic hemorrhagic shock.

## D15 Complexity vs. Uncertainty in Models

*Willem A. Schreuder, PhD\*, Principia Mathematica, Inc, Lakewood, CO 80228*

---

**Learning Overview:** After attending this presentation, attendees will be able to discuss the trade-offs between complex models requiring many parameters to be estimated versus the uncertainty associated with the parameters required in complex models.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making practitioners aware of the pitfalls of overly complex mathematical models.

With the advent of high-performance computing, there has been a tendency to build models that are more and more complex. This is exacerbated by the ability to generate very large data sets using remote sensing, high-speed telemetry-using cell phone networks and similar data networks, and the prevalence of Geographic Information Systems (GIS) to process these data.

In environmental settings such as groundwater modeling where the parameters in these models are uncertain, complex models can result in very large predictive uncertainty. Parameter estimation programs such as BeoPEST can be used to estimate a large number of parameters quite effectively, thus reducing the predictive uncertainty. However, depending on the observation data set, there may be a substantial parameter null space that cannot be estimated.

This presentation provides a review of groundwater models used in litigation over the past 30 years. Many of these models have been used in Interstate Compact litigation and have been the topic of disputes before the Supreme Court of the United States. This presentation explores the complexity of the models and the methods applied to reduce the uncertainty of the model. In particular, this presentation reviews the increase in complexity over time and attempts to answer the question of whether the increased complexity leads to increased or decreased uncertainty in the predictions of the models. In a litigation environment, there is the additional element that the trier of fact may not be well versed in modeling, calibration, and uncertainty, and yet the outcome of litigation where there are competing models may depend on a decision selecting one model over another.

Occam's Razor in a modeling context may require that instead of using very complex models, we ask more fundamental questions. For example, can the question be resolved by targeted measurements, or by a water budget analysis, or using a simpler analytical solution, or perhaps using a change model, as opposed to building a complex model. To what extent does a simpler approach result in predictions that are as reliable as a more complex model?

This presentation demonstrates that complexity does not necessarily translate to greater certainty and, particularly in a litigation context, how complexity often calls into question the results of a more complex model.

### Complexity, Uncertainty, Models

### D16 Bulk and Micro-Scale Trace Element Analysis of Glass Standard Reference Materials (SRMs) Using Modern Nuclear Analytical Methods and Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS)

Nicholas Sharp, PhD\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Jamie L. Weaver, PhD, National Institute of Standards and Technology, Gaithersburg, MD 20876; Maria Martinez, PhD, National Institute of Standards and Technology, Gaithersburg, MD 20899; Ruthmara Corzo, PhD, Gaithersburg, MD 20899-8371; Rick Paul, PhD, National Institute of Standards and Technology, Gaithersburg, MD 20899; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199; Eric B. Steel, National Institute of Standards and Technology, Gaithersburg, MD 20899-8371

**Learning Overview:** After attending this presentation, attendees will understand the importance of fit-for-purpose National Institute of Standards and Technology (NIST) SRMs for calibration of instrumentation for the forensic analysis of glass samples. The goal of this project is to provide the forensic science community with additional data about the suitability of currently available NIST SRMs for micro-scale analyses. This effort will also generate new concentration values for trace elements in existing SRMs. Additionally, the developed techniques for bulk and micro-scale analysis will be used to certify new trace-element glass reference materials specifically designed for use in forensic practice, such as the Organization of Scientific Area Committees (OSAC)-approved American Society for Testing and Materials (ASTM) E2927-16e1 standard test method for analysis and comparison of glass evidence.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community's understanding by providing additional information on currently available NIST SRMs, such as highlighting elements affected by potential heterogeneity biases and providing additional trace element abundance data.

Analysis of glass using micro-sampling techniques, such as micro X-Ray Fluorescence ( $\mu$ -XRF) and LA-ICP/MS, is a key capability for many forensic laboratories. However, the NIST standard reference glasses that are currently available for instrument calibrations and quality control, such as NIST 612/4 and 1830/1, were not designed for forensic purposes. They were designed for chemical analysis of lunar material, such as the 61x series, or for major element analysis, 183x. Both types of analyses were performed on the bulk-scale, with hundreds of mg of material used for each analysis.<sup>2,3</sup> When these materials are used as calibration standards for analyses conducted on the micro-scale, there are potential heterogeneity biases that will inherently affect the precision and accuracy of subsequently reported data.<sup>4</sup>

This study's goal is to re-analyze widely used NIST glass SRMs so that their trace element abundances are reported on a scale that is useful and appropriate for micro-scale forensic glass analyses through a combination of multiple analytical techniques. The first will involve the use of nuclear analytical techniques, such as instrumental neutron activation analysis and prompt gamma activation analysis, to analyze the bulk glass materials and determine additional forensically useful elements.<sup>5,6</sup> The use of LA-ICP/MS will allow us to determine the degree of heterogeneity present on the glass wafers at the micro-scale.<sup>7</sup> The combination of these two techniques will allow for the modification of existing, and provide new, trace-element data that is appropriate for the sample size of forensic analysis. The methods developed during this work will ultimately be used to analyze and report on the trace element abundance of new float glass standards designed to supplement the existing float glass standards (FGS glasses), with the goal to certify the new material as a NIST SRM specifically for the forensic community.<sup>3</sup>

### D17 The Strange Case of the Magnet on the Electricity Meter: When Wrongly Executed Tests Show a Non-Existent Tampering Effect

*Alessandro M. Ferrero, MSc\*, Politecnico di Milano, DEIB, Milano 20133, ITALY; Veronica Scotti, LLM, Politecnico Di Milano, Milano 20133, ITALY*

---

**Learning Overview:** After attending this presentation, attendees will better understand the problems that arise when wrongly collected evidence may result in people being unrightfully prosecuted for aggravated theft. Attendees will learn how to critically analyze all available data to assess whether a magnet laid on the top side of an electronic electricity meter can force the meter to measure less energy than that flowing through the metering section.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight on an incorrect practice for collecting evidence adopted by the Italian Distribution System Operators (DSOs) in an effort to counteract illegal attempts to steal electrical energy by placing electricity meters inside a strong magnetic field in the belief that this may alter the measurement error in favor of the consumer.

In Italy, the task of metering electrical energy at the delivering section for billing purposes is assigned exclusively to the DSOs. At the beginning of this century, they started to replace the old, electromechanical energy meters with more modern electronic meters, which can be read and controlled remotely and allow for implementing customized billing policies.

The very first model, installed before the transposition of the Directive 2004/22/EC of the European Parliament and of the Council on measuring instruments in the national law, exhibited a poor design of the current transducers whose magnetic core could be saturated by a strong DC magnetic field.<sup>1</sup> For this reason, unethical customers placed a strong magnet on the top side of the meter in the hope that this could reduce their energy bill.

After the Measuring Instruments (MID) directive was transposed in the national law in 2007, the DSOs started to replace the very first-generation meters with a new version that complied with the MID requirements.<sup>1</sup> Since the MID requires that in the presence of a magnetic field, the maximum permissible error is not exceeded by more than an additional 2%, the new meters are immune to the effects of external magnets.

However, some customers, generally the owners of small pubs, restaurants, and pizza parlors for whom the electricity cost represents a relevant share in the total costs of their business, still believe that magnets laid on the meters can force the meters to measure lower energy values and the DSO's verification teams still find such situations.

When this happens, the DSO makes a report to the judicial police and the consumer is prosecuted for aggravated theft and quantification of the amount of stolen energy, also determined by the DSO. However, in most cases, the quantification, based on verification tests performed only by the DSO technicians without providing the customer the right to have his/her own technical experts attending the test operations, are incorrect and a strict analysis of the available data, the historical data, and the test report shows that no additional measurement error can be attributed to the presence of the magnet.

This presentation will discuss how those data must be analyzed to state, in a scientifically and technically sound way, whether the electricity meter was tampered with or not and presents the result of some actual cases that led to release of the defendant for not having committed theft.

## D18 Qualifications for Professional Work in Forensic Linguistics

Carole E. Chaski, PhD\*, ALIAS Technology, LLC, Georgetown, DE 19947

**Learning Overview:** After attending this presentation, attendees will better understand the consensus in the field of forensic linguistics regarding what constitutes qualifications for professional work in forensic linguistics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing guidelines for evaluating expertise in forensic linguistics and what can be expected of experts in forensic linguistics.

Linguistics is the discipline that employs scientific methodology to understand language.<sup>1-4</sup> Linguistics uses social science methods for data collection and analysis, statistics for quantitative analysis, and computer modeling. Linguistics is applied in current technologies such as internet search engines, voice-activated assistants, chatbots, and speech-to-text dictation services. Forensic linguistics is usually defined as the application of linguistics to forensic questions such as identifying authorship, assessing types of texts, and classifying communications.<sup>5,6</sup>

In the field of forensic linguistics, many non-linguists have presented themselves to the courts as experts in forensic linguistics. Because few judges have direct experience with linguistics as a scientific enterprise, such non-linguists have sometimes been able to convince courts that non-linguists should be considered experts on linguistic issues. Non-linguists who present themselves as “forensic linguists” often have degrees in computer science, English literature, foreign language literature, education, or rhetoric and technical writing, without any academic training in linguistics.<sup>7</sup> It is now possible for individuals without any training in linguistics to become “forensic linguists” by gaining graduate degrees in “forensic linguistics” (rather than linguistics), take a week-long course in forensic linguistics, or take a six-week online course, or join an organization of “forensic linguists.” These degree programs are controversial in the field because none of them offer strong academic programs in the core fields of linguistics.<sup>8</sup>

For actual linguists who are concerned about the quality and use of experts within the judicial system, the presentation of non-linguists as linguistic experts is troubling. The situation of non-linguists presenting themselves as forensic linguists and experts is becoming more likely as the value of linguistic evidence is more widely recognized. The community of linguists is now responding to this issue. This study presents the consensus in the field of linguistics related to qualifications for professional work in forensic linguistics.

There is consensus among leaders in the field of forensic linguistics that some benchmark qualifications are needed for professional work in forensic linguistics. The necessary and standard qualifications for performing forensic authorship identification are twofold.<sup>1,7-13</sup> First, the forensic linguist must have an earned doctorate in linguistics with demonstrated competence in subspecialties that relate directly to the forensic tasks in which the linguist works. Second, the forensic linguist must have some training or professional experience in forensic science methodology and legal standards for scientific evidence. These two benchmarks are attainable. Linguistics has many subspecialties that relate to forensic issues.<sup>14</sup> Further, there are many avenues through which linguists can obtain training in forensic science and legal standards. These benchmark qualifications ensure that the expert respects and follows legal standards for forensic linguistic evidence by producing “ordinary science” using standard analytical techniques from linguistics. If these benchmark qualifications are used to evaluate forensic linguists, the courts will make wise decisions about hearing forensic linguistic evidence because the evidence will be grounded in linguistic theory and methodology and will be prepared to meet legal standards of admissibility. In reality, only such evidence is useful.<sup>15,16</sup>

Forensic linguistic testimony can also come from non-academic experts, such as the police officers, digital forensic examiners, forensic document examiners, forensic psychologists, and medical examiners. It is not realistic to expect that these experts should spend five to seven years obtaining a doctorate in linguistics from a respectable program in order to meet the benchmark qualifications. Yet these experts certainly are appropriate and necessary consumers of forensic linguistics. For this reason, software has been developed that implements doctoral-level analytical methods. Such software is used by non-linguists to obtain valid results of linguistic analysis, with known error rates, data thresholds, and methodologies.<sup>17</sup> While such software cannot replace the linguist, such software does provide non-linguists access to valid and reliable forensic linguistics. Such experts are known as forensic linguistic technicians and forensic linguistic examiners, but not as forensic linguists.

### Expert Witness Qualifications, Forensic Linguistics, Forensic Technicians and Examiners

## D19 A Validation Test of SynAID in Authorship Attribution Using Legal Transcriptions

Timothy Habick, PhD\*, Reasoning, Inc., Meadowbrook, PA 19046

**Learning Overview:** After attending this presentation, attendees will better understand the feasibility of using one method of Syntax-Based Authorship Identification (SynAID) when part of the evidence involves spoken dialogue.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing quantitative evidence regarding the limitations, if any, of using well-vetted transcriptions of spoken dialogue for the purpose of syntax-based authorship attribution.

This presentation reports the results of a research project to evaluate the ability of a syntax-based method for authorship identification. The SynAID functionality in the ALIAS software program was used to identify the author of each of six samples of transcriptions of spoken responses during legal proceedings. Each of three individuals from a single speech community produced responses to a lengthy set of questions during a deposition; they then produced further spoken testimony at trial. All responses were transcribed by professional court reporters.

In order for an authorship attribution software system and protocol to be considered capable of identifying the author of a questioned document, it should be proved capable of correctly identifying the author of known documents.<sup>1-3</sup> A statistical model of the known documents can then be used to classify the questioned documents, as is the standard practice in classificatory statistics.<sup>4-6</sup>

This project considers six sets of statements spoken by three individuals. Every sentence in each set of statements is analyzed syntactically, and the part of speech (or syntactic function) of each word is coded. Once the coding is complete, Statistical Package for the Social Sciences' (SPSS's) Discriminant Function Analysis (DFA), following SynAID protocols, is used to construct a model of the speaker's typical syntactic structures.<sup>2,3</sup> In this case, two models for each speaker will be created, one from the deposition and the other from court testimony.

The validation testing for the authorship attribution of transcribed speech will be considered successful if, based solely on the speaker's syntactic patterns and without regard to the content of the speaker's utterances, the deposition testimony of Speaker A is identified as having the same author as the court testimony of Speaker A, and so on for the other two individuals. Further, the validation testing will be considered successful if Speaker A is differentiated from Speaker B, and so on for the other two individuals. Since the material is dialogic, this study also measured the amount of overlap between the interlocutors as an indicator of mutual understanding as well as potential syntactic interference.<sup>7</sup>

Validation testing has been previously performed on SynAID for written documents in cross-genre documents, such as business letters, love letters, apologies, trauma narratives, and essays.<sup>1-3</sup> Further, validation testing has been previously performed on SynAID for text messaging, where all documents were within the one genre of texting, with the texts bundled into chronologically sequential units of 100 texts.<sup>8</sup> This is the first validation testing that involves spoken language rather than written language. SynAID has not previously been tested using transcribed speech samples. This project will thus provide evidence that SynAID is or is not an appropriate tool for authorship attribution using transcriptions of spoken dialogues.

Authorship Attribution, Quantitative Evidence, Forensic Linguistics

### D20 Challenges and Opportunities for Integrating Epistemic and Evidential Information Into Author Recognition Systems

E. Allyn Smith, PhD\*, University of Quebec at Montreal, Montreal, PQ H3C 3P8, CANADA

**Learning Overview:** The goal of this presentation is to introduce epistemic modality and linguistic evidentiality to the broader forensic science community, presenting empirical results with respect to the potential fitness of these variables for computational linguistic systems. Attendees should be able to understand and evaluate the relevance of these variables for, as an example, authorship analysis systems.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting theoretical and empirical results related to the integration of semantico-pragmatic variables into existing author recognition systems, putting them in the hands of those who are best positioned to apply them to state-of-the-art computational linguistic systems.

Most successful author recognition systems, whether computational linguistic systems (to be preferred in legal applications) or computational stylometric systems, rely more heavily or even exclusively on morphological and syntactic linguistic variables (including here characters and n-grams), partially because these lend themselves more readily to quantification and computational systems.<sup>1-3</sup> Semantics, roughly the study of the literal meaning of utterances, and pragmatics, the study of meaning in context, are less often present (though mentions incorporating discourse functions, and there is recent interest in moving in this direction).<sup>4,5</sup> Systems sometimes mention semantic information as being important, but this often boils down to word choice, such as identifying low-frequency words occurring at a statistically higher-than-normal frequency in a corpus of texts by a given author. In this case, it is the mere presence of a word and not its meaning as such that is of interest. It is not surprising that meaning tends to be neglected, as it is seen as more ephemeral and, indeed, can be hard to pin down despite being related to the syntax. Many aspects of semantics and pragmatics are also known to be genre-specific, which poses an additional challenge for systems that strive for general application.

The two main steps in true computational linguistic authorship systems are the extraction of variables representing the author's style, and the application of various algorithms to the variables in the first step for the purpose of modeling.<sup>1,6</sup> As explained, efficient variables for these systems will have two features: low within-author variability, and high between-author variability.<sup>4,6</sup> This presentation addresses the variable-extraction step, offering an academic linguist's take on semantic and pragmatic variables that might fit the bill of being variable across authors/speakers and less variable within a given author/speaker.

The variables considered here are epistemic modals and markers of evidentiality. Epistemic modals are words and phrases that speakers use to communicate their degree of certainty or commitment to their utterances (or lack thereof).<sup>7</sup> In English, these might include "I'm sure that," "apparently," "I don't know," or even "ummm" or "well," among many others. These are sometimes also called "hedges" in other literatures, especially when expressing uncertainty. Evidential markers give the basis for a speaker's claim.<sup>8</sup> These include expressions such as "I heard through the grapevine," "I saw," etc. Evidentials can implicate epistemic meanings as well. For example, speakers may choose to specify that their statements are hearsay in order to distance themselves from the information.

In this talk, Empirical results from certain works and previous studies that delve into the application of epistemic modals and evidentials in legal settings will be presented.<sup>9,10</sup> Building on earlier work distinguishing legitimate 911 emergency calls from false calls, corpus studies show that legitimate calls contain statistically more epistemic modals than false calls, including those in which a killer calls and feigns innocence, presumably because real witnesses want to be sure that they do not overstate information they are unsure of in a high-stakes situation.<sup>10,11</sup> Speakers often choose to repeat the subtype of epistemic modals they use, which is a further advantage as it distinguishes them from one another. This study tests whether an authorship identification system could define a group of epistemic modal and evidential phrases and search for their relative usage rather than just searching for the presence/absence of one of the many of them to see whether this variable cluster would correctly distinguish authors.

### D21 Detecting Linguistic Markers of Religious Extremism in an Online Environment: A Pakistan Case Study

Mariam Dar, PhD\*, *The Institute for Linguistic Evidence, London, ON N6M 0B5, CANADA*

**Learning Overview:** After attending this presentation, attendees will better understand the role of the internet, social media, and sermons in radicalization of youth in Pakistan, and of forensic computational linguistic analysis for detecting linguistic markers of religious extremism.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing multilingual English-Arabic-Urdu text analysis for detecting linguistic markers of extremism for proactive investigations.

The phenomenon of “extremism,” “religious terrorism,” or “violent radicalization” has grown in recent years, associated with several ideologies. Pakistan is among the top five on the list of countries affected by terrorism/violent extremism.<sup>1</sup> The war on terrorism has killed nearly five million people in Pakistan, Afghanistan, and Iraq combined, resulting in displacement of families, as well as the clear emotional and mental issues arising from such turmoil.

Social media has been playing a vital role in propagating extremism through radicalization of youth. The advantages of using the internet and social media include communication channels that are not bound to national jurisdictions and that are informal, large groups, cheap, decentralized, and anonymous.<sup>2,3</sup> These channels are used in several ways to attract a young audience, publish violent content based mostly on false information, and persuade/recruit youth for violent acts of terrorism. It has become difficult to differentiate between a religious website that publishes only for the sake of awareness/knowledge and pages/websites where exaggerated/made-up religious stories are posted for a sinister agenda. The current pilot focuses on Pakistan as it is among the top ten internet users in Asia with manifest online problems.<sup>4</sup>

Specialized software can play an important part in identifying such platforms and tracking down terrorist organizations by *detecting warning signals/threats* associated with such activities. Machine learning techniques can be used effectively to detect “weak signals,” “digital traces” of “linguistic markers” that characterize the warning signals/threats associated with terrorism or religious extremism. The warning behaviors that have the highest potential to be discovered in text and speech content are leakage (the communication of intent to do harm to a third party), fixation (increasing perseveration on the object of fixation), and identification (a desire to identify oneself with previous attackers or a terrorist organization).<sup>5-9</sup> Previous examinations of warning signals have been developed from forensic psychology and behavioral sciences, sociology, and computer science.<sup>3,6,7,9,12,17</sup> Based on previous studies, a definition of “extremist ideology” as an invocation to violence against specific groups justified by an ideological position (e.g., religious affiliation, racial superiority, and other extremist ideas) is used. “Extremist language” is then defined as the invocation through language.

The examinations that actually consider language, however, focus on content analysis, sentiment analysis, critical discourse analysis, and basic corpus linguistics.<sup>14-16,18</sup> Rigorous theoretical linguistics has generally been missing from the discussion.

This presentation focuses on developing objective, operational definitions of “leakage,” “fixation,” and “identification” from the perspective of formal linguistics and computational linguistics. Formal linguistics includes both semantic and syntactic theory, and computational linguistics uses algorithms for syntactic, semantic, discursive, and orthographic textual analysis. These methods and techniques can be used for any kind of language-based analysis, but this pilot study focuses specifically on data related to Pakistani radicalization. The pilot for methodological development focuses on detecting the warning signals/threats through linguistic markers of religious extremism in an online environment, with linguistic markers defined from linguistic theory and computational algorithms. Data are collected from social networks (Facebook®, Twitter®), websites publishing religious content, which have more than 10,000 followers/subscribers in active discussions.

Data are analyzed using standard methods in linguistics implemented in the Automated Linguistic Identification & Assessment System (ALIAS).<sup>10,11</sup> First, in line with previous studies, ALIAS is used to calculate quantitative rates for words related and unrelated to extremist ideology. This helps to determine which key words or phrases show up repeatedly and provides a baseline of expected terminology of extremism in the social environment. Second, ALIAS is used to perform syntactic and semantic analysis of passages related and unrelated to extremist ideology to determine if there is a correlation between the content (extremist thoughts/ideas/messages) and syntax (what’s the syntax in extremist vs. non-extremist phrases/sentences). The methodologies based in linguistics offer another tool for identifying radicalization through language, focusing on both salient and sophisticated features of language.

### D22 Forensic Linguistic Research Collaboration Between an Industry Research Institute and a Forensic Science Laboratory

Carole E. Chaski, PhD\*, ALIAS Technology, LLC, Georgetown, DE 19947; Andrea Ledic, MS, Croatian Forensic Science Centre "I. Vucetic," Zagreb 10000, CROATIA

**Learning Overview:** After attending this presentation, attendees will better understand the challenges and feasibility of conducting research in a collaboration between an industry research institute and a forensic science laboratory.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how data can be collected, stored, and managed within the forensic science laboratory for research purposes beyond casework.

Without dispute, the forensic science laboratory's main purpose is investigation of crime science evidence. Laboratories are funded to provide this service to the criminal justice system. Another, less-developed but no less important, function of the forensic science laboratory is research. It is difficult to conduct both investigation and research within the forensic science laboratory because investigation always takes precedence over research. Additionally, investigative analysis must be completed in short amounts of time (e.g., days or weeks), while research projects can extend over longer periods of time (e.g., years). The urgent request demands immediate attention; time allotted to the research project must be allocated between urgent requests.

The disconnection between the forensic sciences and research science is well documented.<sup>1</sup> It has been argued that this disconnection is the cause of failures within forensic science.<sup>2</sup> Therefore, the connection between forensic science and research science must be developed so that forensic science advances and the culture of research science pervades forensic science.<sup>3,4</sup>

This presentation details how a collaboration between the Institute for Linguistic Evidence in the United States of America and the Forensic Science Centre in Croatia is conducting research in forensic linguistics. At the Centre, anonymous letters in Croatian have been collected in relation to crime scene investigation. These anonymous letters and known exemplars from suspects have been used in forensic handwriting examination and other types of investigative methods. Such data can also be used for research purposes.

In order to convert data from its investigative purpose to a research purpose, the forensic laboratory must consider three issues: storage, management of access, and experimental designs.

**Storage:** For casework, the obvious storage of items is within the case folder. Each case has its own folder, and so linguistic data is distributed over the case management system in folders where the case happened to involve linguistic evidence. For research, the items must be stored in a central repository that is designed to hold, identify, and use the items. Exact copies of the linguistic evidence in the case folders must be replicated for storage in a central repository.

**Management of Access:** For casework, the obvious management of access must follow chain of custody and peer-review standards. The investigative items are tracked and tagged within an evidence system. The people who have access to the data are employees of the forensic laboratory. Access to the investigative items is restricted to the forensic scientists conducting the examination and any supervisors who may be conducting peer review of the examination. For research, it is important that researchers who access the linguistic evidence also follow chain of custody. The access must be enlarged because some researchers may not be employees of the forensic laboratory. For instance, researchers may be statisticians, software developers, and linguists who work with the forensic scientists. These researchers must comply with the forensic science laboratory's standards for handling and encrypting data; they cannot remove data from the central repository, and they cannot give access to the central repository to others who are outside the research team. Confidentiality and privacy are shared values in both casework and research.

**Experimental Designs:** For casework, the experimental design is determined by the facts of the case. For research, the purpose of the research can drive the development of experiments beyond the original question posed by the facts of the case. For example, in casework the issue may be authorship, but additional experimental designs may allow the data to be used for threat assessment, suicide note assessment, predatory chat, and other issues in forensic linguistics.

Research within the forensic science laboratory is feasible. It takes time and effort to select the research partner. Such collaboration is a feasible way for forensic science to connect with research search, while maintaining its primary purpose.

### D23 Formalizing Spanish Markedness: Working Toward a Spanish Version of the Automated Linguistic Identification & Assessment System (ALIAS) Syntax-Based Authorship Identification (SynAID)

Ángela Almela, PhD\*, Universidad de Murcia, Murcia 30071, SPAIN; Pascual Cantos, PhD, Universidad de Murcia, Murcia 30071, SPAIN; Moisés Almela, PhD, Universidad de Murcia, Murcia 30071, SPAIN

**Learning Overview:** After attending this presentation, attendees will better understand the motivation, challenges, and feasibility of developing a syntax-based method for Spanish authorship identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enabling multilingual English-Spanish authorship identification for criminal investigations.

The Institute for Linguistic Evidence (ILE) has embraced the forensic computational linguistic paradigm from its inception in 1998, confronting the tradition of academicians functioning as expert witnesses in forensic linguistics without sustaining a proper research agenda in the field or without testing their methods for error rate. An ILE team performs scientific analysis firmly grounded on linguistic theory, in line with Labovian linguistics that “validity and utility are not distinct, [...] theory only has value to the extent that it is relevant to real-life problems.”<sup>1</sup> Thus, ILE researchers develop and/or adopt scientific methods that have been devised and tested for accuracy outside of any litigation, since the ILE paradigm attempts to promote a real forensic science that is useful to the judicial system, involving reliable, replicable, and respectable research.<sup>2</sup>

Within this framework, research conducted at ILE is grounded on research questions arising from the observation of practical problems in the forensic setting.<sup>3</sup> ILE researchers make use of computational linguistic analysis software, specifically ALIAS, as well as statistical software, such as SPSS, DTREG, and statistical analysis algorithms in Python.<sup>3-6</sup>

The main current language in ALIAS is English, and Spanish is among the research-in-progress languages. Accordingly, the present proposal puts forward the ongoing project aiming to develop the Spanish version of this computational tool. In particular, research and development has focused primarily on developing a Spanish version of SynAID.

Specifically, SynAID applies standard techniques of syntactic analysis from the core field of linguistics known as syntax.<sup>7-9</sup> Syntax is the mental process of combining words into phrases and phrases into sentences, so that meaning can be conveyed through language. Syntactic analysis is the process for identifying, within a sentence or phrase, each word’s syntactic relationship to the other words with which it is being combined. In the sentence, “The dog bit the mailman,” the words *the* and *dog* combine to make the phrase *the dog*, a noun phrase; the words *bit*, *the*, and *mailman* combine to make the phrase *the mailman*, which itself combines with *bit* to make the verb phrase *bit the mailman*. and *bit the mailman* combines with *the dog* to make the sentence *the dog bit the mailman*. Although syntax is unconscious and automatic, it has been proven to be psychologically and neurologically real.<sup>10,11</sup> Further, the memory of syntax degrades in milliseconds, as we focus on the meaning rather than the form.<sup>12</sup> Syntax is a core field within linguistics and is accepted within all paradigms of linguistics as central to human language.<sup>7-13</sup>

Further, the SynAID method for authorship identification is based on the advanced analytical method known as syntactic markedness, that is to say, the complexity of phrase structures, materialized in linguistic phenomena, such as extrapositions, dislocations, inversions, and preposings and internal structures of phrases.<sup>7,8,14</sup>

For the syntactic design of structures in Spanish, every syntactic head was listed with all the possible patterns for that head; then, these syntactic patterns were subcategorized into marked and unmarked patterns by considering levels of complexity and other factors in markedness theory.<sup>14</sup> A considerable number of similarities were found across languages (English-Spanish); nonetheless, certain linguistic phenomena unique to Spanish deserved special attention, such as subjunctive mood and clitics.

As for the data collection process, data was elicited using an instrument designed for forensic linguistic evidence.<sup>15</sup> The questionnaire consisted of ten questions, in response to which participants authored a different type of text in Spanish. An Institutional Review Board approval was processed in order to protect the welfare, rights, and privacy of human subjects. Once collected, the data were not altered in any way, which led to protocols for handling severely degraded data. Furthermore, researchers complied with all the ethical requirements for forensic research, namely anonymity, confidentiality, preservation of the data, and restricted access to the data, as presented elsewhere.<sup>16</sup>

### Forensic Computational Linguistics, Syntax, Linguistic Markedness

### D24 Driver Seat and Fuel System Failure in a Rear-End Collision

*Kurt D. Weiss, MS\*, Case Study Collision Science, LLC, Santa Barbara, CA 93190; Mark C. Pozzi, MS\*, Sandia Safety Sciences, Edgewood, NM 87015*

**Learning Overview:** The goal of this presentation is to share with the forensic science community the detailed methodology used to reconstruct a two-vehicle rear collision and to demonstrate the tear-down and examination of a Sport Utility Vehicle (SUV) seat assembly and fuel system that failed. Occupant kinematics analysis and alternative designs to prevent the failures and injuries will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the failure mode of a common SUV seat structure that rendered the lap/shoulder belt ineffective, and multiple fuel tank failures that resulted in the predictable catastrophic injury of a driver in a moderate rear-end collision. Loss of survival space of rear seat occupants, especially children, is also demonstrated.

**Collision Overview:** A stationary 2004 Jeep® Wrangler® was struck from behind by a 2005 Ford® F150 and propelled forward approximately 100 feet into a pole. As a result, the Jeep® spewed gasoline from its ruptured, fully crushed fuel tank and the driver seat back collapsed and rotated rearward, allowing rearward driver ejection and forceful head contact into the rear compartment. The driver's head strike resulted in cervical spinal trauma and permanent paralysis.

**Physical Evidence:** Vehicle examination showed an offset distance of approximately 21 inches between the Jeep® and F150 centerlines at impact. The Jeep® sustained an average rear crush of approximately seven inches. The Jeep® frontal airbags did not deploy. The Jeep® driver's shoulder belt, found wrapped around his lower legs, caused police to misinterpret belt use and placement.

**Reconstruction:** The vehicle crush profile, weights, and stiffness coefficient analysis demonstrated a F150 impact speed of approximately 41mph and Jeep® velocity change of approximately 26mph with a Principle Direction Of Force (PDOF) of 6 o'clock during the rear impact and approximately 15mph impact of its right front corner into the pole.

**Injury and Occupant Kinematic Analysis:** In the rear impact, the properly lap-shoulder belted driver slid rearward relative to his vehicle interior, ramped up his collapsing seat back, struck his head in the rear compartment, and was partially ejected through the rear window. When this occurred, his safety belt was no longer in contact with the body it was designed to protect. The safety belt pass-through latch plate allowed webbing transfer from the shoulder belt to the lap belt, contributing to the ineffectiveness of the safety belt. The driver's catastrophic neck injury and paralysis was the direct result of the identified seat failures.

**Vehicle Defects:** Fuel system and seat defects were identified. The aft-of-axle fuel tank breach and filler neck separation with no check valve resulted in catastrophic fuel leakage. Spilled fuel failed to ignite into what most likely would have been a fatal fire. The fuel system in the rear crush zone was the same as the 1960's design. The driver's seat revealed predictable catastrophic buckling of seat recliner mechanisms at large lightening holes and adjacent weak structures. Static testing of the Original Equipment Manufacturer (OEM) and modified OEM seats replicated this failure mode and demonstrated inadequate seat strength to absorb predictable occupant loads in moderate rear collisions.

**Alternative Designs:** Alternative fuel tank and seat designs were identified and shown to be capable of preventing rearward occupant ejection and catastrophic injury. These designs were available and technologically and economically feasible at the time the vehicle was designed and produced; in fact, these alternate designs were installed by the same automaker in other model vehicles. Absent these defects, the driver seat back would not have rotated rearward, his safety belt would have effectively coupled him to his seat, he would not have ramped up his seatback, there would have been no head contact with the rear occupant compartment, and, therefore, there would not have been injurious neck loading and residual paralysis. Implementation of alternative designs would have prevented the observed failures and injuries.

**Conclusion:** In this crash, the Jeep® demonstrated foreseeable failures of the fuel system and weak driver seat structure resulting in catastrophic injury. Implementation of available, and technologically and economically feasible, alternative designs would have prevented these failures and resulting injury. Principles of crashworthy seats, fuel system design, and preservation of survival space were known to automakers and the Department Of Transportation (DOT) since mid-1960s.

---

#### Seat Failure, Fuel System Failure, Rear-End Collision

### D25 Electrical Bike (E-Bike) Deceleration Analysis Using Advanced Electronic Systems

*Berislav Barišić-Jaman, BS\*, Forensic Science Centre Zagreb, Zagreb, CROATIA; Igor Spoljaric, MA, Forensic Science Centre “Ivan Vucetic,” Zagreb 10000, CROATIA*

---

**Learning Overview:** After attending this presentation, attendees will be more familiar with E-bikes, the operating system of the tested Greyp bike, and possible ways of E-bike examination in digital forensics and road accident analysis areas.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about smart E-bikes, as well as the road accident examiners in their daily work with similar cases.

The goal of this presentation is to explain forensic acquisition of E-bike memory in closed and factory-created systems (such as embedded Linux in Greyp E-bike), as well as the memory analysis using commercial and open source forensic software.

In the area of road accident analysis, deceleration of a vehicle is one of the most important factors to calculate initial speed of the vehicle before a crash. Providing braking tests, this study was able to establish the minimum stopping distance of a vehicle in testing conditions and by using such data, calculate the vehicle deceleration. Yet, testing conditions could be slightly different in comparison with the real road conditions. While the asphalt surface in a test area is usually new and rough, real road asphalt surfaces are often totally different (usually smooth with some cracks and other types of damage, covered with dust or mud).

In the Forensic Science Centre “Ivan Vucetic,” two different methods were used for determining braking distance of a vehicle: static measurement using the ASFT t2Go device and dynamic measuring using the XL meter. Using both methods separately or together, this study could establish or calculate deceleration of a vehicle.

The idea of using data from the Engine Control Unit (ECU) of E-bike Greyp came up as a logical follow-up in this area. By reading the data from the bike ECU, it is possible to get information such as the bike speed, acceleration/deceleration, time and way of braking, route of driving (using Google® Maps or a similar app), and many other data. Data given from the Greyp is automatically stored in the operating system of the bicycle and on the storage server. Some data also gets stored on the user’s mobile phone device paired with the bicycle, making it accessible to the user for viewing through the mobile user application.

This presentation will show the process of the Greyp E-bike physical memory acquisition and Read-Only Memory (ROM) structure of the extended file system (ext). Forensic examination and memory analysis will be conducted with the commercial and open source software. Information obtained from the Greyp ECU and from the Greyp operating system will be compared with the data collected and analyzed by the usual forensic methods after conducting vehicle dynamic tests of the given bicycle.

Using digital forensic techniques (acquisition and extraction) and methods (parsing and analysis), this study can confirm (or deny) results of a road accident expertise and maybe discover new data relevant to similar cases.

### D26 Rear Seat Crashworthiness: Predictable Failures of Seats, Belts, Liftgates, Vehicle Structures, and Loss of Occupant Survival Space in Rear Impacts, Especially in the Third Row

Mark C. Pozzi, MS\*, Sandia Safety Sciences, Edgewood, NM 87015; Carley C. Ward, PhD, Biodynamics Engineering, Inc, Phoenix, AZ 85042; Kenneth J. Saczalski, PhD\*, Newport Beach, CA 92661; Parris Ward, JD\*, Biodynamics Engineering, Inc, Pacific Palisades, CA 90272; David R. Bosch, PhD\*, Forensic Engineering, Inc, Phoenix, AZ 85008

**Learning Overview:** This goal of this presentation is to show rear impact case studies and tests involving forensic investigation of catastrophic ejection, injuries, and fatalities due to failures of vehicle second and third row seating area structures, seats, and restraints. Parents are advised to place children in such seats to avoid airbags, but no tests are performed by automakers to determine actual occupant protection in rear impacts. No rear impact occupant protection standards exist. Flawed and inadequate seat standards allow predictable failures of structures, doors, seats, and belts in low-speed rear crashes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how and why restrained adult and child occupants are predictably ejected, injured, and killed in low-speed rear crashes. Hidden dangers of trailer hitches, weak seat structures, slackened belts, weak liftgate, and door latches are depicted. The lack of testing by automakers or the Department Of Transportation (DOT) to evaluate rear impact occupant protection, especially in rear seats, will be explored in detail. Investigators of such collisions will be better able to evaluate injuries and forensic evidence related to rear seat occupants.

Second and third row rear seats in vehicles receive little to no attention during design, development, or testing because loopholes in United States safety regulations and automaker internal standards do not require meaningful performance evaluation of rear structures, restraints, seats, cargo shift/rear intrusion, or occupant protection. Significant improvement has occurred since 1979 in vehicle frontal and side crashworthiness due to the competitive challenges posed to automakers by the National Highway Traffic Safety Administration (NHTSA) New Car Assessment Program, including front, side, and rollover airbags; adjustable seat belt anchors; pretensioned seat belts, and improved side structures. However, there has been little-to-no corresponding improvements in rear seat crashworthiness and occupant protection. Many vehicles continue to operate with rear lap-only belts, no head restraints, weak seatback structures combined with pass-through bulkheads from rear cargo areas; seat cushions with poor anti-submarining structure, no cargo tie-downs, netting, or shields, and other significant flaws that significantly increase risks to rear seat occupants. In 1996, the DOT admitted that their seat safety standard was “flawed and inadequate.” That same year, automakers and the DOT issued warnings that children should be placed in the second or third row to avoid airbags. The DOT and automakers continue to follow the “flawed and inadequate” seat safety standard. Not surprisingly, due to these flaws, independent crash researchers discovered children are 61% more likely to incur severe or fatal trauma in rear crashes than in any other impact vector.

Case studies, testing, and simulations that illustrate these predictable dangers are analyzed in detail. As demonstrated in numerous investigations, automakers have admitted that as “normal practice,” they never measure, or even evaluate, second or third row designated seating positions in rear crash tests. For example, one automaker conducted more than 15,000 frontal sled tests and only 8 rear tests. The lack of testing, regulation, and automaker interest in rear seat occupant protection has led to significant trauma and death in readily survivable crashes. Predictable loss of rear occupant survival space due to front seat failure and belt slackening, as well as cargo shift and rear intrusion, has caused rear seat occupants to be ejected into rear vehicle structures or out of the vehicle, rammed into the roof, and inadequately restrained by belts slackened due to seatback and seat track failure.

Trailer hitch receivers have been added to rear vehicle structures without any testing to determine what effects those hitch receivers would have on rear impact crashworthiness and occupant protection. This has caused rear “crush zones” to be completely altered and rendered ineffective. This has not only decreased the energy absorption capabilities of vehicles but also translated crush far forward into the occupant compartment, causing loss of survival space. This also increased the severity of crash forces affecting vehicle occupants, with corresponding increased loads on occupants, seats, and belts.

Front and rear crash tests and static tests have been conducted and have demonstrated these predictable hazards, as well as safer alternative designs that are readily available, technically feasible, and cost effective.

#### Rear Impact, Rear Seat Safety, Crashworthiness

### D27 Sliding Distance Measurements and Their Role in Pedestrian vs. Vehicle Accidents

*Omid Komari\*, Los Angeles, CA 90017*

---

**Learning Overview:** The goal of this presentation is to provide educational information concerning pedestrian accident reconstruction and the impact of documenting the physical evidence because analysis using less accurate measurements may change the cause of the collision and therefore affect potential liability of the party.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the importance of physical evidence measurements and documentations in the liability process.

Pedestrian position relative to the vehicle determination in accident analysis often is an important factor to find the true cause of the accident and the liability process. In many accident cases, small derivations in primary parameters would affect the results and, thereby, the liable party dramatically. In many situations, the only elements remaining at the venue are final positions of the vehicle (if the vehicle has not been relocated prior to police officers arrival) and the pedestrian after the crash. One important element that is often not documented at the scene is the sliding distance of the pedestrian. Evaluating the remaining evidence, which could lead to measuring the sliding distance, can define the location of the pedestrian at the time of impact with the vehicle. Hence, often based on those elements, an adequate model can be utilized to reconstruct the accident and provide conclusions about the crash sequences.

There are multiple equations developed to investigate and analyze vehicle-pedestrian impacts. The majority of these calculations are focused on the total throw distance and the vehicle speed at the time of the impact. While those parameters play a significant role in reconstructing the accident scene, often the input parameters to properly calculate those values are not adequately available. One methodology that can often help to locate the position of the vehicle and the pedestrian relative to the roadways and relative to each other is measuring the sliding distance. Oftentimes, crucial measurements of the physical evidence that may provide a more accurate sliding distance are not documented by the investigator. By knowing the geometry characteristics of the vehicle and the pedestrian, and by applying the sliding distance, the launching velocity of the pedestrian can be calculated. This presentation uses a pedestrian vs. vehicle traffic fatality to explore the analysis using slide distance to calculate the total throw distance. Based on the sliding distance in the police report and using the road surface coefficient of friction measured at the site by the expert, the pedestrian's launch velocity was more accurately calculated. Subsequently, the vehicle impact velocity at the time of separation was calculated. As a result, by applying the vehicle range of speed at the time of impact and other parameters, such as the pedestrian launching height and launching angle, the total throw distance can be calculated. Since in many cases it is difficult to measure the total throw distance due to lack of physical evidence and locating the initial impact area relative to the roadways, calculating the total throw distance can play a significant role in identifying the liable party and who was at fault causing the accident.

---

#### Forensic, Accident Reconstruction, Pedestrian vs. Vehicle Collisions

### D28 Face It: A Dangerous Passing Maneuver in an Elite Cycling Event Can Have Fatal Consequences

*Billy S. Cox, Jr. \*, Billy Cox Group, Navasota, TX 77868*

---

**Learning Overview:** The goal of this presentation is to determine the impact speed and forces involved in fatal bicycle crash using GoPro® video and testing of materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the techniques utilized to reconstruct a bicycle crash that occurred during the 2016 Tour of Kansas City (KC). During the race, a crash occurred, resulting in the death of one of the cyclists. The performance of the fencing material used to separate spectators from the racecourse at the Tour of KC cycling race was at issue. Tests were conducted to determine whether fastening the fence panels together with zip ties would have minimized the injuries or prevented the fatal injury that the rider sustained in the collision.

The collision between two cyclists occurred when the fatally injured race competitor attempted to overtake and pass another cyclist on the left side between fatally injured rider's position and the barricades that separated the spectators from the racecourse. The cyclists became entangled and crashed into a spectator barricade. The rider that was overtaken was wearing a GoPro® camera on his helmet. His GoPro® video captured the event.

Upon being struck by the co-joined cyclists, the subject barricade began to move laterally separated from the next barricade in the sequence. The fatally injured cyclist was ejected over the bicycle handlebars. He struck the end of the next barricade panel, exposed due to the lateral crash forces exerted on the panel, with the center of his forehead, just below his bicycle helmet.

The rider that was being overtaken wrote in an email, "I did look at my footage from previous laps and the barriers weren't separated that far as I show on the picture. I believe when he (the fatally injured rider) first made contact with the fence it pushed that panel back, exposing the corner of the next panel. I do think zip ties would fix this issue going forward."

A test protocol was developed and a series of tests were performed to determine the approximate weight of a single barricade, the force required to move an unrestrained single barricade along a paved surface, and the force required to break the zip ties provided on a set of six barricades fastened together in a line. A series of tests was also performed to determine the force required to break the zip ties when they are pulled apart.

When the barricades were aligned in sequence and fastened with a single zip tie, the pulling strap was moved upward toward the top of the barricade (approximately 42 inches above the ground). The zip tie joining the subject barricade and the next in sequence broke when the peak force reached 55.25lbs. The pulling strap was moved upward toward the middle of the barricade (approximately 26.5 inches above the ground). The zip tie joining the subject barricade and the next in sequence broke when the peak force reached 77.79lbs.

The handlebar stem of the exemplar bicycle is about 38 inches above the ground, which is about 8 inches below the top of the barricade. The top of the seat is about 40 inches above the ground, which is about 6 inches below the top of the barricade. A cyclist would tend to load the top of the barricade in a collision wherein the loading force required to break the zip tie was 55.35lbs.

The subject barricade and the barricade which was struck by the fatally injured rider were correctly placed and aligned before the collision occurred. The subject barricade was moved laterally, exposing the next barricade in sequence that the fatally injured rider struck only after subject barricade was struck by the co-joined cyclists. The testing conclusively showed that the use of zip ties to fasten the subject barricade and the next barricade in sequence that the fatally injured rider struck would not have prevented the fatal injury.

This presentation will be highlighted with the GoPro® video, video from the barricade test, and reconstruction of the collision event.

#### Crash, Bicycle, Reconstruction

### D29 Who Was Texting During the Alleged Kidnapping and Rape?

Carole E. Chaski, PhD\*, ALIAS Technology, LLC, Georgetown, DE 19947

**Learning Overview:** After attending this presentation, attendees will better understand how quantitative analysis of language use can identify authorship of texts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of quantitative linguistic analysis for solving crime.

A woman and her estranged husband agreed to meet to discuss whether they were going to divorce or remain married. Since the husband was a long-distance truck driver and the wife stayed at home taking care of the children and horses, the husband and wife regularly texted each other throughout the day, even while they were separated. At one point they agreed to meet at his rig to discuss the state of their marriage. Both sides agreed to the meeting. Both sides even agreed that during the meeting the husband and wife had sexual intercourse. But the wife claimed that her estranged husband kidnapped her, because he would not allow her to leave, and raped her. The husband claimed that he had never kidnapped her and that he had not raped her because their sexual intercourse was consensual. The husband also said that after they had had sexual intercourse and were discussing their marriage, they argued and hit each other. The wife contacted the police; the husband was arrested and charged with kidnapping and rape.

During the investigation, an issue arose, from the defense's perspective, about the timing of the events. The beginning of the meeting was verifiable from text messages; the end of the meeting was verifiable from the police record. But during that time period, when exactly had the kidnapping and rape occurred? The wife's interviews showed that she had changed her mind about the timing of the events. Meanwhile, when the timeframe was finally decided upon by the prosecution and the defense, the text messages showed that there were 24 text messages sent from the wife's phone during that three-hour period. The defense wanted to know: who was texting from the wife's phone during the alleged kidnapping and rape? The wife claimed that her husband had taken the phone from her and was sending texts to her mother, grandmother, boyfriend, and son so that they would not worry about her. The defense, however, claimed that if she had access to her phone and was actually texting her family, she could have texted 911. The linguistic issue then became: who was texting?

Forensic authorship identification applies standard linguistics to the issue.<sup>1-4</sup> In this case, two methods for determining authorship were used. The first method is Syntax-Based Authorship Identification (SynAID).<sup>5,6</sup> The second method is keyboard dynamics, or typing patterns.<sup>5</sup> The data for both of these methods were more than 3,000 known texts sent between the husband and wife. From these known texts, a statistical model of the syntactic patterns of the husband and wife were developed. This statistical model of the possible authors' known writing had 96% cross-validated accuracy. Given the high level of accuracy for the known writing, the model of authorship was applied to the questioned items.<sup>7,8</sup> Of the 24 questioned text messages, 23 were assigned to the wife, with high typicality probability, and 1 was assigned to the husband. With an error rate of 4%, the one assigned to the husband could simply be statistical error, but even if the potential error were taken from the wife's assignments, for the benefit of the doubt, the wife's assignments were such that she would have had ample time to contact 911 or to ask her family to contact 911. The second method focused on the typing patterns since the main issue was who was actually typing on the phone. The husband and wife differed in their typing patterns; in particular, a differentiator was whether the text started with a space or a character. This pattern was favored by the wife rather than the husband. In the questioned texts, more texts started with a space than a character; this result converged with the syntactic method.

The prosecutor dropped the charges of kidnapping and rape. Because the husband admitted to hitting his wife during their argument after sexual intercourse, he was charged and convicted of other crimes.

### D30 Electrical Fire or Arson Crime?

*Helmut G. Brosz, BASc\*, Forensic Science International Group, Markham, ON L3P 3P2, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will recognize that forensic electrical and metallurgical engineers can play an important role in analyzing a suspected arson scene. Electrical and metallurgical engineers can assist criminalists in determining if a fire could have been a criminal act, accidental, or unintentional. The manual sifting through screens of fire debris can yield valuable evidence from fire scenes when combined with metallurgical and electrical tests.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to an improved performance of criminalists and others involved in an investigation of a suspected criminal arson fire by availing themselves of forensic electrical and metallurgical engineering expertise.

This case study covers a fire in a manufacturing facility that puzzled a number of fire investigators. Some investigators opined the cause as arson, others opined the fire as accidental not involving human intervention, and others could not conclude a cause with a sufficient degree of engineering certainty.

The origin of the fire was agreed to be at a work station inside the factory floor open area that consisted of a wooden desk, computer on the floor, monitor, a 500VA Uninterruptable Power Supply (UPS) on the floor, extension cords on the floor, plastic waste basket, and a metal filing cabinet adjacent to flammable, cloth-covered metal screen walls close to the side of the building and next to another work station.

The fire occurred during the middle of a Saturday night when the plant was not in production. A worker had worked at the subject workstation earlier on Saturday morning. No accelerants were found in the vicinity of the workstation. No sign of a break-in or unauthorized entry was found.

Fortunately, all fire debris on the floor was swept up and kept in bags by the initial insurance investigators. cursory examination by investigators found no evidence in the debris that would point to a cause for the fire.

Detailed sifting of the fire debris from the floor, which was stored in bags, through fine screens produced important artifact evidence. Missing brass bus bar pieces and wiring from the 120-volt UPS were found. These artifacts allowed one to reconstruct the electrical bus bar system of this UPS that was heavily damaged by fire. One of the bus bars showed that the brass had been consumed/melted at a solder joint. Other adjacent solder joint locations **did not** exhibit such consumption/melting.

Metallurgical examination revealed that the brass adjacent to the missing brass reached temperatures in excess of 900°C (the melting point of brass). The plastic case material of the UPS was flammable and would ignite at this temperature. A new identical UPS was obtained, disassembled, and the brass bus bar system and its solder joints were compared. Electrical tests and research revealed that low current (less than one ampere of current) can cause overheating and arcing sufficient to initiate a fire under the right circumstances within a flammable material enclosure.

The conclusions reached were that the defective solder joint arced, consumed the brass, some of the copper conductor, ignited the case, and initiated the fire. Arson was ruled out.

---

### Electrical, Arson, Fire

### D31 When Law Enforcement Relies on Some On-Board Vehicle Crash Data to Reconstruct a Crash Reconstruction in Criminal Prosecution, but the Overlooked Data is Exculpatory

*Billy S. Cox, Jr. \*, Billy Cox Group, Navasota, TX 77868*

**Learning Overview:** The goal of this presentation is to discuss the pitfalls of cherry-picking data obtained from downloading the crash data from a vehicle Event Data Recorder (EDR) using the Bosch® Crash Data Retrieval (CDR) tool in criminal prosecutions following a motor vehicle collision.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the use of EDR data from a vehicle that was struck from behind. The pre-crash data revealed critical pre-crash steering data that would indicate the intoxicated driver was not the at-fault driver in the collision.

The Bosch® CDR tool has been utilized for nearly 20 years by crash reconstructionists to assist in crash investigations. As vehicle technology has improved, the data that may be obtained following a crash has also become more detailed and beneficial, especially the pre-crash data. This presentation discusses the implications of ignoring some pre-crash data that is recovered in the imaging of the EDR.

In the subject collision, a RAM® 1500 pickup was being operated in the right, through traffic lane of U.S. 287 in Wilbarger County, TX, at 3:00 a.m. by a 20-year-old male. A Nissan® Pathfinder®, being operated in the through traffic lane was struck from behind, causing it to leave the roadway and roll over. The Nissan® Pathfinder® was occupied by two adults and three children, all of whom were unrestrained. One of the rear-seat occupant children sustained fatal injuries in the collision.

The driver of the RAM® 1500 pickup remained on the scene and attempted to assist the occupants of the second vehicle. He was interviewed by law enforcement at the scene and, after about one hour, voluntarily submitted to a blood alcohol test. His blood alcohol measured 0.11, which was over the Texas legal limit of blood alcohol concentration of 0.08 or more. He was arrested and subsequently tried for Intoxication Manslaughter. In Texas, a conviction for Intoxication Manslaughter has two prongs: (1) a person must be intoxicated, and (2) by reason of that intoxication, causes the death of another by accident or mistake.

During the initial investigation, the Texas Department of Public Safety officers downloaded the crash data from the EDR of the Nissan® Pathfinder® that was struck from behind. The EDR file contained data from two collision events; a front-to-rear collision and a rollover event, plus 5.0 seconds of pre-crash data for both events.

Based on the data contained in the EDR file, the reconstruction revealed that the impact speed of the RAM® 1500 pickup was 75mph, which was the speed limit on the highway. The speed of the Nissan® Pathfinder® was 39mph, yielding a closing speed of about 36mph.

The 5.0-second pre-crash data from the Nissan® Pathfinder® contained information for vehicle speed, service brake (On, Off), and vehicle steering input at half-second intervals, from -5.0 seconds to 0.0 seconds. Although the collision occurred in the center of the traffic lane that was occupied by the RAM® 1500 pickup, the pre-crash data indicated that the driver of the Nissan® Pathfinder® applied 2.0 degrees of left steer for 2.5 seconds, increasing to 10 degrees about 0.5 seconds prior to the crash and finally, 54 degrees of left steer at the time of the crash.

The pre-crash steering was ignored by investigating officers. A set of steering tests was performed with an exemplar vehicle prior to the trial and the steering input indicated that the driver of the Nissan® Pathfinder® executed a rapid lane change from the acceleration lane to the through traffic lane prior to being struck from behind. The reconstruction revealed that the rapid lane change by the driver of the Nissan® Pathfinder® was the cause of the crash and the intoxication of the driver of the RAM® 1500 pickup was not a factor in the crash.

Surveillance video from a convenience store nearby showed that the driver of the RAM® 1500 braked suddenly prior to striking Nissan® Pathfinder® in what could be considered a normal, unimpaired perception/reaction time of about 1.0 second in response to the rapid lane change. A jury of his peers found the driver of the RAM® 1500 guilty of driving while intoxicated, but found that he did not cause the crash.

This presentation will be highlighted with surveillance video, video from the steering tests, and reconstruction video from a subsequent fatality crash wherein the steering data was ignored by state police investigators in a two-fatality collision.

#### **Crash, Intoxication, Reconstruction**

### D32 Spoliation: Willful Loss of Evidence Crime in an Electrocution Case

*Helmut G. Brosz, BASc\*, Forensic Science International Group, Markham, ON L3P 3P2, CANADA*

**Learning Overview:** After attending this presentation, attendees will recognize that forensic electrical engineers and accident or crime scene investigators can play an important role in analyzing an electrocution scene as well as assisting first responders and criminalists in determining if willful spoliation could have occurred. The seizure of all relevant materials and artifacts is important and should not be left behind for someone else to destroy. Such artifacts can yield valuable evidence from an electrocution scene.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to an improved performance of criminalists and engineers involved in an investigation of an electrocution in a civil case. Can the willful loss of evidence lead to criminal indictments?

This case study covers an electrocution in a motor repair shop. The deceased technician was in the process of attaching two test clips to the 480-volt motor that had just been repaired. Upon making the two connections, he was electrocuted and fell to the floor. The assistant eyewitness working next to the deceased technician was of a religious/moral persuasion, which prevented him from applying any form of first aid including mouth-to-mouth resuscitation to the victim. The hard evidence from the scene consisting of test cables, with test clips and insulating boots attached, was turned over to the plaintiff's attorney for the deceased instead of being kept by the Authority Having Jurisdiction (AHJ) over workplace accidents.<sup>1</sup> The subject motor was not examined or retained.

A civil suit was filed by the plaintiff's lawyer against the manufacturer of the red insulating boots which covered the bare 50-ampere test clips. The complaint stated that the red insulating boots were defective and had some form of cuts, holes, or other unspecified defect that allowed contact between the hand and the bare 50-amp clip.

The plaintiff's attorney "lost" the boots, clips, and the wires to which they were attached. The only useful evidence were two photos take upon autopsy of the deceased's hand.

A reconstruction of the electrocution using porcine tissue and identical 50-amp clips demonstrated that the electrocution did not occur due to a slit, cut, or hole in the insulating boot as demonstrated by the burn patterns on the porcine tissue tests. Instead, it was clearly evident that the burn pattern on the deceased's hand and fingers was due to direct contact with the energized bare clips with the insulating boots having been shoved back so as to make it easier to apply the clips to the motor terminals. The deceased obviously forgot to turn off the power to the test clips before making his connections. The accident thus was the result of the deceased's own negligence, not a product liability case.

The law on spoliation (depending on the jurisdiction) says that mere negligence is not sufficient for a spoliation finding. What is required is: (1) that the evidence was destroyed; (2) that the evidence is relevant; (3) legal proceedings were pending; and (4) that the destruction of the evidence was an intentional act of the party, indicative of fraud or intent to suppress the truth.

In the opinion of the defense, spoliation occurred. No motion or hearing on spoliation took place. No criminal proceedings were initiated. The matter settled during trial.

### D33 Criminal Engineering and Science Without Consequences: Why?

*David R. Bosch, PhD\*, Forensic Engineering, Inc, Phoenix, AZ 85008; Mark C. Pozzi, MS\*, Sandia Safety Sciences, Edgewood, NM 87015; Kenneth J. Saczalski, PhD\*, Newport Beach, CA 92661; Carley C. Ward, PhD, Biodynamics Engineering, Inc, Phoenix, AZ 85042; Parris Ward, JD, Biodynamics Engineering, Inc, Pacific Palisades, CA 90272*

---

**Learning Overview:** The goal of this presentation is to share with the forensic science community the concerns and questions regarding the prevalence of criminal engineering and science within the automotive and other product manufacturing communities. The often-nebulous distinction between negligence and criminal behavior by scientists, engineers, and their managers will be explored.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing important and enlightening information and discussion regarding examples of the lack of consequences for those making decisions that predictably, negatively impact public safety.

Why are engineers, scientists, and their managers within this industry not held criminally responsible for their defective designs? Routinely, we find instances where engineers, scientists, and their managers make decisions which negatively affect public safety. The unethical (criminal?) environment that enables “crooked” engineers and their managers to get away with exposing the public to defective designs for sundry reasons are a malignant part of American industry. Personal bonuses and increased corporate profit are basic factors motivating such unethical behaviors. Those responsible typically never suffer the consequences of their designs or the decision to deploy them. For example, the Volkswagen® executives currently under arrest/indictment for spoofing smog controls are for relatively insignificant offenses compared to the design and manufacture of predictably weak seats, slackening seat belts, fuel tanks that are in the crush zone at the rear or side of vehicles, inertially releasing seat belt buckles, exploding airbags, and perpetually weak roof and door latch structures, all of which have killed thousands of children and adults. An example of particularly grievous behavior by the automotive industry, in collusion with the United States Department Of Transportation (DOT), was a regulation governing roof strength (FMVSS 216), which was supposed to be a “temporary” standard, but remained in force for more than 30 years. In 1996, the DOT declared that FMVSS 207 was “flawed and inadequate,” yet automakers continue to design to this standard. Additionally, automakers continue to design seats to the flawed and inadequate FMVSS 207. The latest known instance of negligence that appears to rise to the level of criminal action, is with the Boeing® 737 MAX. Commercial aircraft defects are particularly notable in that hundreds of people die at once, instead of one or two at a time in ground vehicle crashes. If an automobile mechanic cut a hidden portion of a seat belt that later resulted in the failure of the belt and consequent injury/death, he would likely be held criminally liable for “sabotage” of the vehicle’s safety system. This is NOT the case for those that knowingly introduce defective products into the stream of commerce. Why should those who introduce dangerous designs at the engineering department or the board room, be treated any differently than an individual that intentionally disables a safety system?

In 1966, Dr. John Stapp, pioneer of American automotive safety testing and regulation, proposed that the automotive industry and its personnel be held individually criminally responsible for their actions that resulted in dangerous vehicle designs. Obviously, his insightful recommendation, based on well-known and documented human behavior, was rejected. It is this study’s position that the undue political and financial influence of industry and the lack of appropriate laws and/or enforcement are the reasons that such murderous behavior has been and continues to be allowed. Adults and children continue to needlessly die. Why?

---

### Criminal Engineering and Science, Defective Engineering Decisions, Consequences-Negligent Engineering

### D34 Head and Neck Trauma: BioMedical Engineering Analysis of Entrapment Testing

*Laura L. Liptai, PhD\*, BioMedical Forensics HQ CA/FL, Moraga, CA 94556; Ellyson Maleski, BS\*, Biomedical Forensics, Moraga, CA 94556*

---

**Learning Overview:** The goal of this presentation is to inform the forensic engineering community about the importance of integrating various components of a system and testing the design as a whole to prevent real-world head and neck risks of entrapment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a better understanding of the factors that increase risk of injury/death due to entrapment.

**Introduction:** Nearly one million Americans live in some type of senior living community and that number is expected to double by the year 2030. Between 2003 and 2012, there were 155 bed rail-related deaths in which 129 of the 155 deaths occurred in people who were 60 years or older. With the increasing number of seniors residing in assisted living care, there is a greater need to focus on medical research to reduce health risks and provide preventative measures. This includes research of the mechanics of injuries that lead to fatalities. Entrapment of the head and neck can occur as a result of the body being wedged between two objects, creating a mechanism for asphyxiation. Biomedical engineering analysis is important to determine what can be done from a preventive perspective to ensure a safer environment for every patient in this increasing population.

**Case Study:** A facility failed to ensure that half-side rails were safely applied for an immobile resident who was using an alternating pressure mattress. This failure created a real and present danger when her head and neck became wedged between the half-side rail and mattress, resulting in fatality due to asphyxiation.

**Content/Methods:** Tests were performed using the Food and Drug Administration (FDA) -approved Bed System Measurement Device in the seven different possible entrapment zones that have been outlined by the FDA. Testing was conducted to determine if an alternating pressure mattress with the approved half-length bed rail passed or failed in the various zones/settings.

**Results:** During the analysis of entrapment incidents, this study revealed that the interactions between the separately designed components of the bed system were more concerning than any one component alone. Currently, the bed system is under-optimized and leads to entrapment possibilities. Error rates were analyzed and contributing factors of these error rates were determined.

**Conclusion:** The results confirm that there are risks for entrapment even in a bed system unit in which all components individually passed the FDA regulations for entrapment. This is due to their specific interactions between various bed components that were not properly designed and tested as a system. One contributing factor to this current issue is having different manufactures design the mattresses, bed frames, and bed rails that are frequently used interchangeably. The customized testing, in which all components of the system were tested as a unit, resulted in identifying entrapment risks and presented an unnecessary risk for users.

## D35 An Experimental Study of Inertial Mechanisms of Motorcycle Helmet Accident Retention Failures

*Kenneth J. Saczalski, PhD\*, Newport Beach, CA 92661; Mark N. West, BS, Environmental Research & Safety Technologists, Newport Beach, CA 92661; Mark C. Pozzi, MS\*, Sandia Safety Sciences, Edgewood, NM 87015; Todd Saczalski, BSMET, TKS Consulting, Inc., Colorado Springs, CO, CO 80907*

**Learning Overview:** This goal of this presentation is to demonstrate an experimental method for forensic study of motorcycle and motocross helmet inertial-induced detachment mechanisms during motorcycle crashes by using the National Highway Traffic Safety Administration (NHTSA) Pendulum anthropomorphic Hybrid-III head-neck test device for comparison of potential defective helmet retention systems.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing an experimental method to evaluate the tendency of motorcycle and motocross helmets to be displaced from the head during inertial loading in a collision prior to the rider impact-contact with the ground.

Discussed in a prior American Academy of Forensic Sciences (AAFS) presentation, the protective capability of a motorcycle and motocross helmet is diminished or becomes non-existent if the helmet becomes displaced or ejected during an accident or sudden impact.<sup>1</sup> Earlier helmet research on displacement-detachment during crashes was published by Richards and Hurt, et al.<sup>2,3</sup> The United Kingdom Department for Transport reported “helmet detachment...in 10% to 14% of casualties.”<sup>4</sup> Restrained helmets can be significantly displaced or ejected off the head in motorcycle impacts, due to loose fastening of the chin strap and possibly a loose-fitting helmet. Hurt noted, “helmets properly fitted, retention system securely fastened, but the helmet is ejected.”<sup>3</sup> Richards diagrammed how properly fitted and securely fastened helmets can eject in frontal impacts where “the torso is slowed...but forward inertia of the helmet, the geometric attachment of the chin strap system, plus head rotation, allows the helmet to roll off the head before impact with another vehicle, and/or other fixed objects.”<sup>2</sup>

Manner in which helmet is detached at high speed, showing (left) normal position and (right) helmet pivoting forward on strap during accident.

In this current study, the NHTSA Pendulum anthropomorphic Hybrid-III head-neck test device was used for experimental evaluation of helmet detachment due to inertial unloading caused by the helmet design and retention system. Experimental methodology is based on earlier research by the United States Army Aeromedical Research Laboratory related to helicopter and military helmet retention during inertial impact loading.<sup>5</sup> The figure below, from reference 5, shows phases of head/helmet flexion (head bend toward chin), head/helmet extension (head/helmet bend reward), and helmet lofting from the head due to centrifugal forces.

The figure below shows video clips of similar testing recently conducted at IDIADA-KARCO on motorcycle helmets, using the NHTSA pendulum. New helmet models were impacted at different impact speeds (6.8 and 5.3m/s) and helmet sizes (M & L).

The figure above shows four inverted video clips (i.e., top of head in pendulum test is actually oriented toward floor) from different time frames of NHTSA pendulum impact testing at 5.3 meters per second (m/s) on a new, large-size motocross helmet mounted to a Hybrid-III 50<sup>th</sup>tile male head/neck. The upper left video clip is taken at the start of pendulum contact-impact just before the pendulum arm crushes an aluminum honeycomb pad. Prior to testing, the helmet

was tightly cinched to headform. The upper right video clip is 41msec after impact. The upper two video clips show initially, during the neck-flexion phase, the helmet becomes loose from the headform, lags behind the head rotation so the headform chin protrudes noticeably below the chin-bar, and the forehead rotates into the face opening of helmet. Detachment of the helmet from the headform is caused by the centrifugal force induced into the combined headform and flexible neck, which are affixed to the base of the rigid pendulum bar stopped suddenly by crushing of the deformable honeycomb pad. The next time clip at 176ms shows the helmet rotated back to almost the same position as the contact impact. Then the head-neck system goes into neck “extension” rotational mode such that the helmet is displaced from the headform and the chin again protrudes beneath the chin bar of helmet (i.e., 260ms clip). Although tightly cinched before impact, the helmet easily slides “loosely” back and forth over several degrees relative to the start of inertial impact.

In summary, the experimental methodology utilized by authors discussed in this presentation enables a more realistic, proper forensic evaluation of helmet system retention performance, regardless of compliance with limited government or independent safety standards, such as the “roll-off” test. It has been pointed out that existing helmet Standards FMVSS 218, British Standard 6658, and ECE Standard 22.05 do not adequately evaluate helmet retention deficiencies or potential head injury risks like the inertial testing employed in this study.<sup>5</sup> Typically, these standards only utilize a simplified “roll-off” test where a small weight is attached by a loose cable to the rear edge of the helmet mounted on an inclined metal headform. Weight is then dropped about 0.6 meters to cause limited “sudden jerking motion” to helmet. This method does not address the more realistic “flexion” and “extension” kinematics achieved with the pendulum test method.

### D36 The 1921 Death of Nino Martoglio, Pirandello's Mentor: A Cold Case and Literature Review

Massimiliano Esposito, MD\*, University of Catania, Catania 95123, ITALY; Giuseppe D. Albano, MD, University of Catania, Foggia 95123, ITALY; Antonino Barbaro Paratore, MS, Carabinieri Scientific Investigation Department, Messina 98122, ITALY; Sebastiano Battiato, PhD, University of Catania, Catania 95125, ITALY; Pasquale Malandrino, MD, University of Catania, Catania 95123, ITALY; Fabrizio Vanaria, MD, Department of Italian State Police, Catania, ITALY; Sabrina Franco, Catania, ITALY; Monica Salerno, MD, PhD, University of Catania, Catania 95123, ITALY; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY; Cristoforo Pomara, MD, PhD, Catania, Foggia, ITALY

**Learning Overview:** The objective of this presentation is to establish the cause of death of a man who lived 100 years ago through a multidisciplinary approach of forensic pathologists, anthropologists, and software engineers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the importance of an analytical and scientific method that can change the cause of death even in a case from 100 years ago. Anthropological investigations, forensic radiology, and engineering informatic study could reconstruct the bone lesions and the possible kinematics of the fall.

Forensic pathologists who deal with blunt force injuries to the head are often asked to determine whether the trauma is related to a fall or induced by blows. This is a challenge for forensic pathologists that have to discriminate falls and blows in blunt head trauma. A recent and 1800s literature review was performed. Guyomarc'h, Pierre et al. demonstrated that in the discrimination of falls versus blows, the Hat Brim Line (HBL) rule is one of the most useful single criteria.<sup>1</sup> According to this rule, an injury located at the level where the brim of a hat would lie is more likely the result of a fall, while a blow would generally produce a wound above this line. According to Petaros et al., falls from lower heights (<3.5m) are characterized by occipital, temporal, and parietal fractures and produce lesions like scalp lacerations and linear or radial fractures of the skull.<sup>2</sup> In the height group (4–10m and 10.5–30m), there is a more generalized distribution with fractures localized in the upper/middle body, lower body, and throughout the whole body. Unlike falls, blunt trauma often causes injury above the HBL and depressed fractures (type IV according to Guyomarc'h, Pierre et al.) that reproduce the shape of the used object.<sup>1</sup> Lacerations at the injured site and defensive lesions at the level of the hands are present as well. A review of 3D models for simulating head impact biomechanics was performed, too. O'Riordain, K. et al. thought MADYMO software (Mathematical Dynamic Models-TNO, 1999) established that fall from the lower height of <3m caused a right frontal linear skull fracture, right frontal extradural hematoma, left posterior temporal basal contusion.<sup>3</sup>

**Case Report:** The case reported happened nearly 100 years ago. Antonino Martoglio is a Sicilian historical figure, a famous poet, writer, one of the first film directors, and Pirandello's mentor who died in mysterious circumstances. The morning of September 16, 1921, the cadaver of the well-known Sicilian poet was found in the lift shaft of the hospital. The night before, he left the room where his son was hospitalized, and went to an isolated under-construction area of the same building. The lift shaft was 3.35 meters high and measured 1.80x1.30 meters. With the approval of the prosecutor's officer, an engineer inspected the building and an external examination was conducted by the local medical examiner. The medical examiner reported an extended medial-frontal bruise with an irregular lacerated-contusion wound and a depressed fracture of the frontal bone. The medical examiner established that the death was due to a violent frontal trauma resulting from a fall from a low height (<3.5m); for this reason, he established it was not necessary to proceed with an autopsy. An 1800s literature review about falls from different heights and related lesions support the hypothesis that those injuries reported can exclude a 3.35m precipitation of a corpse and an autopsy.<sup>4</sup> Moreover, depressed fractures were described exclusively in blunt traumas. The data that emerged from the review were sent to computer scientists who performed an engineering informatic study. Through computer software, informatic engineers evaluated all the possible injuries involved by a fall of 3.35m and established that the most affected region was the head. The 3D computer simulation will be presented.

#### Fall From a Height-Blunt Trauma, Engineering Informatic Study, Literature Review

### D37 Skull Fracture Risk: An Experimental Comparison Between Elastic (Drone) and Inelastic (Wood Block) Impacts Focused on Fracture Type and Tolerance Using Instrumented Postmortem Human Subjects (PMHS)

John H. Bolte, PhD\*, The Ohio State University, Columbus, OH 43210; David Stark, PhD, The Ohio State University, Columbus, OH 43210; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH 43210; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH 43210

**Learning Overview:** After attending this presentation, attendees will have an appreciation for interdisciplinary research in skeletal trauma analysis, specifically focused on the cranial vault. Attendees will learn how to conduct experimentally driven biomechanical validation of skeletal trauma for forensic engineering purposes and will understand the importance of utilizing experimental data to better understand the differences in fracture type and threshold between elastic and rigid blunt force impacts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for interdisciplinary biomechanical analyses of skeletal trauma in the cranial vault due to both elastic and rigid blunt impacts. Increased understanding of the differences in fracture tolerance and type due to elastic and rigid blunt force trauma will serve to improve skeletal trauma analyses in forensic engineering.

Currently, there are over one million recreational drones in the United States, with forecasts predicting increases to more than three million by 2021.<sup>1</sup> Originally, the Federal Aviation Administration (FAA) regulations limited drones to weights below 55lbs and top speeds below 100mph.<sup>2</sup> Recently, the FAA has begun allowing more widespread Unmanned Aircraft Systems (UAS) operations through a waiver program. As more drones populate the airspace and more lenient regulations are enacted, there is a need to understand and quantify the risk associated with drone impacts. To date, there have been several documented cases of concussion and whiplash injuries resulting from UAS impacts as well as one case of an Abbreviated Injury Scale (AIS) 3 level skull fracture.<sup>3</sup>

The focus of this study was to impact Postmortem Human Subjects (PMHS) over a range of drone head impact scenarios (including a wooden block) to: (1) investigate differences in fracture type between drone (elastic) and wooden block (inelastic) blunt impacts; and (2) assess current automotive-based injury criteria to predict the fracture thresholds of the cranial vault. The experimental variables included: drone impact orientation, drone vehicle type, and impact velocity.

The tests were conducted by using a catapult device to accelerate the drones and wooden block into five separate PMHS, with each PMHS receiving multiple impacts focused on separate bones of the cranial vault. A total of 41 blunt impacts were conducted using five different drones and a wooden block at speeds up to 22m/s. The PMHS were instrumented with strain gauges on the bones that comprise the cranial vault and two different arrays of accelerometers and Angular Rate Sensors (ARS) mounted to the skull to measure six-degree of freedom head kinematics. In-between each impact, X-rays of the head were taken to document if a fracture had occurred due to the preceding drone or block impact. Following the test series for each PMHS, an anatomical dissection was completed to document all fractures that occurred to the cranial vault due to the blunt impacts.

Of the 35 elastic drone impacts carried out, one AIS 2+ injury was observed: a 13cm linear skull fracture in the frontal bone resulting from a Phantom 3 impact. In addition, three rigid wood block tests all resulted in fractures to the cranial vault, one of which was an AIS 4 severity injury. Kinematics measured during PMHS tests indicated that automotive injury metrics may not be able to accurately predict skull fracture due to drone or elastic blunt impacts. To assess the risk of skull fracture, the Head Injury Criteria (HIC<sub>15</sub>) and its associated risk curve were compared to PMHS head kinematics.<sup>4</sup> Based on the HIC<sub>15</sub> criteria, five drone impacts had greater than an 85% probability of causing a skull fracture; yet only one skull fracture was observed. Additional investigation is needed to determine appropriate criteria or limits to be used for predicting the severity of head fractures due to elastic blunt impacts.

#### Skull Fracture, Injury Biomechanics, Blunt Force Trauma

## D38 Cervical Spine Injury of Postmortem Human Subjects in Rear-End Impacts

*Yun-Seok Kang, PhD\**, The Ohio State University, Columbus, OH 43210; *John H. Bolte, PhD*, The Ohio State University, Columbus, OH 43210

**Learning Overview:** After attending this presentation, attendees will have an appreciation for interdisciplinary research in skeletal trauma analysis, specifically regarding the cervical spine. Attendees will learn why cervical spine injury still occurs in rear-end impacts based on experimentally driven biomechanical responses for forensic engineering purposes and understand the importance of utilizing biomechanical data to investigate potential injury mechanisms of the cervical spine in rear impacts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for interdisciplinary biomechanical analyses of trauma in the cervical spine in moderate-speed rear-end impacts. Biomechanical data for intervertebral kinematics and injuries of the cervical spine in moderate-speed rear-end impacts will help attendees understand a potential injury mechanism for the cervical spine and ultimately improve injury analyses in forensic engineering.

In the United States, claims of cervical spine injuries (e.g., whiplash) in rear impact collisions are very common and result in enormous societal cost, with estimates of \$2.7 billion annually.<sup>1</sup> Even though cervical spine injuries can result from frontal and rear impact crashes, their risk in rear impact crashes is twice that of frontal impact crashes.<sup>2</sup> Several types (e.g., muscles, ligaments, facet joints, intervertebral discs, nerves) of cervical spine injuries in rear-end impacts have been reported.<sup>3</sup> Although extensive research using both volunteers and Postmortem Human Subjects (PMHS) has been conducted with a focus on cervical spine injuries due to low-to-moderate rear impacts, relevant anatomical sites, clinical evidence for injury, and the mechanisms of injury are still unclear. Therefore, the aim of this study was to investigate intervertebral kinematics and injuries to the cervical spine of whole body PMHS by exposing them to moderate-speed rear-end impacts in both experimental and production seats.

Twenty-one rear impact sled tests using 15 PMHS (73 ± 12 year old, 178.6 ± 6.3cm of stature, and 78.7 ± 6.2kg of weight) were conducted with Delta Vs ranging from 17 to 24km/h (Federal Motor Vehicle Safety Standard [FMVSS] 202a, Japan New Car Assessment Program [JNCAP], and 10.5g/24km/h). PMHS were placed in both experimental and production seats that exhibited seat back rotations ranging from 5 to 35 degrees. Head kinematics of the PMHS were measured using six accelerometers and three Angular Rate Sensors (ARS) mounted on the head. In order to measure both gross and intervertebral kinematics of the cervical spine, three accelerometers and three ARS were installed on the anterolateral aspect of the cervical vertebral bodies using custom wing mounts. A three-point belt without a pretensioner or a load limiter was used to restrain the PMHS on the seats, with initial belt tensions of 17.8N (4lb) for the lap-belt and 26.7N (6lb) for the shoulder-belt. The initial seat-back angle was approximately 25 degrees from vertical.

Results show that the intervertebral rotations of the cervical vertebrae represented flexion (i.e., relative forward rotation of upper vertebra relative to lower vertebra), although all cervical vertebrae rotated rearward in the global coordinate system. This relative forward rotation occurred in all three moderate speed conditions, at all intervertebral levels, for both experimental and production seats: 6.5 ± 3.6 and 4.2 ± 2.8 degrees for C2/C3, 6.2 ± 4.2 and 4.0 ± 2.3 degrees for C3/C4, 10.2 ± 5.8 and 6.3 ± 3.8 degrees for C4/C5, 7.6 ± 4.7, 6.1 ± 3.5 degrees for C5/C6, and 6.7 ± 3.8 and 5.8 ± 3.2 degrees for C6/C7, respectively. Several laxities between cervical vertebrae were discovered and identified from post-test dissection. The cervical flexion kinematics observed in this study using both experimental and production seats are not representative of traditional neck extension injuries, but results from this study indicated that intervertebral flexion kinematics may be regarded as an additional potential injury mechanism of the cervical spine during moderate-speed rear-end impacts.

### Cervical Spine, Injury Biomechanics, Rear-End Impacts

## D39 Head Injury Criteria (HIC) Scaling for Assessing Closed Head Injury Risk

Robert D. Anderson, MS\*, Biomechanics Analysis, Tempe, AZ 85281-0023; Billy S. Cox, Jr., Billy Cox Group, Navasota, TX 77868

**Learning Overview:** The goal of this presentation is for attendees to learn how to scale HIC.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a method for estimating head injury from available crash test.

Due to the expense associated with automobile crash testing, it is desirable to develop an appropriate scaling technique in order to utilize existing test results to predict the head/brain injury risk at a particular crash severity.

All head impacts involve linear and angular accelerations, as the two head accelerations are inextricably coupled by impact vector and head-neck structures.<sup>1,2</sup> Concussion risk has been correlated with both peak linear and angular head acceleration.<sup>3</sup> Unfortunately, angular parameters are not measured in standardized automotive crash or sled testing.

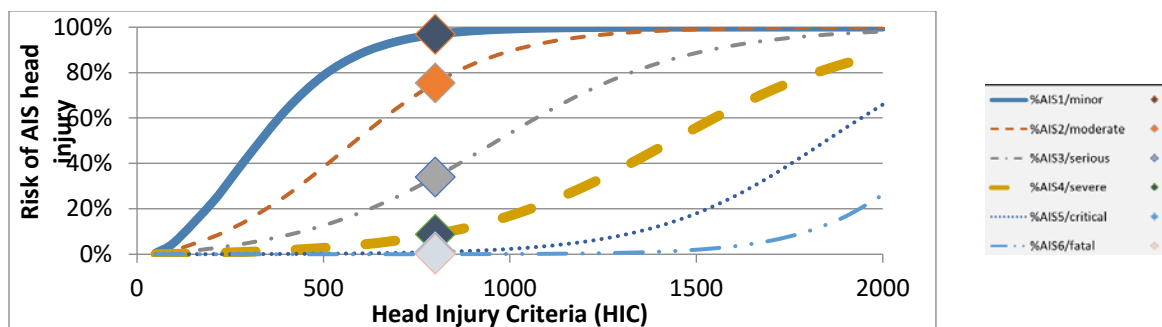

The Head Injury Criterion (HIC) is based upon the linear resultant head center of gravity acceleration. The HIC is the maximum calculated value over a time frame where  $t_2 - t_1 = 15$  or 36 msec using the formula shown in Figure 1.

$$HIC = \left\{ \left[ \frac{1}{t_2 - t_1} \int_{t_1}^{t_2} a(t) dt \right]^2 (t_2 - t_1) \right\}_{max}$$

**Figure 1. Head Injury Criterion<sup>4</sup>**

Excluding combined linear-angular and tissue strain based methods, HIC has been found to be the best predictor of mild traumatic brain injury when compared to other methods, such as the Gadd Severity Index, linear acceleration, and rotational acceleration.<sup>5</sup> HIC is the current worldwide standard for assessing head impact severity and head/brain injury risk and is inherent in Federal Motor Vehicle Safety Standards.

The Abbreviated Injury Scale (AIS) is a standardized system to describe injury severity that ranges from AIS 1 to AIS 6, representing minor through fatal/untreatable injury.<sup>6</sup> Prasad and Mertz set forth a risk curve for severe, AIS  $\geq 4$ , head or brain injury as a function of HIC.<sup>1</sup> The National Highway Traffic Safety Administration (NHTSA) later expanded the risk curves for all AIS levels.<sup>7</sup> As shown in Figure 2, an event with an HIC of 1,000 is considered to have about a 1 in 6 chance of a severe head or brain injury. Below 50, there is effectively no chance of even the most minor (AIS 1 or 2) head injury.<sup>8</sup> Volunteer studies are routinely conducted in a range that produce HIC's below 50 without consequence.

**Figure 2. Probability of Head Injury Severity as a function of HIC<sup>8</sup>**

Delta V is a common measure of crash severity. Proportional scaling the HIC for Delta V is not appropriate since the HIC is non-linear for head acceleration. However, if head acceleration varies linearly with Delta V, then Delta V can be used to scale head accelerations from a crash test to that of an occupant of an accident vehicle. The head injury risk for that occupant can be estimated using the HIC calculated from the scaled head accelerations, then applied to the Prasad-Mertz curves to estimate head/brain injury risk.

Crash tests at two different Delta Vs, but with comparable vehicles, occupants, restraints, seat positions, etc., are uncommon. An example from a 10mph rear-end sled test scaled down to live human exposure to a rear-end car-to-car impact with same year, make, and model of vehicle, seat belt use, and active head restraint deployment is shown in Figure 3 (left). The live human that was close in stature to that of the 50<sup>th</sup>-percentile Rear Impact Dummy (RID). Another example is scaling a 25mph barrier impact to a 30mph barrier impact with the same year, make, and model of vehicle, both with an unrestrained 5<sup>th</sup>-percentile female HBDIII dummy with the passenger seat adjusted to the same position, shown in Figure 3 (right).

**Figure 3. Results of scaling a rear sled test to a bumper-to-bumper impact (left) and frontal barrier crash tests (right)**

By scaling the resultant head acceleration, the estimated HIC<sub>15</sub>'s compared favorably but somewhat over-estimated the actual values from the lower speed crash tests. As would be desirable in practice, in these examples as many parameters as possible were kept constant. Inherent in this technique is the assumption that the collision durations are approximately the same so that the vehicle and head acceleration varies approximately linearly with Delta V.

#### HIC, Scaling, Risk

## D40 Forensic Motor Vehicle Accident Investigation

David Pienkowski, PhD\*, University of Kentucky, Lexington, KY 40536-0298

**Learning Overview:** After attending this presentation, attendees will have gained an awareness of current knowledge regarding the relationship between automobile body paint color and motor vehicle accident prevalence and severity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the importance of automobile body paint color and its relationship to motor vehicle accident prevalence and severity.

Engineers have long sought to improve occupant safety by inventing vehicle crash avoidance or crash energy mitigation strategies, structures, systems, or devices. Numerous studies have shown that high center-mounted third brake lights, stability control systems, seat belts, and crush zones (to name a few) help prevent accidents or reduce injury severity. However, few studies have addressed automobile body paint color as a factor. This is unfortunate because automobile body paint color is among the simplest and least expensive means of enhancing vehicle visibility. Despite public demand for increased vehicle safety, automobile body paint color and its relationship to motor vehicle accident prevalence and severity is largely unaddressed.

Color of consumer goods has deep roots in society. From the days when only quality fabrics could take dark dyes to Henry Ford's statement that "...the customer could have any color wanted as long as it was black," color has played a role in consumer choice. Ford's "black" strategy worked for low-cost mass production. Black (and gray) also work as important accent colors in the clothing and automobile industries. Consumers feel these colors suggest dignity, formality, solemnity, and power.

Mid-century consumers witnessed a wider array of automobile body paint colors to show product distinctiveness (two-tone color schemes), owner personality (bright psychedelic reds, pinks, yellows), or increasing technological sophistication (metallic or pearlescent colors enabled by metal particle suspension or multi-layering). Recent (2018) data shows consumer preferences for new automobile paint colors: white: (19.3%), silver (18%), black (12.4%), dark blue (11.4%), dark gray (7.5%), red (7.1%), dark green (6.7%), and brown (5.1%). Since 2006, white has been the primary color choice of the American automobile consumer. The popularity of this color is also increasing internationally.

So what's color got to do with forensic analyses of automobile crashes? Plenty, according to a decade-old study by the Monash University Accident Research Centre. They assessed the relationship between vehicle color and crash risk. Actual crash data reported to police in two Australian states were stratified by vehicle type, light conditions, and legal jurisdiction. The results showed a statistically significant relationship between vehicle color and crash risk. White vehicles had the least reported crashes, and thus the risk of all crashes were indexed to such vehicles. Compared to white cars, black, blue, gray, green, red, and silver were associated with greater crash risk. Crash risk associated with other colors were statistically indistinguishable from white, but this may be a Type II statistical error. The association between vehicle color and crash risk was strongest during daylight hours when relative crash risks were as much as 10% greater for black vehicles compared to white vehicles. The data also suggested that environmental factors are potential covariates modifying the relationship between vehicle color and crash risk. Crash severity was also related to vehicle color: lower visibility vehicle colors were associated with greater risk of more severe crashes.

Strength of the relationship between various automobile body paint colors and crash prevalence or severity was unclear. Although the Insurance Institute for Highway Safety and federal government studies estimated that crash reduction due to Daytime Running Lights (DRLs) is 3% to 5%, DRL data is distinct from automobile paint color data because other factors, such as vehicle shape, size, orientation, surroundings, backlighting, etc., may also be involved in relationship with crash prevalence and severity.

The Uniform Police Traffic Collision Report form includes vehicle color; however, Red, Orange, Yellow, Green, Blue, Indigo, and Violet (ROY G. BIV) type entries are generally insufficient given the wide variety of paint colors (and visibility) with the same name. The investigating forensic engineer should also record the manufacturer's paint code number to identify vehicle color. This code is typically a three-digit number printed (embossed) on the metal specifications tag riveted to the driver's B-pillar. Colors of the surrounding environment at the time of the accident, given the perspective and lighting conditions seen by the observer, also must be documented and considered.

### Forensic Motor Vehicle Accidents, Motor Vehicle Body Color, Automobile Visibility

### D41 Body-Mounted Camera Motion Analysis—Accuracy and Validation of 3D Camera Match Solutions

*Michael Callahan, BSME\*, Collision and Injury Dynamics, El Segundo, CA 90245; Brady Held, BFA\*, Courtroom Animation, Redondo Beach, CA 90278; Sean G. Snyder, BS\*, Collision and Injury Dynamics, El Segundo, CA 90245*

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of dynamic camera analysis, applying photogrammetric techniques to validate results, and the various challenges faced by investigators, engineers, and scientists in solving for evidence in a moving camera system.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing forensically sound methodology in the photogrammetric analysis of video evidence from body-mounted camera systems, using widely available tools from both the accident reconstruction and motion picture industries.

The analysis of video evidence captured by a moving camera system is one of the most difficult tasks faced by reconstruction professionals. While static photogrammetry techniques can be utilized with individual video frames, the vast number of image frames in a single video file make this method both time- and cost prohibitive. High frame rates (images per second), camera lens distortion, low-light scenarios, and image compression artifacts further complicate solutions using traditional photogrammetry. The motion picture industry heavily relies on the ability to solve for moving cameras in video compositing—that is, combining live video footage with rendered 3D objects. In movie production, the solution of moving camera footage is referred to as match-moving or camera-tracking. In this study, camera-tracking techniques are employed to solve for the motion of two of the most common sources of video evidence: Axon® body cameras (commonly worn by peace officers), and GoPro® action cameras (commonly worn by civilians and athletes). This report presents a study validating match-moving techniques used to solve for dynamic camera positions and objects within video frames.

In the first phase of a validation study, body-mounted action cameras are used in an environment optimized for photogrammetry: an indoor laboratory with uniform overhead lighting, a checkerboard floor texture, and a pre-defined motion capture area. The human test subject is equipped with a body-mounted camera and a biomechanical 3D motion capture suit that records body segment locations, speeds, rotations, and accelerations. The human motion is also recorded by static overhead video cameras. Key camera locations in the dynamic sequence are solved using static terrestrial photogrammetry. The statically solved camera positions are then compared with the solutions obtained using match-moving/3D camera tracking and the biomechanical motion capture suit.

After validating the optimized camera solutions using match-moving software, the study is extended into a non-optimized environment. The outdoor scene selected is a typical mixed-use industrial area, with large variations in sunlight/contrast, and very few idealized tracking references. The human test subject is instrumented with the motion-capture suit and a body-mounted camera and put through a series of motions, including walking, running, backing away from another human, and climbing a fence. The camera motion is solved using match-moving/3D camera tracking, and the solution is compared with the validated motion capture data set.

The results of this study show that 3D camera tracking or match-moving software can be used accurately to automate body-mounted camera motion solutions. Recommended guidelines include specific (key frame) static photogrammetry solutions to verify important locations in video footage. Pitfalls and other potential issues with frame rate, lens distortion, rolling shutter effects, and artifacts are discussed in detail. The presented methodology can be extended to both the criminal (officer-involved incidents) and civil (collision analysis) domains of reconstruction.

---

#### Photogrammetry, Video, Analysis

## D42 3D Computer Photogrammetric Analysis of Multiple Surveillance Cameras Synchronized Into a Single Data Set to Track the Movement of a Vehicle

Jorge Mendoza, BS, ME\*, *Litigation Animation, Inc, San Jose, CA 95120*

**Learning Overview:** After attending this presentation, attendees will have learned the process of using a laser scanner, aerial mapping drone, 3D animation software, aerial mapping software, and computer reverse projection photogrammetry to reconstruct the vehicle’s velocity and trajectory, which will be discussed.<sup>1</sup> Attendees will understand how the final photogrammetric solution is composited into ground photos and aerial images used to generate accurate exhibits for trial.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing the procedures, equipment, and software used to combine multiple surveillance video sequences into a single 3D computer model for photogrammetric analysis, and from the results create a 3D animation file for trial.

Through the case study of *People v. Nathan Campbell* attendees will learn how photographic evidence, 2D physical evidence diagrams, 3D laser scan data, 3D optical scan data, aerial images, and the footage from multiple surveillance cameras were integrated into a single 3D model for photogrammetric analysis of a vehicle’s movement.<sup>1</sup>

On August 3, 2013, a vehicle entered the Venice Beach boardwalk at Dudley Avenue and traveled approximately 600 feet before exiting at Sunset Avenue. The driver, Nathan Campbell, claimed that he accidentally put the vehicle into drive entering the Ocean Front Walk. The vehicle struck 17 people, killing 1 person. Mr. Campbell claimed that the vehicle, a 2008 Dodge® Avenger®, had malfunctioned as he repeatedly attempted to stop the car. As the vehicle traveled down the boardwalk striking people and various objects, it generated an extensive debris field. The vehicle’s movement and collisions were captured by several shop surveillance cameras located on the boardwalk. Physical evidence such as skid marks, pieces of the vehicle, broken vendor equipment, bicycles, trash cans, blood splatter, and the decedent’s body location were valuable bits of information in refining the vehicle’s position at those locations.

After reviewing crime scene photos, surveillance video, laser scan data, police reports, and witness statements, a site visit was made. An additional optical scan was conducted by flying an autonomous drone with Pix4D® aerial mapping software. After conduction of a pre-visualization of the crime scene, key vantage points were identified and photographed from the ground and the air. These key images would later be composited into the final 3D

Copyright 2020 by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained by the AAFS.

photogrammetric model for the creation of trial exhibits. The surveillance cameras were located, photographed, and their positions on the buildings measured. The subject vehicle was then photographed, examined, and its dimensions documented for modeling.

Having completed the field work, a 3D wireframe model of the scene and a 3D surface model of the vehicle were developed. At this point, the vehicle surface model, point cloud, and surveillance videos were all imported into 3D Studio Max® for analysis. The virtual cameras were created for each video sequence and positioned in the 3D environment, then the camera was matched to their respective video. Next, the vehicle movement from each video sequence was tracked frame by frame and the 3D vehicle animated to each position. Finally, courtroom trial exhibits were created. Mr. Campbell was sentenced to 42 years to life in state prison.

The process of using a laser scanner, aerial mapping drone, 3D animation software, aerial mapping software, and computer reverse projection photogrammetry to reconstruct the vehicle's velocity and trajectory will be discussed.<sup>2</sup> The attendees will understand how the final photogrammetric solution is composited into ground photos and aerial images used to generate accurate exhibits for trial. Aerial images captured by drones are extremely valuable in that they are capable of capturing large areas that provide a clearer understanding of an event. Attendees will learn how to treat the scene as if it were a Hollywood movie set. Attendees will understand the value of performing a pre-visualization of the scene to capture key ground and air images from select vantage points that will later be camera matched with the final 3D photogrammetric model to create exhibits for trial.

Image resolution and quality are key elements that directly impact the accuracy of the analysis. The benefits of computer-based photogrammetry over traditional modified camera photogrammetry will be made evident.

### D43 Vehicle System Forensics and Criminal Investigations Involving Automobiles

Wesley Vandiver, BA\*, Collision Forensics, Inc, Temecula, CA 92592

**Learning Overview:** After attending this presentation, attendees will have been exposed to the rapidly growing science of vehicle system forensics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by disclosing how the discovery of vehicle system data and the development of tools for data acquisition have opened an entirely new source of key evidence in investigations involving automobiles.

Attendees of this presentation will be exposed to the rapidly growing science of vehicle system forensics. Like other forms of digital forensics, the acquisition of data from automobiles centers on the retrieval of digital data from various forms of storage media, and there is an overlap with some data from familiar digital forensics sources, including phone data (phone call histories, call logs, contacts, and text messages). However, unlike traditional digital forensics, the data acquired from vehicles can include key evidence regarding historical vehicle whereabouts (breadcrumb trails), vehicle velocities, hard acceleration/braking, traction events, doors opening or closing, gear shift selector changes, etc. Examples of the successful use of vehicle system data in criminal cases will be presented, including the case described below in which the data were key evidence in a vehicular murder case prosecuted in the United Kingdom.

The storage of digital data in automobiles is not a new concept, but the usefulness of such data in criminal investigations has developed more recently. Digital data in automobiles began with diagnostic data used for the purpose of maintenance and repair, along with the control and monitoring of emissions. Apart from diagnostic data, many vehicles have recorded crash data since the late 1990s and early 2000s. Event Data Recorders (EDRs) have advanced over time to record tri-axial acceleration traces and pre-crash vehicle data. The latest, and perhaps most powerful, entry into the available data from automobiles is the development of vehicle system forensics.

On August 5, 2017, there was an altercation at Bar Form, a bar in Enfield, United Kingdom. The altercation moved outside to the parking lot, where Bradley Clifford, 24, had parked his Ford® Mustang®. Mr. Clifford was arguing with Jashua Francis, 19, regarding his girlfriend. The two men agreed to go to a car park for a fist fight. Mr. Clifford got in his Mustang® and Mr. Francis got on his moped. Riding pillion on the moped was Sobhan Khan, 18, a friend of Mr. Francis. As the parties drove away, Mr. Khan smashed a bottle on the side of the Mustang®. Mr. Clifford then pursued the moped at high speed through the city streets of Enfield until finally catching it and ramming it from the rear. The impact ejected both Mr. Khan and Mr. Francis. Mr. Khan died from his sustained injuries. A crime scene image, used with the permission of the metropolitan police, is shown as Figure 1.

The Mustang® was manufactured with a Ford® Sync Generation 3 infotainment system, which yielded direct evidence of the crime, including vehicle track logs (breadcrumb trails) and velocity logs derived from Global Positioning System (GPS) data, as well as wheel speed data reported on the vehicle's Controller Area Network (CAN) bus. Equally valuable was the indirect evidence the system provided. The breadcrumb trail in the data gave investigators a highly accurate trace of the pursuit path. With this, police personnel searched the surroundings along this path for sources of video evidence (i.e., security cameras). With the prevalence of security cameras in today's world, investigators were able to identify numerous cameras that captured video footage of the chase. The gathered video clips provided corroborating evidence of vehicle speed, but also the aggressiveness of the pursuit, the vehicle spacing at points along the route, evasive actions by the moped, etc. The volume of evidence that included the direct vehicle system data and the indirect evidence that resulted from it overwhelmingly disputed any claims that the impact and resulting death of Mr. Khan were accidental.

### D44 The Development of an Intelligent Mobile Application to Enhance the Quality of Latent Fingerprint Acquisition

Nicholas Frey, BS\*, Sam Houston State University, Huntsville, TX 77340; Carilyn J. Santisteban, BS\*, Sam Houston State University, Huntsville, TX 77340; Khalid Noman\*, Sam Houston State University, Huntsville, TX 77340; Mingkui Wei, PhD, Sam Houston State University, Huntsville, TX 77340; Jom Chi-Chung Yu, PhD, Sam Houston State University, Huntsville, TX 77341

---

**Learning Overview:** During this presentation, attendees will be introduced to an intelligent mobile application that is developed to assist the process of latent fingerprint acquisition. The application uses integrated cameras of smart phones to capture latent fingerprints and is able to indicate the quality of such fingerprints with both a graphical color-map and a numerical reliability score in real time. As such, it assists crime scene investigators to capture the optimal black-on-white fingerprint image.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of mobile computing and the potential to integrate Artificial Intelligence (AI) into crime scene investigation and latent fingerprint acquisition. The mobile application runs real-time algorithms to identify usable and unusable areas of a latent fingerprint image and, furthermore, leverages techniques, such as Augmented Reality (AR), to provide graphical indicators (i.e., green and red color-maps) to inform the investigator of the quality of such images. This application makes it possible for investigators to determine the optimal camera angles, distance, illumination, etc. during the latent fingerprint acquisition and, therefore, enhance the quality of the acquired latent fingerprint image.

Latent fingerprint image capturing used in the forensic investigation field requires that quality images be taken in order to accurately match fingerprints to those stored in a database. The goal of this project was to implement a mobile application to aid forensic investigators in the latent fingerprint acquisition process. In a typical use scenario, the investigator points the camera of the smart phone to a latent fingerprint, and the application is able to recognize and analyze the latent print in real-time and display a graphical indicator (i.e., green/red color-map) for useable/unusable fingerprint areas, as well as a numerical score evaluated based on the overall fingerprint quality. The acquired latent fingerprint image can be directly send to a remote Automated Fingerprint Identification System (AFIS) for latent fingerprint searching or matching.

The application development process was sectioned into three major components: *mobile application* development, *reliability score algorithm* development, and *client-server system* development. The *mobile application* development creates a camera application and photo gallery, which allows latent fingerprints to be captured and stored on the smart phone. The *reliability score algorithm* development is currently based on and modified from the SourceAFIS, an open-source fingerprint analysis and matching project. The algorithm provides the basis for a green/red color-map overlay to the application that indicates the usable and unusable areas of a captured latent fingerprint image. The *client-server system* is also developed based on the SourceAFIS, which accepts images acquired from the mobile application, and is able to conduct 1:1 fingerprint matching, or 1:N fingerprint searching. It is also noteworthy that the modular design of this project is flexible enough to allow various algorithms to be easily exchanged, and one of the research goals is to develop and integrate AI-aided algorithms to enhance the quality of latent fingerprint development and acquisition during crime scene investigation.

All in all, this mobile application serves the purpose of being informative to forensic investigators during the process of latent fingerprint development, analysis, and acquisition.

---

#### Latent Print, AFIS, Crime Scene Investigation

## D45 The Bisected Man: An Uncommon Pattern of Injury in a Fatal Motorcycle Crash

Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Federica Gori, MD, University of Pisa, Pisa 56100, ITALY; Sara Turco, MD\*, Pisa, ITALY; Alice Chiara Manetti, MD, University of Pisa, Forensic Pathology, Toscana, Pisa 56126, ITALY; Costanza Filomena, Florence 50036, ITALY

**Learning Overview:** The goal of this presentation is to present an unusual case of a fatal motorcycle crash.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by evidencing the importance of the medicolegal and engineering evaluation in an uncommon motorcycle fatality crash.

Powered two-wheel riders are one of the most vulnerable groups of road users. The object most frequently struck in an accident is a passenger car, followed by the roadway itself, either as a single-vehicle accident or as an attempt to avoid a collision with another vehicle.<sup>1</sup>

The most common sites of injuries in motorcycle crashes are the head—even when a helmet is worn—and the limbs, but lesions of the thorax and the abdomen are described as well.<sup>1-3</sup> Typical lesions described in motorcycle accidents are basicranium fractures, like the so-called “motorcyclist’s fracture” or the “ring fracture” around the magnum foramen.<sup>4</sup> Other typical lesions are the “fuel tank injury,” produced by the impact of the inguinal region against the fuel tank.<sup>5</sup> The upper limbs frequently present hematoma of the palms and fracture of the wrists due to the impact against the handlebars, which are strongly grabbed during the crash.

**History:** This case report concerns the death of an 18-year-old man involved in a fatal motorcycle collision against a very large loaded truck, the size of which exceeded the transversal size of the lorry. The collision between the motorcycle rider and the loaded truck caused the transection of the rider’s body at the abdominal level.

The external examination revealed a severe lesion of the abdomen with partial extrusion of the intestine and the mesentery. This lesion was accurately measured to compare its characteristics with the truckload: it was 39cm long and 25cm away from a transversal plane passing through the hips. It extended from one hip to the other, and had a transverse major axis. On the upper part of the laceration, there was a net-shaped excoriation. The area also presented multiple linear excoriations. The upper limb presented millimetric excoriations and lacerations and the compound and exposed fracture of the left wrist. The lower limbs presented diffuse excoriations. After the removal of the helmet, which was correctly worn, no external lesions were documented on the head.

The autoptic examination revealed several thoracic fractures, involving all the ribs bilaterally. There was a gastric laceration in the abdomen, though no gastric material ran into the abdominal cavity. There was a huge laceration of the liver, spleen, and left kidney. The thoracic aorta was lacerated. There was the complete transverse fracture of the bodies of the first dorsal vertebra and the second lumbar vertebra. The brain section revealed the subarachnoid hemorrhage of the left temporal lobe, cerebellum, and pontomesencephalon. The cervical examination revealed the linear fracture of the body of the fifth vertebra.

A combined engineering and medicolegal evaluation was performed to investigate the exact dynamics of the road accident. The two vehicles were examined, highlighting the damages of the left anterior part of the motorcycle and some stains on the loaded truck, that were the same color as the motorcycle. The lateral loaded truck side protrusion and the height from ground level were measured, as well as the distance of the seat and the handlebars of the motorcycle from the ground. The comparison of all these data with the injury pattern of the body allowed the reconstruction of the chain of events that ended with the crash of the motorcycle against the loaded truck.

This case is unusual because of the devastating injuries of the body of motorcyclist involving the thorax and the abdomen. The autoptic examination compared with the engineering evaluation allowed the reconstruction of the dynamic of the crash, confirming that the transection of the body matched with the action of the loaded truck.

### Motorcycle, Traffic Accidents, Forensic Sciences

## E1 The Detection of Latent Bloodstains Covered With Three Types of Current Top-Selling Paint/Primer Mixtures Using BlueStar®

*Mark Vecellio, MFS\*, Methodist University, Fayetteville, NC 28311; Catia P. Dombaxe\*, Methodist University, Fayetteville, NC 28311; Lisa B.B. Kasamba\*, Methodist University, Fayetteville, NC 28311; Devin Walker\*, Methodist University, Fayetteville, NC 28311-1498*

**Learning Overview:** After attending this presentation, attendees will better understand the effectiveness of using BlueStar® to detect latent bloodstains covered with up to seven layers of commonly sold paints available in retail stores throughout the United States.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting a better understanding of the capabilities of BlueStar® in presumptively detecting the presence of human blood under one to seven layers of three commonly sold paint/primer combinations. Similar research has previously been completed; however, much of it is outdated and does not include paint/primer combinations commonly available at United States retail stores. Furthermore, most of the previous research involved the use of luminol, not BlueStar®, to detect blood.

Approximately .05mL of undiluted human blood was projected onto Gold Bond® ½" drywall samples in a manner to simulate impact spatter stains. The bloodstains were allowed to air dry for a minimum of 24 hours prior to painting. Four drywall samples were each painted with between one and seven layers of three of the most commonly sold paints within the United States: (1) Colorplace® Antique White Ultra interior paint plus primer; (2) Glidden® Warm Caramel interior paint plus primer; (3) Glidden® White Flat interior paint plus primer. Each layer of paint was allowed to air dry before the next layer was applied. BlueStar® was then applied, in total darkness, to the samples using a fine mist spray bottle. Results were photographed using a Nikon® D5200 Digital Single-Lens Reflex (DSLR) camera.

Chemiluminescence was observed upon application of BlueStar® in 83 of 84 samples. One of the Colorplace® Antique White samples covered with six layers of paint did not yield chemiluminescence upon application of BlueStar®. The intensity of the chemiluminescence was rated as medium or high in all samples with three or fewer coats of the paints. The intensity of the chemiluminescence gradually declined with the fourth, fifth, sixth, and seventh coats of paint.

Research has previously established the effectiveness of luminol in detecting latent blood that had been painted over; however, BlueStar® presumptive testing has been less studied. In addition, many of the previous studies resulted in inconsistent and variable results. Prior studies did not involve commonly sold paints currently available in retail stores and did not involve paint/primer combination mixtures. The focus of this study is to provide tangible results that relate to three of the top-selling, contemporary paint/primer mixtures sold by retail stores in the United States. Additional study recommendations include using BlueStar® to detect bloodstains painted over with additional layers of the paints used in this study, using diluted blood in a similar constructed study, and performing this study using different volumes of blood.

### BlueStar®, Blood, Paint

### **E2 The Visualization of 9mm and .40 Caliber Gunshot Residue (GSR) From Various Ranges of Fire With Alternate Light Sources (ALS) and Infrared (IR) Imaging**

*Mark Vecellio, MFS\*, Methodist University, Fayetteville, NC 28311; Sarah V. Morello\*, Raeford, NC 28376; Ryan Greaney\*, Spring Lake, NC 28390-2075*

**Learning Overview:** After attending this presentation, attendees will better understand the capabilities of ALS and IR imaging when viewing GSR on dark-colored fabrics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting a better understanding of the capabilities of, and differences between, ALS and IR in visualizing GSR on dark-colored fabrics.

GSR is composed of smoke resulting from combustion of propellant, metallic fragments from the bullet, unburned and partially burned gunpowder particles, and lubricants. GSR may be deposited on surfaces of objects at a crime scene or on clothing or skin of persons present during the weapon discharge. Visualization of GSR is an important task during preliminary phases of criminal investigations. Early presumptive detection can provide immediate insight for investigators by helping to establish if a bullet defect is an entry site, determining if a person may have handled a weapon or had been in close proximity to the weapon at the time of discharge, and in determining a broad, estimated range of fire.

GSR is easily observed on light-colored surfaces due to its inherent dark color. Dark surfaces, however, often obscure GSR. The two visualization methods chosen for this research include IR and ALS. Both of these methods can be practically employed by investigators during preliminary phases of investigations, including crime scene examinations to detect GSR on dark surfaces.

Magtech® .40 caliber 180 grain Full Metal Jacket (FMJ) and 9mm Luger® 115 grain FMJ ammunition were fired five times each from distances of 3 inches, 9 inches, and 18 inches into black, cotton T-shirt samples. Later observed were the samples using a Sirchie® TMX ALS (450nm) with orange barrier filters. Images were taken using a Nikon® D5200 camera and orange filter. A Fuji® XT1 IR camera with IR 830 and 850 filters was utilized, in conjunction with 100-watt incandescent light sources, to observe and photograph the samples with IR. For control purposes, all samples were viewed with the same ALS and IR equipment prior to shooting. No particles were detected on any of the samples prior to shooting.

GSR was visualized on all samples using both IR and ALS; however, differences were observed. ALS was more effective in identifying scattered particles while IR was more effective in identifying scorching, burning, and bullet wipe. The scorching and burning observed with IR was visible at the 3-inch range of fire for both types of ammunition, but not at 9- or 18-inch ranges. Bullet wipe was visible with IR for both types of ammunition at all ranges of fire. The scattered particles observed with ALS, as expected, formed increasingly tighter patterns as the range of fire decreased. Scorching, burning, and bullet wipe were not able to be detected with ALS.

The GSR observed with IR effectively revealed scorching, blackening, and bullet wipe in proximity to the bullet hole, allowing clear evidence of the bullet entry site, while the particles observed with ALS were scattered and more useful in generating a presumptive range of fire estimate. Any range of fire estimates derived from presumptive visualization, however, should not be considered scientifically reliable or conclusive, but can be helpful to investigators in early stages of shooting incidents.

The GSR identified with IR could be easily interpreted due to its close proximity to the bullet holes. The scattered particles detected with ALS, however, could potentially cause interpretation difficulties when other trace particles are present. Using IR and ALS in conjunction provides maximum benefit by allowing visualization of bullet wipe, burning, and scorching, along with the scattered particles.

#### **Gunshot Residue, Alternate Light Source, Infrared Imaging**

## E3 Forensic Art—Know the Terms: Understanding Forensic Art Terminology

*Sandra R. Enslow, BA\*, Los Angeles County Sheriff's Department, Monterey Park, CA 91755; Daniel Marion, Jr., PhD\*, Denver, CO 80205-5630*

**Learning Overview:** After attending this presentation, attendees will understand the terminology used in forensic art. Facial reconstructions, composite drawings, age progressions, and video approximations are some of the examples that will be highlighted. This presentation will assist in understanding the complexities of the work performed by forensic artists and recognize the different uses for each application.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the definitions for each category of the forensic artist's work. In this presentation two General section forensic artists will present examples of casework they have handled and the definitions involved with each. These experienced forensic artists are collaborating to present this general knowledge to the Academy.

A confluence of facial anatomical sculpting ability and the data from a detailed forensic anthropological report are used in order to reconstruct the most reasonable likeness of the face the deceased wore in life. Facial reconstructions are cold cases. Given that the forensic artist begins with a skeletonized human skull, the following forensic anthropological terminology must be understood. Postmortem Interval (PMI), and its particulars, which include disarticulation (lost mandible or lost bones of the splanchnocranium), trauma (blunt force/sharp force, gunshot) and scavenging (animal gnawing) will be described. Any one of these or any combination of the above particulars can influence the outcome of a facial reconstruction. The presented 3D facial reconstruction was sculpted Fremont County, CO, by a member of the Colorado Coroners Association.

A combination of facial anatomical drawing ability and the data from a detailed forensic anthropological report were used in order to reconstruct the most reasonable likeness of the face of the deceased. A photographic image was used to develop a drawn 2D image of the face, rather than clay on the skull. This version of the 3D facial reconstruction is a faster process for getting the image to the investigators. As with 3D facial reconstructions, all 2D reconstructions are cold cases. PMI and its particulars, including disarticulation, trauma, and scavenging will be described. Any one of, or any combination of, the above particulars can influence the outcome of a facial reconstruction. The presented 2D facial reconstruction was drawn by the Los Angeles County Sheriff's Department lead forensic artist.

The composite drawing is a hand-drawn image. That drawing may be done with a pencil and paper, drawn on computer, or on a tablet with a stylus—any of these variations are composite drawings. Composites are traditionally developed using the cognitive interview process. Training is extensive for professional forensic artists in rendering the human face, understanding the anatomy, and interviewing witnesses. The presented composite was drawn by the lead forensic artist at the Los Angeles County Sheriff's Department for the Burbank Police Department, California. The description of the suspect was given by two different witnesses.

Forensic images are created from viewing video of persons of interest. Understanding the influence of light and shadow as well as Light Source is crucial in developing these approximations. Distortion, distance, and angle are three aspects that are taken into consideration in this process. These aspects assist investigators with a better understanding of who they are looking for.

Investigators, working on cold cases, often use an age progression. The image is developed using a combination of reference tools (early photos of the suspect, siblings, and parents) and knowledge of the Human Aging Process. Wrinkles, weight gain, and life style are other considerations taken into account.

Forensic art is a rapidly expanding discipline that requires specialized training, beyond advanced drawing skills. The forensic artist is called on for many different skill sets that assist in the identification process. These applications relate closely with those of other disciplines of the forensic sciences, especially forensic anthropology, forensic odontology, and forensic psychology.

---

### Forensic Art, Facial Approximations, Facial Reconstructions

## E4 Extraction and Quantification of DNA From Buccal Cells of Peruvian Coca Leaf Users and Non-Users

*Maher Nouredine, PhD\**, ForensiGen LLC, Oak Ridge, NC 27310; *James A. Bailey, PhD*, Minnesota State University Mankato, Bailey, NC 27807; *Gian C. Iannacone, MS*, Instituto de Medicina Legal, Lima Lima 21, PERU; *Martha R. Palma Malaga, MG*, Ministry of Justice and Human Rights, Lima, PERU; *Michele Rosso, PhD*, Copan Italia, Brescia Italy 25125, ITALY; *Santina Castriciano, BSc*, Brescia 25125, ITALY

**Learning Overview:** After attending this presentation, attendees will be familiar with the practice of coca leaf use as a stimulant by a Peruvian population and the mechanism of studying the impact of coca leaf alkaloids on DNA samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the variability in DNA yields obtained from buccal samples and illustrating a study design to investigate the impact of alkaloids and other compounds on DNA yields from swabbing human subjects.

**Background and Objective:** The *Erythroxylon coca* plant, also known as the coca shrub, is a plant from the Andes mountain range in Western South America. Historically, Peruvian people have used coca leaves as a mild stimulant and some continue to use it today. Coca leaf users typically remove the stem or midrib from each leaf, fold the leaf in half twice, and place it in the cheek. Leaves are continuously added until a ball of plant material, approximately 2–3cm in diameter, is formed. The leaves are not masticated but moved around the cheek with the tongue while in contact with saliva for a period of time before being discarded. The primary alkaloid in the coca leaf is cocaine and the dried leaves contain approximately 0.6% cocaine; however, there are 18 other alkaloids present in the leaf, which may affect DNA yield from buccal cells or cause inhibition during DNA amplification. The purpose of this research was to collect buccal swabs from coca leaf users and non-users to determine if there are any differences in the quantity or quality of DNA recovered from the subjects.

**Experimental Design:** Buccal swab samples using 4N6FLOQSwabs™ Genetics were collected from 13 coca leaf users and 10 non-coca users in the village of Rosaspata in the Huamanga province of Peru after signing an informed consent form. A survey of the donors indicated that the age range for coca leaf users was 18 to 74 years. Three of the donors were male and ten were female. Three of the donors reported they use coca leaves once a day, four reported two or three times a month, and six said two to three times a week. Seven donors reported that they added a pinch of lime (CaCO<sub>3</sub>) to the cheek when using coca leaves. The number of leaves used ranged between 10 and 30 with an average of 17, and the length of time in the mouth ranged between 15 to 60 minutes with an average of 30 minutes. The non-coca leaf users included three males and seven females ranging in age from 14 to 44 years. All samples were extracted with the PrepFiler® Express™ Forensic DNA Extraction Kit. The Quantifiler® Trio DNA Quantification Kit was used for DNA sample quantitation and the GlobalFiler® DNA Amplification Kit was used for typing. The AB3500 Genetic Analyzer was used for Capillary Electrophoresis (CE) and the data files were analyzed using the GeneMapper® ID-X v 1.4 software (AT=100RFU).

**Results and Conclusions:** DNA samples were obtained from all 23 buccal swabs with observed differences in the quantitation values that can be attributed to, and expected from, normal variance in sample collection. No significant differences in the quantitation value means were observed between the 13 coca leaf users ( $M=8.98\text{ng}/\mu\text{l}$ ;  $SD \pm 4.199\text{ng}/\mu\text{l}$ ) and 10 non-coca users ( $M=47.39\text{ng}/\mu\text{l}$ ;  $SD \pm 23.69\text{ng}/\mu\text{l}$ ). The differences observed between the two groups did not reveal a statistical significance using the unpaired, two-sided *t*-test statistic ( $p=0.372$ ). All buccal swab samples yielded full DNA profiles with no apparent inhibition or degradation. All male subjects were coca leaf users ( $n=3$ ). No appreciable differences were observed in DNA yields from males versus females. Furthermore, DNA yields do not appear to be affected by the frequency, duration, or recency of cocoa leaf use. Based on the donor survey, the most recent coca leaf use was one day prior to the DNA sample collection ( $n=7$ ). It is possible that the lag in time of one day resulted in the metabolism of the alkaloids and/or the recovery of the mouth mucosa in which any impact on the DNA quantity and quality would have been attenuated to reveal any appreciable effect on the DNA sample.

### DNA Yield, Coca Leaf, Buccal Swab

## E5 No Lab, No Problem! Practical Active Learning Ideas for a Forensic DNA Course

Kelly L. Knight, MS\*, *George Mason University Forensic Science Program, Fairfax, VA 22030*

---

**Learning Overview:** The goal of this presentation is to provide attendees with practical ideas for incorporating active learning into a forensic DNA course.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the benefits of active learning in the classroom, specifically the forensic science classroom. This presentation will dispel the myth that active learning in science can only be done through wet laboratory exercises. This presentation will emphasize that active learning in forensic science is not only a benefit, but it is essential for planting the seeds of success for our future forensic scientists.

This presentation will acquaint attendees with practical ideas for incorporating active learning into a forensic DNA course. These ideas can be modified for both undergraduate and graduate courses. Current education literature supports the active learning pedagogical technique, which is a technique that encourages students to take ownership of their learning through hands-on, interactive, and problem-based learning done both outside and inside the classroom. Theoretically, most instructors would agree that this type of learning is more beneficial for students in comparison to traditional lecture-style teaching; however, the problem lies in trying to figure out how to practically implement this in the classroom, especially when it comes to science courses.

In most science courses, active learning is typically done in the form of wet laboratory exercises. So what happens when the course does not have an associated laboratory? How can instructors implement active learning in science without one? These are questions many instructors struggle to answer. With much time spent already on course design and implementation, it can be difficult to find additional time to redesign a course to properly implement these active learning techniques.

The George Mason University Forensic Science Program aims to give students hands-on and interactive experiences in their forensic science courses both inside and outside traditional laboratory settings. Two of those courses are the undergraduate *Forensic DNA Sciences* course and the graduate *Survey of Forensic Chemistry, Biology, and DNA* course. Neither of these courses, at present, have a formal laboratory component; therefore, a mock case was added to these courses, which gives the students the experience of working a forensic DNA case from the moment it is received in the laboratory through the Combined DNA Index System (CODIS) upload. Student Assessment of Learning Gain (SALG) surveys were administered in both the fall and the spring semesters to evaluate the students' experiences with the mock case and how the active learning exercises impacted their experience in the course.

To aid in alleviating the difficulties many instructors face when attempting to implement active learning, attendees will be offered numerous examples that can be used in their own courses as well as a detailed explanation of the mock case exercises used in the forensic DNA courses presented.

---

### Education, Active Learning, Forensic DNA

## E6 A Unique Case of Death by Electrocutation in Water in an Abandoned Building

Justin L. Wilson, BS\*, Cleveland, OH 44106; Elizabeth R. Mooney, DO, Cuyahoga County Medical Examiner's Office, Cleveland, OH 44106

**Learning Overview:** The goal of this presentation is to provide the attendees with a case study that includes several variables that need to be taken into account in order to properly rule on a cause and manner of death while investigating a high-voltage electrocution in water death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing those involved in investigating electrocution deaths the tools and information necessary to provide a ruling on cause and manner of death.

Electrocution deaths are a rare occurrence in the field of death investigation and account for approximately 1,000 deaths in the United States per year.<sup>1</sup> The mechanism of death in electricity-related fatalities is most commonly ventricular dysrhythmia. The single most important factor to consider while investigating these deaths is the number of amperes involved, which is derived from the voltage and resistance of the electrical conduction system.<sup>2</sup> Oftentimes, high-voltage electrocutions result in readily apparent thermal injuries; however, no electrical burns or autopsy findings may be present to support electrocution in approximately one-half of low-voltage electrocutions, creating a diagnostic challenge for investigators and pathologists alike.<sup>3</sup> Additionally, in wet conditions, cutaneous burns can be rare because water provides an energization of the body that is too diffuse to cause focal electrothermal skin damage while also decreasing the resistance of the skin surface.<sup>2,4</sup>

The case presented here is a of a male found deceased in an abandoned building. The decedent was found by police lying in a pool of water in an electrical room. Initial assessment indicated the need for immediate inquiry to the local electrical company to assess for the presence of live electrical current provided to the building. The electrical company responded to the scene and reported a reading of 11,000 volts in two exposed wires. After the electricity had been safely disconnected, the scene was thoroughly investigated and photographed. Exposed wiring was noted in the room, along with tools indicating the decedent had been scrapping for material. A piece of black electrical tape was noted on the decedent's finger. In addition, paraphernalia consisting of two burnt glass pipes were found in his jacket pocket, suggestive of possible recent drug abuse. Apparent injuries noted to the body included lacerations of the forehead. At autopsy, additional minor injuries were noted, including a focal geographic, pale lesion of the right thumb, adjacent to the aforementioned electrical tape; samples of skin were taken for histological examination. Significant natural disease consisted of moderate cardiovascular and pulmonary disease. Results revealed microscopic characteristics consistent with electrothermal injury of the skin sample submitted; toxicological analysis was positive for cocaine and ethanol.

In electricity-related fatalities, a careful examination of the circumstantial data and a thorough scene investigation are essential. In this unique case, multiple alternative causes of death had to be considered due to the presence of illicit drug paraphernalia with positive toxicological results, significant natural disease, standing water (drowning), and external trauma. After thorough investigation and postmortem examination, the cause and manner of death was determined to be accidental high-voltage electrocution. This rare and unique case study reviews the key steps and investigative methods necessary to safely conduct a vital scene investigation and properly rule an electrocution death.

## E7 A Survey of Deaths in Judicial Control Areas in South Osaka

*Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School Legal Medicine, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University, Osaka 545-8585, JAPAN*

**Learning Overview:** After attending this presentation, attendees will be informed about custody death cases that occur in Japan and prevention steps that could be done in the near future.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by stating the different types of death between the years in the south part of Osaka, Japan. From the legal medicine perspective, this presentation will show how to prevent the death of a suspect while in custody.

In Japan, when suspects or people in custody die in judicial control areas, specifically police stations, jails, or prisons, an autopsy is performed by a forensic doctor from the perspective of the responsibility of the officials holding them. The cause of death, mechanism of injury, and other matters are examined. Previous reports on cases of death in judicial control areas include cases of natural death, drug-related death, suicide, suffocation, and sudden cardiac death associated with violence toward or capturing of the suspect or person in custody by law enforcement, as well as death from violence by a cell mate in prison, although this is not directly related to law enforcement officers. From the perspective of legal medicine, however, no detailed investigations of deaths in judicial control areas have been reported, at least not in Japan. This study surveyed deaths in judicial control areas in the southern part of Osaka, the city with the second-largest population in Japan. This study examined the causes of death of suspects or people in custody, the possibility that the death could be foreseen, and the possibility that the resulting death could have been avoided. A legal medicine class analyzed cases of death within judicial control areas, including police stations, jails, and prisons, from among the forensic autopsies performed over the past 11 years (2008–2019). There were 1,705 cases of forensic autopsy and 22 deaths in the judicial control area. These 22 deaths included 14 deaths in prison, 4 in jails, 1 in a police station interrogation room, 1 in a police station holding cell, and 2 after persons found drunk on the street were held in a police station. Of these 22 people, 21 were male and 1 was female. Most of the cases were in their 40s, followed by their 70s.

The cause of death was violence in four cases, of which only one was a crime committed by a cell mate. The cause of death was suicide by hanging in ten cases, blunt force trauma in four cases (three of which were injury to the head), natural death in five cases (two cases of heart disease), drug poisoning death in two cases, and heatstroke in one case. Seventeen people were taken to the hospital and five were not. Of the 17 people taken to the hospital, 7 died at the hospital. The reason for not taking individuals to the hospital was that death was confirmed on the spot, evidenced by rigor mortis. Among those who were taken to the hospital, no one was taken to advanced treatment hospitals with more than 400 beds, six were taken to hospitals defined as general hospitals with about 300 beds.

The results of a survey of the causes of death by year showed that although many suicides by hanging were seen from 2008 to 2017, more acute drug poisoning deaths, natural deaths, and head injuries were seen in 2018 and 2019. These results indicate that in recent years, there has been a thorough awareness among overseers to prevent persons in custody from committing suicide. In 2018 and 2019, there were only cases of death of people held temporarily in police stations; no cases of death within prisons were confirmed. Thus, for these two years, this study surveyed only people held at police stations. Delays in taking individuals to the hospital, despite having a recognized injury, were due to judgments regarding the severity of an injury made by judicial control area overseers with no specialized knowledge. These judgments resulted in individuals being taken to the hospital only after their condition had deteriorated. If they had been taken to the hospital as soon as their injuries were discovered, it is possible that their survival could have been prolonged. From the results of this study, it is conjectured that while there is a declining trend in the number of suicides in judicial control areas, delays in dealing with recognized injuries may delay the possibility of anticipating a death and avoiding that result, ending with the person's death.

### Custody of Death, Judicial Control, Prison Death

## E8 Death of a Five-Year-Old Child in a Drum-Type Washing Machine: An Autopsy Case Report

*Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School Legal Medicine, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN*

**Learning Overview:** The goal of this presentation is to explain the characteristics of children who die in drum-type washing machines according to postmortem imaging, blood gas analysis, biochemical examination, and pathological examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying the characteristic pathophysiology of children who die after becoming trapped in a drum-type washing machine by various postmortem examinations.

The risk of children becoming trapped in the tubs of drum-type washing machines has long been noted in forums, such as the internet. However, few reports have examined cases in which children have actually died in washing machine tubs. An autopsy was performed in a case involving a child who died after entering the tub of a drum-type washing machine. This study examined the pathophysiology that resulted in death and similar previous reports and describes the findings.

The patient was a 5-year-old boy who was found in a state of cardiorespiratory arrest in the tub of a washing machine (diameter of opening, 60cm; depth, 29cm; washing machine tub volume, 82L) with the door closed. The boy was immediately transported to a hospital, where cardiopulmonary resuscitation was performed. However, cardiorespiratory function was not restored, and death was confirmed. Forensic autopsy was performed approximately two days after death.

The boy was 118cm tall and weighed 20.0kg (averages for a male Japanese 5-year-olds are 110cm and 19kg, respectively). Autopsy findings included severe facial congestion and petechiae of the facial skin and palpebral conjunctivae. Several organs exhibited congestion. Hemorrhagic spots were seen on the serous membranes of various organs, with particularly marked hemorrhagic spots apparent on the lungs. The heart contained fluid blood without soft clots. No findings indicative of marked trauma, intoxication, or hyperthermia were identified. These examination results suggested that asphyxia had occurred in this case. However, there were no findings indicative of cervical compression, oronasal obstruction, or the presence of a foreign body in the respiratory tract. Image analysis showed the child's body volume to be 19,329cm<sup>3</sup>, indicating that he would have been able to make postural changes inside the washing machine tub (82,000cm<sup>3</sup>). Consequently, impaired thoracic movement and postural asphyxia were considered unlikely to have occurred. Blood gas analysis showed no evidence of marked hypercapnia as compared with a group that had died from other causes.

In conclusion, the cause of death in this case was asphyxia due to hypoxia associated with being trapped in a closed space (i.e., a washing machine tub). Based on the respiratory volume of the child and the space in the washing machine tub, it was estimated that he became asphyxiated approximately one hour after entering the tub. To prevent such accidents, families should be informed of the possibility of accidents involving children when using a drum-type washing machine.

### Drum-Type Washing Machine, Asphyxia, Hypoxia

## E9 Parenting Behavior and Nutritional Deficits: Three Cases of Child Neglect

*Luana Bonaccorso, MD\**, University of Turin, Turin 10126, ITALY; *Caterina Bosco, MD\**, Department of Public Health and Pediatrics, Torino 10126, ITALY; *Lucia Tattoli, PhD*, AOU Città della Salute e della Scienza Torino, Torino, Turin 10126, ITALY; *Francesco Lupariello, MD*, University of Torino, Torino 10126, ITALY; *Sara S. Racalbutto, PsyD*, Dipartimento di Pediatria d'Emergenza, AOU Città della Salute e della Scienza Torino, Turin 10126, ITALY; *Elena Coppo, MD*, Department of Pediatric Emergency, Turin, Metropolitan City of Turin, ITALY; *Giancarlo Di Vella, MD, PhD\**, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the challenges of differential diagnosis of accidental and deliberate natures in some cases of malnutrition in children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by understanding that prompt recognition of Failure To Thrive (FTT) in toddlers is essential to avoid negative effects on growth and long-term deficits in intellectual, social, and psychological functioning.

Neglect is a form of Child Abuse (CA) that also includes physical, sexual, and psychological abuse.<sup>1</sup> Child neglect is a rising but underreported problem in industrialized countries. Two main categories of neglect are described: deprivation-of-needs neglect (the caregiver's inability to provide for the child's basic needs) and supervisory neglect (failure of a caretaker to provide adequate supervision and safety for the child's developmental age).<sup>2</sup> Insufficient nutrition in children leads to FTT, clinically characterized by inadequate weight gain or growth, persistently falling below the fifth percentile for sex and corrected age of standard child growth charts.<sup>3</sup> Accurate investigations should be performed to rule out organic disease and ascertain nutritional deficits.<sup>4</sup> This form of neglect can lead to death by starvation in extreme cases.<sup>5</sup>

In order to contribute to the knowledge of the topic, this study describes three cases of various severity child neglect due to inadequate nutrition observed in the multidisciplinary "Bambi" Unit, dedicated to CA, of the Pediatric Hospital "Regina Margherita" in Turin, Italy. The involved children were all hospitalized with severe clinical symptoms and signs, including dehydration, muscle atrophy, wrinkled skin, and respiratory tract infection. All cases were referred to social services and reported to the judicial authorities.

Case 1 involved a 26-month-old baby girl sent to the Emergency Department by a general pediatrician because of impaired growth, multiple respiratory tract infections, and dermatitis. The infant weighed 9.64kg for a height of 83cm, less than the third percentile and between the third and the tenth percentile, respectively. Laboratory analysis detected iron deficiency anemia and excluded thyroid or celiac disease. Her mother exhibited severe parent-child interactional difficulties leading to inconsistent feeding patterns of the daughter.

Case 2, a 9-month-old baby boy, was admitted to the Pediatric Hospital with severe dehydration, hypotonia, muscular hypotrophy, and acrodermatitis. The infant weighed 6.02kg, less than the third percentile. Clinicians suspected milk protein allergy or malabsorption, but laboratory tests showed low levels of amino acids, cobalamin, and zinc as well as high ketones in the urine as signs of poor food intake. Moreover, spectroscopy showed delayed myelination due to a low level of cobalamin. During the hospitalization, a lack of supervision by his single mother was noticed as she was more interested in using her cell phone.

Case 3 involved a 17-month-old baby boy who was born at home without medical assistance and primary care; he had never received vaccinations. His mother weaned him with a vegan diet, resulting in the lack of many nutrients. In the past few months, he had developed suck-swallow incoordination, sialorrhea, anasarca, and walk and speech regression. At admission to the hospital, the infant weighed 7.70kg, less than the third percentile. Laboratory tests showed severe anemia, low proteins, undetectable cobalamin, and hyperhomocysteinemia. Magnetic resonance imaging of the brain showed diffused atrophy of the cortex; spectroscopy showed delayed myelination. A feeding nasogastric tube was placed with implementation of vitamins; speech therapy was required. Despite medical treatment, psychomotor delay persisted. The parents were worried about their child's health, and they carefully followed all the doctors' prescriptions in spite of their firm vegan and anti-vaccination beliefs.

This presentation provides attendees with a better knowledge of child neglect as one of the many causes of FTT. An early recognition of signs indicative of child neglect and abuse can be vital to prevent the situation from worsening, requiring prompt medical care and social support. Missed diagnoses of abuse and neglect because of carelessness or peculiar beliefs could put the child's life in danger.

### Child Abuse, Neglect, Failure to Thrive

## E10 A Storm of Knives: Femicide and Attempted Suicide in an Ordinary Family

*Maria Silvestre, MD, Section of Legal Medicine, University of Foggia, Foggia 71122, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Santina Cantatore, Foggia 71100, ITALY; Dania De Carlo, MD, Ospedale Colonnello D'Avanzo, Foggia 71100, ITALY; Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Angelo Montana, MD, University of Catania, Catania 95123, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY*

**Learning Overview:** After attending this presentation, attendees will recognize the characteristics of a double crime scene dominated by multiple “white weapon” injuries. This case includes femicide and attempted suicide of a woman’s murderer husband.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a multidisciplinary approach applied to crime scene investigations in a case of femicide and attempted suicide, following a love quarrel.

The term “femicide” defines an extreme act of violence against a woman perpetrated by a man that often occurs within a relationship or cohabitation. In this case, the weapon used was a kitchen knife. Knives are considered white weapons and are frequently used as sharp and/or sharp-point weapons; this kind of weapon produces typical wounds for their site and morphology. The characteristics and the extension of these wounds must be evaluated to differentiate homicidal from suicidal wounds.

On a cold winter night, two children, respectively eight and ten years old, frightened by the cries of their parents closed in the bedroom, went to the neighbor, who called the police. The police arrived in the house and found the master bedroom door closed from the inside. The policemen forced the door open and found the bodies of the two spouses, one over the other, on the floor. During the crime scene investigation, the forensic team found a knife block with two missing knives in the kitchen.

The lifeless body of the woman was inspected by the forensic pathologist: the wounds, all with clean and regular margins, were located on the face, neck, trunk, and upper limbs. Almost all the wounds were superficial: only two of them were broad and deep enough to cause death. The two injuries in the left hemithorax, at the autoptic examination, described two oblique intracorporeal traits parallel to each other. The first had the entrance wound located along the parasternal line between the second and third intercostal space, was directed from top to bottom and from right to left. This trait injured the left pectoralis major muscle, the underlying intercostal muscles, the pericardium, and the anterior and posterior walls of the right ventricle. The exit wound of the trait was on the back.

The second trait was located 8cm below and laterally to the first and involved the left ventricle of the heart. Below the woman’s body, her husband was surprisingly still alive despite the presence of a knife in the middle of his chest. The blade was the same model as those missing from the kitchen set. The man was taken to the nearest hospital, a chest Computed Tomography (CT) examination was performed with the *in situ* knife, then he underwent surgery. The hypothesized dynamics, based on the circumstantial evidence, were confirmed by the results of the autopsy performed on the woman and by data collected from the instrumental exams and body inspection conducted on the husband. Indeed, the presence of a deep wound with a knife in a highly vital area, such as the chest, in addition to the presence of multiple superficial stab wounds in self-attacking regions, such as wrists and elbow folds, with the parallel trend corresponding to test injury, suggested a suicide attempt by the man. The presence of wounds on the arms of the wife suggests a defense action; in literature, indeed, the defense wounds are common on the outer sides of the forearms, the backs of the hands, and the knuckles. The other typical knife defense wound is on the web between the base of the thumb and index finger when the blade is grabbed in an attempted pincer action, as in this case.

The presented case highlights and compares cutting wounds related to a homicidal event and a suicidal event, demonstrating how the two different diagnosis can be related by the circumstantial data; by the results of inspection; by the sites of the wounds, distinguishing between self-attacking areas or less; by the distribution and number of inflicted wounds; by the presence of defensive injuries (active and passive); or, conversely, by the presence of test wounds.

### Femicide, Knife Crime, Attempted Suicide

## E11 Fatal Dog Attacks: A Case Report and the Application of a New Forensic Approach

*Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Maria Silvestre, MD, Section of Legal Medicine, University of Foggia, Foggia 71122, ITALY; Lorenzo Spagnolo, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY; Alessandra Radogna, MD, University of Foggia, Legal Medicine, Foggia 71122, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY*

**Learning Overview:** This presentation will impact the forensic science community by providing scientific data from a real case report of a Dog Bite-Related Fatality (DBRF), allowing discussion about a new forensic approach that could be applied to similar cases. Notably, the presented case demonstrated that the identification of a guilty dog through a buccal swab in the dog's mouth, while the most used methods to identify an offending dog are the application of forensic odontology and DNA analysis.

**Impact on the Forensic Science Community:** After attending this presentation, attendees will be able to apply a new forensic approach used to identify the offending dog when dog bite-related accidents occur. In light of this case report, the forensic community should consider using this approach in real casework studies with the goal of collecting new data, validating this technique for forensic use.

Statistics show an increase in the number of dog attacks; this phenomenon represents a hazard for the public health, both for the severe injuries and, in some cases, for fatalities. The identification of the guilty dog is necessary, considering the civil or criminal consequences for the animal's owner. Forensic investigations in dog attacks involve different pathological methods, most evaluating the canine Short Tandem Repeat (STR) typing in saliva traces on wounds, even if this technique cannot always be applied. The effort to perform new methods to identify guilty dogs represents a very interesting field for the forensic community. This case report aims to describe an interesting case report of DBRF, proposing an innovative approach based on the identification of the victim's profile in the dog's mouth by using a buccal swab on the suspected aggressor dog to find the victim's genetic profile.

This case concerns an 86-year-old woman who lived in a country house with her grandson. The grandson had a pit bull dog, who lived free in the garden with the aim of protecting their property. One day, at 5:00 p.m., the woman's nephew had gone away on several errands. At 6:00 p.m., the neighbors saw the old woman watering the garden. At 7:00 p.m., the nephew came back home; passing through the garden, he saw his grandmother on the ground with the dog eating her face. The grandson hunted the pit bull with a stick and called the police and rescue, even though the woman had died. When the police arrived, the dog had escaped, but he was found in a farmhouse near the woman's home about one hour later. The prosecutor alerted the forensic team.

At the external examination, the body of the woman was found lying on the left side, with arms outstretched. The woman's face was disfigured, which led to the exposure of the facial bones. The scalp was no longer present, leaving the skull exposed. The left arm was found partially disconnected, with exposure of muscles, tendons, and the humerus. The right forearm was damaged as well. The neck and upper portion of the chest had widespread linear wounds, compatible with scratches. In addition, roundish lesions were present on both her arms and neck.

After finding the dog, the veterinarian put him to sleep, allowing the collection of a buccal swab to the forensic examiner. This swab was performed approximately 1.5 hours after the assault. Another swab was performed on the victim's wounds with the goal of identifying the guilty dog. The dog's feces were not able to be used for forensic examination as the dog had escaped after the fatal attack.

The genetic analysis carried out on the dog's swab allowed identification of the victim's profile. Moreover, the dog's STR profile obtained by the swab performed on the victim's wounds was the same as the suspected dog. Finally, the veterinarian verified compatibility with the dog's dental arch and the roundish lesions found on the body. The autopsy ascertained the cause of death: the excision of the left brachial artery, with subsequent hemorrhagic shock, compatible with a dog attack, was described. In light of the genetic analysis, the dog's owner was accused of murder. Per research, this is the first time a new forensic approach was applied to DBRFs. Moreover, it was also confirmed by traditional forensic techniques.

### **Dog Bite-Related Fatalities (DBRFs), Buccal Swab, Forensic Dog Investigation**

## E12 Anabolic Androgenic Steroids (AASs) Use/Abuse: The First Italian Report

*Francesco Sessa, MS\**, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; *Luigi Cipolloni, MD, PhD\**, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; *Daniela Pisanelli, MS, Viale Pinto, Foggia, ITALY*; *Monica Salerno, MD, PhD\**, University of Catania, Forensic Medicine, Catania 95123, ITALY; *Cristoforo Pomara, MD, PhD\**, Catania, Foggia, ITALY

**Learning Overview:** After attending this presentation, attendees will be familiar with the first Italian report about the dimension of AASs use/abuse. Notably, for the first time, this study was conducted on the data obtained through anonymous questionnaires to evaluate the voluptuary practices with a particular focus on AAS or smart drug use in Italy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the first data about the scope of AASs use/abuse in Italy, where it is illegal to sell AASs. Moreover, considering that the questionnaires map the voluptuary habits of the interviewees and their habits and perception about the use of “smart drugs” and “energy drinks,” a better comprehension highlights the way of AAS auto-administration, with or without other substances.

Even if AAS abuse is associated with a wide number of collateral effects, adolescents and athletes frequently use a large group of synthetic derivatives of testosterone, both for aesthetic uses and for improving performance. The market for performance-enhancing drugs is now huge and continuously increasing. The phenomenon of doping no longer affects only professional athletes but also subjects practicing sports activities at the amateur level. The adverse events for long-term usage among adolescents are very similar to those of adults, even if doses and duration are significantly less. On the other hand, acceleration of pubertal development and early epiphyseal closure, resulting in reduced adult height, are typical adolescent adverse effects; while masculinization of females and acne appears to be more severe in the adolescent.

This experimental study aims to realize the first map of the Italian phenomenon through anonymous questionnaires to evaluate the voluptuary practices linked to AAS or smart drug use in southern Italy. To achieve this goal, two questionnaires were administrated: Survey 1 was the Multidimensional Body-Self Relations Questionnaire (MBSRQ); Survey 2 was composed of 48 questions regarding the voluptuary habits of the interviewees about the use of smart drugs, energy drinks, and AAS, and the interactions with physicians regarding performance-enhancing drugs. Both questionnaires were administrated to a group of university students. Both surveys were performed between October 2018 and March 2019.

Two hundred forty-seven subjects correctly filled out the questionnaires; 48.2 % were male, 51.4% were female (age  $M=36.04 \pm 13.72$  years). All subjects enrolled were Italian and residents in southern Italy. The main results of the questionnaire demonstrated that eight people admitted the use of AASs (about 3.23%). Moreover, three people revealed they used them for more than 24 months. The motivations to use AASs are the same as described in the literature: they used them to improve their physical aspect and performance. Moreover, about 10% of the interview subjects admitted to the use of substances containing Tetrahydrocannabinol (THC). Interesting results are revealed about energy drink ingestion: about 50% usually used it to improve their mental activity. Furthermore, all subjects who admitted to the use of AASs have also consumed energy drinks and, in one case, THC. Comparison between these results and the results of the Section 1 test revealed that all AASs users had experienced previous body acceptance problems at some point in their personal history, which has now been resolved.

In conclusion, the questionnaire data demonstrated that the use of AASs in the young Italian population is about 4%; considering that in Italy, AAS sales are not allowed, online markets, the black market, gym friends, or physicians seem to be the first distributors of these substances. This aspect linked to the provenience of the AASs has to be recognized as very important both by the police and by the forensic examiner. Indeed, other unknown substances could be added to the anabolic agent, generating not only the adverse effects linked to the AASs use/abuse but also the organ damages linked to these unknown addicted substances. The last consideration is related to the combined use between AASs and energy drinks or THC: it is clear that the AASs adverse effects can be increased by their combined use.

### Anabolic Androgenic Steroids (AASs), AASs Italian Report, Energy Drink

## E13 Human Bones and the Estimation of the Postmortem Interval (PMI): An Experimental Study

*Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; Santina Cantatore, Foggia 71100, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; Luigi Cipolloni, MD, PhD, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; Daniela Pisanelli, MS, Viale Pinto, Foggia, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY*

**Learning Overview:** After attending this presentation, attendees will have the results of an experimental study performed to define the PMI. Several authors have distinguished the forensic relevant postmortem interval between PMI <50 years and PMI >50 years. For these reasons, it is very important to define simple techniques that could be applied in every forensic laboratory to establish the PMI of human bones.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing experimental data of a study conducted in order to define the PMI on human bones. Several techniques were tested in this experimental study, and the histological and immunohistochemical examinations have shown a pivotal role in the determination of PMI.

Determining the PMI of human skeletal remains is a challenging part of the daily practice of forensic osteology. To clarify if further criminal investigations by law enforcement agencies are necessary, the PMI plays an important role. Skeletal remains can either be historical or recent. In a historical case, there will most likely be no interest in criminal investigations. On the contrary, further criminal investigations may be needed if human skeletal remains turn out to be recent. Therefore, it is of criminal interest to distinguish between historical and recent human skeletal remains by estimating their PMI.

The present study seeks to analyze the technical applications to define the best techniques to determine the PMI with simple techniques that could be applied in all forensic laboratories. All samples were selected analyzing documentations of all autopsies performed by the Institute of Legal Medicine of Foggia from 2001 to date (about 1,700 autopsies). Five cases of human bones were analyzed: in case 1, the bones were found in a natural ambient; after the forensic investigation, it was defined that they belonged to a subject who died ten years before the study. In case 2, the bones were buried in a glass box, considering that it was believed that they belonged to a saint's death in 232 AD; after the radiocarbon analysis it was established that they were dated between 200 and 400 AD. In case 3, the bones were found in a ravine 15 years after the death. In case 4, the bones were recovered under the natural soil; after the radiocarbon analysis, the bones were dated between 1300 and 1500 AD. Finally, in case 5, the bones were collected during the exhumation operation of a man had died and was buried 60 years before.

After the selection of the cases, all bones were worked in blind by the personnel of the forensic laboratory in order to define if each case was of forensic interest (PMI <50 years). Different non-invasive techniques were applied: a luminol test, an Ultraviolet (UV) -induced fluorescence test, histological tests (Hematoxylin-Eosin [H&E] and Masson's trichrome stains), and an immunohistochemical test (Glycophorin A antibody).

The results of the present study allowed the determination that only cases 1 and 3 are of forensic interest (PMI <50 years), while cases 2, 4, and 5 have a PMI >50 years. The differences are marked for all techniques comparing all cases, with an exception for case 5. Indeed, the PMI determination for this case was more complex: to define if it was of forensic interest, the application of the histological and immunohistochemical techniques were discriminant. Indeed, both the evaluation at luminol test and UV-induced fluorescence test were not able to define with certainty the PMI >50 years. In this particular case, to define the PMI, the histological and immunohistochemical examinations identified several changes in the bone cells that allowed the classification of the case as of non-forensic interest.

In conclusion, the results of the present study put in light the possibility of applying several non-invasive techniques to define, through the PMI, if the case can be considered of forensic or non-forensic interest. Moreover, the luminol test and UV-induced fluorescence test could be used as a preliminary investigation because their exclusive use is not always sufficient to define the correct PMI, while histological and immunohistochemical examinations could be very helpful for the forensic examiner.

### Skeletal Remains, Postmortem Interval (PMI), Immunohistochemical Stain

## E14 Fatal Attraction: A Case Report of a Homicidal Drowning Involving a Couple

*Michela Ferrara, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Francesco Sessa, MS\**, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; *Alessio Marangelli, State Attorney General of Foggia, Foggia 71122, ITALY*; *Luigi Cipolloni, MD, PhD, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY*; *Lorenzo Spagnolo, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY*; *Santina Cantatore, Foggia 71100, ITALY*; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY

---

**Learning Overview:** This presentation aims to explain a complete methodological approach, from the crime scene investigation to autopsy, and subsequent analysis (such as histological, immunohistochemical, and toxicological analysis) in a rare case of homicidal drowning. This case concerns a 32-year-old woman's homicidal asphyxia, due to drowning in a bathtub, after the loss of consciousness by manual strangulation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining a case of homicidal drowning in an adult, infrequent in the pathologist practice, showing the importance of using a complete forensic approach to solve the crime.

Homicidal drowning of adults is a rare event; according to the literature, this type of crime involves mainly children. This is due to the difficulty in realizing the homicide when the victim can defend herself. In these circumstances, the diagnosis of drowning is an important medicolegal issue. In cases of this type, it is possible to research the bone marrow diatoms. Their presence indicates that the decedent was breathing at the time of submersion and died due to drowning. Often the diatoms are helpful in the differentiation of drowning in a bathtub versus a naturally occurring body in water.

The following case concerns a homicide in which a double asphyxic mechanism was used: strangulation to stun the victim and drowning to kill her. A 37-year-old man went to the police station saying his girlfriend was dead in her apartment. The prosecutor's office organized an inspection of her house that was turned upside down. The corpse of the woman was discovered in a prone position in the bathtub, lying in a few centimeters of water. At the external examination, facial abrasions, petechial hemorrhaging in the conjunctivae, abundant froth exuding from the nostrils, and bruises on the forearms were found. An accurate inspection of the neck revealed little reddish abrasions in the anterior face and two little purplish bruises, of linear form, parallel to each other, on the left side of the neck. The suspicion of a struggle induced the forensic pathologist to perform fingernail swabs.

Simultaneously to medicolegal investigations, the prosecutor questioned the boyfriend of the woman. He confessed to having strangled his partner and then, to resuscitate her, placed the body under the water in the bathtub. When he realized that the woman was dead, he left the corpse there. The day after, an autopsy was performed showing scattered petechiae on the internal face of the scalp, on temporalis muscles and visceral pleura of both lungs and epicardium; hemorrhages of the left sternocleidomastoid and omohyoid muscles, of both sternothyroid muscles, right thyrohyoid muscle and hyoid bone; and red-tinged froth in the trachea.

Histological analyses showed scattered areas of contraction band necrosis in the myocardium, pulmonary emphysema, and alveolar edema. The immunohistochemical study performed on the neck muscles with anti-CD15, anti-tryptase, and anti-IL15 antibodies were positive, indicating the vitality of the lesions; the expression of HIF1- $\alpha$  on endothelial cells of lung vessels confirmed the asphyctic death. A DNA profile found on fingernails of the victim matched with the murderers, compatibly with the statements of the man.

In addition, a diatom test on femoral bone marrow was performed. The analysis of the sample using a phase-contrast microscope showed diatom frustules. This evidence represented the keystone to determine the manner of death: the fatal mechanism was attributed to drowning. By applying a methodological forensic approach, the actual dynamic of the event was reconstructed: the murderer knocked the victim unconscious by strangulation, then left the body in the bathtub, where the death occurred.

In complex criminal cases, in addition to the pathologist's work, the involvement of other figures is mandatory. Indeed, in this case, the contribution of the forensic pathologist was fundamental to identify the victim's marks on the murderer and vice versa; the ability of genetic investigations to place the murderer's DNA on the victim and the reverse; and the contribution of histopathological and immunohistochemical examinations to determine the exact cause of death. This case highlights the difficulty for a forensic pathologist to perform differential diagnosis between two mechanisms of death having overlapping pathological findings. The use of a rigorous forensic method in complex cases represents the essential tool for the forensic pathologist in identifying the true cause of death.

---

### **Bathtub Drowning, Methodological Approach, Homicide**

## E15 An Evaluative Look at Shotguns: Pellet Spread

*Kimberly Butler-Derose, MFS\*, National University, La Jolla, CA 92037; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037; Amy Zimmer, MS, San Diego, CA 92101*

**Learning Overview:** The objectives of this study were to determine: (1) if shotgun shells from different manufacturers would produce the same pellet count and pellet spread; (2) if those variables could be used to differentiate between 12-gauge and 20-gauge shotguns; (3) if pellet spread (impact area) correlates with firing distance; and (4) test the widely held concept that one inch of pellet spread is equal to one yard in muzzle-to-target firing distance.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing more accurate assessment of firing distance and observations of impact area as they relate to possible crime scenes where it is unknown what weapon and ammunition utilized. This could provide important investigation leads as well as corroborate any suspect or eyewitness statements.

At a firing range and target set-up, 12- and 20-gauge shotguns were used. The 12-gauge shotgun was an FNH SLP™ competition semiautomatic shotgun, full choke, 24-inch barrel. The 20-gauge shotgun was a Winchester® Model 12 pump-action, full choke, 24-inch barrel. These were used to test fire various brands of shotgun ammunition: Estate®, Remington®, and Seller-Bellot®. After firing 196 shells, the average values for pellet count, pellet spread area, and correlation with shotgun used and firing distances were analyzed for statistical significance ( $p < 0.05$ ) with an Analysis of Variance (ANOVA) and Regression Analysis tests.

The results indicated that firing distance and shotgun pellet spread were correlated. The data refuted the long-held notion that every inch of pellet spread is equal to a one-yard distance to the shooter. Additionally, it was determined that the pellet pattern alone could not be used to distinguish between the 12- and 20-gauge shotguns. The pellet count is different between gauges; but due to the amount of damage caused by close range shooting (<12 yards), is not an accurate assessment. No significant difference ( $p > 0.05$ ) was observed in the pattern between Estate®, Remington®, and Seller-Bellot® (00 buck). More importantly, when comparing firing distance and pellet spread, a significant difference was observed, ( $p < 0.0002$ ). Regression Analysis of spread at impact area vs. distance gave a  $R^2$  value of 0.97. This indicates a very strong and significant correlation ( $p = 0.01$ ). In conclusion, this study has provided a solid foundation to build upon in future research that will provide a new standard to accurately and quickly judge distance to shooter from pellet spread.

### Crime Scene Reconstruction, Forensic Ballistics, Shotguns

## E16 Examining Potential Degradation Between Antemortem and Postmortem Fingerprints

*Anielle Duncan, BA\*, University of Tennessee, Knoxville, TN 37996; Samantha Upton, BA\*, University of Tennessee, Knoxville, Knoxville, TN 36996; Kathleen Flor-Stagnato, MA, University of Tennessee, Knoxville, Knoxville, TN 37916; Dawnie W. Steadman, PhD, University of Tennessee, Department of Anthropology, Knoxville, TN 37996*

**Learning Overview:** After attending this presentation, attendees will understand the influence of health-related conditions on the deterioration of fingerprints between antemortem and postmortem collection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying the effect of death and various antemortem health conditions on the quality of biometric data between living and postmortem scans.

Various medical conditions and the early decomposition process cause both internal and external deterioration of the human body. If fingerprint deterioration occurs between the time of antemortem and postmortem print captures, the viability of a positive identification could be compromised. This project is a first step in understanding the correlations between medical conditions, fingerprint degradation, and biometric data quality. Through this research, law enforcement and other agencies will begin to understand how a subject's prior medical conditions can inform collection protocol used for biometric identification and facilitate decision making on the best methods for obtaining a positive identification.

Biometrics are measurable physiological characteristics that are used to classify both living and deceased individuals. Research has indicated that fingerprints are comparatively the most successful biometric indicator for positive identification. Therefore, in this study, fingerprints were used as the primary indicator to examine biometric degradation and quality data acquisition from an antemortem to a postmortem scan. For the purposes of this study, "quality data" refers to a threshold met by a ratio of numerical scores provided by two types of biometric scanning technologies. Fingerprint quality was determined by the National Institute of Standards and Technology (NIST) Fingerprint Image Quality (NFIQ) v.2 algorithm where prints are scored on a 1–5 scale, with 1–3 denoting adequate to excellent prints and 4–5 denoting poor quality prints.

Biometric scanning technologies have been used to capture all ten digits, where applicable, of 395 living predonors (individuals who have pre-registered to donate their bodies to the Forensic Anthropology Center). Of these 395 individuals, 15 are now deceased and had their postmortem images captured upon their intake into the Bass Body Donation program. For the purposes of this study, quality scores were relied upon to compare the antemortem captures to the companion postmortem images. Comparing the antemortem directly with initial postmortem capture determines if print degradation occurred between the living and deceased scans.

This study examines the correlation between certain mortality-inducing health conditions (e.g., cancers, diabetes, heart disease, pulmonary disease) and the time (in months) between the living scan and death with the change in quality of biometric data. In addition to the antemortem fingerprint images, Cause Of Death (COD) and date of death for the 15 individuals in this study were collected from the Forensic Anthropology Center's donation database. The goals of this study were to examine: (1) if any changes in fingerprint quality occur between the antemortem and postmortem captures; and (2) if so, could such changes be a result of known health conditions.

The preliminary results of this study show that fingerprint quality is generally consistent through end stages of life. Of the 40% of individuals ( $n=6$ ) who died of cancer, only one individual showed degradation in quality, while another individual had a slight improvement in quality. The other four individuals exhibited no change. Thirty percent of individuals ( $n=5$ ) died of heart-related conditions and two showed slight print degradation. All other postmortem prints remained of the same quality as their antemortem counterparts. The time between the antemortem scan and death similarly does not affect the quality of fingerprints. There was no change in the 30% ( $n=5$ ) of individuals that passed a year after their antemortem captures. However, two of the 30% that passed less than six months after their living scans showed slight degradation. Of the five individuals that passed seven months to one year after antemortem scans, two showed slight degradation.

This study has yet to show any apparent trends in the relationship between time between antemortem and postmortem scans or health-related conditions on the degradation of print quality between living and deceased print scans; however, analyses are ongoing. This study builds upon previous work and continues to support the utility of physiological biometric identifiers to obtain positive identifications in postmortem contexts. Postmortem biometric research has the potential to make important contributions to forensic anthropology and the law enforcement, military, and medicolegal communities.

### **Biometrics, Antemortem vs. Postmortem, Health Conditions**

### **E17 Training Needs for Search and Rescue (SAR) Teams During Mass-Disaster Fire Scene Recoveries: Lessons Learned From the 2018 California Camp Fire**

*Leigh Hayes\**, Greenville, WI 54942; *Alyssa Straub, BA\**, California State University, Chico, Chico, CA 95926; *Eric J. Bartelink, PhD*, California State University, Chico, Chico, CA 95929-0400; *Ashley E. Kendell, PhD*, California State University, Chico, Chico, CA 95929-0400; *Colleen F. Milligan, PhD*, California State University, Chico, Chico, CA 95929-0400

**Learning Overview:** After attending this presentation, attendees will gain a better understanding of the training needs of SAR teams that are involved in large-scale fire scene recoveries. The lack of osteological training of SAR teams can hinder the search and recovery process of fatal fire victims, especially in large disaster zones. With this in mind, this presentation will provide insight on the key aspects of search and recovery that are most pertinent to SAR teams who lack training in fatal fire scenes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a training guide that will be used to educate SAR teams and other recovery workers on the search and recovery of burned human remains in the context of mass-fatality fire scenes. This training guide will provide SAR teams with the basic tools to identify burned osseous material in the field, resulting in better outcomes for the search efforts, victim identification, and closure for families.

On November 8, 2018, the Camp Fire in northern California resulted in the destruction of 18,804 structures and 85 fatalities, making this the deadliest wildfire in California history. In large-scale disasters such as this, it is unfeasible for forensic anthropology teams to search every burned residence. For the Camp Fire recovery, many of the burned structures were first searched by SAR, California Department of Forestry and Fire Protection (CAL FIRE), and National Guard teams that lacked osteological knowledge, especially for burned remains. This disparity in knowledge concerning osteological identification and, more specifically, the appearance of bone within a burned context became evident early in the recovery process. SAR teams often requested short lessons on osteology and general tips for bone identification and human remains recovery in order to more confidently approach the large number of fire scenes. This research and its resulting product, a SAR fire scene recovery guide, will provide these individuals with the basic tools and knowledge needed to streamline search and recovery efforts for fatal fire victims.

The information within this SAR guide will address two main issues: first, where remains are most likely to be located within a structure fire, to streamline search efforts; and, second, how to distinguish human bone from materials that are commonly misidentified as human remains, including animal bones and burned debris. Data from the Camp Fire regarding the location of recovered remains will be used to extrapolate trends of high-priority areas within burned structures to be searched first. Tips on how to locate these areas within the debris will be outlined with accompanying photographs from prior house fire scenes. Furthermore, trends regarding materials commonly misidentified as human remains are detailed through professional experience from members of the California State University (CSU), Chico Human Identification Laboratory. Tips to aid in the determination of osseous from non-osseous material, and human remains from faunal remains, are provided through straightforward descriptions and archetypical pictures.

Ultimately, many individuals who participate in search and recovery efforts, including firefighters, police officers, and search and rescue personnel, would benefit from a training guide that outlines how to approach a scene and that serves to dispel common misconceptions surrounding house fire recoveries and the appearance of burned human remains. While this SAR guide provides information on how to approach a scene, it in no way serves to replace the role of forensic anthropologists, but rather to streamline the search and recovery process overall. Therefore, this guide will allow for a more expedient search and recovery process of fatal fire victims by providing SAR with tips and trends to more confidently approach mass disaster fire scenes.

---

#### **Fire Scene, Search and Recovery, Human Remains**

## E18 Ice Cold Cases: When Glaciers Give Back Corpses

Serena Maria Curti, MD\*, Azienda USL Valle d'Aosta, Quart 11020, ITALY; Pasquale Beltempo, MD\*, Azienda USL Valle d'Aosta, Quart, Valle d'Aosta 11020, ITALY; Maurizio Castelli, MD, Azienda USL Valle d'Aosta - SC Medicina Legale, Quart 11020, ITALY; Mirella Gherardi, MD, SC Medicina Legale, Aosta 11100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the complexity of personal identification on human remains recovered after a prolonged stay in a high-altitude environment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the peculiar effects of glacier environment on corpses after a long period of time since death.

The Alps are the highest mountain system in Europe, with dozens of summits that reach over 4,000m and some massive glaciers. The region called “Valle d’Aosta” includes the Italian side of many legendary mountains, such as Mont Blanc, Monte Rosa, and Cervino. These mountains welcome countless hikers and skiers, and every year many people are involved in fatal accidents. While most of the corpses are recovered in a short time, in some cases, this is not possible due to the prohibitive environmental conditions that would put the rescue teams in serious danger. The fate of unrecovered bodies depends on where they lay. Glaciers are dynamic settings that significantly alter and gradually expose once-hidden corpses as part of their turnover process.<sup>1</sup> The glacier movement, which reaches speeds of about 100m per year, can affect where remains are ultimately recovered.

This presentation reports the data about the human remains of eight people returned by Alps glaciers from 1974 to 2018 at altitudes above 2,000m. They were recovered by the “Guardia di Finanza,” the military Italian enforcement that patrols the “Valle d’Aosta” summits, and were studied by the Aosta Office of the Medical Examiner. The aim of the identification effort after such a long time since death was to restore family links and clarify the fate of the missing people.

The recovered remains included bones and frozen soft tissues: in two cases, the entire bodies were recovered; in one case, bone fragments were not identifiable, while in the remaining five cases, a combination of numerous bones and teeth were collected. They were found in the hottest periods, following the melting of the glaciers. In all cases, the remains were accompanied by personal effects, such as clothing, technical equipment, or medicines. Personal identification required a holistic approach. In fact, achieving the goal was complicated by the large number and heterogeneous origin of the people missing in “Valle d’Aosta,” who were mostly tourists from all over the world.

The suspect’s identity was first tracked down through the careful examination of anthropometric characteristics and personal effects. The plausibility of the attribution was then assessed by estimating the trajectory that the corpse should have followed due to the glacier movements from the point where the person was last seen alive to the recovery location. Finally, DNA analysis was used as confirmation evidence, through the National DNA Database or if close relatives were available.

Six out of eight victims were identified: they were all adult male subjects (average age was 36.7 years) involved in accidents during excursions or skiing from 1954 to 1992. Two out of six were French, two were German, one was Turkish, and one was Italian. The average gap between the disappearance and the recovery of the corpse was 20 years. The average altitudes of the points of disappearance and of recovery were respectively 3,400m (range 4,000–3,000m) and 2675m (range 3,100–2,000m). The dynamics of the fatal accidents have been hypothesized as follows: two people were buried by avalanches; in two cases, trauma due to precipitation along crevasses was the cause of death; in one case, there was the combination of the previous two dynamics; and in one case, the victim froze to death during a snow storm. Bone analyses helped to distinguish peri-mortem from postmortem lesions and corroborated the hypothesis about death dynamics.

Factors such as cold temperatures, freezing, freeze-thaw cycles, and glacier movement are unique taphonomic agents.<sup>2</sup> Therefore, it is important to be familiar with these environmental agents and with their effects on bones. In fact, while glaciers have always been typically remote, in the foreseeable future, materials of anthropological interest may increasingly be revealed due to global warming and glacial retreat worldwide. This presentation provides attendees with a greater awareness of the importance of a multi-step approach to highly complex cases of personal identification on human remains that have been altered by extremely cold and ever-changing environments.

## E19 An Overview of 3D Printing in Forensic Science: The Tangible Third-Dimension

Rachael M. Carew, MSc\*, University College London, London WC1H 9EZ, UNITED KINGDOM; David Errickson, PhD, Cranfield University, Shrivvenham SN68LA, UNITED KINGDOM

---

**Learning Overview:** After attending this presentation, attendees will be informed of the current state of 3D printing in forensic science and learn about the benefits of incorporating tangible 3D reconstructions into the forensic science process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing attendees' understanding of the potential applications and benefits of 3D printing reconstructions of forensic materials.

The goal of this research was to investigate the use of 3D printing across the forensic sciences and demonstrate examples in which 3D printing could feasibly be applied together with the useful and potential benefits to forensic science. Rapid development of 3D imaging and 3D printing technologies over the past decade have led to the increased affordability and availability of the techniques across health care and engineering industries. 3D-printed replicas provide a physical 3D object that users can hold, rotate, and inspect, facilitating greater haptic and spatial cognizance than with traditional 2D photographs or virtual 3D models.<sup>1</sup> These qualities make this technology ideal for demonstrating concepts around the inspection and interpretation of forensic materials. Further, 3D-printed reconstructions of forensic materials could provide a useful tool in many forensic science disciplines, such as crime scene analysis, intelligence gathering, and the presentation of evidence in court. While existing research has investigated the use of 3D replicas in areas such as medicine and anatomy, there is a distinct lack of published research investigating 3D printing across the forensic sciences.<sup>2,3</sup>

This research provides an overview of 3D printing in forensic science. An introduction into the different 3D printing technologies is followed by a review of the scientific literature and media publications to identify examples that have utilized 3D printing. A critical discussion of disciplines that may benefit from the inclusion of 3D printing reconstructions is put forward, including in forensic anthropology, forensic taphonomy, pattern and impression evidence, forensic archaeology, crime scene reconstructions, ballistic reconstructions, forensic engineering, forensic odontology, and facial reconstructions.

Further insights into the advantages and limitations of 3D printing technologies and printed replicas are given, including the potential effects of utilizing 3D prints as demonstrative evidence in courts of law. Examples of replicated “exhibits” and “scenes” that were 3D documented and 3D printed using Fused Deposition Modeling (FDM) are provided to illustrate several novel applications. These examples also show how 3D prints can be produced as scaled-up or scaled-down replicas, thus facilitating opportunities to exhibit objects at a manageable size, while providing an accurate, tangible reconstruction of the original material. This research demonstrated that despite the wide scope of 3D printing, this technology is underresearched and underreported in the forensic sciences. 3D printing reconstructions in forensic science can be affordable and attainable and deliver a tangible medium that can assist users with the interpretation and presentation of forensic materials.

### 3D Printing, Forensic Science, Evidence Reconstruction

### E20 The Detection of Sodium Hypochlorite Adulterated Foods and Salsas in a Poisoning Investigation

*David S. Jackson, BS\*, U.S. Food and Drug Administration Forensic Chemistry Center, Cincinnati, OH 45237; Lisa A. Kaine, BS, U.S. Food and Drug Administration Forensic Chemistry Center, Cincinnati, OH 45237; David F. Crockett, BS, U.S. Food and Drug Administration Forensic Chemistry Center, Cincinnati, OH 45237*

**Learning Overview:** After attending this presentation, attendees will better understand how to investigate a food adulteration in which bleach (sodium hypochlorite) was used as the adulterant. The goal of this presentation is to provide information to the scientist who may have to conduct future bleach-tampering investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing methodology that the scientist can use to detect and verify the presence of bleach and its breakdown products in difficult food matrices. This methodology can also be applied to other scenarios in which bleach has been used in a crime.

Two people were hospitalized after eating at two separate open food bars. Video footage at one of the food bars showed a man with a backpack putting an unknown substance on and in several food items. The man was later arrested by police and found to have a caustic bleach-containing product in his possession. This product was believed to have been used in the incident that caused injuries to the two people. Several samples of salsa and Chinese chicken entrees were analyzed by the United States Food and Drug Administration's (FDA's) Forensic Chemistry Center (FCC) and compared to the caustic bleach-containing product from the suspect. Bleach (sodium hypochlorite) is inexpensive, readily available, and found in numerous cleaning products. Household bleach contains between four to six percent sodium hypochlorite. Bleach is caustic, a strong oxidizer, and harmful if swallowed. The determination of the presence of bleach in foods can be difficult due to the instability of bleach in food matrices and interferences from the food with the detection of bleach.

The FCC has previously developed published methodology for detecting bleach (sodium hypochlorite) contamination in suspect beverages. Using these previously established protocols, seven suspect food items, one empty cup rinsed with a small amount of water for analysis, and a suspect adulterant (the caustic bleach-containing product) were characterized for the presence of bleach and bleach breakdown products. Characterization of the samples included the use of two oxidizing agent spot tests, iodometric titration, ion chromatographic analysis, headspace Gas Chromatography/Mass Spectrometry (GC/MS), and Liquid Chromatography (LC) /Charged Aerosol Detection (CAD). With the exception of LC/CAD, these techniques are routinely used at FCC to characterize samples suspected to have been adulterated with bleach or bleach-containing products. LC/CAD analysis has proven useful in providing a surfactant profile of cleaners. In this case, LC/CAD was used to identify surfactant characteristics of the suspect adulterant in comparison with the suspect food items.

Using the established protocol for the detection of adulteration involving bleach, all of the submitted food items were tested. The analyses showed that seven of the items and the caustic bleach-containing product were positive for the presence of oxidizing agents using the acidic diphenylamine and the potassium iodide starch test paper wet chemical tests for oxidizers. One of the food items had quantifiable levels of sodium hypochlorite still present. This food sample was analyzed using iodometric titration to determine its sodium hypochlorite content. Determinations were made as to whether the tested items contained active bleach, evidence to support the presence of bleach at one time, or no evidence to support the presence of bleach at any time.

#### **Bleach, Adulteration, Poisoning**

### **E21 Applying a Standardized and Scientific Approach to Recognize and Investigate Co-Occurring Criminal Forms of Fatal and Non-Fatal Asphyxiation in Order to Broaden Assessments to Include the Possibility of Other Types of Criminal Asphyxiation That Include at Least One Type of Aquatic Asphyxiation**

*Andrea Zaferes, BA\*, Dutchess County Medical Examiner Office/Team LGS, Shokan, NY 12481; Allyson Cordoni, MSN\*, Davenport, IA 52807; Kathy Bell\*, Tulsa Police Department, Tulsa, OK 74103; Kelsey P. McKay\*, Respond Against Violence, Austin, TX 78759*

**Learning Overview:** The goals of this presentation are to: (1) describe and list at least two types of criminal aquatic asphyxiation; (2) state at least three reasons why law enforcement, medical personnel, social workers, victim advocates, death investigators, and the jurisprudence community should be trained to be capable of identifying victims of fatal and non-fatal Co-Occurring Criminal Asphyxiation (COCA); (3) identify at least three approaches for continued improvement of identification and investigation of COCA; (4) list at least five questions that can be asked of potential victims of COCA; (5) provide at least four examples of what to look for, document, and collect on possible COCA crime scenes; (6) describe at least five injuries to look for and document when examining the bodies of possible victims of fatal or non-fatal COCA; and (7) list at least five current or past medical history diagnoses or symptoms that should be considered when investigating possible COCA incidents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the existence of COCA cases by presenting examples of fatal and non-fatal COCA case histories that include at least one form of aquatic asphyxiation. This presentation will impact the forensic science community by introducing practices to better identify multiple forms of criminal asphyxiation.

There have been significant improvements during the past two decades in the identification, investigation, documentation, research, prosecution, and prevention of Intimate Partner Violence (IPV) fatal and non-fatal strangulation cases.<sup>1,2</sup> Research, training, and tools, such as investigation forms for law enforcement and medical personnel, are continuing to make strides in overcoming challenges, such as the lack of victim self-reporting.<sup>3,4</sup> A next step is to broaden the net in order to do the same with additional types of criminal asphyxiation, such as manual suffocation, dunking, and waterboarding that occur to victims of IPV as well as additional populations, including pediatric, political prisoner, and trafficking victims.<sup>5-7</sup>

Once a possible strangulation assault has been identified, the investigation needs to continue looking for possible COCA that is defined as a criminal fatal or non-fatal assault involving more than one type of criminal asphyxiation. Some COCA incidents include a poorly understood type of asphyxiation that involves the use of water or other fluids to assault, torture, or kill victims. This study focuses on COCA incidences in which land asphyxiations (e.g., strangulation or manual suffocation) occur in conjunction with aquatic asphyxiation (e.g., dunking or waterboarding).

There are several challenges to recognizing cases of COCA, or a single-type of non-strangulation, fatal or non-fatal criminal asphyxia. It has been shown in several case histories that when effective strangulation investigation questioning results in an admission of non-fatal strangulation, those victims may not self-report that they also endured criminal aquatic asphyxiation. There have been cases in which children reported being the victims of non-fatal aquatic asphyxiation and were not initially believed so that timely investigations were not initiated. Although more law enforcement and medical investigators are becoming aware of the physical signs and symptoms of strangulation, this is not yet true for aquatic and other types of criminal asphyxiation.<sup>3,4,8</sup>

Fatal drowning is mainly a diagnosis of exclusion, making it challenging to recognize incidents of fatal criminal aquatic asphyxiation if the deaths are staged to appear as having different causes or manners of death, such as opioid overdoses or accidental drowning. Alternatively, there are cases of homicidal strangulation cases that were initially misdiagnosed as accidental drownings. In some locations, decedents who appear to have died from accidental drug overdoses or drownings may not have autopsy examinations.<sup>9</sup>

COCA incidents require evidence-based investigative questions specific to each type of asphyxiation as has been demonstrated by the need for specific assessment questions for the identification of strangulation. The first step to combating these crimes is creating an awareness of their existence within forensic, medical, and social work communities. The next step is the creation of effective, evidence-based, investigative questions and checklists that can be used by COCA-trained law enforcement, medical personnel, forensic interviewers, death investigators, and members of the jurisprudence community to identify cases and provide effective documentation of physical and psychological injuries and scene evidence that otherwise could be overlooked.

This study will explain the importance of applying a standardized scientific approach to the recognition and investigation of COCA. The forensic community will also be provided with suggested questions and checklist items that can be used as tools to help identify COCA victims. It is hoped that one result of this presentation is open discussions within medical and forensic communities to better identify, document, investigate, prosecute, and, most importantly, prevent COCA incidents.

### Co-Occurring Criminal Asphyxiation, Strangulation, Drowning

## E22 An Evaluation of Various Swab Types for Recovery of Touch DNA From Firearms

*Raven DeWeese, BS\*, Glenside, PA 19038-3930; Catherine O. Brown, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Thomas V. Walsh, MSFS, NMS Labs, Willow Grove, PA 19090; Heather L. Harris, JD, Glenside, PA 19038; Megan M. Foley, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how new commercial products for the collection of touch DNA compare to traditional swab types for recovery of genetic material from firearms evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by evaluating both the adsorption and initial collection capabilities of the various swab types as well as the release and, thus, overall recovery of DNA based not only on swab substrate but shape, informing the practitioner community as to which swab types are best suited for the recovery of DNA from handled firearms evidence.

Amidst efforts to reduce illegal firearms and gun violence, laboratories have seen increased submissions of firearm-related evidence for genetic testing. Obtaining quality DNA profiles by following optimized protocols is instrumental in assisting with these criminal investigations. Published literature has established that the substrate of a swab (cotton, foam, nylon flocked, polyester, rayon, etc.) affects adsorption capacity and even DNA release, but more recent product designs have focused on the overall shape of the swab head to further enhance collection and concentrate touch DNA from challenging sample types, such as firearms. Currently, DNA collection from firearms is most often performed utilizing cotton- or nylon-flocked swabs that have rounded tips. Cotton swabs have an absorbent core that will draw samples to the center and potentially trap them. Nylon-flocked swabs have been developed to increase the amount of DNA released from swabs by having no internal absorbent core, keeping the sample on the surface for quick release.

This project focused on evaluating recently developed products by Gentueri, which include: SimpleSwab™, SimpleSwab2™, SimpleSwab3™, and SimpleSwab4™ that vary in material thickness and shape of the swab head. The efficacy of these new products will be compared to two commonly used swabs, including: general round cotton-tipped swabs and nylon 4N6FLOQSwabs™. Both the collection and recovery efficiencies of these swabs were evaluated. First, release of DNA from each swab was determined for a direct comparison between all swab types. Known concentrations of DNA were placed directly onto swabs to evaluate release and then again on a substrate and collected with each swab type to evaluate recovery and release combined. Each swab type was then used for the recovery of touch DNA from a firearm to simulate real casework samples. A double-swab technique was utilized for collection of touch DNA from four locations on each firearm, including the trigger/trigger guard, slide serrations, grip, and the magazine. Each sample will be separated into two halves and treated as two samples to determine variability among one swab. The swabs will undergo an organic extraction followed by quantification using Quantifiler® Trio, amplification using PowerPlex® Fusion 6C, separation on an ABI® 3500 Genetic Analyzer, and analysis using GeneMapper® IDX software.

A one-way Analysis Of Variance (ANOVA) statistic was performed for a quantitative comparison using resulting DNA concentration values. No significant difference was observed in DNA release from swab types tested with 125 picogram (pg) and 500pg total DNA [ $F(5)=3.11$ ,  $p=0.63$  and  $0.36$ , respectively]. Further work to evaluate additional DNA concentrations is currently in progress. Through quantitative and qualitative analysis of the DNA recovered, the optimum swab type/shape for the recovery and release of touch DNA from firearms evidence was determined. With the completion of this project, valuable information regarding the ability to increase genetic profile strength from front-end sampling of touch DNA will be disseminated.

### Firearms, Touch DNA, DNA Collection and Recovery

### E23 Validation of a Paper Analytical Device Through Analysis of Illicit Substances Found at Fatal Overdose Scenes

*Tracy-Lynn E. Lockwood, BS\*, South Bend, IN 46615; Philip Hyunh, Indiana University, Indianapolis, IN 46202; Katie Bailey, Indiana University, Indianapolis, IN 46202; Alfarena Ballew, MBA, Marion County Coroner's Office, Indianapolis, IN 46225; Brad Ray, Indiana University-Purdue University Indianapolis, Indianapolis, IN 46202; Marya Lieberman, PhD, University of Notre Dame, Notre Dame, IN 46556*

**Learning Overview:** The goal of this presentation is to demonstrate the validation of a paper analytical device designed to identify various illicit substances with street samples collected from the scenes of overdose deaths. Attendees will leave the presentation with knowledge of the fabrication, chemistry, and testing ability of a new Paper-based Analytical Device (idPAD). The collaboration between a chemistry research lab, social scientists, and Coroner's office will also be discussed as a tool strengthen local communities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic community by introducing an idPAD as a presumptive field test that can be used as an alternative or supplement to the current testing methods that can be used by law enforcement and first responders. This idPAD uses less solid than current presumptive tests, costs less than the test pouches, can be used in fewer than five minutes, and generates a complex color matrix to limit single color identifications. This presentation will lay out the different field samples and complex mixtures that were used to validate the device.

A 12-lane idPAD has been developed to detect and classify illicit substances, such as cocaine, heroin, and methamphetamine. The idPAD houses 12 different color tests that each target a different chemical functional group and react with a colored response. By running the tests simultaneously, a complex color "bar-code" is produced unique to each substance that can be read using an image library. The idPAD's ability to produce a unique color bar code for each substance, or mixture, presents a capability not currently seen in modern field presumptive tests. Initial testing of the idPAD with pure drug standards and fabricated mixtures demonstrated a 94% sensitivity and 100% specificity for cocaine, heroin, and methamphetamine in a lactose matrix. The limit of detection is well within the microgram range for all substances, and stability is consistent with current methods.

To validate the idPAD with collected street samples, a collaboration was started with the Marion County Coroner's Office in Indianapolis, IN. Many coroner's offices do not analyze the drugs found at the scene of the overdoses, relying only on toxicology data from the deceased. However, for this study, samples found at overdose scenes were collected and tested on the idPAD, with the results compared to Liquid Chromatography/Mass Spectrometry (LC/MS) of the drug samples and toxicology reports from the decedent. Trends on common drug mixtures as well as the highlights in differences between physical drugs found at scenes compared to in the toxicology report will be discussed.

#### Microfluidics, Paper Analytical Device, Presumptive Field Test

## E24 Success Rate Comparison of Latent Prints and Touch DNA From a Pistol

Siera Ramirez, BS\*, Huntington, WV 25705; Stephen C. King, BA, West Virginia State Police, South Charleston, WV 25309; Kelly Beatty, MSFS, Marshall University Forensic Science Center, Huntington, WV 25701; Catherine G. Rushton, EdD, Marshall University Forensic Science Program, Huntington, WV 25701

**Learning Overview:** The goal of this presentation is to inform the community on the likelihood of obtaining prints of value from latent prints and/or obtaining a full DNA profile from touch DNA on a pistol.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by guiding and supporting decisions made by forensic scientists and investigators when processing evidence.

Firearms are a commonly shared evidence item between latent prints and DNA. This study determined the success rate of both disciplines regarding the processing of 80 pistols. The sample group was made up of 60 different pistols with a variety of 22 different brands. The samples were split into three groups: 20 pistols that were unclean with no documentation of their background that added a single contributor, 40 pistols that were cleaned and added a single contributor, and 20 samples that were cleaned and a variety of known contamination contributors were added before the main contributor to create a manufactured multiple source sample. Each main contributor had two minutes of handling for each pistol. The only requirements for the main contributor were to mock use the pistol twice, abstain from purposefully leaving prints or overloading with DNA, and handle the pistol in ways that could be reflective of prevalent handling. The handling was intentionally left open-ended in an attempt to have “normal” variation that could be seen in casework.

Using a wet double-swab technique, the DNA was collected from the grips and other textured surfaces that would not allow for prints of value. The pistols were then fumed in a cyanoacrylate chamber for latent prints. Using MBD, a fluorescent dye, and Alternate Light Source (ALS), it was expertly determined that from the 80 pistols, 11 contained prints of value, an overall success rate of 13.75%. This percentage is agreeable with the national average.<sup>1</sup> The DNA was amplified with GlobalFiler<sup>®</sup> chemistries and analyzed with GeneMapper<sup>®</sup> IDX. The analytical threshold was set at 50 Relative Fluorescence Units (RFU) and mainly spikes and off-ladder alleles were justifiably removed before collecting data. The touch DNA yielded full main contributor profiles for 73.75% of the samples. Of the remaining samples, 15% were missing only four or less alleles for the entire profile.

This study recorded if the alleles were present but did not expertly decide if each profile was of value. The target concentration was 0.4ng. The smallest target concentration to yield a full profile was 0.1035ng, which initially quantified at 0.0028ng/μL and had to be concentrated. There was not a noted correlation between obtaining a print of value and obtaining a full DNA profile, but the type of material used to manufacture the pistol could have affected the ability to leave a latent print or prevent leaving substantial DNA for testing. When there was a print of value, 63.63% of the time a full DNA profile was also observed. The degradation index was also calculated for each sample, and degradation was observed in multiple samples. The main factors for not obtaining a full DNA profile were degradation and insufficient DNA. This study could not incorporate every variation in casework, but serves as a foundation of what results could be obtained. This study is meant to guide investigators and forensic scientists to support their decisions for sending evidence to be processed by latent prints and/or DNA.

### Touch DNA, Latent Prints, Firearm

## E25 Unique Dangers in the Medicolegal Death Investigation Process

*Brett E. Harding, MBA\*, Office of the Coroner/Medical Examiner, Las Vegas, NV 89106; Barbara C. Wolf, MD, Districts 5 & 24 Medical Examiner's Office, Leesburg, FL 34748*

**Learning Overview:** After attending this presentation, attendees should be able to recognize potential dangers encountered during the medicolegal death investigation process. Attendees will also understand how, when unrecognized, these dangers could potentially lead to illness, injury, and even death of individuals involved in such investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the dangers involved in medicolegal investigations that may not be readily apparent. These unusual scenes generate concerns by law enforcement, medicolegal investigators, forensic technicians, and forensic pathologists because of the potential for illness, injury, or death.

Unrecognized, the unique dangers in the medicolegal death investigation process could potentially lead to illness, injury and even death of individuals involved in such investigations. This could include law enforcement, medicolegal death investigators, forensic autopsy technicians, pathologists, and threats to public health. Attendees will also understand how these types of dangers necessitate the utilization of a multidisciplinary medicolegal investigative approach to be able to identify and minimize or neutralize potential hazardous situations, elements, or environments.

The presentation of potential dangers in investigation, while not always foreseeable, often follow familiar patterns consistent with the suspected cause of death. Suicidal deaths involving the utilization of vehicle exhaust present the foreseeable risk of carbon monoxide poisoning within the investigation environment. Individuals dying from high-voltage electrocution present an environment that could be a risk for electrical shock. Persons dying from firearm deaths often present a scene where a loaded weapon is present and is an intimate part of the investigation. Conversely, death scenes often arise in which both the cause and manner of death are not immediately apparent, nor are potential hazards. This presentation describes multiple cases in which the dangers involved in the medicolegal investigation were not readily apparent. These unusual scenes generated concerns by law enforcement, medicolegal investigators, forensic technicians, and forensic pathologists because of the potential for illness, injury, or death.

**Case 1: Ricin**—Law enforcement and the coroner/medical examiner's office were summoned to the home of a 36-year-old Caucasian male. The death was reported as a possible suicidal overdose. At the scene, apparent drug paraphernalia was found as was a suicide note. After the initial investigation, the medicolegal death investigation found castor beans, acetone, and other materials that could be used for the production of ricin. This was communicated to law enforcement, who had observed the material but had not recognized this to be a potential threat. This led the medicolegal death investigator to discount her initial concerns and transport the decedent without taking further precautions.

**Case 2: Grenade**—Law enforcement and the coroner/medical examiner's office responded to a reported gunshot wound suicide that had occurred in a car. Upon arriving at the scene, the decedent was noted to have suffered an apparent perforating gunshot wound to the head. A semi-automatic handgun was in the vehicle in close proximity to the body. Photographic documentation was initiated and the firearm removed. During the examination, the body was leaned forward to visualize the back before removal from the vehicle. At that time, a safety pin from a hand grenade was heard, then visualized to have fallen to the ground. A grenade was then identified behind the back of the decedent. All personnel were evacuated and the bomb squad alerted. The grenade was removed and detonated by the bomb squad.

**Case 3: Firearm**—Law enforcement responded to the traffic crash deaths of two individuals attempting to elude police. The fleeing persons were driving at a high rate of speed within a business district. As they turned a corner, the vehicle struck a production class wheel loader. Both individuals were unidentified at the scene, and the vehicle was stolen. While the medicolegal death investigator was examining and photographically documenting the decedent, a cellular telephone began to ring from within the vehicle rubble. The medicolegal death investigator was asked to "grab the phone" before it stopped ringing. Upon picking up a pile of rubble, the medicolegal investigator felt something slip from the debris. He then observed a firearm falling to the pavement. It fell and stuck the pavement with the barrel pointing in the direction of the investigator. Inspection of the weapon revealed it to be loaded and ready to fire with the safety not engaged.

These usual cases required a multidisciplinary approach to facilitate and complete the medicolegal investigation process. These and additional cases illustrate the importance of remaining vigilant during the investigation process and how the utilization of a multidisciplinary approach may be necessary to assure the safety of all persons involved.

### Dangers, Multidisciplinary, Medicolegal

## E26 “Comet-Tailing” Associated With an Intermediate-Range Gunshot Entrance Wound

Samuel P. Prahlow, MPH\*, Florida State University, MPH Program, Tallahassee, FL 32308; Theodore T. Brown, MD, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be more cognizant of the fact that, in certain instances involving susceptible ammunition, gunshot entrance wounds may display an associated “comet-tailing” pattern of vaporous lead/soot. This report will alert police, death investigators, forensic pathologists, and others of this rare but classic-appearing lesion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a multiple gunshot wound homicide case in which one of the entrance wounds had associated “comet-tailing.”

Projectiles can be completely composed of lead or contain a lead core covered by a partial or full “jacket” of metal. Bullets are jacketed in part to prevent fouling of the weapon’s barrel while being fired. Metal bullet coverings can range from fully jacketed to “gilded.” Jacketed bullets have a relatively thick metal (usually copper, sometimes other metals) covering, while many .22 caliber rounds are “gilded” or “washed” with a copper-colored coating that appears to be sprayed onto the bullet surface. “Plated” or “electroplated” bullets can be considered “in-between” gilded and traditionally jacketed bullets. The metal covering of plated bullets is not as thick as the metal on classic jacketed bullets, but it is thicker than the light “wash” present on gilded bullets. Because this coating is thinner than classic jacket material, the thinner metal plating can, in some instances, fracture while being fired.<sup>1,2</sup> A homicidal gunshot wound demonstrating an unusual feature associated with a fractured plated bullet known as “comet-tailing” is presented.

A 23-year-old male was shot outside of his father’s house after visiting family. His wife, who was inside the residence at the time of the shooting, described hearing five to ten shots. The male was found by the driver’s side tire in front of his vehicle. Police and Emergency Medical Services (EMS) were called. Police found five 9mm casings and a fragmented bullet at the scene. EMS attempted resuscitation but was unsuccessful. At the medicolegal autopsy, the examination of the body was most significant for multiple gunshot wounds, predominantly of the head and neck. A perforating intermediate-range gunshot wound of the right side of the face had a very unusual feature, characterized by a dense area of soot-like material spiraling in a counter-clockwise direction, outward from the entrance defect, with a greatest dimension of approximately twice the diameter of the entrance wound. Although not previously described in the forensic pathology literature, the finding is nearly identical to what has been previously described in the firearms literature as “comet-tailing.”

“Comet-tailing” is an effect that can occur with certain bullets, usually those that are electroplated or plated.<sup>1</sup> This unusual effect occurs when a plated bullet’s electroplating material fractures upon firing.<sup>1,2</sup> Vaporous lead (presumably from the energy/heat caused by the firing of the projectile) escapes through the fracture site of the plating material.<sup>1</sup> Since the bullet is spinning along its longitudinal axis as it flies through the air, the vaporous lead stream spins as well. Thus, when the bullet enters the target, a spiral-shaped, so-called “comet tail” deposition of vaporous lead can appear on the surface surrounding the entrance site.<sup>2</sup> It has been suggested that in addition to the susceptibility of plated bullets to fracture when fired, features of the firearm itself, such as a flaw in the barrel, may predispose to fracturing of the electroplated covering of these bullets.<sup>1</sup> In the presented case, the entrance wound associated with “comet-tailing” was an intermediate-range shot, with an estimated distance of one to three feet. This case serves to alert police, death investigators, and forensic pathologists of this unusual feature that may be seen in certain cases of gunshot wounds wherein plated bullets fracture when fired from a weapon.

### Comet-Tailing, Gunshot Wound, Forensic Pathology

## E27 Biomechanical Considerations in 3D Reconstruction of Shooting Events

*Parris Ward, JD\*, Biodynamics Engineering, Inc, Pacific Palisades, CA 90272*

**Learning Overview:** After attending this presentation, attendees will learn how analysis of human motion can aid 3D reconstruction of shooting events.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the accuracy and validity of 3D shooting reconstruction can be enhanced through surrogate studies.

3D computer modeling and animation software is an important tool in analyzing and illustrating shooting incidents because it allows us to accurately demonstrate the interaction between projectiles and objects in terms of time and space. Using 3D laser scanners, we can create highly accurate models of a scene. 3D models representing people, referred to as mannequins or character models, can be added to show the approximate body position of the person who was shot. Just as a pathologist places rods through a cadaver, lines can be added to depict bullet paths through the body of the mannequin.

One limitation of computer-generated mannequins is that they are not always able to replicate the body position or movements of a person. Computer models of people can be comprised of a series of articulated polygons or can be a mesh structure rigged with an internal bone system that deforms the mesh. In some situations, the mannequin will not accurately replicate how a real person bends, nor will it be limited to human range of motion. The mannequin's movements are controlled by the animator and may not accurately replicate human kinematics. Hollywood animators can create extremely complex and lifelike human models, which are controlled using motion capture data recorded from human actors. This level of sophistication with its associated cost is not often available to the forensic investigator.

In complex shooting events, it may be necessary analyze video of human subjects performing similar movements. Synchronized cameras can record surrogates from multiple angles as they attempt similar movements or body contortions. The video can then be analyzed frame-by-frame to derive motion data and body positioning, lending foundation to the accuracy of the reconstruction. A surrogate study may also reveal how surrogates approach a task or respond to stimuli.

This presentation will examine two officer-involved shooting incidents in which it was necessary to analyze the movement and positioning of surrogates performing certain tasks. In one case, an officer opened the door of her patrol car when she arrived at the scene of an alleged kidnapping attempt. A male suspect ran toward her car and jumped inside the vehicle on top of her. The officer fired two shots, striking the suspect in the shoulder and back. In analyzing the incident, surrogates were used to recreate the incident. A male surrogate ran toward a vehicle with an open car door and attempted to grab a female surrogate inside. Video analysis of the reenactment showed that when the male surrogate approached the vehicle, he slowed his pace and reached out with his right hand to brace himself against the B-pillar of the vehicle. He then dropped his left shoulder and led with his left arm as he ducked inside the open car door. This motion created the correct positioning for the shot angles to occur. The muzzle-to-target distances were consistent with stippling found on the body and blood spatter in the vehicle correlated with the location and orientation of the suspect's wounds.

In another case, an armed suspect was jumping over a backyard garden fence when he was shot by a police officer. The bullet entered the buttocks and traveled upward through the torso into the left chest. The bullet appeared to change direction, laterally, ending up in the left shoulder. There was what appeared to be an exit and reentry wound in the area of the left shoulder, suggesting the possibility that the suspect was shot while on the ground. As part of the analysis, surrogates were videotaped jumping over a similar fence. The surrogate study showed that there are numerous ways a person can approach and launch their body over a fence. However, going over headfirst, with one's left arm extended, created an alignment between the shoulder and the bullet path through the torso. It also created a crease in the skin that would explain the unusual shoulder wound.

---

### Shooting Reconstruction, Biomechanics, 3D Modeling

## E28 Detection, Identification, and Characterization of Gunshot Residue (GSR) Using Raman Spectroscopy

Igor K. Lednev, PhD\*, University at Albany, State University of New York, Albany, NY 12222; Shelby R. Khandasammy, BS, State University of New York, Albany, NY 12222

**Learning Overview:** After attending this presentation, attendees will have a better understanding of recent advancements of the application of Raman spectroscopy for GSR analysis, identification, and discrimination. The implementation of advanced statistics to differentiate experimental Raman spectra collected from non-equivalent GSR samples will be discussed.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the accuracy and effectiveness of shooting incident investigations.

Raman spectroscopy has numerous applications in forensic chemistry.<sup>2</sup> Raman spectroscopy is a technique that can obtain confirmatory class identification of analytes through low-intensity laser light scattering. The technique is non-destructive, rapid, sensitive, and requires little or no sample preparation. Raman spectroscopy offers several advantages over the current methodology for GSR analysis. The technique has been shown to detect components from both the organic and inorganic constituents of GSR on adhesive tape.<sup>3</sup> This is contrary to current GSR elemental analysis methods which rely solely on the detection of the heavy metals (lead, barium, and antimony).

Raman microspectroscopic mapping and multivariate analysis was recently utilized for the detection of GSR on adhesive tape. The study included a validation of the reproducibility/ruggedness and specificity of the approach.<sup>4</sup> Raman mapping for GSR detection was performed on an independent Raman microscope, not used to generate the training set. These independent spectra were classified against the original training dataset using Support Vector Machine Discriminant Analysis (SVM DA). The resulting classification rates of 100% illustrate the reproducibility of the technique, its independence upon a specific instrument, and provide an external validation for the approach. Additionally, the same procedure for GSR collection (tape lifting) was performed to collect samples from environmental sources, which could potentially provide false-positive assignments for current GSR analysis techniques. Thus, particles associated with automotive mechanics were collected. Automotive brake and tire materials are often composed of the heavy metals lead, barium, and antimony, which are the key elements targeted by current GSR detection technique. It was determined that Raman spectroscopic analysis was not susceptible to misclassifications from these samples.

Results from these validation experiments illustrate the great potential of Raman microspectroscopic mapping used with tape lifting as a viable complimentary tool to current methodologies for GSR detection. Furthermore, current methodologies are not well-developed for automated Organic GSR (OGSR) detection. A new two-step method for the detection and identification of OGSR was also developed.<sup>5</sup> This method utilizes highly sensitive fluorescence hyperspectral imaging of a sample area to detect potential GSR particles, followed by confirmatory identification of the detected particles using Raman microspectroscopy.

*This project was supported by an award from the National Institute of Justice, Office of Justice Programs, United States Department of Justice. The opinions, findings, and conclusions or recommendations expressed in this publication are those of the authors and do not necessarily reflect those of the Department of Justice.*

### E29 A Serial Killer and Seven Homicides: Finding the Graves—A Multijurisdictional Investigation

*Michelle S. Clark, MS\*, Farmington, CT; James R. Gill, MD, Office of the Chief Medical Examiner, Farmington, CT 06032; Kristen Hartnett-McCann, PhD, Office of the Chief Medical Examiner, Farmington, CT 06032*

---

**Learning Overview:** The goal of this presentation is to highlight the methods used in multijurisdictional investigations involving local and state law enforcement, the Federal Bureau of Investigation (FBI), and the medical examiner's office to find the location, then recover a serial killer's burial site of seven victims.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the resources of local, state, and federal agencies to assist the medical examiner's office in uncovering mass graves and how this was achieved.

In 2007, scattered human bones were found on the ground behind a strip mall in Connecticut. At that time, it was suspected that the bones were from three individuals. Two skulls were recovered and later identified via dental radiographic comparisons. A third identification (by DNA) was made in 2014 from a few long bones that were recovered. These three individuals were from separate cities. Four local police departments had a possible suspect and compiled a list of missing persons, dates they went missing, and when they had been in contact with the suspect. Local police departments, working together with the department of corrections, state police, and the FBI, were able to track the suspect's movements and when he had been in the areas of the missing persons.

Once all the agencies concluded how many missing persons there were and if they could possibly be buried at the same location, the Connecticut Office of the Chief Medical Examiner was invited to the monthly Serial Killer Task Force meetings. This task force was comprised of investigators from local, state, and federal jurisdictions that convened once a month to share information and decide the next steps. A list of seven victims was compiled from evidence that was tested from the suspect's vehicle. In 2015, a comprehensive search of the 7.3-acre wooded area was performed using an FBI cadaver dog from Quantico, VA, a line search, soil probes, and ground-penetrating radar.

Based on the information obtained from the forensic analysis of the area, the anthropologist and medicolegal investigator focused on a 0.66-acre area. Once the smaller area was marked, back hoes were brought in, along with local, state, and federal personnel to assist with the excavation. After two weeks of searching and methodical test trenching excavations, five graves were uncovered, including the body of the victim whom the suspect was originally incarcerated for killing based on blood in his vehicle. The cooperation of multiple agencies across jurisdictions and the use of a variety of forensic tools helped determine the location of five grave sites where the remains of seven homicides were concealed (two were scattered on the surface and found in 2007). The suspect has since been tried for their deaths and found guilty.

---

#### Forensic Search, Serial Killer, Excavation

## E30 Spicing Things Up: Death Due to the Use of the Synthetic Cannabinoid ADB-FUBINACA

Anita Roman Hasert, BS\*, Charleston County Coroner's Office, North Charleston, SC 29405; Demi B. Garvin, PharmD, Forensic Science Network, Columbia, SC 29201

**Learning Overview:** After attending this presentation, attendees will be able to apply their understanding of thorough medicolegal death investigation practices to suspected Novel Psychoactive Substance (NPS) exposures. Attendees will be able to describe the elements of a multidisciplinary approach in NPS-related death investigations in order to facilitate effective communication and collaboration with law enforcement and medical, forensic, and public health providers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the literature regarding fatal synthetic cannabinoid exposure while underscoring the need for ongoing identification of these compounds in both postmortem specimens and drug paraphernalia.

Synthetic Cannabinoids (SC) are characterized as NPS and have been available for the past decade in the United States' illicit drug market. They are typically promoted as herbal preparations, branded as "not for human consumption," and sold in association with a variety of creative packaging and product names, such as "Spice," "K2," "Black Mamba," etc. Synthetic cannabinoids act as full agonists at the CB1 and CB2 receptors and as such they may be used as a substitute for cannabis.<sup>1-3</sup> Ever-shifting changes in NPS chemistry, manufacture, and distribution have continued to present challenges to the identification and interdiction of these compounds as well as the treatment of exposures and public health education strategies to combat their use.

This study presents the case of a 31-year-old male who was transported to an emergency department after he was found on the ground in a postictal state at a city park. A bystander witnessed him smoking an unknown substance in a glass pipe. He admitted to emergency medical services personnel that he had smoked "Spice" but was otherwise uncooperative. Clinical presentation included a severe tachycardia with an initial heart rate of 170 beats per minute and diaphoresis. He received symptomatic and supportive care and was discharged after approximately five hours of observation. Forty-eight hours later, friends found him unresponsive on the balcony of a house that had been rented for a bachelor party. He was pronounced dead at the scene. A black foil package labeled "Spanish Devil AKA Diablo" was found in his pants pocket, and a glass pipe was located near the body. Each item appeared to contain brown plant material.

In acute exposure, synthetic cannabinoids have been reported to produce nausea, agitation, tachycardia, hypertension, hyperthermia, delirium, seizures, renal failure, myocardial injury, and death.<sup>1-3</sup> Drug variability, dose, and potency as well as the presence of other licit or illicit substances may intensify the toxic effects of these compounds.

ADB-FUBINACA was identified in the postmortem peripheral blood specimen and in the drug paraphernalia. In 2018, Shanks et al. published the first case report of a death attributed to use of ADB-FUBINACA.<sup>3</sup> In 2019, this compound was among several synthetic cannabinoids to receive permanent Schedule I status by the United States Drug Enforcement Administration.<sup>4</sup> Structurally related to AB-FUBINACA, ADB-FUBINACA has a strong affinity for the CB1 receptor, which explains its clinical effects. Pathology, toxicology, and drug chemistry findings specific to this case will be presented in the context of previously published ADB-FUBINACA toxic exposures and fatalities. Based on the circumstances surrounding the victim's social history, clinical presentation, temporal relationship of SC use as well as the toxicology, drug analysis, and autopsy findings, the cause of death was attributed to ADB-FUBINACA intoxication. The manner of death was classified as accident.

### E31 Collaboration in Action—A Case Study on Implementing the National Best Practices for Sexual Assault Kits: A Multidisciplinary Approach Recommendations

Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064

**Learning Overview:** After attending this presentation, attendees will understand the process from a Mountain West state in successfully implementing the *National Best Practices for Sexual Assault Kits: A Multidisciplinary Approach* recommendations in the instructions, guidelines, and content in their statewide sexual assault kits.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging collaboration between forensic scientists, forensic medical/nursing examiners, and other multidisciplinary partners in implementing the *National Best Practices for Sexual Assault Kits: A Multidisciplinary Approach* recommendations.

**Synopsis:** In 2013, Congress passed the Sexual Assault Forensic Evidence Reporting (SAFER) Act, which recommended the development of national best practices and protocols related to sexual assault kits.<sup>1</sup> The SAFER Working Group, comprised of multidisciplinary subject matter experts, was created to generate collaborative best practice guidelines. After multiple in-person and virtual meetings over two years, the United States Department of Justice released the SAFER Working Group's recommendations in the *National Best Practices for Sexual Assault Kits: A Multidisciplinary Approach* in August 2017.<sup>2</sup>

Upon release of the *National Best Practices*, forensic scientists and forensic nurses in a Mountain West state (Utah) met to discuss implementation of the multidisciplinary SAFER Working Group recommendations. Specifically, the meetings focused on implementation of recommendations from Chapter 2: The Medical-Forensic Exam and Sexual Assault Evidence Collection. This presentation will explore the process of reviewing the sexual assault evidence collection recommendations in terms of the needs of the community and criminal justice system in Utah. Changes were made to the instructions, guidelines, and content of the sexual assault kits. This presentation will delve into specific changes made to the sexual assault kit content and guidelines, such as including masks for examiners in the sexual assault kits, no more collection of control swabs, and reducing swab numbers to focus on concentrating DNA material on swabs. Education was then disseminated to forensic scientists and forensic nursing and medical teams across the state on the changes and rationale for the changes.

The importance of a strong, collaborative relationship between forensic scientists and forensic nursing/medical examiners will be reinforced with suggestions on how to build local multidisciplinary teams to achieve best practices. Recommendations from *The National Best Practices* document were also used in recent Utah legislative bills regarding the submission and testing of all sexual assault kits and the creation of a tracking system with a victim portal. Thus, the *National Best Practices* document has positively influenced both practice and policy related to sexual assault in Utah.

#### Sexual Assault Kits, Best Practices, Collaboration

## E32 Meningitis as a Cause of Death in a Medical Examiners Setting

Breanna M. Cuchara, MFS\*, Manassas, VA 20110; Ariel C. Viramontes, MD\*, MedStar Georgetown University Hospital, Washington, DC 20007; Francisco J. Diaz, MD, Office of the Chief Medical Examiner, Washington, DC 20024

**Learning Overview:** After attending this presentation, attendees will understand the risk factors within the District of Columbia (DC) and the causes of fatal meningitis cases. This study will explore medical and social histories of each case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging other medical examiner's offices to investigate the causes and specific risk factors of meningitis cases that occur in their jurisdictions. This is of great importance to decrease the likelihood of fatalities among patients diagnosed with bacterial or other forms of meningitis.

Meningitis is the inflammation of the meninges surrounding the brain and spinal cord.<sup>1</sup> The etiology of meningitis can be divided into bacterial, viral, parasitic, fungal, and non-infectious types. Each type can be caused by reasons such as injury, illness, substances, or chemicals. Viral meningitis is the most common form in the United States.<sup>1</sup> It is not as fatal as bacterial meningitis and has no specific treatment. It can be spread through bodily fluids, such as coughing, kissing, etc. Bacterial meningitis is primarily caused by a few different species of bacteria. It can be fatal and/or lead to brain damage. The population who is most at risk are patients with weakened immune systems and/or living in a college dorm or group home, where the exposure is high.

According to the Centers for Disease Control and Prevention (CDC), in the United States between 2003 and 2007 there were approximately 4,100 cases and 500 deaths due to bacterial meningitis each year.<sup>2</sup> Meningitis caused by the bacteria *Neisseria meningitidis* can be prevented with the MenB and MenACWY vaccines.<sup>3</sup> However, vaccine ignorance (lack of awareness about the vaccines) and vaccine hesitancy are on the rise. In fact, the World Health Organization cites vaccine hesitancy as one of the top ten threats to public health.<sup>3</sup>

This study analyzed autopsy, laboratory analysis, and investigative reports for significant medical history, signs/symptoms, residencies, and social history. This study looked over DC Office of the Chief Medical Examiner (OCME) cases over the past ten years (2008–2018). Overall, there were 22 cases of meningitis in DC. It was found that 55% were male and 45% were female. Decedents in this study were 68% Black, 22% White, and 9% Hispanic. The average age was 43 years old (the youngest was ~18 days old and the oldest was 70 years of age). It was found that bacterial meningitis was the most common cause of death in this study (91%), followed by viral (5%) and non-infectious meningitis (5%).

Interestingly, the 12 DC residents in this study were from every ward, averaging one to two decedents per ward. It was also discovered that decedents either had no medical history documented (22%), a history of strokes (27%), skull fractures/trauma (13%), and hypertension (27%). It was also found that 41% had a history of ethanol and crack cocaine abuse (22%) and used tobacco (27%). This is interesting because Phencyclidine (PCP) is one of the most abused drugs in DC, but was not present in any of these cases.

This research will provide statistical data for public health officials regarding the risk factors for meningitis. Given the amount of people that reside in the DC and the drug addiction rate, the risk of potential exposure is possible. This study shows that although some citizens in different wards have little to no access to major hospitals, this disease crosses all socioeconomic statuses. This study provides evidence of how important it is for medical examiner's offices to search for immunization records for each meningitis case, if accessible. Vaccines are available now and continuing education about these vaccines and meningitis could decrease the number of deaths per year.

### Meningitis, Public Health, Death Investigation

### E33 Drug Abuse and Misuse Leading to Death in Tippecanoe County, Indiana (1993–2013): A Five- Year Update (2018)

*Matthew C. Wietbrock, BS\*, Lafayette, IN 47909*

**Learning Overview:** The goal of this presentation is to provide an five-year update to a previous report of drug abuse and misuse in Tippecanoe County, IN. In part, this will help gauge what, if any, impact recent awareness and prevention campaigns have had regarding the prevalence of drug- and alcohol-related deaths.

**Impact on the Forensic Science Community:** This presentation will benefit the forensic science community by focusing upon the current state of prescription drug abuse and by displaying the frequency with which such drugs are encountered in deaths investigated by the Tippecanoe County Coroner's Office. This will be accomplished by comparing a previous 20-year study to the past five years.

In 2014, the Tippecanoe County Coroner's Office conducted a comprehensive survey of all drug- and alcohol-related deaths for the previous 20 year period (1993–2013). The scope of this study was to evaluate what contributions prescription drugs, illegal drugs, and alcohol had played in the deaths of residents of Tippecanoe County, IN, from 1993 through 2013. This results of this study were discussed at the 2014 AAFS Annual Scientific Meeting, and widely reported around the local Tippecanoe County area. Five years have passed since this effort, and further work on this topic is eligible for discussion. The prevalence of mind-altering substances compared to all cases investigated by the Tippecanoe County Coroner's Office will also be discussed. This data will also be compared to national trends.

Tippecanoe County is located 68 miles northwest of Indianapolis, 124 miles southeast of Chicago, and is home to a population of 190,500. Tippecanoe County has a large manufacturing base. Caterpillar®, Inc., Subaru® in Indiana, Fairfield Manufacturing, and Wabash National® are all represented in the county. Tippecanoe County is also home to a major research university, which is still the area's biggest employer.

Drugs, like alcohol, which lower inhibitions or which can induce high-risk behavior, have long been recognized as being prevalent in cases where the manner of death is found to be accidental, suicide, or even homicide. Minimally, the presence of drugs, including alcohol, are investigated for regularly. Alcohol being readily available, and easily abused, can often be encountered in death investigations. Similarly, hard street drugs, such as cocaine, heroin, or synthetic drugs, have also been long known to play significant factors in death investigations. Use and availability of these drugs, especially heroin, have continued to rise in the North Central Indiana Region.

However, Indiana has experienced a meteoric rise in the use opioids such as methadone and oxycodone for pain management. The potential for chronic abuse of these prescriptions has become of rising concern for public health officials as is the potential for opioids to be combined with benzodiazepines and/or alcohol, which often lead to harming results. Nationally, these numbers have continued to rise, and Tippecanoe County is no exception. Several high-profile celebrity deaths on the national stage have added to the public awareness. The Centers for Disease Control report that overdose deaths related to the misuse of methadone have increased to account for one in three pain killer overdose deaths since 2009. The examination of 20 years of death statistics in Tippecanoe County yielded the frequency in which illegal, prescription drugs and/or alcohol were detected in decedents toxicological examinations, post mortem. This current study will provide updated data to consider.

---

#### Drugs, Alcohol, Death

### E34 The Application of Virtual Reality in Training First Responders in the Proper Handling of the Dead

*Ivett Kovari, PhD\*, Paris 75014, FRANCE; Pierre M.M. Guyomarc'h, PhD, International Committee of the Red Cross, Geneva, GVA 1202, SWITZERLAND; Christian Rouffaer, MS, International Committee of the Red Cross, Bangkok 10110, THAILAND*

**Learning Overview:** After attending this presentation, attendees will have a clearer understanding of the application of virtual reality as a training tool in the humanitarian forensic domain.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting: (1) the complexity of Management of the Dead (MotD) training for first responders; and (2) the need and importance of an experience-based, innovative, pragmatic approach of training modules.

The International Committee of the Red Cross (ICRC) has been assisting in humanitarian forensic response globally since the end of the 20<sup>th</sup> century; the nature of its assistance includes, but is not limited to, the training of first responders in the proper MotD in emergencies. Following disasters (natural or man-made), the role of the first responders in the search and recovery of the dead is crucial. Their swift, professional, and accurate actions can lead to a higher percentage of positive identifications if the correct information is collected at the early stages and adequately traced. Proper training for the shareholder agencies in the adequate response procedures is therefore essential. The challenges of the MotD training in different countries are extremely diverse, such as language limitations, differences in cultural, religious, and social needs, geographical and timely constraints, financial restrictions, changing jurisdiction of actors, the constant rotation of the acting personnel, etc.

Recently, education technology companies revolutionized teaching when they brought Virtual Reality (VR) technology to the classrooms. A 360-degree view of the content gives a more realistic feel to the trainees, while the interaction with VR content helps them explore the subject in more depth; the technology is not limited to any specific age group of students. In the MotD setting, the VR tool is also proving to be tremendously useful. The module does not require deploying heavy training material (mannequins, body recovery equipment, etc.); after launching the software, the trainees are immediately in the arranged and adjusted simulation. They can examine the environment in order to make decisions on their personal protection equipment necessities prior to going to the field to search for and recover disaster victims. The simulation can be modified regarding the stress situation (e.g., bombing, earthquake, tsunami) and the language can easily be adjusted. During the simulation, the trainer observes the trainee's advancement, as the whole simulation can be viewed on the computer or projected to a big screen; they can stop the process, give immediate feedback and recommendations. Moreover, the trainees can work in teams as other team members can, as well as follow what is happening inside the simulation—they can cooperate as they would on the field. Furthermore, the trainer does not have to be in the same room (or even location, town, or province) as the trainees; they can study the training process via computer connection, which is an added value in remote areas.

Applying the VR tool to MotD training does not intend to dismiss traditional training. On the contrary, it is intended to complement it. Ultimately, a better response is achievable via training following a disaster situation to avoid a high number of persons who remain unaccounted for and to return the missing to their families.

#### Humanitarian Forensics, Virtual Reality, Training

## E35 Examining the Impact of Trauma and Stress Across Forensic and Investigative Contexts

*J. Amber Scherer, PhD\**, Washington/Baltimore High Intensity Drug Trafficking Area, Greenbelt, MD 20770; *Amanda L. Farrell, PhD\**, Marymount University, Arlington, VA 22207; *Timothy J. Ainger, PhD\**, University of Kentucky, Lexington, KY 40536

**Learning Overview:** After attending this presentation, attendees will better understand contemporary literature and research with regard to trauma and stress in the world of forensic professionals, as well as the outcome variables subsequent to trauma exposure, which pose many risks for personal wellbeing.

**Impact on the Forensic Science Community:** The emotional and cognitive impact of trauma is of great concern for forensic professionals, who are at a significantly increased risk of exposure, but for whom there is a paucity of research understanding and even less on managing how individuals are impacted. This study seeks to elucidate these concerns as well as discuss a groundbreaking, comprehensive research study aimed at increasing not only our understanding of trauma in the forensic workforce, but the efficacy of trauma management.

While there has been a recent increase in attention to first responders and the impact of trauma (direct and vicarious), other investigative personnel or non-front line personnel are often overlooked or an afterthought in addressing these issues. It is important to understand and recognize how stress and trauma are tied to the forensic and investigative professions specifically, including in the form of vicarious trauma, and how exposure to trauma and stress impacts an employee's personal and professional performance. Raising the awareness of the various types of trauma that investigators and investigative personnel routinely encounter and the potential impacts this may have, not only on the individual, but on the investigation and/or service provision, is a critical next step in future-proofing the forensic and investigative workforce.

Paths forward and the development of Evidence-Based Policy (EBP) from related or tangential professions, such as police officers, dispatchers, firefighters, emergency medical services, trauma nurses, and other medical professionals may be adapted to the needs of various disciplines within the forensic and investigative workforce. However, a detailed understanding of unique and common stressors to those roles and responsibilities must be conducted to aid in the evaluation of existing policies and assistance typically available in agencies, if any, as well as to aid in empirically based policy development.

In seeking to serve communities as investigators or forensic professionals, many individuals are exposed to things that the average citizen cannot understand. These can include violent crime scenes, death investigations and autopsies, exposure risks, processing clandestine graves or receiving donated bodies for research purposes, reviewing materials in indecent images and child exploitation investigations, and so on, and sometimes these experiences stay with the individual. Recognizing that certain trends, such as the opioid crisis, can exacerbate the existing levels of stress and trauma faced by various personnel who often work in an interconnected environment, best practices suggest that an agency that is trauma-informed and has made preparations for employees will have better success in terms of keeping employees happy, healthy, and productive.

This presentation seeks to enhance the understanding of factors negatively impacting the emotional and cognitive impact of adverse experiences on forensic professionals. There is a paucity of research available with regard to resiliency, wellness, and burnout, and even less still addressing those for whom high-stress, violent, and traumatizing stimuli are not adverse risks, but job descriptions. These elements are endemic to the lives of first responders and forensic professionals, and yet extremely little is known about the long-term impact of chronic exposure to them, and the emotional, as well as cognitive, effect they may have.

This research seeks to evaluate a variety of factors via multiple avenues. The first is by identifying the prevalence of burnout in multiple forensic populations, including forensic anthropologists, sworn officers, medical examiners, and undercover operatives. Then cross-sectional analyses to scrutinize common and differential variables will be performed. Subsequently, participating agencies will have the opportunity to participate in an assessment of "trauma-informedness," with the opportunity for interventional recommendations. Finally, this ongoing research will use a targeted, brief neurocognitive assessment for individuals to evaluate the impact of burnout variables. Funding for this research is pending, but the current proposal is for a three-year study that is prepared to implemented at the end of FY2019–2020.

### Stress/Trauma, Burnout, Resilience

### E36 The Effect of the Medicolegal Evaluation on Asylum Seekers: The Proposal for a New Operating Model

Antonietta Lanzarone\*, University of Palermo, Palermo 90127, ITALY; Stefania Zerbo, MD, Palermo 90100, ITALY; Francesca Korte, Watertown, MA 02472; Valeria Tullio, Department of Psychology, Educational Science, Palermo 90128, ITALY; Elvira Ventura Spagnolo, MD, University of Palermo, Palermo 90127, ITALY; Antonina Argo, PhD, University of Palermo, Palermo 90100, ITALY

---

**Learning Overview:** The goals of this presentation are: (1) to record the physical and mental consequents in migrant people (asylum seekers) that are victims of mistreatment and torture, distinguishing between consequents of mistreatments suffered in their own country, consequents of mistreatments suffered in Libya, scars of accidental injuries, and scars of tribal rites; (2) to focus attention on severe human rights violations in Libya, taking into account the data collection of medical visits performed; (3) to point out the need to increase the collaboration between forensic doctors, ethnopsychiatry experts, lawyers, and cultural mediators; (4) to show the collected data about correlation between medicolegal certificates and judgment of Italian territorial commissions; and (5) to present new operational proposals; that is, define new guidelines for torture assessment, starting from the Istanbul Protocol.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how sociopolitical conditions and processes shape the work of forensic scientists in this context, explaining the complexity of working in the current system, pointing out the need for a new approach to the evaluation of mistreatments and torture, going beyond the past protocols in order to respond to new sociopolitical needs, and explaining the importance of a new approach in light of the data that has been collected.

From May 2018 to July 2019, 93 asylum seekers were visited (most of them provided by local authorized community and health care units for immigrants). Approximately half of these were supported by social workers, psychologists, and lawyers who work in the extraordinary reception centers of the Sicilian island, while the approximately other half were sent by the Human Rights Legal Clinic of Palermo University. The asylum seekers were directed to medical-legal assessment and were subjected to a long audit that included the presence of the cultural mediator and the psychologist after they signed (informed consent) documents. The interview included a long anamnesis: family history (not only about health but also about relational life); schooling; past and present medical history (focusing on traumatic events, discriminating accidental events from abuse and/or torture). A separate section was dedicated to the abuse and torture suffered in Libya.

During the audit, subjects explain in detail: the means and methods that perpetrators used, the circumstances (location, for example, a prison/ghetto) and frequency; in this phase, the presence of the psychologist is very important in order to contain the risk of retraumatization. After the interview, the victims were subjected to objective structured clinical examination and photographic collection of scars. In relation to the needs of the case, radiological assessments (Magnetic Resonance Imaging [MRI], X-ray, ultrasound), specialized medical assessments (urology, otorhinolaryngology, dentistry, maxillofacial surgery, plastic surgery, neurology, gynecology) and non-medical assessments (anthropology and experts in sociology and transcultural psychology of gender identity) were requested. Researchers collected all the elements and wrote a report to send to the local governmental commission, while taking into account the Istanbul Protocol.<sup>1</sup>

Of the total number of asylum seekers assessed, 12 were women, 77 were men, and 11 were unaccompanied foreign minors. The countries of origin were mainly from the African continent: Nigeria, Niger, Senegal, Gambia, Libya, Guinea, Ghana, Ivory Coast, Somalia, Eritrea, Ethiopia, Sierra Leone, Benin, Cameroon, Liberia, Guinea Bissau, Guinea Conakry, and Bangladesh. Of the total number of asylum seekers, 32 have obtained international protection (12 by territorial commission; 20 by judges of the courts), in detail: 9 humanitarian protection, 1 subsidiary protection, 1 special case protection, 22 refugee status; of the remaining 54 subjects, 30 are awaiting the judgment of the court and there is no news on 28 because they were shifted in extraordinary reception centers in other regions of Italy. The data collected explain the need to prefer the medical-legal evaluation of the asylum seeker in a multidisciplinary context, not only in a medical context but also social and legal, pointing out the importance of the dialogue between forensic experts and lawyers to build a new protocol adapted to these new socio-political needs.

### E37 “V for Vendetta”: A Hidden Revenge Murder

*Alessandra Radogna, MD, University of Foggia, Legal Medicine, Foggia 71122, ITALY; Stefania C. Bello, MD, Ospedale Colonnello D’Avanzo, Foggia 71100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Lorenzo Spagnolo, MD\*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Maria Silvestre, MD, Section of Legal Medicine, University of Foggia, Foggia 71122, ITALY; Michela Ferrara, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY*

---

**Learning Overview:** The goal of this presentation is to demonstrate the relevance of a complete crime scene investigation and the meticulous postmortem analysis to define the differential diagnosis between suicidal or homicidal hanging.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by giving an useful example of the meticulous forensic approach to conduct during crime scene investigation and how it must be combined with a following multidisciplinary investigation.

In the literature, hanging has been reported principally as a suicidal modality or also as an accidental death. Homicidal hanging is exceptionally rare. The characteristics of ligature marks can be very important to distinguish between a suicidal or postmortem hanging but it cannot be the only nor the main element of discrimination. This presentation illustrates a failed attempt to hide a violent murder in a suicidal hanging, showing the importance of a complete and multidisciplinary forensic investigation.

A 48-year-old Tunisian laborer was found lifeless next to a farmhouse, suspended by two ropes wrapped around his neck at one end and anchored on a metal rod to the other, which was itself placed between two concrete poles. The victim’s head was covered by clothes. The local prosecutor requested the presence of the forensic team to perform a complete crime scene investigation. At the crime scene, policemen found a blood-stained stick in the farmhouse and drag marks on the ground around the house and next to the corpse.

The external examination was confusing: the body was covered by purple bruises, probably caused by an external blunt force trauma. Some typical signs of a suicidal hanging (such as the double ligature mark around the neck, swollen face, and protruding tongue) were also present. The Computed Tomography (CT) scan demonstrated multiple fractures of the facial bones and of the third cervical vertebra. At the autopsy, diffuse subarachnoid and intraventricular hemorrhages and multiple rib fractures were found. Tissues of the neck revealed diffuse hemorrhagic areas at subcutaneous tissues and at the left sternohyoid and mylohyoid muscles.

The histological examination, performed using Hematoxylin-Eosin (H&E) staining, revealed poly-visceral stasis in all samples; brain samples showed extensive subarachnoid and intraventricular hemorrhages and cytotoxic and vasogenic edema. The lung specimens demonstrated a massive pulmonary edema. The histological examination of ligature-marked skin and of cervical muscle samples revealed a massive presence of erythrocytes. The same skin samples were also studied with immunohistochemical technique using anti-CD15, anti-tryptase and anti-IL15 antibodies, that appear to be reliable parameters in the determination of ligature mark vitality. Results showed a dermal strong positivity to CD15, tryptase, and IL-15 in the marginal zones above and below the hanging marks. Toxicological examination revealed alcohol in the blood (154.91mg/dL).

According to these findings, the cause of death was attributed to homicidal hanging. In fact, despite multiple and massive blunt injuries on the head and thorax, the victim was alive at the time of hanging, because of the vital reaction of the ligature mark. Afterward, police identified the murderer, a Tunisian man, retired from the Foreign Legion. He revealed he had hit the victim with kicks and punches, then with several sticks and wooden shelves. At last, he hanged him to simulate a suicide. He then reported murdering the victim as revenge for all the mistreatment he had suffered by the victim during the period they passed together in the Foreign Legion. Indeed, the police discovered that the victim was a senior military officer in the Legion and the murderer was only a soldier.

In conclusion, the use of hanging to commit a homicide is very rare and a difficult interpretation finding for a forensic pathologist. In fact, the vitality of the ligature mark leads to a suspicion of suicide; generally, homicidal hanging was used in the past for executions, and it is really difficult to suspend a person against his will. In this case, it was possible to perform a murder because the victim was stunned by the alcohol and blows. The complete crime scene investigation conducted allowed finding the blunt instrument dirty with the victim’s blood, the drag marks of the corpse; combined with a complete postmortem investigation, this prevented forensic pathologists from making mistakes.

#### Homicidal Hanging, Forensic Approach, Differential Diagnosis

## E38 Killer Tractor: A Forensic Methodological Approach in Work-Related Deaths

*Lorenzo Spagnolo, MD\**, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; *Pietrantonio Ricci, PhD*, University of Catanzaro, Catanzaro, ITALY; *Alessandra Radogna, MD*, University of Foggia, Legal Medicine, Foggia 71122, ITALY; *Stefania De Simone, MD*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Michela Ferrara, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Luigi Cipolloni, MD, PhD*, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY

**Learning Overview:** The aim of this study is to present a careful forensic methodological approach to be performed in cases of work-related deaths due to polytrauma. A case of death due to a tractor equipped with a mechanical cutter is hereby presented. Attendees will be shown how crime scene investigation elements and macroscopical findings were used to reconstruct the dynamics of the accident and to identify the cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the fundamental importance of combining a complete forensic methodological approach with crime scene investigation and a subsequent careful autoscopic examination in the case of work-related accidents with significant trauma. The autopsy should be based on the systematic evaluation of the vascular axes close to the lesions in order to highlight the source of the bleeding and attribute the correct cause of death. Given the proper cause of death, the association with the elements of the crime scene investigation allows the reconstruction of the accident dynamics with the final aim of highlighting critical issues in the security protocols.

One morning a 60-year-old man went to work on a farm where he had to mill olives after collecting them on a tractor with a mechanical cutter. Suddenly, the man got off the tractor and reached the front portion of it, getting sucked into the blades of the cutter. Shortly after, a colleague passing by noticed the man stuck in the blades and immediately called the ambulance. The medical staff quickly reached the accident site and positioned tourniquets at the lower limbs of the man, practicing a massive infusion therapy. Despite their efforts, the man died shortly after.

The crime scene investigation has highlighted that the tractor had the first gear engaged and the cutter indicator light turned on. Near the cutter and among its blades, multiple fragments of fabric similar to that of the victim's trousers were found in the proximity of a large pool of blood. At this point, the corpse was removed and a preliminary external inspection was carried out, confirming the presence of multiple and polymorphic lacerations located at various portions of the body, especially on the lower limbs. Particularly, two lesions appeared to be deeper, the first located at the upper third of the right thigh, the second located at the middle third of the left leg where it determined the nearly complete amputation of the lower third and the foot. For a complete definition of the cause of death, an autopsy was then ordered by the judicial authority.

The forensic investigation proceeded by single anatomical layers and highlighted the presence of areas of hemorrhagic appearance of the muscles underlying the abrasions and bruises. No traumatic lesions were found at the gross examination of the organs. The evaluation of the two deepest wounds was performed by proceeding equally to the dissection for single anatomical layers. The main vascular branches of the examined districts were then isolated. The evaluation of the left femoral artery and vein excluded the presence of laceration of the vessels, which were in any case characterized by widespread hemorrhagic appearance of the external walls. The evaluation of the left anterior and posterior tibial arteries and veins showed a complete laceration of both vessels. The histopathological examinations carried out later confirmed the generalized blood loss, therefore the cause of death was attributed to methemorrhagic shock due to the complete lesion of the main arteriovenous branches of the left leg. This data, together with the elements of the crime scene investigation, allowed the reconstruction of the dynamics of the accident, consisting of the victim's trousers getting caught in the blades of the cutter, which caused the death of the man.

### Polytrauma, Vascular Lesion, Work-Related Death

### E39 A Kindle Dinner With a Friend: Great Start, Bad Finish

*Alessandra Radogna, MD, University of Foggia, Legal Medicine, Foggia 71122, ITALY; Marco Savito, MD, Viale Degli Aviatori 1, Foggia 71121, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; Irene Riezzo, MD, PhD, SC di Medicina Legale, Foggia 71100, ITALY; Marcello Rendine, DBA, Department of Forensic Pathology, University of FOGGIA, Foggia 71100, ITALY; Michela Ferrara, MD\*, Department of Forensic Pathology, Foggia 71122, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY*

**Learning Overview:** The goal of this presentation is to highlight how the forensic pathologist needs advanced technology and the expertise of specialists in other forensic fields, without which solutions of crime scenes would not be found.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the importance of a multidisciplinary approach during a crime scene investigation.

From a review of the literature, it emerges how crime scene investigations give the best results when conducted by a multidisciplinary team. This case reports an example of how, during the crime scene investigation, the intervention of the police with only the forensic pathologist would not have been sufficient for the solution of the case. This case regards a Romanian man found dead in an abandoned cottage. Inside the cottage, several rooms were inhabited and in deplorable hygienic conditions. The corpse was found lying on the floor in a supine position at the center of one of these rooms. His clothes were dirty with blood. His head rested on a pillow also covered with blood. Other bloodstains were found on the sheets near the corpse and on the floor at the left of the victim. One of these stains reproduced a shoe sole and except for these stains, the messy room was clean of blood. The inspection of the other rooms was unremarkable, except for the last ambient where a plastic bowl, containing clothes immersed in a reddish liquid, was found. It was the scene of a murder, but nothing more than the body had been found. Thus, the prosecutor requested the intervention of the forensic team, with the K-9 dog unit and Obelux CR9 LED forensic lights. The team inspected all rooms, starting from the victim's body. This inspection revealed many biological liquid stains that, starting from the corpse, continued on the corridor walls and in the next room. In this room, the dog unit found two hidden wooden sticks, but when seen with CR9 forensic light, they turned out to be covered with biological liquid at one end. Clothes in the plastic bowl were also examined with CR9 forensic light and they too were covered with biological fluid, a sample of which was taken and analyzed by the geneticist.

The external examination partially confirmed the suspicion: the victim's chest and abdomen were covered by stamping bruises, which exactly matched in form and dimension the two wooden sticks. The entire body also presented extensive bruising and laceration due to hitting and kicking, especially to the face. The victim had multiple bilateral serial rib fractures and a pneumothorax. The final confirmation came thanks to the genetic investigation carried out on a suspect arrested a few days later by policemen. The forensic geneticist used swabs, both subungual and palmar, on suspect's hands. He also studied the bloodstain's DNA found on the suspect's trousers and even on the T-shirt found in the plastic bowl in the cottage. The genetic exams showed negative results of subungual swabs and positive palmar swabs for the victim's DNA. The biological stains on the trousers and T-shirt were blood from which was obtained mixed profiles linked to those of the victim and the suspect. The suspect, also a Romanian man, then revealed that he illegally lived in the cottage with the victim and that night after getting drunk together they started beating themselves until death. In conclusion, the current general tendency of the forensic community during crime scene investigations must necessarily hold a multidisciplinary approach, making use of technologies and collaborating with professional figures, every day, as this is indispensable for the correct solution of a case.

### E40 Hanging Games: An Unusual Case of Accidental Hanging in a Child

Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; Alessio Marangelli, State Attorney General of Foggia, Foggia 71122, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; Luigi Cipolloni, MD, PhD, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY

**Learning Overview:** The goal of this presentation is to show that in cases of hanging, immunohistochemical markers should be used in order to reach the diagnosis of vitality of the ligature marked skin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing a rare case of accidental hanging of children and the use of new immunohistochemical markers to determine the vitality of the ligature mark.

Hanging is a form of ligature strangulation in which the force applied to the neck is derived from the gravitational forces of the body or a part of the body. Accidental hanging in childhood, although rare, has been reported worldwide. Hanging is an important cause of homicidal and suicidal damage in adults, but in children, it is usually accidental. According to available data, strangulation ranks fourth for causes of accidental deaths in children, following roadside accidents, drowning, and burns.

Some studies have shown that 80% of deaths by accidental hanging involved children under ten years old. The most common tools associated with these accidents are clothes or personal items, while young children explore the environment, unconscious of potential dangers. In cases of accidental hanging, it is more common to find an incomplete hanging; that is, when a part of the body is in contact with the ground. From the external examination, it is possible to identify the vitality characteristics of the ligature mark, such as small petechiae, serous vesicles, and hemorrhagic crests. During the autopsy, the hemorrhagic infiltration of the subcutaneous tissue and the neck muscles could be evident.

This case concerns a 9-year-old boy who was found hanged in the garage of his country house, partially suspended with the handle of a sack around his neck. According to the circumstantial data, the local prosecutor called the forensic team to investigate the crime scene in the suspect of *culpa in vigilando* of his parents. Indeed, the child was found unconscious, with his head in the handle of the sack, by his brother. The latter called their mother, who moved the son from the handle to try to resuscitate him, uselessly. During the crime scene investigation, the aforementioned sack was examined. This sack was on a wooden platform and had four blue jute handles. The handle where the mother found the child, according to the police data, was a distant 104cm from the upper edge of the platform below the sack. The platform had a height of 12.5cm.

The body of the boy was found in a sitting position, with the legs touching the ground. The child was 136cm tall. Ligature marks encircling the neck with bruises were described at the external examination. Other injuries were not present on the corpse, and only subconjunctival petechiae were described. Traumatic injuries were excluded after external examination and Computed Tomography (CT) scan investigation. The autopsy showed diffuse hemorrhagic infiltration of the neck muscles, pleural and pericardial petechiae, and marked pulmonary emphysema. No fractures of the hyoid bone or laryngeal cartilages were found. A routine histopathological study was performed using Hematoxylin-Eosin (H&E) staining. The microscopic observation of the brain specimens showed the presence of vasogenic and cytogenic edema; the lung specimens demonstrated massive endo-alveolar edema. The histological analysis of other organs was unremarkable. The skin specimens from the ligature mark presented the formation of intra-epidermal mild leukocytes reactions. Also, immunohistochemical investigation of skin samples was performed using antibodies anti-tryptase, fibronectin, TNFalpha, IL-6, IL-8, IL-10, MCP-1, IL15, IL1beta, CD45, CD4, CD3, CD8, CD68, CD20, CD15, and Langerhans cells to confirm the vitality of reactions in the ligature mark. The police investigation was oriented to an escape of the child from the house to the garage, probably for a joke. The prosecutor complied with this theory, supported by the forensic evidence of a rapid death by asphyxiation, and declared the parents innocent.

#### Accidental Hanging, Ligature Mark, Immunohistochemical Markers

### E41 The New Italian Law on Legitimate Defense: New Scenarios on the Crime Scene

*Maria Silvestre, MD\**, Section of Legal Medicine, University of Foggia, Foggia 71122, ITALY; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Francesco Sessa, MS\**, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; *Mauro A. Ciavarella, University of Foggia, Forensic Department, Foggia 71121, ITALY;* *Pierrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY;* *Luigi Cipolloni, MD, PhD, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY*

**Learning Overview:** The objective of this presentation is to analyze the innovative aspects of the new Italian law on legitimate defense approved in the Italian Senate on March 28, 2019, and entered into force beginning May 18, 2019.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by focusing on a much-discussed topic, the legitimate defense. Particular attention will be paid to the new Italian law and to the new changes and perspectives emerging in this legislative framework.

In the Italian legal system, self defense occurs if an individual is in imminent danger and must defend him or herself when no time is available to contact local authorities. Self defense should not be confused with revenge. The self defense institution is governed by Article 52 of the Criminal Code, entitled “legitimate defense” which reads: “It is not punishable who has committed the fact to have been forced by the need to defend a right of his own or others against the current danger of an unjust offense, provided that the defense is proportionate to the offense.” For a self defense instruction, there must be the sudden unjust onset of danger caused by unjustified aggression. The danger must be an immediate threat to either self or family. The amount of force used in self defense must be proportional to the aggression. The modification of Article 52 of the Italian Criminal Code extended self defense to include guests in another person’s home, a commercial residence, or in protection of personal belongings. It further allows the defender to use a weapon or other item to defend self or others.

The new Italian law, which consists of nine articles, incorporates traditional home defense and crimes against property. Article 1 of the law states that “there is always a proportional relationship” in cases of legitimate defense at home or in the workplace if someone “uses a legitimately held weapon or other suitable means to defend: a) their own or others’ safety; b) own property or that of others, when there is no resistance and there is danger of aggression.” Further, the law states, ‘he always acts in a state of legitimate defense who performs an act to reject the intrusion carried out with violence or threat of use of weapons or other means of physical coercion.’ Article 2 protects a person from penalty if they acted for the safety of themselves or others.

The law increases penalties for the offenses of home invasion theft, robbery, or housebreaking. The law excludes civil compensation for injury the home invader may have incurred, even if acquitted of the offenses in criminal proceedings. The law also allows for reimbursement or expenses for those acquitted based upon self defense. Finally, the law prioritizes the cases in the judicial system.

A recent example that used the new law was a recent argument between two neighbors, one of which murdered the other with a firearm. The assailant was acquitted because the decedent invaded the neighbor’s home and destroyed windows using a golf club. In this case, the courts found that the aggression and need for self defense were justified, in compliance with the new law.

#### Italian Law, Legitimate Defense, Crime Scene

## E42 Post-Coital DNA Recovery in Minority Proxy Couples

Patricia M. Speck, DNSc\*, Hoover, AL 35226; Erin K. Hanson, PhD, University of Central Florida, Orlando, FL 32816; John Ballantyne, PhD, University of Central Florida, Orlando, FL 32816-2366; Peng Li, PhD, University of Alabama at Birmingham School of Nursing, Birmingham, AL 35290; Simone Nouer, PhD, University of Tennessee Health Science Center, Memphis, TN 38103; Pamela D. Connor, PhD, University of Tennessee Health Science Center, Department of Preventive Medicine, Memphis, TN 38105

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the challenge faced in the timing of post-coital collections in extended intervals.

**Impact on the Forensic Science Community:** Combining the previous post-coital study data with the minority post-coital study, using enhanced Y-chromosomal Short Tandem Repeat (Y-STR) methods, DNA detection is possible for up to nine days in 65%–70% of reproductive-aged participants. Additionally, this study discovered a 20% increase in allele detection when swabs were combined. The recommendation is consideration for triage of delayed post-coital samples by forensic laboratories.

Minorities are less likely to report rapes. The Post Coital DNA Recovery (PCDR) study (2009–2014) subjects were White (93%) where expanded collection times were not generalizable to minority populations. Aims: (1) What is the time period for collection of post-coital DNA in minority women using Y-STR laboratory methods? and (2) when compared to the former study sample, what are the physiological conditions, factors, or activities in minority couples influencing post-coital DNA recovery? The design includes mixed-methods duplication perfected in the first study, embracing descriptive and inferential techniques. Aim 1 analysis used in PCDR in Minority Proxy Couples (PCDR-M) data only. Aim 2 combined data from both PCDR and PCDR-M studies. Combined, DNA recovery, a binary outcome accounting for repeated methods in population regression analysis, used Generalized Estimating Equation (GEE) methods.

To answer the first aim with PCDR-M data, studies data combined to test association of minority to non-minority allele detection and found there is no association using standard methods ( $p=0.6768, 0.9015, 0.4687, 0.7537$ ) or enhanced methods ( $p=0.3283, 0.4166, 0.5981, 0.3304$ ) across all times and locations, implying no allele difference between minority and non-minority populations. Fifty-three minority couples ( $N=106$ ) completed the complex PCDR protocol. The laboratory accepted 39 PCDR-M kits, but rejected 16 for allele levels, 1 for duplicate, and others for PCDR protocol non-adherence. Of the 23 (59%) kits accepted for study analysis, 19 had full and expected allele levels for baseline and post-coitus allele levels (4-, 7- or 9-days post-coitus) and 4 had 1 timepoint removed, resulting in 130 samples possible for analysis (46 4-days, 44 7-days, and 40 9-days). Of the 130 samples, the standard Y Filer® Plus method revealed 64 (48%) had at least one allele, and 66 (52%) had no detectable alleles. The enhanced Y Filer® method revealed 98 (75%) had at least one allele. Standard testing revealed 48% allele detection, and enhanced testing revealed 75% allele detection, duplicating the results from the first PCDR study and providing homogeneity necessary for comparison of the two data sets in Aim 2. To answer the second aim, data from study kits in the first PCDR study were combined with the PCDR-M study data for analysis, revealing the two populations were homogenous and met the inclusion criteria. The combined kits ( $N=89$ ) and potential 356 samples, 66 from PCDR and 23 from the PCDR-M, had full and expected allele levels for baseline and post-coitus allele levels (4-, 7-, or 9-days post-coitus). Standard methods revealed at least one allele detected at baseline (22.09%), 4-days (52.87%), 7-day (29.07%), and 9-day (33.33%). Conversely, standard methods revealed no alleles detected at baseline (77.91%), 4-days (47.13%), 7-day (70.93%), and 9-day (66.67%). Enhanced methods revealed at least one allele detected at baseline (63.64%), 4-days (91.01%), 7-day (78.41%), and 9-day (82.56%). Conversely, standard methods revealed no alleles detected at baseline (36.36%), 4-days (8.99%), 7-day (21.59%), and 9-day (17.44%).

The first PCDR study developed a validated *in vivo* study protocol and data model for establishing a valid scientific foundation for understanding extended interval post-coital DNA recovery and influencing variables of menses and hormone birth control use, which were duplicated with the PCDR-M study. Combined data also supports a single regional swabbing practice change—cervix and posterior fornix. Both study results validate collection from victims with expanded post-coital intervals, where laboratories use individual capacities and current science to determine which laboratory method is best suited for the submitted sample. The generalized findings to minority populations of victims increased the evidence for decisions made about DNA collection timing, recovery, and influences, with implications for improving laboratory capacities and algorithms for testing choices, minority victim engagement, and justice for the victim and accused alike.

### Post-Coital DNA, Y-STR, Rape

### E43 A Ten-Year Review of Opioid-Related Deaths at West Tennessee Regional Forensic Center: 2007–2017

Haley M. St. John, BS\*, University of Tennessee Health Science Center, Memphis, TN 38103; Juliette Scantlebury, MD, St Louis City Medical Examiners' Office, St. Louis, MO 63103

**Learning Overview:** The goal of this presentation is to analyze autopsy data from the West Tennessee Regional Forensic Center (WTRFC) from 2007 to 2017 to gain a better understanding of the effects of the opioid epidemic on West Tennessee and the surrounding areas.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying trends in race, age, gender, location, types of opioids, and drug combinations involved in opioid-related deaths in West Tennessee. Understanding the changing trends of opioid abuse is critical in order to predict the trajectory of the epidemic moving forward.

Prescription opioid deaths have tripled since 1999. Opioid overdoses kill 115 Americans per day on average.<sup>1</sup> Prior to 2014, prescription opioids were the primary driver of opioid-related mortality. In recent years, the United States has seen a steady decline in the rate of opioid prescriptions. At the same time, there has been a significant increase in the number of deaths attributed to non-prescription opioids, such as heroin, illicitly manufactured fentanyl, and fentanyl analogs. In 2017, among 70,237 drug overdose deaths nationally, 47,600 (67.8%) involved opioids, with increases across age groups, racial/ethnic groups, and county urbanization levels in multiple states.<sup>2</sup> The opioid epidemic is especially profound in Tennessee, which had the third-highest opioid prescription rate in the country in 2017 and an opioid-related death rate of 19.3 deaths per 100,000 persons, compared to the national average of 14.6.<sup>3</sup>

The WTRFC Death Investigation and Decedent Information database was searched for all deaths that listed opioid toxicity in the cause of death during the ten-year period from 2007 to 2017. Data gathered included age, sex, race, day, month, and year of the incident, location of death, manner of death, and cause of death.

Prescription opioids, such as methadone and oxycodone, were most common in the earlier half of the study period, but were quickly overshadowed by the rise in heroin beginning in 2012. The number of overdose cases involving fentanyl, most likely illicitly manufactured, rose precipitously beginning in 2015, spiking from 8 cases in 2014 to 51 in 2015, and peaking at 120 cases in 2017. Fentanyl analogs, such as acetyl, furanyl, and despropionyl fentanyl, began to appear as a cause of death in 2015 and 2016. Benzodiazepines were the most common class of drugs combined with opioids (46.3% of opioid-related deaths in 2016), followed by cocaine, ethanol, and amphetamines. Out of 1,344 cases of opioid-related deaths in 2007–2017, a total of 838 were male (62.4%) and 506 were female (37.6%); 1,108 were White (82.4%) and 231 were Black (17.2%). The most prevalent group across all ten years was White men, which comprised 50.8% of cases. Although Shelby County has a majority Black population, the White population was the most prevalent racial group involved in opioid-related deaths. In 2007–2010, the most prevalent age group involved in opioid-related deaths was ages 45–54. In the second half of the decade, people aged 25–34 were the most prevalent group.

In conclusion, illicitly manufactured opioids have become the new face of the opioid epidemic as opioid prescription rates have steadily declined across the country. Understanding the changing trends of opioid abuse is critical in order to predict the trajectory of the epidemic moving forward.

## E44 Epidemiological and Toxicological Profile of Homicide Victims in a Legal Medicine Unit in Brazil

Yara V. Lemos, MS\*, *Medical Legal Institute of Minas Gerais, Belo Horizonte, Minas Gerais 30510160, BRAZIL*; Alberto J.A. Wainstein, *Faculdade Ciências Médicas de Minas Gerais, Belo Horizonte 30110-130, BRAZIL*; Larissa M. Savoi, *Faculdade Ciências Médicas de Minas Gerais, Belo Horizonte 30110-130, BRAZIL*; Ana P. Drummond-Lage, *Faculdade Ciências Médicas de Minas Gerais, Belo Horizonte 30110-130, BRAZIL*

---

**Learning Overview:** After attending this presentation, attendees will understand the epidemiological and toxicological profile of homicide victims in Brazil.

**Impact on the Forensic Science Community:** This presentation will impact the forensic scientific community by highlighting what type of substance (legal or illegal in the context of a Brazilian legal medical unit) was found in the victim at the time of death. This presentation will also address the differences in substance types and the epidemiological profile of the victim. Finally, this presentation will study the seasonality of homicides and requests for drug testing.

Some studies point to an increase in homicide in Brazil since the end of 1970.<sup>1</sup> In recent years, there has been general stability in the homicide rates in Brazil, but considerable heterogeneity between the regions and various states of this continental country. The homicide rate in Brazil, per year, is 28.9:100,000 inhabitants, with gunshots being the most common cause (71.9%)<sup>1</sup>. Minas Gerais, the focus of this study, is a state located in Southeastern Brazil. It ranks as the second most populous state, third largest by Gross Domestic Product (GDP), and fourth largest by area. The state's capital and largest city, Belo Horizonte, is a major urban area and the sixth largest municipality in Brazil, but its metropolitan area is the third largest in Brazil with just over 5,500,000 inhabitants. The state has a homicide rate of 21.7:100,000, 71% by gunshot.<sup>2,3</sup> The use of illicit drugs is a risk factor for victimization by lethal violence and is frequently found in autopsies of homicide victims. This study aimed to evaluate the profile of these victims.

A cross-sectional retrospective study was performed on 1,382 homicide victims from 2014 for which toxicology had been performed in an Official Forensic Laboratory (Minas Gerais-Brazil). The results revealed a higher proportion of men ( $p=0.003$ ); black/brown skin ( $p < 0.001$ ); firearm history ( $p=0.007$ ); and a lower mean age ( $p < 0.001$ ); 943 homicide victims had a positive toxicology test; 72.2% of the positive tests were for cocaine or benzoylecgonine; 67.7% were positive for Tetrahydrocannabinol (THC) and/or its metabolite; and, finally, 43.1%, were positive for both cocaine and THC.

These findings indicated young Black or mixed race men have an increased risk of homicide. The role of illicit drugs in homicide goes far beyond intoxication as they are directly associated with age, skin color, and gender. These findings point to the importance of investing in social actions, public safety, and efforts to reduce drug use in this at-risk population.

## E45 Characterizing Deaths Related to Hurricane Michael Using Vital Statistics Data

Samuel P. Prahlow, MPH\*, Florida Department of Health, Tallahassee, FL 32399; Heather Rubino, PhD, Florida Department of Health, Tallahassee, FL 32399; David Atrubin, MPH, Florida Department of Health, Tallahassee, FL 32399; Allison Culpepper, BS, Florida Department of Health, Tallahassee, FL 32399

**Learning Overview:** After attending this presentation, attendees will: (1) understand the process utilized by the Florida Department of Health (FDOH), Bureau of Epidemiology, to identify potential cases of death due to a natural disaster, such as a hurricane; and (2) recognize ways in which the partnership between public health and the death investigation community can be strengthened.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an example of collaborative interaction between the medical examiner system and death data in public health information systems, such as syndromic surveillance systems.

In October 2018, Hurricane Michael was the first Category 5 storm to make landfall in the contiguous United States since 1992.<sup>1</sup> This storm quickly developed and struck the panhandle of Florida. The storm resulted in 40 deaths in Florida, with a variety of manners of death and causes of death. These deaths were reported in the media for longer than three months post-storm.<sup>2</sup>

The FDOH is responsible for surveillance of events of public health significance. FDOH utilizes the Electronic Surveillance System for the Early Notification of Community-Based Epidemics (ESSENCE-FL) to monitor for events of public health significance and maintain situational awareness. ESSENCE-FL contains data from eight information sources. Data from Emergency Department (ED)/Urgent Care visits (UC), poison control calls, and death records are used in post-storm surveillance. ESSENCE-FL is one of the most robust syndromic surveillance systems in the country. These data are utilized for a number of public health program areas.

Before, during, and after Hurricane Michael, ESSENCE-FL data were leveraged daily to monitor visits at EDs, UCs, and Disaster Medical Assistance Team (DMAT) clinics. Post-storm electronic media reports of deaths attributed to the storm were tracked using Google® Alerts, which were monitored immediately post-storm through mid-March 2019 by FDOH to understand the health impacts of the storm. Death record data were utilized to review media-reported deaths related to Hurricane Michael as reported by the office of the medical examiner.

The media reported 40 deaths related to the storm; 8 were unable to be identified in the death record data. The decedents ranged in age from 24 to 94 years, with a median age of 66 years. Eight decedents were female and 32 were male. Thirty-four were white, and 6 were African American. Education level was reported as less than high school for 6 cases, high school or equivalent for 17 cases, some college or associate degree for 9 cases, bachelor's degree for 6 cases, 1 case had a master's degree, and 1 case's education status was unknown. Most decedents were Florida residents, but four decedents were residents of other states. The Manners Of Death (MODs) for these reported deaths were accident (19), natural (17), suicide (2), and homicide (2). Autopsies were performed on 23 of the 40 cases.

There was a higher incidence of deaths (58%) in those who had lower education levels (i.e., high school or less). Those with lower levels of education typically have a lower income, which impacts their ability to prepare or evacuate for a coming storm.<sup>3</sup> This suggests an opportunity to improve public health messaging and support for those with a lower education status. In addition to providing some of the details of the deaths, this report will highlight areas of intersection between public health data and medical examiner/death investigation information.

This event illustrates the importance of collaboration and coordination between medical examiners/death investigators and public health practitioners. Increased collaboration in the future via electronic record data sharing would improve the timeliness of reporting death data of significance. This will result in decreased delays in public health interventions immediately following a disaster. Syndromic surveillance systems like ESSENCE-FL are able to facilitate near real-time data sharing and allow better access to records for other public health use purposes, such as opioid overdose fatalities and injury prevention.

## E46 Modeling Postmortem Submersion Interval (PMSI) Estimation From the Microbiome of Bone in a Freshwater Lake

Claire M. Cartozzo, MS\*, Richmond, VA 23220; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how microbial community changes across Accumulated Degree Days (ADD) can be used to aid medicolegal death investigators and forensic pathologists when skeletal remains are recovered from freshwater lake environments.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing proof of concept for the use of microbial succession on skeletal remains submerged in a freshwater lake to predict the long-term PMSI.

Understanding decomposition and its associated factors is imperative to aid medicolegal death investigators and forensic pathologists in estimating the Postmortem Interval (PMI) on land or the PMSI in water. Because human remains deposited in aquatic environments are exposed to conditions distinct from those of terrestrial environments (i.e., water salinity, temperature, depth, tides, currents, pH, aquatic scavengers, floating or sunken debris, oxygenation, etc.), traditional PMI methods (i.e., invertebrate succession) are not transferable. With advancements in next-generation sequencing technology, improved bioinformatic pipelines, and the identification of changing microbial communities in animal models, recent studies have sought to utilize bacterial succession as a method for estimating PMSI. While initial studies provide a foundation for understanding microbial communities in aquatic decomposition, their applicability to humans is limited due to the fundamental differences between aquatic (e.g., salmon) and terrestrial organisms.<sup>1</sup> In addition, studies performed with porcine remains have not focused on long-term PMSI estimation extending to the skeletal stages.<sup>2,3</sup>

Fresh pig (*Sus scrofa*) bones ( $N=100$  rib and  $N=100$  scapula samples) were obtained from a butcher. Bones were placed in cages attached to a flotation device and submerged in Henley's Lake, White Hall, VA, from November 2016 to June 2018. Water temperature and environmental parameters (i.e., pH, Dissolved Oxygen [DO], salinity, etc.) were recorded using waterproof loggers and a YSI® Sonde, respectively. Every 250 ADD, five scapulae, five ribs, and 500ml of water were collected and stored at either -80°C or 4°C until processed. Water samples were filtered on 0.22µm filters. Bone samples were cut and ground into a powder using liquid nitrogen in a mortar and pestle. DNA from filters and powder was extracted and purified using ChargeSwitch® gDNA Plant Kit and DNeasy® PowerClean Pro Cleanup Kit, if necessary. Following the protocol established by Kozich et al., sequencing-by-synthesis of microbial 16S recombinant DNA (rDNA) variable region 4 was performed via Illumina's® MiSeq® 2X300 paired-end sequencing.<sup>4</sup> Data analysis and visualization was completed via the MiSeq® mothur SOP, mothur version 1.35.9, and R studio.<sup>5</sup>

Preliminary analyses indicate significant differences in bacterial communities among sample types (i.e., rib-water-scapula). For rib and scapula samples, phylum-level relative abundances differed significantly across ADD. Similarly, beta-diversity (Bray-Curtis) successional patterns were visible in ordinated space for both sample types. Spatial ordination was correlated with environmental parameters and ADD. Additionally, bacterial communities identified on scapula and rib samples differed significantly with ADD. With regard to alpha diversity (shannon), rib and scapula samples demonstrated a curvilinear relationship with ADD; therefore, fifth and fourth polynomial regression models were applied, respectively. Based on these results, bacterial succession patterns were used to develop a long-term PMSI estimation model.

### E47 Entrance and Exit Hole Characteristics: Bullet Types, Substrates, and Firing Distance

*Brienne Lukes, MFS\*, Millennium Health Inc, San Diego, CA 92127; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037*

---

**Learning Overview:** The goals of this study focused on the ammunition, the target substrate, comparing the shape of the entrance and exit holes, and the diameter of the entrance bullet hole from two firing distances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating the correlation between class characteristics of bullets and the diameter of entry and exit bullet holes in different substrates. This presentation will also help the forensic science community by providing guidance for further firearms research.

This study was designed to compare the shape and diameter of bullet entrance holes fired from two different distances. The comparison concentrated on ammunition and target substrate. A Smith and Wesson® SD9VE 9mm Luger® firearm was used in this study. Three types of bullets used were: Ruger® (ARX), Federal® (FMJ), and 2<sup>nd</sup> Amendment® (HP). Target materials were bicycle inner tubes, aluminum, and glass bottles. Three test fires were performed for each bullet type into each substrate at distances of five and ten feet. A total of 51 test fires were performed. The firing and firearm data were analyzed using the Analysis of Variance (ANOVA) and Student *t*-tests. Significance was determined when the  $p < 0.05$ .

The results showed that there was a significant difference in the size of the entrance hole when comparing a hollow point bullet fired into the three different substrates. There was a significant difference when using the different types of ammunition and comparing the bullet hole sizes in the various substrates. There was no significant differences when comparing the size of the bullet entrance and exit holes when these were obtained at the two different firing distances. Ruger® (ARX) bullet holes were more irregularly shaped than the circular-shaped bullet holes from the Federal® (FMJ) and 2<sup>nd</sup> Amendment® (HP). The shape of the 2<sup>nd</sup> Amendment® (HP) bullet holes in the rubber and aluminum were circular and symmetrical, while the bullet holes in glass were relatively rounded but irregularly shaped. In some of the target substrate, there were visual differences noted between the various bullet types used, but this was not investigated in the present study. In conclusion, with the increase in criminal use of firearms violence, it is especially important to obtain probative evidence and expert testimony from firearm examiners. It is recommended that using shorter muzzle-to-target distance be investigated in addition to the visual impact on the targets.

## E48 Undergraduate Forensic Physics Education in Turkey

*Aylin Yalçın Sarıbey, PhD\*, Uskudar University, Istanbul 34662, TURKEY; Kemal Akin, BS, Uskudar University, Istanbul, TURKEY; Sevil Atasoy, PhD, Uskudar Üniversitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY*

**Learning Overview:** The goal of this presentation is to provide information about undergraduate forensic physics education in Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with: (1) a brief review of forensic science programs currently offered in Turkey; and (2) a detailed discussion of undergraduate physics education for forensic applications.

The Uskudar University Forensic Sciences Program (UUFS), established under the Faculty of Engineering and Natural Sciences, is the first college-level program in forensic science in Turkey. UUFS offers a natural sciences-oriented curriculum which mainly consists of introductory and advanced level mathematics, statistics, physics, biology, and chemistry courses. Half of the weekly course hours are allocated to laboratory trainings so that students are exposed to concepts, methods, and instrumentation that are commonly used in forensic science. There are also semester-long criminalistics, crime scene investigation, and law courses. The natural science courses are revised for forensic applications and taught as Forensic Mathematics, Forensic Physics, and so on. The program is currently the only available Forensic Science bachelor's program in Turkey. The curriculum satisfies Forensic Science Education Programs Accreditation Commission (FEPAC) standards.

Introductory forensic physics courses are divided into two semesters as Introduction to Forensics Physics I–II with accompanying laboratory sessions for students to gain hands-on experience in the field. The first part of the class focuses on the fundamentals of mechanics and provides theoretical background for forensic applications. Topics covered include: basic measurements, vectors, coordinate systems, Newton's Laws of Motion, conservation of energy and momentum, simple harmonic motion, simple and ballistic pendulum, and the fundamental applications of those topics. Students are equipped with a basic knowledge of physics and take a second course in physics that focuses on the physical basis of devices used during the investigation and evaluation of evidence. The covered topics in the Forensic Physics II class are fundamentals of optics, electromagnetic spectrum, nature of light, and alternate light sources and their applications in the field. UUFS does not consider the undergraduate forensic science degree as the terminal degree; hence more advanced forensic physics courses are provided in the graduate forensic science program.

The UUFS curriculum offers more than 20 elective courses, which enable students to specialize in various fields. These elective courses, such as Ballistic Examination, Shooting Incident Reconstruction, and Forensic Document Examination, helps students increase their knowledge in physics. The physics-based elective courses also have accompanying laboratory trainings; thus, courses include not only underlying physical principles but also direct and indirect applications of the underlying principles.

### Forensic Science, Crime Scene Investigation, Physics Education

## E49 Surgical Fire: A Case Report, Literature Analysis, and Medicolegal Considerations

Salvatore Rocuzzo, MD\*, University of Palermo-Messina, Messina 98124, ITALY; Patrizia Gualniera, University of Messina, Messina, ITALY; Daniela Sapienza, University of Messina, Messina, ITALY; Cristina Mondello, MD, Department BIOMORF, University of Messina, Messina 98123, ITALY; Elvira Ventura Spagnolo, MD, University of Palermo, Palermo 90127, ITALY; Serena Scurria, PhD, University of Messina, Messina, ITALY; Alessio Asmundo, University of Messina, Messina, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the principles of a Surgical Fire (SF), its origin, its development, its consequences, and how to prevent it.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a key aspect of medicolegal implications of SF, analyzing each phase of the event before (propriety of informed consent), during (recommendations of best practices, protocols, and medical liability), and after (entity of lesions, necessity of reactive root cause analysis) the ignition.

SF is defined as fire that occurs in, on, or around a patient undergoing a medical or surgical procedure and is considered a “sentinel event.” Other sentinel events include wrong-site surgery and retained surgical items. These are “never events,” due to potentially serious or fatal consequences.<sup>1</sup> While data and reports published in Italy and Europe are lacking, in the United States, the prevalence of SFs has been estimated at approximately 600 events per year, and the total number of events is probably underestimated. The “fire triangle” theory is utilized for explaining the fire’s origin. Fire is composed essentially of three elements that are always present in the Operating Room (OR): (1) ignition—represented by electrosurgical units, lasers, defibrillators, etc.; (2) oxidizer—oxygen, nitrous oxide, medical compressed air, ambient air, etc.; and (3) fuel—alcohol skin preps, drapes/gowns, gauze/sponges, patient’s hair/skin, Endotracheal Tube (ETT)/nasal cannula, intestinal gases, etc. These devices and components are commonly used in the modern OR, and the complete elimination of fire risk is impossible. The American Scientific Society has provided recommendations of best practices to reduce the risk of SF.<sup>2</sup>

The reported case regards a 65-old woman with suspected thyroid carcinoma recovered in the University Hospital of Messina (Sicily, Italy). The patient was undergoing Video-Assisted Thyroidectomy (VAT) and suffered an SF during the wound closing surgical phase, which involved surgical drapes of the perioperative field. The surgical procedure was under general anesthesia (with ETT and 30% 2/L min O<sub>2</sub> supply). The fire was most likely produced by the ignition of the applied alcohol-based disinfectant (chlorhexidine gluconate) by monopolar electrocautery. Although the fire was promptly extinguished by the OR team, the patient reported disfiguring second- and third-degree burns to the antero-lateral surface of the neck.

An analysis of this case and a literature review suggest the following medical-legal considerations: informed consent must include the risk of this potentially high-grade surgical complication; and establish an Italian national best practice and intra-hospital protocol to calculate the fire risk score during surgery and develop a strategy for effective communication between the OR team (particular attention should be paid to the head/neck and pelvic regions, which are the most frequent regions that involve SF); finally, a reactive root cause analysis of each SF case should be done to collect data to identify health care improvement strategies. Current international best practices/strategies, designed to establish medical malpractice, include a delay of less than three minutes between application of an alcohol-based disinfectant and activation of electrocautery.

### Surgical Fire, Burns, Medical Liability

## E50 Never Trust Appearances: A Case of Screwdriver Homicide

Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Federica Gori, MD, University of Pisa, Pisa 56100, ITALY; Sara Turco, MD\*, Pisa, ITALY; Claudia Giacconi, MD, University of Pisa, Pisa 56100, ITALY; Francesca Iannaccone, Pisa 56123, ITALY; Costanza Filomena, Florence 50036, ITALY

**Learning Overview:** The goal of this presentation is to present an uncommon pattern of injury in a case of screwdriver homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by focusing on the advantages of postmortem Computed Tomography (CT) and autopsy in studying uncommon patterns of injuries.

Lesions of the head caused by screwdrivers, while uncommon, are potentially lethal.<sup>1-4</sup> Skull bones are very resistant and most weapons usually break or bend when hitting the skull. Screwdrivers are much more resilient and are less likely to break or be deflected when striking the skull.<sup>5</sup> According to the literature, skull lesions caused by screwdrivers are most frequent in temporal (28.6%), parietal (23.8%), and orbital (9.5%) areas. The mortality rate of craniocerebral screwdriver injuries is approximately 47.6%. This presentation concerns a reported case of homicide committed by using a screwdriver, found embedded in the posterior part of the neck, simulating a fatal injury of the upper spinal cord. The forensic examination demonstrated that the cause of death had to be searched for elsewhere.

An 89-year-old man tried to commit suicide by jumping from the third floor of his apartment where he lived with his wife, who suffered from neuropsychiatric disorders. He was found still alive and transported to the local hospital, where he died a few hours later. The police entered the apartment where the man lived and discovered his 82-year-old wife lying on the bed with a blood pool under her body and a screwdriver embedded in the posterior part of the neck. The screwdriver was not removed to avoid potential neurologic damage, and she was transported to the hospital where she died a few minutes after her husband. At the apartment, a letter authored by the husband was discovered which begged forgiveness for his actions. No other weapons used on the woman were discovered in the apartment.

An autopsy was conducted on both bodies. The man's cause of death was confirmed as polytrauma due to a fall from height. In the woman's case, the autopsy was preceded by a total body CT, which revealed that the stem of screwdriver didn't hit the spine, but it was embedded in the soft tissue near the third cervical vertebra. Radiological examination revealed several fractures of the cranial bones and brain damage. The screwdriver stem protruded 5cm and, upon removal, was found to have a total length of 13cm. The layer-by-layer autopsy, which started from the neck, revealed diffuse hemorrhagic infiltration of the soft tissues, while the bony-ligament structures, cervical spine cord, and cervical organs were undamaged. There were 13 lacerations on the skull that were widely different from one another in shape and size. The bones on the right side of the skull buckled inward with several linear fractures in the parietal-temporal-occipital right bones. There was subdural hemorrhage of the left temporal lobe and bilateral subarachnoid hemorrhage of the parietal lobe and of the left parietal-temporal left lobe. The screwdriver produced a total of 13 lesions of different shapes and sizes. The radiological and the autoptic examination proved that the killing weapon was the screwdriver. The cause of death was not the penetrating injury of the neck as initially observed, but rather blunt force trauma to the head.

Penetrating injuries of the skull are most common in the thinnest bones, such as orbit and temporal. Screwdrivers are rarely used in assaults, but they can produce severe penetrating injuries. This case is peculiar because it is an uncommon case of homicide with a screwdriver found embedded in the posterior part of the neck. The screwdriver was indeed used to produce lethal blunt trauma to the head. Without discovering the screwdriver, identification of the single instrument used to inflict the injuries the multiple different lacerations of the scalp would have been very difficult. This case amplified a pitfall common in the forensic experience.

### Screwdriver, Postmortem CT, Head Trauma

### E51 Accidental Autoerotic Death: An Unusual Case of Lethal Asphyxiophilia Associated With Autogynephilia

*Elena Lucenti, MD\*, University of Ferrara, Ferrara 44121, ITALY; Lorenzo Marinelli, AOU Arcispedale Sant'Anna, Ferrara 44124, ITALY; Omar Bonato, MD, University of Ferrara, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Ferrara 44121, ITALY; Raffaella Marino, MD, University of Ferrara, Ferrara 44121, ITALY; Chiara Marini, MD, University of Ferrara, Department of Legal Medicine, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Matteo Marti, PhD, University of Ferrara, Ferrara 44121, ITALY; Matteo Fabbri, MS, University of Ferrara, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY; Paolo Frisoni, MD, University of Ferrara, Ferrara 44121, ITALY*

**Learning Overview:** The goal of this presentation is to expose a case of lethal asphyxiophilia associated with multiple paraphilias, underlying the features that can be useful in a forensic investigation to exclude the possibility of sexual homicide or suicide in a case of suspicious autoerotic asphyxia.

**Impact on the Forensic Science Community:** Cases of autoerotic deaths are relatively rare in the forensic medical practice. In such cases, establishing the cause and manner of death is quite challenging for the forensic professionals. This presentation, due to the unusual methods used by the victim, will impact the forensic science community by providing important support for the management of similar forensic cases.

A 56-year-old man was found dead in the bedroom of his house, which was locked from inside, partially suspended over the edge of the bed by the neck and the torso while both the legs and the pelvis were lying on the mattress. The body was discovered with a diving mask over his head, dressed in female's clothing, including panties, bra, a corsage, and black stockings. Suspension was from a hook fixed to the wall behind the corpse, with a rope attached to a collar around the neck. The torso was suspended from the hook by two separate ligatures, one secured to a metallic wire that held two plastic funnels together fixed around the breast, and the other fastened to a leather belt placed at the waist. Pornographic pictures of bondage, depicting a set-up similar to the victim's, were displayed on the wall in front of the body. The deceased was divorced with one child, was employed, and had no diagnosed psychiatric illnesses. No suicide note was found at the crime scene.

During autopsy, two plastic discs were found under each funnel placed on the breasts. Both of the devices showed numerous pins with the sharp extremities pointed toward the skin. The male genitals were stretched by the means of a string knotted to another belt, fastened at the waist. There was marked facial congestion with massive petechial hemorrhage in the face and conjunctivae. The ligature mark was slightly oblique, pale, approximately cm wide, and encircled the neck above the thyroid cartilage, continuing up both sides of the neck to the occipital region where it ended. The internal examination showed hemorrhage in the area of the ligature mark that penetrated the thyrohyoid muscles. There were no hyoid bone or larynx cartilage fractures. All organs were congested, with petechiae on the epicranium, serosal surfaces of epicardium, and visceral pleura. There were no other significant findings at autopsy. Cause of death was mechanical asphyxia due to hanging while engaged in autoerotic activity.

Accidental autoerotic death is defined as a solitary, accidental death caused by a lethal paraphilia, such as asphyxiophilia. It is characterized by the use of a variety of techniques to produce the oxygen depletion needed to enhance sexual arousal, including hanging, self-strangulation, and suffocation with plastic bags or gas masks. This paraphilia could be associated with others, such as bondage, fetishism, and autogynephilia (male's propensity to be sexually aroused by the thought of himself as a female). In this case, the mechanism of asphyxia involved suffocation by a diving mask over the head and strangulation by neck ligature, combined with pain-stimulating agents, while wearing female's clothing. The peculiar variety and complexity of these mechanisms, combined together, made it difficult to exclude the possibility of a third-party involvement. However, suicide and homicide were excluded since all the characteristic features for an act of autoerotic asphyxia, described in the forensic medicine literature, were found thanks to a detailed crime scene investigation and the reconstruction of the victim's psychological history, which are of the uttermost importance in order to correctly establish the nature of an autoerotic death.

#### **Autoerotic Death, Asphyxiophilia, Autogynephilia**

## E52 School Bullying Affecting America's School Children: A Look at Statistical Trends

Christina A. Leija, MS\*, San Antonio, TX 78227; Tyler J. Perkins\*, Cameron University Undergraduate Research Team, Duncan, OK 73533; Rikki A. Tasso-Thompson\*, Cameron University Undergraduate Research Team, Cache, OK 73527; Viktoriya Tikhonova\*, Cameron University Undergraduate Research Team, Fort Sill, OK 73503; Ashley I. Unsinn\*, Cameron University Undergraduate Research Team, Lawton, OK 73505; Hunter N. Gault\*, Cameron University Undergraduate Research Team, Elgin, OK 73538; Levi E. Peck\*, Cameron University Undergraduate Research Team, Duncan, OK 73533

**Learning Overview:** After attending this presentation, attendees will understand bullying by school-aged children and the perceived psychological effects it has on victims, the perpetrator, and the community. The goal is to provide a statistical insight on bullies, their home life, and their effects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering insight into current statistical data collected from the 2018–19 and 2019–20 academic years for primary-level school administration and historical timelines over the past five years to showcase a trend in bullying and its effects.

Bullying in every form has continually received growing attention as the serious nature of violence perpetuates into extreme forms. Bullying has become more reliably recognized as empirical research is being conducted. This research has fixed its attention on the underlying characteristics and behaviors of both the school bully and their victim(s), and how professional school administrations recognize these traits. Two questions that attendees will be presented with are: (1) Are there any programs being utilized to counteract the ongoing problem of bullying or to prevent it from happening?; and (2) Is there a trend that can be identified with bullying and is it possible for administration to step in without violating civil rights?

With more than 250 people dying in active shooter and mass casualty events since the Columbine shooting, there is a need to place these characteristics and behaviors into the framework of the situation in which they occur to expand the research and allow for the expatriation of more in-depth and inclusive educational, prevention, and intervention programs.<sup>1</sup> This research focuses on professional school administrators in southwestern Oklahoma to identify the signs of bullying and determine if current school bullying education, prevention, and intervention is successfully administered. If not, can there be a change implemented and what change should occur? A look into what programs should be available and funding possibilities to help assist the schools will also be explored.

The goal of this research and presentation is to provide forensic psychological insight to the warning signs and predispositions of bullies. This includes their home life, social habits, and school life to better understand what drives a bully to bully. Understanding motivation is essential since most past research concentrated on the bully after he/she commits the behavior instead of what causes them to act in such a manner.<sup>2</sup> In turn, this research should show a consistent statistical data trend to help identify triggers and warning signs that can be changed before the incident(s) occur and develop into a deadly scenario without violating civil rights and privacy to all individuals involved.

### E53 Choose the Cause of Death: A Complex Suicide

*Mauro Coppone, MD\*, University of Ferrara, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Ferrara 44121, ITALY; Omar Bonato, MD, University of Ferrara, Ferrara 44121, ITALY; Raffaella Marino, MD, University of Ferrara, Ferrara 44121, ITALY; Enrica Calabrese, MD, University of Ferrara, Ferrara 44121, ITALY; Matteo Fabbri, MS, University of Ferrara, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Matteo Marti, PhD, University of Ferrara, Ferrara 44121, ITALY; Paolo Frisoni, MD, University of Ferrara, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY*

**Learning Overview:** The goal of this presentation is to present a multidisciplinary approach to a case of complex suicide. In order to assist the judicial authorities and police inquiries in classifying the crime, toxicologists and forensic pathologists have to be involved. In this case, the role of the forensic pathologist was of primary importance to clarify time and causes of death and to distinguish between suicide and murder.

**Impact on the Forensic Science Community:** Complex suicides are an uncommon form of suicide in which multiple suicide methods are associated, representing a challenge for forensic pathologists. They are classified as typical (two suicide methods associated) and atypical (more than two methods involved) forms of suicide. In the case of a complex crime scene like this, the differentiation between homicide and suicide can be difficult; this presentation will impact the forensic science community by providing important support for the management of similar forensic cases.

This case report is about an atypical, complex case of suicide. This 55-year-old woman was found by her sister, deceased in her bedroom. The sister immediately called for medical assistance, police, and, ultimately, the medical examiner was notified.

The woman was discovered lying on her bed with her left hand tied to her right foot with Scotch® tape. Three plastic bags were wrapped around the head. She had superficial incisions on her left wrist. There were bloodstains on the floor, which led to the hypothesis that the victim moved after suffering injuries. A bedside table was leaning against the door, inside the room. There were many empty packages of drugs (acetaminophen, levothyroxine, diazepam, and Acetylsalicylic Acid [ASA]) found in the bedroom.

A multidisciplinary forensic approach, including full autopsy, histological, immunohistochemical, and toxicological analyses, were performed. The autopsy revealed pulmonary and cerebral edema. In addition, thrombosis of the left middle cerebral artery was observed, occluding 80% of the vascular lumen. Histological analysis confirmed the autopsical evidences of pulmonary and cerebral edema and showed massive acute emphysema. Histological analysis of the heart revealed severe myocarditis and advanced coronary disease. Brain tissue showed signs of subacute ischemic suffering. The liver showed signs of centrilobular necrosis. Toxicological analysis revealed a lethal concentration of acetaminophen (4,026.2µg/ml), and therapeutic concentrations of diazepam. The results of autopsy and subsequent examination, combined with the result of crime scene examination, determined the cause of death as smothering. There were not signs of forced entry and no defensive wounds. The absence of these elements eliminated homicide as a manner of death. These findings suggest that a methodological approach, which involves forensic pathologists, toxicologists, and crime scene investigation is essential in cases like this. This collaboration properly identifies the cause and manner of death.

#### Complex Suicide, Toxicology, Asphixiology

## E54 Strategies for Reconciliation of Personal Identifying Information and DNA Profile Data at a State DNA Index System (SDIS) Databasing Laboratory

*Christopher Piwonka, BS, Texas Department of Public Safety, Austin, TX 78752; Rebecca A. Shane, BS, Texas Department of Public Safety, Austin, TX 78752-4402; Kelly Bell, BS, Texas Department of Public Safety, Austin, TX 78752; Gary J. Molina, BA, Texas Department of Public Safety Crime Laboratory, Austin, TX 78752; Mariela Rivera, MS\*, Austin, TX 78754; Charles I. Stokes III, BS, Texas Department of Public Safety, Austin, TX 78752; Ryan Strand, MS, Texas Department of Public Safety, Austin, TX 78752; Erik Werzner, BS, Texas Department of Public Safety, Austin, TX 78752*

**Learning Overview:** After attending this presentation, attendees will be aware of how the Texas State Combined DNA Index System (CODIS) Offender Databasing Laboratory addresses unique challenges with known offender samples to include: (1) sex/gender discrepancies between reported biographical data and DNA profile data; (2) twins in the Texas State CODIS Offender Database; and (3) multiallelic offenders and/or chimeric DNA profiles.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the complexities of known offenders' biographical data and DNA profile data and how these complexities can affect casework and/or law enforcement interpretations.

The Texas Department of Public Safety (DPS) CODIS Offender DNA Databasing Laboratory (Texas SDIS Lab) encounters challenges that differ from traditional forensic DNA casework laboratories. Because the main role of CODIS is to provide law enforcement with investigative leads, accurate identifying information is emphasized. Biographical data provided with each sample is compared with crime record data to verify identification prior to processing their DNA sample. In some cases, the information obtained from the DNA profile leads to questions about the offender's reported biographical data. The following discrepancies are rare but important to investigate for internal laboratory quality assurance: accurate familial searching and providing accurate identifying information associated with a CODIS hit.

Sex/gender discrepancies are queried in the internal Laboratory Information Management System (STACS-DB from STACS DNA, Inc.) to yield discrepancies between biological sex data collected during DNA analysis and biological sex data manually entered into the database during sample data entry. Data entry errors were resolved without retesting. Retested samples included 81 Fast Technology for Analysis (FTA) blood samples, 67 non-FTA blood samples, 40 buccal samples, and nine samples on GenTegra® GenPlates®. All samples were retested using GlobalFiler® Express amplification kit and a portion tested for Y-chromosomal Short Tandem Repeat (Y-STR) using the Y Filer® kit. Following processing, amelogenin, DYS391, and Y-chromosome insertion/deletion (Y-indel) loci results for each sample were compared with the reported biological sex. While the project is ongoing, results suggest that there are sex-typing issues as a result of genetic insertions, deletions, and primer site polymorphisms at amelogenin, or other genetic anomalies, such as XXY females. Of the portion tested for Y-STR, 12% of male samples exhibiting apparent female STR profiles produced a Y-STR profile consisting of 12, 14, and 15 null loci. Results also suggest that reported sex may contradict with DNA sex based on an individual's self-identification. Many discrepancies were in fact updates to reported sex in crime records as an individual changes the way they report their identity at arrest, such as in a case of gender dysphoria.

Texas currently has over 950,000 offender and arrestee samples in SDIS and receives approximately 3–7 sets of identical twins each month. Possible sets of twins are initially identified when two individuals in Texas SDIS appear to have identical DNA profiles. First, the samples are researched to rule out duplicate samples that were accidentally processed as two separate individuals due to biographical data errors within crime records. The possibility of twins is then researched through contacting supervising agencies and sporadically analyzing requested vital records. As of 2018, over 800 sets of identical twins exist in Texas SDIS. Currently, there is no method within CODIS to differentiate individuals from a set of identical twins. When a match occurs with twins, both individuals are reported to the investigating agency and the local lab working their forensic case.

Chimeric offender samples are rare in Texas SDIS, with just 22 chimeric samples identified as of 2018. However, a chimeric profile could mislead an investigation if the sample is interpreted as a mixture and devolution is performed, when in fact the source of the DNA is from one contributor. Explanations vary from embryonic development to bone marrow transplants. Chimeric or mixed profile offender samples are initially identified at analysis. Once contamination is ruled out, an additional DNA sample is requested from a supervising agency, if possible. If the original sample was a blood sample, a buccal sample is requested to compare DNA derived from different biological material. Once confirmation testing of the mixed profile is performed with a second collection, the sample is uploaded into CODIS to be searched in the Multi-Allelic Offender (MAO) specimen category. Information about the research into these samples is documented internally.

### Databasing, Gender, Chimeras

## E55 Sex and Race Determination Based on Attenuated Total Reflection/Fourier Transform Infrared (ATR/FTIR) Spectroscopy of a Bloodstain

*Ewelina M. Mistek, MS\*, University at Albany, State University of New York, Albany, NY 12222; Lenka Halamkova, PhD, University at Albany, State University of New York, Albany, NY 12222; Igor K. Lednev, PhD, University at Albany, State University of New York, Albany, NY 12222*

---

**Learning Overview:** After attending this presentation, attendees will gain knowledge about: (1) the limitations of current methods for bloodstain analysis during forensic investigation; (2) the importance of human phenotype profiling for forensic purposes; (3) the significance of a non-destructive method for examination of trace evidence at a crime scene; and (4) the advantages of FTIR spectroscopy in forensic investigation. The goal of this presentation is to disseminate results of FTIR spectroscopy for bloodstain examination as well as the results of chemometrics for distinguishing between human sexes and races.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by disseminating results of the non-destructive and rapid human sex and race determination from a bloodstain at a crime scene immediately after discovering a crime scene.

Human phenotype profiling is one of the most important analyses during a forensic investigation. It can play a crucial role in the early stages of investigation. All current methods of phenotype profiling based on the analysis of body fluid traces are destructive to the sample and, most importantly, need to be performed in a lab and not at a crime scene.

In this study, ATR/FTIR spectroscopy was evaluated as a potentially non-destructive, rapid, and *in situ* method for discriminating sex and race based on the analysis of human bloodstains. It is known from the literature that the biochemical composition of blood changes with donor sex and race. ATR/FTIR spectra were acquired from dry bloodstains, and an advanced statistics methodology was utilized to enhance the differentiation capability of the method. Specifically, Partial Least Squares Discriminant Analysis (PLSDA) was employed to create models for differentiating Caucasian (CA), African American (AA), and Hispanic (HI) donors according to their sex and race. This approach was evaluated by subject-wise Leave-One-Out Cross-Validation (LOOCV), resulting in a greater than 90% correct classification. In addition, the main models were validated externally with four hold-out samples, which were not used for the training data set. The validation with hold-out samples resulted in 100% accuracy for both sex and race predictions at the donor level.

Overall, this proof-of-concept study demonstrated the great potential of ATR/FTIR spectroscopy and chemometrics for phenotype profiling for forensic purposes based on dry bloodstains. Translating this technology to a portable instrument would provide an excellent opportunity for conducting human phenotype profiling immediately after the crime scene is discovered.

### Bloodstains, Phenotype Profiling, Nondestructive Analysis

---

**E56 A Chemical and Biological Analysis of a Medieval Skeletal Collection From the Archaeological Site at Lohor, Croatia**

*Zdravka Hincak Daris, Faculty of Humanities and Social Sciences, Zagreb 10000, CROATIA; Siniša Merkaš\*, Zagreb, EU, CROATIA*

---

**Learning Overview:** After attending this presentation, attendees will have an overview of the importance of forensic analysis methods application on ancient skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by giving insight into the challenges and cooperation of both archaeology and forensic sciences because it deepens interdisciplinary communication and collaboration, taking a step forward in the reconstruction and the interpretation of such results.

Material culture is the primary source of information in archaeological science. The possibility of improvisation and understanding of a holistic approach generates a range of new connections between both areas. The true direction is what must be seen as the final goal of the study of materials in archaeology using forensic methods. During archaeological research in Lohor in 2011, three different sections of cemetery burials were examined. The first was to the east, outside the enclosure wall of the shrine of Our Lady of the Mountain. The middle and most intriguing burial phase included individual graves of five persons. This group of skeletons from the 11<sup>th</sup> century were discovered in an unattractive part of the cemetery, positioned behind the front end or on the North side of the pre-Romanesque church. The skeletons were found in a contracted and a semi-contracted position.

The primary anthropological identification, which includes sex, age at death, and stature determination, together with the analysis of bone pathological conditions and the development of musculoskeletal attachments have provided an abundance of data. The anthropological analysis determined all five skeletons were male and ranged in age from juveniles to a nearly senile phase. Stature varied from medium to tall, medium to robust, with a wide shoulder breadth. Pathological changes on bones diagnosed as leprosy were visible on all skeletons, with only one skeleton highly impacted.

Multiple stable isotope analysis (<sup>13</sup>C, <sup>15</sup>N, <sup>18</sup>O) has provided an insight into the personal migrations and the chemical description of the regions where these persons spent their early childhoods, as well as of the regions that marked the last years of their lives. Chemical isotope inspection of individuals revealed that the M<sub>1</sub> tooth was enriched in comparison to the bone in <sup>13</sup>C and <sup>18</sup>O isotopes but not in <sup>15</sup>N isotopes. The lack of an enrichment of nitrogen leads to the conclusion that the mother's diet was likely poor in animal proteins. The carbon values are higher in one sample than others, indicating a higher diet of C<sub>4</sub> plants. In contrast, other individuals displayed enrichment in the M<sub>1</sub> tooth in <sup>18</sup>O and <sup>15</sup>N and depletion of <sup>13</sup>C. The mother's diet was in part based on C<sub>4</sub> plants, while that of the adult was based only on C<sub>3</sub> plants.

The values calculated for the ingested water are rather negative, indicating a provenance from continental and mountainous inland areas. The skeletal and dental material from each grave was sampled for ancient DNA analysis, which was performed with the Investigator<sup>®</sup> 24plex QS Kit for human identification to gain information of possible kinship within a family group. In total, five male DNA profiles were analyzed that were not related to one another. For further kinship statistical analysis, Y-chromosome or mitochondrial sequence analysis should be considered on a larger number of skeletal remains.

**E57 Evaluating Medicolegal Examinations of Turkish Detainees During the Recent State of Emergency in Turkey Within the Scope of the Istanbul Protocol**

*Alper Keten\*, Institut für Rechts-und Verkehrsmedizin, Heidelberg, CA 69115, GERMANY; Johannes Nicolakis, MD, Heidelberg Institute for Forensic and Traffic Medicine, Heidelberg 69115, GERMANY; Ramazan Abaci, PhD, Köln University, Köln, GERMANY*

---

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the recent human rights violations in Turkey and the importance of the Istanbul Protocol for detecting torture.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to the importance of the Istanbul Protocol for protecting human rights in the recent State of Emergency.

Maltreatment and torture during detention continues to be a serious problem in many countries. For this reason, medical evaluations of maltreatment and torture should be performed appropriately. The Istanbul Protocol is a United Nations document guiding doctors and legal experts in terms of investigating and reporting torture. The protocol provides minimum standards for investigating torture claims, examining potential torture victims, and documenting physical and psychological evidence for torture. After a failed coup d'état in Turkey on July 15, 2016, a state of emergency was declared; 150,348 people were dismissed from their professions, while 500,650 people were detained. To date, 30,947 people are still jailed. This present study will evaluate the reported medical examination procedures in Turkish detention facilities of Turkish detainees finding asylum in Germany after their detention in Turkey, the present process of medicolegal reporting, will evaluate the compliance to the Istanbul Protocol, and discuss the issue in the light of literature.

Adult Turkish citizens who sought asylum in Germany after the 2016 coup attempt in Turkey were eligible to participate in this study. Participants were recruited via announcement in a mobile messaging support group for Turkish citizens in Germany. The study participants were asked questions regarding the examination steps stated in the Istanbul Protocol. The questionnaires were created with Google® Forms and were sent to the participants via mobile messaging applications. Descriptive statistics were used to describe the data.

Fifty-one people participated in the study. Forty-five (88.2%) participants were male, while 6 (11.8%) participants were female. Considering the educational background of the participants, 29 (56.9%) participants had a bachelor's degree, 13 (25.5%) had a master's degree, and 9 (17.6%) had a PhD. Most participants were in the age range of 36–45 ( $n=24$ , 47.1%), while 19 participants were under the age of 36. Twenty-five (49%) participants were not asked for their personal information before examination. Forty-five (88.2%) participants stated that police officers were present during medical examinations. The examinations lasted between ten seconds and ten minutes and 29 participants (56.8%) were examined in less than five minutes. The statements of 36 (70.6%) cases related to the detainment were not requested. A detailed examination regarding maltreatment or torture has not been performed on any participant. Considering the location of the medical examination, 6 participants (11.8%) were examined in a hall, 1 (2%) was examined in a police car, and 24 (47%) were examined in jail or a police station. While 7 participants (13.7%) stated that they had not been exposed to any kind of physical maltreatment, the other 42 participants (82.3%) had been exposed to maltreatment, such as beating, handcuffing, extended periods of standing, sleeping on bare concrete floors, imprisonment in confined spaces without fresh air, or psychological torture and maltreatment.

The practice of torture and maltreatment seems to continue despite all international attempts of prevention. When one considers the fact that thousands of people were detained for similar reasons during the recent state of emergency in Turkey, the impact of this event is evident. The most significant points to prevent torture are the medical examinations made during detention. The responses given by the participants revealed that not all medical examinations during detention were performed in accordance with the Istanbul Protocol. For this reason, it is believed that proper physical examinations would have been legally problematic for involved officials. In this respect, practicing the appropriate medicolegal examination in accordance with the Istanbul Protocol and sharing those reports are of great significance. Because this study only included a small number of participants, further studies are needed to draw definite conclusions and to avoid sampling bias.

**Istanbul Protocol, Torture, Detention**

---

## E58 The Medicolegal Evaluation of Detention Procedures During the Recent State of Emergency in Turkey

*Alper Keten\**, Institut für Rechts-und Verkehrsmedizin, Heidelberg, CA 69115, GERMANY; *Johannes Nicolakis, MD*, Heidelberg Institute for Forensic and Traffic Medicine, Heidelberg 69115, GERMANY; *Ramazan Abaci, PhD*, Köln University, Köln, GERMANY

---

**Learning Overview:** After attending this presentation, attendees will better understand the recent human rights violations in custody in Turkey through the eyes of a well-educated group of people who migrated to Germany from Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to troubles faced by well-educated refugees who migrated to Germany from Turkey.

The United Nations defined torture as infliction of physical or psychological harm by public officials or other persons acting in an official capacity. According to 2013 data from the United Nations, more than 50 million people are affected by forced displacement as a result of conditions such as war, oppressive regimes, or natural disasters. The rate of exposure to torture among those people is estimated to be between 5% and 35%. It is predicted that there are between 3–17 million victims of torture among people affected by forced displacement. However, a large portion of torture victims continue to live in their home counties where they are exposed to torture. In Turkey, the number of people directly exposed to torture is predicted to be several million. During the recent state of emergency in Turkey, many academicians, journalists, teachers, and doctors left Turkey as refugees, and mostly chose Europe to apply for asylum because of geographical closeness and a large Turkish community. This present study discusses the medicolegal examination of detainees in Turkey.

Eligible participants consisted of Turkish citizens aged 18 and older who fled Turkey during the recent state of emergency and applied for asylum in Germany. The participants were recruited with an announcement in a mobile messaging group which functions as support group for Turkish citizens in Germany. The participants answered a questionnaire, including demographical data and detention procedures, without disclosing their identity. Google® Forms was used to conduct the questionnaire with the participants.

A total of 294 people participated in the survey. Males comprised 284 (84.4%) of the participants, while 46 (15.6%) were female. There were 91 (31%) teachers, 30 (10.2%) academicians, 10 (3.4%) doctors, 33 (11.2%) members of the army or police, 19 (6.4%) businessman, 16 (5.4%) lawyers or prosecutors/judges, and 23 (7.8%) were from other occupational groups. All participants stated that they had not been previously sentenced or detained. When the educational backgrounds of the participants are considered, 166 (56.5%) participants had a bachelor's degree, 66 (22.4%) had a Master's degree, and 40 (13.6%) had a PhD or specialty in medicine. Researchers found that 91 (31%) participants were detained for four to seven days, while 100 (34.0%) participants were detained longer than seven days. Lawyers were not available for 120 (40.8%) of the participants and 257 (87.4%) were unable to meet with family members.

Physical trauma was reported by 57 (19.3%) participants during detention, while 219 (74.5%) participants stated that they were subjected to psychological violence. Most participants stated that they were refused medical help ( $n=273$ , 92.8%). Adequate nutrition during the detention process was not provided to 248 (84.4%) participants, while 155 (52.7%) participants pointed out that they were exposed to water restrictions. Restricted washing facilities were reported by 219 (74.4%) participants, while 166 (56.5%) participants reported inadequate access to toilets. Other reported measures included constant lighting ( $n=182$ , 61.9%), unsuitable cooling or heating ( $n=168$ , 57.2%), exposure to loud music ( $n=28$ , 9.5%), or verbal abuse ( $n=161$ , 54.8%).

In this present study, the reported detention procedures and practices do not comply with human dignity and appear to be a violation of the United Nations convention against torture. This cross-sectional study indicates that further studies regarding those practices should be conducted and these processes should be illustrated in detail. Because the study only included a small number of participants, further studies are needed to draw definite conclusions and to avoid sampling bias.

### Turkey, Detention Procedures, Torture

### **E59 Health Care Professionals as Persons of Interest? Preventing Strategies, Medical Liability, and Italian Jurisprudence Through the Analysis of an Inpatient Psychiatric Suicide**

*Federica Gori, MD, University of Pisa, Pisa 56100, ITALY; Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Sara Turco, MD\*, Pisa, ITALY; Alice Chiara Manetti, MD, University of Pisa, Forensic Pathology, Toscana, Pisa 56126, ITALY; Francesca Iannaccone, Pisa 56123, ITALY*

**Learning Overview:** The goal of this presentation is to analyze preventing strategies in cases of inpatient suicide through a case report and a review of international and Italian jurisprudence, to reflect about risk management and prevention, but also to highlight the critical elements related to this highly debated theme.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting an overview of the medicolegal aspects of inpatient suicide, focusing on medical liability and risk management.

Sentinel events are unexpected occurrences involving death or serious physical or psychological injury, or the risk thereof. In-patient suicide is a sentinel event that can be significantly reduced by adopting specific prevention measures. Literature recommends accurately registering medical history at admission to stratify the risk of suicide and level of surveillance required. Published authors have stated the most important prevention strategy is related to eliminating the physical instruments that could be potentially used for self-harming.

This case report concerns a 43-year-old woman suffering from severe anorexia who had been treated with an antipsychotic and who recovered. At admission, her Body Mass Index (BMI) was 12.3Kg/m<sup>2</sup>, compared with a normal BMI of 20–25 Kg/m<sup>2</sup>. She was aware of her severe physical condition, which led to her acceptance of the therapies required for treatment. She was initially fed by parenteral nutrition, but developed anxiety and suicidal thoughts related to this treatment; as a result, antipsychotic therapy was initiated. She also had daily interviews, but she refused to take part in group therapy. After initial improvement, her psychical condition worsened. She tried to injure herself with an insulin needle and refused to eat. After these episodes, surveillance was initiated during meals, and her room was thoroughly searched. Medical staff found scissors, a lancet, and a telephone wire. The telephone wire had likely been passed through the window despite the window handle having been removed. Recommendations included observing her visitors and continuation of antipsychotic therapy.

One night, approximately six months and two weeks after admission, the patient was reported to have used the toilet several times. About 6:00 a.m., nursing staff could not locate her. Local police were notified about 7:00 a.m. About 4:55 a.m., a human body was discovered on the tracks of the local train station. An underweight female, wearing pajamas, a nightgown, a pair of slippers, and a cannula was observed lying prone with her head on the track and the remainder of her body next to the track. The woman had cranial burst fracture with cranial vault avulsion and brain exposure.

The woman was quickly identified as the missing psychiatric ward patient. An examination of her room revealed that the window of her room had been opened, using the handle that had been previously removed and presumably hidden. An external examination at autopsy confirmed the injuries were consistent with a train accident. The time required to travel to the train tracks, the victim's medical records, and other circumstantial data suggested a gap of approximately five hours in patient surveillance.

Health care liability in cases of inpatient suicide arises from the duty to supervise patients who are under care. Prevention can significantly reduce the number of inpatient suicides, but some strategies are not always viable because of limited resources or are inefficient due to the unpredictability of suicide. The risk of self harm is not always foreseeable. The Italian criminalistic jurisprudence concerning in-patient suicide is unclear. Health care personnel are sometimes cleared of wrongdoing in consideration of the right of freedom and self determination by the patient; however, it most frequently recognizes medical liability due to the duty of the medical staff to protect and look after patients. This case has not been sentenced yet, but there is high probability that health care professionals will be charged for the death of the patient due to the inadequate surveillance and the organizational gaps.

#### **Medical Liability, Inpatient Suicide, Prevention**

## E60 A New Approach and Suggestions for Child Sexual Abuse Cases

Sila Aslan, Cukurova University School Of Medicine, Balcali 01330, TURKEY; Mete K. Gulmen, PhD, MD\*, Cukurova University, Adana 01330, TURKEY; Ahmet Hilal, MD, Çukurova Üniversitesi, Adana, 0 01330, TURKEY

**Learning Overview:** After attending this presentation, attendees will understand a new approach in child sexual abuse and examination as well as reporting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of children's rights, sexual abuse cases, and all dimensions of the forensic aspects.

The World Health Organization (WHO) defines child sexual abuse as “the involvement of a child in sexual activity that he or she does not fully comprehend and is unable to give informed consent to, or for which the child is not developmentally prepared, or else that violate the laws or social taboos of society.”<sup>1</sup> Children are exposed to abuse in many countries. Reports of child sexual abuse cases have risen considerably in recent years.<sup>2</sup> Child sexual abuse is usually associated with other violence, such as physical violence, threats, frightening, drugging, or “obtaining consent” from individuals who are unable to do so, either because of age or mental disease.

The management of cases of sexual violence is a complex, long, and difficult process from the first encounter to the completion of treatment and rehabilitation of the patient. The process requires a multidisciplinary approach, with emphasis on the health and well-being of the patient. The process of disclosure is very difficult for children.<sup>2,3</sup> The investigation begins after being notified of an allegation of child sexual abuse. Some investigative practices lead to the identification of other victims or to allegations of False reports. Because of these factors, the forensic investigation must consider the need of the child and the accused person.<sup>4</sup>

During an 18-month period between 2018 and 2019, 156 sexually abused children, all below the age of 15 years, were examined and evaluated at the Cukurova University Forensic Medicine Department. Turkish Medical Clinics categorizes children below the age of 15 years as pediatric patients. Similarly, under Turkish law, children below the age of 15 years are unable to consent to sexual activity. The cases examined included 111 (71.2%) females and 45 (28.8%) males. The children's ages ranged from 4 to 15 years, with the average age of 11.78 years. There were 79 (50.6%) cases of repeated abuse and 77 (49.3%) cases of one-time abuse. There were 45 (28.8%) cases of reported vaginal abuse, 45 (28.8%) cases of anal abuse, and 66 (42.3%) cases of sexual touching. Most of the victims were female, and 69.8% of the time they recognized the male perpetrator. Mental retardation was present in 7% of the victims. Examinations of victims took place in the first 72 hours in 41 (26.3%) cases of abuse. Of those examinations, 39 (25%) had positive physical findings during clinical examination. All examinations were completed both with traditional visual clinical forensic sexual victim examination and by digital multispectral video colposcopy to evaluate and document the case properly for court. The type and frequency of the abuse was obtained from either the victim's history, the health care facility, or some other official entity.

Child sexual abuse usually impacts the victim during childhood, adolescence, and even adulthood. The long-term impact can compromise the life of productivity as a result of the maltreatment of the victims. Sexual assault victims should not be repeatedly traumatized by clinicians and other official authorities. For this reason, a new clinical examination technique and psychiatric evaluation methodology has been implemented. The major point should be the victim's higher benefit, and this should always be protected.<sup>5,6</sup> A well-trained clinical forensic examiner should always complete proper methodologies at a proper medical facility, and other professionals should always consult with clinicians.<sup>2,4,7</sup> The rights of children and women should always be accepted as a part of human rights. Society working as a whole should understand the unity of the body of a child or woman.<sup>2,5</sup>

### Children Rights, Sexual Abuse, Clinical Examination

## E61 An Evaluation of Child Suicide Death Cases

Mete K. Gulmen, PhD, MD\*, Cukurova University, Adana 01330, TURKEY; Necmi Cekin, MD, Cukurova University School of Medicine, Adana 01330, TURKEY; Kenan Kaya, Çukurova University, Adana, Saricam 01330, TURKEY; Sila Aslan, Cukurova University School of Medicine, Balcali 01330, TURKEY

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the importance of child deaths from suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness and identifying children at risk for suicidal behavior.

Adolescent suicidal attempts are a serious public health concern. It causes psychiatric, economic, and physical problems. The incidence of suicides increases rapidly until the age of 18 and accounts for 1.5% of all deaths worldwide, making it the tenth-leading cause of death.<sup>1</sup> It is the third-leading cause of death among children and adolescents aged 10 to 18 years.<sup>2</sup> The most prevalent factors of adolescent suicide are family conflict, school-related problems, bullying, impulsivity, and depression.<sup>3</sup> Psychiatric disorders in young adults significantly increase the risk of suicide. These individuals are more affected by relationship problems. Although suicidal thoughts and suicidal behavior are rare before puberty, there is increasing concern about identifying individuals at risk for suicidal behavior.<sup>2</sup> This study examined the socio-demographic characteristics and forensic medical significance of suicidal child death cases.

This study examined 204 suicides from 2018 that were autopsied at Adana Group Presidency of Forensic Medicine Institution. This study evaluated age; gender; suicide method; suicidal environment; dates; presence or absence of a diagnosed psychiatric disease; and the presence or absence of prior suicide attempts. The review consisted of the postmortem examination and autopsy records.

The youngest age at suicide was 12, and 20 cases (9.8%) were under age 18. Males comprised 75% ( $n=15$ ) and females comprised 25% ( $n=5$ ). Suicide occurred in domestic settings in 80% of the suicides. The most common month was September, with 20% of the suicides occurring that month. Thursday was the most common day of the week with five cases (25%). Three cases (15%) had received prior psychiatric treatment. Two cases (10%) had previously attempted suicide. Hanging was the most common method of suicide (35%), followed by jumping from height (30%), firearms (20%), and self-poisoning (15%). Firearms were the second preferred method of suicide in adults, while children chose jumping from height as the second most common method. This study hypothesizes that the inability of children to obtain firearms led to the choice to jump.

There are effective techniques for lowering suicide rates.<sup>4</sup> Once someone attempts suicide, the risk of attempting suicide again may increase. Society and the State must adapt their approaches to suicide. The most important thing to do in this regard is to restrict access to the means of suicide (firearms, chemicals, etc.).<sup>1</sup> The media should avoid suicide contagion by avoiding front-page coverage and sensationalizing suicide, and can assist by providing information on treatment resources. Suicide screening at schools can identify adolescents who have mental health problems. The accurate diagnosis of psychiatric disorders and their successful treatment can significantly reduce suicide rates. Treatment of psychiatric patients should be financially and morally supported; health professionals should be trained on the subject; maximum sensitivity should be shown during the rehabilitation process; and patients should be returned to the community as healthy individuals.<sup>5,6</sup> Literature highlights the noticeable existence of childhood suicide, although oftentimes unstudied. Recognizing psychic distress and suicidal behavior in childhood is extremely necessary for children to have adequate psychiatric treatment.<sup>7</sup> Protocols should be developed for the early recognition of suicidal behavior. Health professionals and teachers should be empowered to be able to help children with suicide risk predisposing signs.<sup>6,7</sup>

### Child Death, Child Suicide, Suicide Prevention

### E62 Rapid, Real-Time, and In-Field Detection of Fentanyl Residue: A New Approach Using Ion Mobility Spectrometry (IMS)

John Z. Wang, PhD\*, Artesia, CA 90701

**Learning Overview:** After attending this presentation, attendees will understand a new technology to detect fentanyl residue (<10ng) in a rapid (<5 seconds), real-time (instant peak display), and in-field (a portable device) manner.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a cutting-edge method of detecting opioid-fentanyl-based drugs in the field. Attendees will learn how the IMS is capable of displaying the detection results in less than five seconds and also related testing procedures, which may have a strong implication for law enforcement and public health agencies in addressing the current fentanyl crisis worldwide.

Currently, it is argued that opioid-fentanyl is the number one enemy in the opioid crisis and costs thousands of lives each year in the United States. Due to fentanyl's potent nature, law enforcement and public health agencies need a portable technology to determine its existence in certain situations, such as crime scenes, dead bodies, mail parcels, and/or abandoned drug apparatus. A new portable technology is based on the principle of IMS, weighs only 5kg, and can provide a real-time detection result on fentanyl residue in less than five seconds in field tests. Further, the technology can be connected to a Wi-Fi system for a remote communication. Finally, the IMS system has nine unique functions similar to the capacities of a Mass Spectrometry(MS) system.

With a quasi-experimental study by black box sampling, two spots on a school backpack were located for testing purposes: one spot (1mm<sup>2</sup>) was dipped with a drop of fentanyl (medical use) by a syringe, and the other spot (1mm<sup>2</sup>) with a drop of water. Two glean wipes on both spots using two separate swabs (a special material) were inserted into the machine inlet slot. The device was able to provide both readings within five seconds with accurate results. The system's internal cleaning process between two tests takes about 30 seconds. Therefore, the two consecutive tests require just under one minute on an area of less than 1mm<sup>2</sup> for less than ten Nano-grams of fentanyl in concentration under a normal atmosphere condition.

This IMS system consists of two parts: (1) the compounds that are used in testing must be ionized to become ions; (2) the ions pass through an electrical field so that different types of ions will be separated by the size, charge, and mass of the compounds. It is similar to the MS method except that IMS is a portable system and does not require a vacuum. The detection happens in a normal atmospheric environment so that it is relatively less expensive and easily made as a portable detector in the field. In fact, its detection sensitivity may reach the one Nano-gram level, depending on the types of fentanyl tested, which is quite adequate for detecting fentanyl variations on international and domestic parcels in real-life postal inspections. One of the special features of this technology is its use of Very Deep Ultra-Violet (VDUV) photons to ionize the sample, instead of a traditional radioactive ionization source, such as Ni63 isotope material. Therefore, it is non-radioactive and thus very safe to operate in the field. Finally, the drift time  $t$  can also be deducted into a  $kO$  parameter, which is the universal constant for each individual compound ( $kO$  is a physical parameter determined by the physical nature of the molecule/ion).

This study hypothesizes that a rapid, real-time, and in-field determination of fentanyl is one of the technical challenges in fighting the current fentanyl crisis in the United States. From this study, it is concluded that the application of the IMS is able to provide a practical method at the scene, in the lab, or even during courtroom testimony. This study strongly contends that the study results add a new effective approach for law enforcement and public health agencies. It is believed that if such technology can be utilized as a common practice, our duties and performance in addressing the fentanyl crisis will certainly be advanced from the past toward a more science-based future.

**Fentanyl Detection, Ion Mobility Spectrometry (IMS), Forensic Toxicology/Chemistry**

## E63 Forensic Palynology: Pollen and Its Role in Crime Scene Investigation, National Security, and Forensic Science

Taylor Strunsee, MS\*, East Troy, WI 53120

**Learning Overview:** After attending this presentation, attendees will be familiar with the area of forensic palynology and how pollen and spores have been recently used within the forensic science community to assist with determining postmortem intervals, investigating major crimes, and assisting with national security issues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing awareness to a subfield of forensic science that is up and coming within the United States. By providing awareness to this field, the forensic science community will be able to see how pollen has been used to solve crimes around the world and the benefits it can bring by being utilized in forensic casework and on-going investigations.

Forensic palynology is an up and coming discipline within the forensic science community. A science that has been utilized in New Zealand is now being used across the globe in Australia, the United Kingdom, and the United States. Forensic palynology uses spores, pollen, and other acid-resistant microscopic plant bodies to assist with criminal and civil cases.<sup>1</sup> The results from the analysis are used to help aid investigators by providing information that links to certain geographic locations. Forensic palynology has also been used in cold case investigations, postmortem interval estimations, and national security issues. Though normally used for outdoor scenes, more research is being conducted on the value of pollen analysis in crimes such as forgery and fraud. Although this science is not prevalent in the United States, it is slowly becoming more recognized through its recent use in cold case work and its current use with national security and organized crime cases with the United States Customs and Border Protection agency.

One of the most recent cases in which forensic palynology was used in the United States was the Bella Bond case or, at the time, the Baby Doe case. An unidentified female was found in the Boston Harbor area of Massachusetts. By utilizing forensic palynology, scientists were able to trace the pollen found with the body to the northeast region, specifically around the Arnold Arboretum in Boston, MA.<sup>2</sup> This data assisted investigators by providing a geographic location of where the child lived, or was, prior to her death.

Pollen has the ability to withstand most acids and the decay process, which allows it to be found on skeletal remains or heavily decomposed bodies.<sup>1</sup> Due to pollen having these properties, studies have been conducted to try to see if pollen analysis can be used to determine a postmortem interval with skeletal remains, specifically trying to determine a potential season of death. One of the first studies conducted with pollen analysis was on skeletal remains to try to determine a postmortem interval in Magdeburg, Germany, in 1994.

Using pollen analysis, investigators are able to determine where illegal substances are being grown or produced and are able to test the substances to see if they are being locally grown or imported. In one case study, investigators were able to determine that the substance was locally grown and they were not dealing with a larger drug trafficking issue.<sup>3</sup> The analysis of marijuana and trying to link the origin of it became very successful, which has then led to pollen analysis being used in other cases involving illegal substances, such as cocaine and methamphetamines.<sup>2</sup>

### Forensic Investigation, Pollen, National Security

## E64 A Forensic Comparison of Cable Ties to Create a Database

Celeste M. Lambert, BS\*, Cedar Crest College, Allentown, PA 18104; Ted R. Schwartz, MS, Westchester County, Valhalla, NY 10595; Brandi Clark, Valhalla, NY 10595; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** The goal of this presentation is to show the variation in characteristics with cable ties and their potential usefulness as physical evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the foundation for a cable tie database. This database could eventually provide valuable investigative leads in forensic cases.

Cable ties are often overlooked as forensic evidence since their characterization has not been extensively studied. However, cable ties may be used in criminal events in a variety of capacities, such as binding the hands of victims, in the design of homemade explosives, and during strangulations. Cable ties are made by injecting molten nylon plastic into metal molds. Two metal plates with a certain number of molds are brought together and the molten plastic injected. Each cable tie mold on the metal plate has a series of numbers and letters. Often, the molds are in numerical order and the highest number is the maximum number of cable ties that can be formed from one batch on that machine. The molten plastic is then ejected from the mold using pins.<sup>1</sup> Due to the nature of the manufacturing process, class and individual characteristics are created.

Class characteristics of the cable ties include general dimensions, color, and the mold number/letter combination impressions. To document all class characteristics for future use and comparison, cable ties were purchased from various national hardware stores. To start the database, a total of 29 bags of cable ties were purchased from Lowe's®, Home Depot®, and Harbor Freight®. From each store, 8", 11", and 14/15" cable ties were purchased. Ten cable ties were randomly selected from each store and size for examination. Twenty-five areas were selected to be measured or observed from different areas of the cable tie, including the clasp, body, and tail. These measurements and observations were made using a calibrated digital caliper and a stereomicroscope. The measurements were averaged over the sampled cable ties and a 95% confidence interval was calculated for each class characteristic.

Pin impressions from each manufacturing mold leave individual characteristic striation patterns on cable ties. When the plastic is ejected from the mold, striations can be imparted onto the malleable plastic. With larger quantity bags of cable ties, there are often multiple cable ties with the same mold number. Thus, cable ties with the same mold number impression can be compared to each other. To study how strongly the striation pattern matches between cable ties of the same mold and between ties of different molds, 12 bags of 100 cable ties were purchased from Nelco™ Cable Ties (Pembroke, MA). The 12 bags were from four separate lots. The first six bags were from the manufacturer Hua Wei Industrial (Taiwan) and were natural colored. The next six bags were black colored and from the manufacturer Kai Suh Enterprise (Taiwan). The majority of the bags had mold numbers in numerical order with multiple cable ties with the same mold number. The cable ties with the same mold number were compared to each other and had high amounts of matching striations whereas cable ties of different mold numbers had almost no matching striations. This indicates that matching striations are successfully transferred to cable ties with the same mold numbers.

Creating a cable tie database could be an extremely useful tool for forensic investigations. A database containing multiple measurements will yield a better chance for successful identification of brand/manufacturer. A large enough database may even provide an estimate to the likelihood of finding a particular cable tie from a random location, such as a crime scene. This study shows the potential evidentiary value of cable ties and should provide a practical reason for their collection by crime scene personnel and their subsequent examination in the laboratory.

### Cable Ties, Database, Class and Individual Characteristic

## E65 “What's Wrong With Putting Crime Victims in Jail?”

Patricia C. Smith, MSL\*, Harris County District Attorney's Office, Houston, TX 77002

**Learning Overview:** The goal of this presentation is to bring awareness to the forensic science community and educate society about the importance of crime victim rights and ensuring crime victims are not revictimized during the legal process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing practical and educational tools to ensure crime victims and their feelings are a factor in the legal process and encourage interdisciplinary outreach to better treat and protect crime victims.

The United States Criminal Justice System is arguably the best system in the world; however, it has a tendency to let society down and get it wrong. The system has its flaws, but not always in the way people think. Society empathizes with crime victims, but arguably crime victims are the most ignored group within the Criminal Justice System.<sup>1</sup> However, the Criminal Justice System has helped and held those accountable more often than not. There are thousands of crime victim programs, advocacy and watchdog groups, and legislation tailored for crime victims. Yet, crime victims still continue to feel let down by a system that vows to protect and obtain justice for them.

In Texas, there are approximately 146 organizations in 94 cities that provide various types of crime victim support.<sup>2</sup> According to Domesticshelters.org, case management, resources, and referrals are the most common services utilized. The federal government developed crime victims' rights as outline in Title 18 U.S.C. section 3771, which states crime victims have a “right to be reasonably protected ... right to reasonable, accurate, and timely notice of any public proceeding, ... right to be reasonably heard at any public proceeding, and ... right to confer with the attorney for the Government in the case.”<sup>3</sup>

It's important for crime victims to know they have rights. Unfortunately, at both state and federal levels, crime victims appear to be the least aware of their rights.<sup>4,5</sup> Part of their rights are to not participate, regardless of the reason.<sup>6</sup> There are many cases where the victim recants, outright lies, or says they do not want to participate. The primary motivations were the victim did not want to be the one to send their loved one to jail, they just wanted the offending person to leave, or they were angry with that person.<sup>7,8</sup> The reasons a crime victim does not want to testify or participate in the process are important and should be taken into consideration.<sup>7,8</sup>

Prosecutors take crime victims seriously and generally want to know the “whys.” However, prosecutors will not stop communicating with the victim or continuing to prosecute the offender.<sup>9</sup> Typically, prosecutors will not force a victim to testify, but there have been instances where prosecutors felt there was necessity to put or keep an offender in jail, despite the desires of the victim.<sup>1,10</sup> Prosecutors across the nation and specifically, in Harris County, TX, have a legal right to detain a crime victim in order to ensure their presence in court.

Local and national cases will be examined.<sup>11-13</sup> Federal and state laws will be reviewed. It is important to include the psychological impact when a crime victim is detained and what the state can do to eliminate or lessen the emotional and sometimes physical damage.<sup>14</sup> Furthermore, there will be discussion of possible alternatives prosecutors can use to prevent the crime victim from feeling like the defendant and what society can do to improve their understanding and role in the Criminal Justice System. Finally, there will be a discussion of the repercussions for prosecutors.<sup>15</sup>

### Crime Victims, Detention, Jail

### E66 Computed Tomography (CT) Scans and Autopsy Results of Nine Civilian Casualties of a Terrorist Attack

*Vincenzo M. Grassi, MD, Catholic University, School of Medicine, Rome 00168, ITALY; Simone Grassi, MD, Università Cattolica del Sacro Cuore, Rome 00168, ITALY; Tommaso Tartaglione, MD, Rome 00168, ITALY; Vincenzo L. Pascali, MD, PhD, Università Cattolica del Sacro Cuore, Rome, ITALY; Antonio Oliva, MD, PhD\*, Università Cattolica Del Sacro Cuore, Rome, ITALY*

**Learning Overview:** The goal of the presentation is to offer an overview of the injuries that can be found in victims of terrorist attacks and to explain how to integrate the autopic data, the information given by multi-planar reconstruction, and 3D volume-rendering techniques.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exposing the wide spectrum of features that can be found at the imaging and autopsy stages and demonstrating the importance of performing CT scans in order to provide accurate/full forensic autopsies in terrorist attack cases.

Prior to the rise of domestic terrorism, in many Western countries, pathologists experience of injuries caused by bombs and other particular types of unusual weapons, such as swords and unusual firearms, was limited to war casualties. In an Asian country, nine tourists were killed during a terrorist raid in a restaurant. The group used pipe bombs, machetes, and various types of firearms (handguns, submachine guns, and AK-47 assault rifles) loaded with illegal bullets. Local pathologists performed full forensic autopsies on the bodies. CT scans and new autopsies were performed on all nine victims. For the postmortem radiologic investigation, two techniques (multi-planar reconstruction and 3D volume-rendering) were used, obtaining both 2D images and 3D reconstructions. The first two cases presented slash wounds of the head and neck inflicted by machetes, while in the last seven cases, gunshot wounds were found (in two cases associated with injuries caused by explosive devices).

The terrorists used firearms that shot at different velocities: handguns, submachine guns, and AK-47s. One of the most important ballistic characteristics was the fact that prohibited ammunition (expansion or hollow point bullets and fragmenting bullets) were used. Expansion bullets are also called “hollow point,” because they collapse upon impact with hard surfaces such as bone, which increases and expands the kinetic energy transfer. Fragmenting bullets break into several pieces, which exponentially increases the injury area.

In general, CT is considered particularly useful in the imaging of terrorist attack victims, since it is highly sensitive in detecting firearm and blast injuries (in particular, fractures), and it can reliably detect glass or metallic fragments. In these cases, CT scans proved to be very useful to reconstruct the bullet track, revealing the bone and metal fragments deposited during cavitation. Moreover, in many of the described cases, death was caused by headshots. CT scans were able to identify entrance holes in the skulls (characterized by the typical conic shape). Moreover, in two cases, CT scans revealed miscellaneous objects identified as low-energy shrapnel released by Improvised Explosive Devices (IEDs). Shrapnel is oftentimes added to IEDs by terrorists to increase their destructive potential. Terrorists also consider location of the attack to enhance severity. In confined spaces, the energy released by explosions can be increased four-fold to eight-fold.

In conclusion, as demonstrated in these cases, casualties of terrorist attacks exhibit a huge spectrum of injuries whose characteristics are relatively unusual for those who practice forensic pathology in Europe. In victims presenting explosives or firearms injuries, multi-planar reconstruction and 3D volume-rendering proved to be highly valuable to understand the types of weapons used and the dynamics of the attack.

#### Terrorism, Military Weapons, Postmortem Imaging

### E67 Forensic Facial Reconstruction in Identification vs. Archaeological Investigation: Science or Art?

Sharon K. Moses, PhD\*, Northern Arizona University, Anthropology Department, Flagstaff, AZ 86011-5200

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how 3D forensic facial reconstruction in plastiline clay is conducted, using anatomical knowledge to identify and follow markers on the skull for recreating a face. It has been argued that forensic art is a subjective rather than objective endeavor and employs artistic license more than science. While it is true that there are areas of subjective artistic interpretation involved, forensic facial reconstruction is capable of nearly 70% accuracy in the hands of a well-trained forensic artist and when executed within acknowledged scientific guidelines.<sup>1</sup> Healed bone from facial injuries or bone loss from dental problems contribute unique markers to identifiability. Attendees will come to understand how scientific guidelines and methods for “reading” a skull are based upon evidence of musculature, activity, and ethnicity that all contribute to craniofacial morphology. Measurements based upon data sets of specific populations and historical periods are used to attain as much accuracy as possible. Conversely, attendees will also learn where and when artistic license is necessary for those areas of the skull that do not provide information about facial features. Attendees will learn the difference in goals of forensic facial reconstruction in aiding identification versus that of forensic reconstructions applied toward archaeological investigations to bring images of past peoples to life.

**Impact on the Forensic Science Community:** This presentation will impact the forensic community by demonstrating and promoting the value of forensic facial reconstruction artists who are also forensic anthropologists or have access to them for interpretation of facial structures. Forensic anthropologists trained in forensic art are uncommon but not unheard of. Nuanced cues for musculature attachments to facial bones are easy to miss for the untrained eye, as well as the ability to differentiate bone trauma remodeling from trauma that contributed to death or incurred postmortem. Forensic facial reconstruction in conjunction with forensic anthropology creates specialty skills that go beyond artistic interpretation. It is a goal of this presentation to encourage greater understanding and appreciation for those skills and dispel the misunderstanding that forensic facial reconstruction is primarily “art” over science.

This presentation will demonstrate that forensic art benefits most from the artist who is also a forensic anthropologist. The value of this in-depth knowledge toward determining the proper approach to each facial reconstruction, whether in a purely forensic context or for historical and archaeological purposes, cannot be overstated. Misinformation about the deceased provided to forensic artists leads to inaccurate reconstructions. Forensic art in combination with anthropological knowledge can offer unique value toward reconstructing images that aid in identification and visual understanding of human beings past and present.

### E68 Clinical Implications of Using Alternate Light to Assess Bruises

*Daniel J. Sheridan, PhD\**, Texas A&M University College of Nursing, Bryan, TX 77807; *Katherine N. Scafide, PhD*, George Mason University, Fairfax, VA 22030; *Nancy R. Downing, PhD*, Texas A&M University College of Nursing, Bryan, TX 77803; *Matt Hyat, PhD*, Georgia State University, Atlanta, GA 30303

**Learning Overview:** At the end of this research-based session, attendees will be able to identify the benefits and challenges of incorporating alternate light into the clinical assessment of cutaneous bruises in living subjects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how victims of violence often have cutaneous bruises that are challenging to see when subtle, when found on older persons, and when found on persons of darker skin tones. Using an Alternate Light Source (ALS) in clinical settings can provide findings in support of a history of new blunt force trauma and weeks-old trauma.

After attending this presentation, attendees will identify the efficacy of using alternate light as an adjunct in the clinical assessment of blunt force trauma. Violence victims are often subjected to blunt force trauma that, due to skin color/pigmentation and injury age, can result in cutaneous bruises that are latent or barely visible. Additionally, family violence victims across the life cycle often receive serial physical abuse resulting in contusions of different ages. Failing to identify bruises can result in legal and health care treatment disparities.

In a recently completed longitudinal, randomized controlled study, an ALS found intentionally created upper and lower arm bruises were better visualized at 415nm to 450nm with yellow and orange filters when still visible in white (ambient) light and when no longer visible to the naked eye. Test subjects were assessed up to 21 times over 30 days. The findings were statistically significant in subjects from six known skin tones (dark, brown, tan, intermediate, light, and very light).

The findings from this study strongly support the use of alternate light in clinical settings to assist in the assessment of reported blunt force trauma in the presence of visible bruises in white light and bruises no longer visible in white light. However, alternate light absorption is not pathognomonic for the presence of current or recent bleeding from bruises under the skin surface. This presentation will trace prior research of using colorimetry alternate light in the assessment of bruises, topical products, and other naturally occurring skin artifacts that could mimic bruises. Attendees will learn to differentiate ALS findings that fluoresce versus absorb light and why escaped blood under the skin will absorb light.

The use of an ALS in a clinical setting can be used to support the consistency of the location of blunt force trauma obtained per patient history and to further support finding on a physical examination, such as pain or tenderness at the site(s) of absorption. Photographs of bruises under different alternate light wavelengths will be presented as well as clinical tips on taking photographs of ALS findings in a darkened exam room.

This presentation will discuss future bench and clinical research needs based on the study's findings. For example, in this study, researchers used yellow and orange goggles with plastic lenses sold and distributed by the ALS manufacturer. However, using a colorimeter, there was inconsistency in the measured values of all the yellow and orange goggles. In addition, other companies sell yellow and orange goggles that also vary in color from one set of goggles to another. Future research is needed on assault victims, especially those of darker skin tones, who report manual strangulation.

---

#### ALS, Bruises, Absorption

## E69 Ocular Measures in the Detection of Deception

Frank M. Marchak, PhD\*, *Veridical Research and Design, Bozeman, MT 59771*

**Learning Overview:** After attending this presentation, attendees will understand the principals behind the use of eye movement tracking, pupil diameter changes, blinks, and other oculometric parameters as measures of deception.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about alternative physiological measures that can be used in place of, or in conjunction with, traditional polygraph measures, along with data on their effectiveness. Current state-of-the-art commercial systems that employ these methods will be reviewed.

Law enforcement, military, and governmental agencies need robust credibility assessment and deception detection tools to keep up with an increasingly large number of investigative cases. Humans historically have shown poor performance when performing this task without aid. Polygraphy has been the predominant method of credibility assessment since it was first used by law enforcement in the 1920s. While this methodology can claim a high degree of accuracy when properly administered and used to investigate specific instances of events, it has proven to be less than optimal in several situations, leading to the investigation of alternative techniques and technologies. The National Research Council of the National Academies of Sciences has noted: *The limitations of the polygraph, especially for security screening, justify efforts to look more broadly for effective tools for deterring and detecting security violations.*<sup>1</sup>

Polygraphy hypothesizes that individuals in deceptive situations experience an emotional response that causes arousal of the Autonomic Nervous System (ANS). Increase in arousal is detected through measurement of changes in physiological functions in respiration, blood pressure, and skin conductance. Change in the responses of cognitive and perceptual processes can be measured and employed in a similar manner. Changes in eye movement patterns can serve as an indirect measure of memory and effectively indicate concealed knowledge. Like polygraph measures, pupil diameter is affected by arousal in the ANS but also by cognitive workload through the Central Nervous System (CNS). This provides the potential to combine CNS and ANS measures to investigate prior knowledge and deception detection. Similarly, research has shown that blink parameters are diagnostic in determination of deception, with the differences accounted for by both theories of cognitive load as well as arousal-based theories.

Ocular measures of veracity have applicability across a variety of domains. Determination of concealed knowledge and credibility assessment are obvious applications for use in law enforcement and suspect questioning. Source verification is another application well suited to this technique as it permits a quick screening of an individual to determine if other credibility assessment methods should also be employed. The various protocols can be applied in other areas including customs, border crossing, and questioning of enemy combatants.

As this technology moves from research to commercial products, this report will provide a background to both better understand the potential of such applications as well as determine their effectiveness for specific situations. After presenting information on the principles and practicalities of collecting ocular measures, an overview of currently available commercial systems will be provided. Attendees will leave with a better understanding of the benefits and limitations of this approach and how it compares with current deception detection methodologies.

### Deception Detection, Polygraph, Ocular Measures

## E70 Breaking the Code to Better Understanding Asian Youth Gangs

*Cliff Akiyama, MPH, MA\*, Akiyama and Associates, LLC, Philadelphia, PA 19143*

**Learning Overview:** The goals of this presentation are to present timely data on Asian Pacific Islander youth gangs and offer strategies on how to recognize and interpret various tattoos and graffiti associated with these gangs, which could assist the medical examiner/coroner and death investigator in the positive identification of the decedent out in the field and/or in the autopsy room. In addition, this presentation will also discuss some of the recent gang enhancement laws that California, North Carolina, Virginia, and Idaho have in place to help tackle this deadly problem.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering new strategies to help keep medical examiners/coroners, death investigators, law enforcement officers, and first responders safe when dealing with these gang members so everyone can go home safe at the end of their shift.

Every day we hear of someone who has fallen victim to gang violence. Youth gangs throughout the United States continue to terrorize the neighborhoods they claim as their own, causing citizens in these gang-infested neighborhoods to live in constant fear of their lives. As a result of the recent influx of gang violence and gang-related homicides in all communities, the safety of first responders and investigators at crime scenes are jeopardized. This leaves medical examiners/coroners, death investigators, and detectives as possible targets of intramural shootings because they are at the scene. Crime scene personnel shootings have increased nearly 55% in the past year. Throughout the United States, gang violence has risen over 65% in the past 12 months. Every state has gangs, and the problem is getting much worse in areas that traditionally do not have gang problems. Gangs are not just an urban problem, but a suburban and rural problem as well.

With the population of Asian and Pacific Islander Americans (API) continuing to rise in the United States, so do their needs. Unfortunately, not all Asian Americans are as uniformly educated, acculturated, and financially stable as the myth of the “model minority” suggests. Although adults from the API region have adapted well to life in the United States, serious problems have emerged among Asian American youth. In particular, youth gang violence in the API community has dramatically increased in the past few years by nearly 85% nationwide according to the United States Department of Justice, Office of Juvenile Justice and Delinquency Prevention. In Los Angeles County, CA, there are currently 275 Asian youth gangs, with a total gang membership of over 12,000. In neighboring Orange County, CA, gang involvement has reached an all-time high with more than 87 documented gangs and a membership of more than 4,000. Demographics show gang members’ (male and female) average age is 15 years with a range of 8–22 years. Even more disturbing is the increase of Asian females involved in gang activity. In Orange County, where the Asian gang population makes up 18% of all gang members, there are 225 Asian female gang members, up 78% from last year. Other surrounding counties in California and the cities of Philadelphia, PA, Portland, OR, and Fairfax County, VA, have seen similar trends with the rise of Asian youth gangs. For this study, more than 700 gang members were interviewed in the streets, jails, and juvenile halls in California, Virginia, and Pennsylvania. This study identified ten distinct manifestations of gang violence and eight ethnic differences and similarities among Asian gangs (i.e., definite cultural differences between Asian gangs and various other ethnic gangs; drugs; weaponry; killing over turf/territory; extortion; defacing property/graffiti; women in gangs).

This study found ethnic characteristics of the Asian street gang are different from other ethnic street gang (African American or Latino). The primary motivation of the Asian gang is monetary profit. Asian gangs tend to be extremely violent, prey on their own culture, and are extremely mobile, meaning that they move from one geographic area to another to commit crimes or evade law enforcement. What makes this study unique is that this study has identified and categorized Asian gangs as either “traditional” or “non-traditional” in their motivations and crimes that they commit.

One group of Asian gangs is the “Pacific Islander” gangs. The Pacific Islanders are a category comprised of Filipinos, Samoans, and Chamorros, who will often follow the “traditional” patterns of gang behavior. In essence, they are “traditional” in the sense that they model themselves from the Latino and African American gangs.

---

### Asian Gangs, Gang Enhancement Laws, Youth Violence

## E71 Characteristic Injuries of Organized Dogfighting

Rachel Touroo, DVM\*, Gainesville, FL 32608-1166

**Learning Overview:** After attending this presentation, attendees will be able to identify dog breeds commonly utilized for animal fighting, recognize the pattern of injuries associated with organized dogfighting, and how to appropriately document dogs suspected of being exploited in the commission of this crime.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the recognition of this clandestine crime. Animal fighting, such as organized dogfighting, represents intentional, severe abuse of animals. Animal fighting is illegal in all 50 states and the federal Animal Welfare Act prohibits animal fighting ventures. Still, this organized abuse of animals is rampant throughout the United States. Organized crimes, such as racketeering, illegal gambling, illicit drugs, and firearms offenses, are frequently associated with animal fighting. Therefore, it is critical that law enforcement possess a basic understanding regarding the animals involved, the pattern of injuries associated with organized animal fighting, and how to appropriately document these animals.

Often, veterinarians are requested by law enforcement to examine animals alleged to have been utilized in organized animal fighting. In such cases, the veterinarian must be able to identify, collect, and properly preserve evidence found on the animal(s). Though veterinarians are typically unfamiliar with the pattern of injuries associated with this crime and how to properly handle evidence, this presentation will further serve to assist veterinarians in recognizing, responding to, and assisting law enforcement in the investigation of animal fighting, while highlighting the most current research and techniques.

In the United States, higher-level (professional and hobbyist) fighting dogs are almost exclusively American Pit Bull Terriers. Research by Intarapanich et al. compared the distribution and extent (number of body zones affected) of injuries observed in Pit Bull-type dogs seized in conjunction with organized dogfighting to dogs of various breeds of the same sex and similar weight involved in spontaneous dogfights.<sup>1</sup> The five most commonly injured areas associated with organized dogfighting, in decreasing order of frequency, were the front legs, dorsal and lateral aspects of the head, muzzle and oral mucosa, dorsal and lateral neck, and ventral neck and chest. The most commonly injured areas associated with the spontaneous dog fights, in decreasing order of frequency, were the pinna followed by the dorsal and lateral neck as well as the front legs. Looking closely at the percentage of dogs in each group that sustained injury, a clear difference was appreciated, as dogs engaged in organized dogfighting were much more likely to present with multiple injuries in these areas, as opposed to those engaged in spontaneous dog fights, where there were only single or limited injuries. Therefore, when prevalence was considered along with the most commonly injured areas, there was a distinct difference in the pattern of injury between spontaneous and organized dogfighting.<sup>1</sup>

The distribution of organized dogfighting injuries were further validated by Miller et al., who found that scarring and wounds associated with organized dogfighting were primarily concentrated on the front legs, dorsal and lateral head, and muzzle and oral mucosa.<sup>2</sup> Additionally, it was found that dogs with ten or more injuries to the front legs, dorsal and lateral head, and the muzzle and oral mucosa to be a reasonable threshold for high risk of dog aggression, especially in male dogs.<sup>2</sup> Therefore, when documenting medical findings it is of the utmost importance that all wounds, scars, and lack thereof be thoroughly documented and photographed. A “scar chart” or wound-and-scar body diagram should be completed to demonstrate the distribution of scars and/or wounds. However, typically not all dogs in a dogfighting yard will have wounds and/or scars present. Some dogs may simply be too young to have yet been fought, while others may be utilized primarily for breeding purposes or may be maintained to act as a guard dogs or may serve as pets.

### E72 The Use of Forensic Osteology in Animal Cruelty Investigations

*Amanda Fitch, MS\*, American Society for the Prevention of Cruelty to Animals, Newberry, FL 32669*

---

**Learning Overview:** The goal of this presentation is to inform attendees of the value of forensic osteology analysis in animal cruelty investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating that the use of forensic osteology in cases of animal cruelty may not only offer more specific information than radiographs, but also how this information could be used to file additional charges against the abuser.

Forensic anthropology is a common discipline utilized in the identification of human remains that are decomposed or otherwise unrecognizable. Unfortunately, it is not possible to glean all the same information from animal bones as is possible with a forensic anthropological analysis of human skeletal remains. For example, ancestry/breed and sex are often indeterminable. These factors, in addition to the technical definition of anthropology (the study of man), make the term forensic anthropology inappropriate in an application to animals. Therefore, the phrase forensic osteology is recommended when referring to the analysis of non-human skeletal remains. Applied to both humans and non-humans, forensic osteology is the study of skeletal remains to determine the causes and circumstances of death. In addition to developing in the same manner as human bones, animal bones also respond to trauma in generally the same manner. While there are structural and morphological differences (such as the shape of the cranium) that result in different effects, how bones react under force is generally predictable, making it possible to employ similar practices to the analysis of trauma in animals as are utilized for human victims.

The discipline of forensic osteology is not generally utilized in the investigation of animal cruelty crimes. The forensic examination of deceased animals is performed by veterinarians who typically rely on radiographs or Computed Tomography (CT) scans to visualize the skeleton. Although it is possible for injuries to not be visible through imaging, many veterinarians do not have the time, resources, equipment, or training to process deceased remains down to just skeletal elements. Similarly, veterinarians are trained to analyze skeletal trauma in regard to fixing it—not as it applies to a cause of death. This lapse in analysis occurs despite the results of a survey that was conducted of prosecutors and indicated that “bones” ranked higher than DNA when survey participants were asked what types of evidence from the scene influenced their decision(s) to prosecute animal cruelty crimes.

This presentation will discuss two specific animal cruelty cases for which the discipline of forensic osteology was utilized. Both victims to be discussed were dogs, with one death the result of multiple gunshot wounds and the other related to blunt force injuries. In both cases, the osteological analyses were able to offer additional and more specific information than the radiographs. In one case, this additional information resulted in an additional felony animal cruelty charge. Finally, there will be discussion of the osteological findings that have been found to be suggestive of dogfighting.

---

#### Animals, Cruelty, Osteology

## E73 Gap Assessment of Stress, Vicarious Trauma, and Resiliency for Forensic Science Professionals

Andrew P. Levin, MD\*, Adult and Forensic Psychiatry, Hartsdale, NY 10530; Heidi Putney, MA\*, Central Michigan University, Tacoma, WA 98407; Danielle M. Crimmins, MS\*, Purdue University, West Lafayette, IN 47907; Jonathan G. McGrath, PhD, National Institute of Justice, Washington, DC 20531

**Learning Overview:** After attending this presentation, attendees will understand: (1) the unique characteristics of vicarious trauma experienced by Forensic Science Professionals (FSPs); (2) factors correlated with stress and burnout among these professionals; and (3) recommendations for improved resiliency.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and medicolegal death investigation communities by addressing the gap in scientific literature related to stress, vicarious trauma, and burnout for FSPs. Attendees will learn the results of a recent study that used the Vicarious Trauma-Organizational Readiness Guide (VT-ORG) developed by the Office for Victims of Crime (OVC) modified for FSPs. Vicarious Trauma (VT) has been characterized by intrusive thoughts, avoidance and withdrawal, and symptoms of tension and disturbed sleep.<sup>1</sup> Responses are related to the indirect exposure to a traumatic event through second-hand materials, such as images or stories. Professionals suffering from these symptoms report lower job satisfaction, emotional exhaustion, increased thoughts of leaving their position, and stress in their family lives.<sup>2</sup> Similarly, burnout is characterized by fatigue, poor sleep, headaches, anxiety, irritability, depression, hopelessness, cynicism, and a lack of professional efficacy.<sup>3</sup> Burnout and VT often develop together and many of the symptoms overlap. Attendees will learn suggestions for future research and policy implications regarding resiliency resources.

A subset of VT literature has documented a litany of issues in first responders, law enforcement, legal professionals, and human services providers.<sup>4-6</sup> A handful of studies have attempted to characterize stress responses and identify effective coping strategies in FSPs. One study of crime scene investigators' physical responses to stress found that heart rates increased by approximately 50 beats per minute at crime scenes compared to routine activities.<sup>7</sup> A 2011 study found that although virtually all of the digital investigators who participated were satisfied with their jobs, 68% felt they were under a lot of stress and half stated that aspects of the job made them upset.<sup>8</sup>

Studies with first responders, such as police, firefighters, and emergency medical services, have supported several strategies for addressing stress and increasing resiliency. Resiliency is the ability of individuals exposed to highly disruptive events to maintain both healthy psychological and physical functioning. Studies of effective interventions have concluded that organizations must train employees to accept and recognize stress as a routine part of the job and offer them strategies to reduce the stress.<sup>9</sup>

The current study used an anonymous, online survey of seven laboratories to ask FSPs about their self-reported stress levels and their perception of organizational support for stress reduction. The first instrument, the VT-ORG, modified for FSPs, gathered information about the perception of the organization's efforts to support this stress in employees. The second survey, Professional Quality of Life (ProQOL), contained self-reported questions about the employee's stress responses and job satisfaction. Additionally, a demographic questionnaire asked questions relevant to job stressors. The results will be fully discussed as well as suggestions for future research and policy implications regarding resiliency resources for FSPs.

### Forensic Science Professionals, Vicarious Trauma, Stress

## E74 Advances in Color and Texture Analysis of Human Hair

David S. Hernandez Funes\*, Orlando, FL 32826; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816

**Learning Overview:** After attending this presentation, attendees will understand that color and texture of hair samples can be quantified to support the classification of hair features in forensic analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing methods to quantifying these features and various statistical techniques that can be used to classify different hair samples.

Hairs and fibers are very common types of trace evidence found in crime scenes. Hairs in particular are naturally shed by most mammals, giving them a higher transfer potential at a crime scene. The first stage in the forensic analysis of hair evidence is the attempt to determine the source of the hair and whether the hair is animal or human. Animal hairs contain significantly different features when compared to human hair and, in some cases, the animal species may be determined. As for human hair, it contains ancestral differences such as color, texture, cross-sectional shape, shaft form, and others that can aid in suspect identification. The analysis of human hair can sometimes be problematic due to the subjectivity of the descriptors used. Broad categorical descriptors derived from the examiner's skills and experience are sometimes used to classify different features, and these may vary between examiner. Also, there exists the potential for experimenter bias, which can be mitigated through the use of empirical data and more objective/quantifiable descriptors.

Forensic hair analysts evaluate features observed at both macroscopic and microscopic levels. Macroscopic features are those that can be easily seen by the naked eye, such as length, color, and hair form. Microscopic features evaluate the three main areas of the hair: the cuticle, the cortex, and the medulla. Each of the areas contain features that can be used to associate or discriminate between two samples. The cortex contains many characteristics that can be used for comparison (e.g., the texture and the color of the hair). However, when analyzing these two features, subjective and relative descriptors are usually used to describe them. Efforts have been made to empirically determine color with some success; however, little has been conducted to analyze the texture. Development of high-resolution digital microscopes allows researchers to closely examine these characteristics and obtain more accurate measurements. In this study, a VHX 6000 Keyence® digital microscope was used to explore the variance within the color and texture characteristics throughout the hair, as well as the inter- and intra-person variability. The color distribution of hair and texture analysis were obtained using MATLAB® image software. The samples consisted of 25 fallen hairs from 75 individuals of different ancestries between the ages of 18 and 35 years. Only samples with natural hair color were considered for this study. Analysis of variance was performed to assess the inter- and intra-sample variability among hairs. The color distribution of the hair was determined using a Red-Green-Blue (RGB) color model. This enables a more accurate description of the color of the hair given that it encompasses the natural variability of color change through the hair, allowing for a more comprehensive assessment. Clear differences can be seen in the distribution between the most common hair colors (black, brown, red, and blond). As for texture analysis, neural networks were used to attempt to classify the texture of hair based on grayscale images, allowing for a more objective analysis of texture.

This presentation will increase the knowledge of the variability within hair features and provide a novel method for quantitatively assessing color and texture of human hair. It is important to note that this study is aimed at supporting the forensic hair community by providing a tool to quantify features to classify unknown and known hair samples, not necessarily to compare hair samples directly.

### Hair Analysis, Macroscopic Measurement, Neural Networks

---

### E75 Discrimination Between Human and Animal Blood by Attenuated Total Reflection/Fourier Transform Infrared (ATR/FTIR) Spectroscopy for Forensic Purposes

*Ewelina M. Mistek, MS\*, State University of New York at Albany, Albany, NY 12222; Igor K. Lednev, PhD, State University of New York at Albany, Albany, NY 12222*

---

**Learning Overview:** After attending this presentation, attendees will gain knowledge about: (1) the limitations of current methods for bloodstain analysis during forensic investigation; (2) the importance of species identification from blood traces found at a crime scene; (3) the significance of a non-destructive method for examination of trace evidence at a crime scene; and (4) the advantages of FTIR spectroscopy in forensic investigation. The goal of this presentation is to disseminate results of FTIR spectroscopy for bloodstain examination as well as the results of chemometrics for distinguishing between human and animal blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by disseminating results of the non-destructive and rapid discrimination between human and animal blood at a crime scene immediately after discovering a crime scene.

Bloodstain identification is one of the most essential aspects of forensic casework involving violence. Presumptive tests can be used for unveiling the presence of blood. Unfortunately, false positive results may be obtained from substances other than blood. Subsequent DNA profiling can be performed to compare the profile with those in a DNA database. This can waste time, money, and other resources if the DNA was obtained from a stain of non-human origin, in cases where human DNA was of intention. Therefore, another very important step of forensic casework is the identification of origin of a stain: human or non-human blood. Discrimination between species can be especially critical in hit-and-run incidents for confirming suspect's testimony whether an animal or a human was involved in an event. Therefore, having a reliable method for non-destructive species identification from a bloodstain would be extremely beneficial and would save time, money, and other resources.

This study proposes the use of ATR/FTIR spectroscopy for identification and characterization of bloodstains. Specifically, this technique in combination with advanced statistical analysis, showed promise for differentiating between human and non-human blood traces from a pool of forensically relevant species. The statistical modeling demonstrated high prediction accuracy of bloodstains from unknown samples. The great advantage of this technique is its non-destructive nature, which makes it practical for forensic applications. The non-destructive examination can be performed on the same sample using ATR/FTIR spectroscopy and subsequent DNA analysis. Commercially available portable instruments make on-scene examination possible. Rapidly obtained results on scene give the great benefit of saving time, money, and other resources combined with immediate results during the first, critical hours of a criminal investigation.

---

#### Bloodstains, Human Origin, Non-Destructive Analysis

## E76 Linking Footprints to Feet: Research Advances and a *Daubert* Case Study

Michael S. Nirenberg, DPM\*, *Friendly Foot Care, PC, Crown Point, IN 46307*; Kewal Krishan, PhD, *Panjab University, Chandigarh 160 014, INDIA*

**Learning Overview:** After attending this presentation, attendees will learn the current scientific foundations and limitations of utilizing a footprint or footprints found at crime scenes to identify the criminal.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight and knowledge into the relatively new field of forensic podiatry, with a focus on footprint impression analysis.

Footprints recovered from crime scenes do not always display papillary ridge marks like those of fingerprints and, in these situations, footprint analysis involves measurement and comparison of the footprint's outline, shape, and consideration of other features.<sup>1</sup> The discriminatory and individualistic value of bare footprints is well-established, as are their use in linking (and unlinking) suspects to crime scenes. Research has found the odds of a chance match of a bare footprint to be one in 1.27 billion.<sup>2</sup> Numerous factors contribute to this individualistic nature of footprints, including a person's biomechanics, anatomy, weight, footwear, and particular habits or activities.

While bare footprint individuality has been proven, research on sock-clad footprints and foot impressions in insoles has been sparse. This research will present findings from a study published on the analysis of sock-clad footprints that established similar individuality to bare footprints. There will also be discussion on initial findings from a recently completed study on foot impressions in shoes.<sup>3</sup> The ability to establish the individuality of a footprint, whether bare, sock-clad, or inside footwear, has important consequences for forensic experts comparing suspects to such impressions.

Further, previously numerous methods of footprint measurement and comparison were proposed, some utilizing descriptive statistics to establish their validity. A method, tested with inferential statistics, was recently advanced by Reel et al. and has been found to be highly reliable across a combination of reliability tests.<sup>4</sup> This method, known as the "Reel Method," is now considered by some experts to be the gold standard for determining 2D linear footprint measurements for forensic comparison.

The state of the science of forensic footprint analysis will be reviewed with particular emphasis on meeting the *Daubert* standard, which was met in an analysis of a bloody sock-clad footprint found at a homicide scene. The case study of the *Daubert* challenge will be reviewed in the context of the latest scientific advances. Limitations remain in the analysis and comparison of footprint evidence and the presentation will highlight research that remains to be done as well as the aspects that can be relied on to link (or unlink) a footprint found at a crime scene to a suspect.

### E77 A Tale of a White-Tailed Deer: Anomalous Serology and DNA Results Offer Clues in an Alleged Hit-and-Run Case

*Maheer Nouredine, PhD\*, ForensiGen LLC, Oak Ridge, NC 27310; AnnMarie Clark, MS, William R. Maples Center for Forensic Medicine, Gainesville, FL 32608; James A. Bailey, PhD, Minnesota State University Mankato, Bailey, NC 27807*

**Learning Overview:** After attending this presentation, attendees will be familiar with certain types of biological evidence that can be encountered in hit-and-run cases and the potential for erroneous identification of evidence using DNA and serology testing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that forensic analysis of biological evidence in hit-and-run cases can lead to false conclusions and underscores the importance of integrating wildlife testing as a critical component in forensic identification.

Serious bodily injury or loss of life can result from an accidental or intentional impact between a motor vehicle and a pedestrian. In cases involving allegations of hit-and-run, the recovery and testing of biological evidence can assist in advancing investigative efforts and incident reconstruction. Testing for the presence of blood can become the driving force in the pursuit of the offending vehicle and ultimately the suspect. Presumptive tests for blood, such as the phenolphthalein-based Kastle-Meyer test, the Hemastix<sup>®</sup> test, and the luminol/Bluestar<sup>®</sup> test are easy to use and are relatively inexpensive to screen samples for the possible presence of blood. However, those tests are not specific to human blood and can result in false positive reactions to substances other than blood. The tests will react to hemoglobin-containing blood from any mammal as well as blood from other organisms. Using both the Kastle-Meyer test and the Bluestar<sup>®</sup> test, this study observed positive reactions to blood samples collected from birds, reptiles, amphibians, and bony fish. Also observed were positive reactions to samples collected from circulatory fluids of many invertebrates, such as annelids (earthworms), arthropods (spiders), and others. The circulatory systems of those organisms contain iron-rich hemoglobin or copper-rich hemocyanin for respiration. Prudence is warranted in general when testing suspicious stains or biological samples on motor vehicles with presumptive tests for blood. The opportunity exists for encountering stains from various wildlife species, thus potentially leading to false conclusions. To illustrate this issue, an actual case study with complex parameters involving two vehicles and an allegation of a hit-and-run scenario will be discussed.

A female decedent was killed after being struck by a motor vehicle. The case parameters indicated another vehicle, which initially fled the scene. Examination of that vehicle revealed the presence of suspected biological material that was pursued as evidence of involvement in the same incident. Ultimately, the investigation focused on the second vehicle and the driver was charged with homicide because, among other reasons, biological tissue that appeared to be of human origin was found adhered to the undercarriage of his vehicle. Samples from the biological tissue were tested and revealed positive results with the presumptive Kastle-Meyer blood test. Additional confirmatory tests for blood using the RSID<sup>™</sup> blood card revealed negative results. DNA analyses using the Identifiler<sup>®</sup> Human Identification typing kit were unsuccessful in developing a DNA profile from the tissue samples. The failed DNA testing was initially blamed on sample degradation. However, close examination of the profile data revealed the presence of an allelic peak near the amelogenin marker that has been previously described as an artifact of animal DNA amplification with the amelogenin locus primers.

Testing for wildlife DNA is a relatively simple genetic assay using Polymerase Chain Reaction (PCR) technology. It targets a portion of the mitochondrial DNA (mtDNA) commonly used for population studies of various species. Population genetics has provided ample material for comparison of sequence data to determine species from unknown samples. The tissue samples in this case were tested for DNA from a wildlife species. A small piece of the tissue was removed using a sterile scalpel. The sample was then extracted using a QIAGEN<sup>®</sup> DNA Investigator Kit. The extracted DNA was quantified and PCR amplified using primers that target the cytochrome b portion of the mtDNA. The resulting sequence was compared to all sequences contained in<sup>®</sup> via the Basic Local Alignment Search Tool (BLAST). In this case, the sequence aligned with *Odocoileus virginianus* (white-tailed deer) and not *Homo sapiens*. The results confirm the need to keep an open mind about the source of biological material that is adhered to a vehicle. In this case, the biological material found on the undercarriage of the suspect vehicle was most likely picked up when that vehicle ran over the remains of a deer.

### E78 Digital Photography of Decomposed Fingertips for Postmortem Fingerprint Identification

Rachael Landrie\*, *Office of the Chief Medical Examiner, Washington, DC 20024*

---

**Learning Overview:** After attending this presentation, attendees will understand a method using digital photography and enhancing software to obtain postmortem fingerprints of decomposed decedents who are otherwise unidentifiable and traditional ink/digital fingerprint methods are ineffective.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a cost-effective and non-destructive postmortem digital photography fingerprint method to identify decomposed decedents in the medical examiner field.

In many medical examiner offices, the primary means of decedent identification is through fingerprints using ink or digital technologies. However, some decedents are too decomposed to utilize these technologies. When a decedent is desiccated or macerated, the fingertips are often dried, hard, and wrinkled or too moist to use standard ink/digital methods. In these cases, medical examiner offices must rely on alternate identification methods, such as radiograph/dental comparison, fingertip rehydration techniques, or DNA. These alternate methods can be labor intensive, costly, and destructive, and at times are ineffective. Radiograph/dental comparison and DNA often require the decedent to be tentatively identified. As a result, a method for capturing fingerprints of desiccated and macerated decedents is needed.

An improved method using digital photography and enhancing software, Adobe® Photoshop®, was developed to obtain suitable fingerprints from decomposed bodies for identification. The method requires a digital single-lens reflex camera, a macro-enabled lens, a tri-pod, and a suitable light source to photograph each fingertip. Each fingertip is photographed with a one-inch ruler held in plane with the fingertip. The ruler must be labeled to identify the fingertip (e.g., RI, RII, etc.) and ideally the case number. All images are captured in JPEG, for viewing purposes and RAW file formats. The RAW images are imported into Adobe® Photoshop® and are adjusted to mimic a fingertip that has been captured with ink. The workflow includes converting the image to black and white, rotating the image to the correct position, inverting the image so the ridge detail is black, flipping the image, and adjusting the image to a 1:1 ratio using the ruler. Minor non-destructive enhancing techniques, such as contrast, brightness, and dodging/burning, are used to enhance the ridge detail further. Each image is placed onto the corresponding location on a digital ten-print card and the card is submitted digitally to the Federal Bureau of Investigation (FBI) for analysis.

The method has resulted in the positive identification of several decedents. Ten-print cards have been successfully entered into the Automated Fingerprint Identification System (AFIS) by the FBI Special Processing Center as well as analyzed by the Latent Print Unit. Several tips have been learned during method development that ensures the best possible fingerprint image is captured. These case studies and lessons learned will be presented.

---

#### Fingerprints, Photography, Postmortem Decomposition

## E79 Development of Baseline Performance Levels for Standardized Field Sobriety Tests in Sober Individuals

Zoe Foglia\*, Arcadia University, Glenside, PA 19038; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038; Scott M. Davis, Pennsylvania State Police, Harrisburg, PA 17110; Heather L. Harris, JD, Glenside, PA 19038

**Learning Overview:** After attending this presentation, attendees will better understand the standard procedures used for the administration of field sobriety tests and the validity of the Horizontal Gaze Nystagmus (HGN), Walk And Turn (WAT), and One Leg Stand (OLS) tests at assessing impairment through the development of baseline performance levels in sober individuals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining how sober individuals perform on the Standardized Field Sobriety Test (SFST) to determine if the currently used battery of tests is fit for its purpose of identifying an impaired driver.

According to the Substance Abuse and Mental Health Services Administration (SAMHSA), in 2013, approximately 28.7 million people admitted driving while under the influence of alcohol at some point during the year.<sup>1</sup> One of the ways law enforcement has chosen to combat this problem is through the use of observations and qualitative tests to determine if a driver could potentially be impaired. The qualitative tests have become known as the SFST battery. The three components of the official SFST battery include HGN, WAT, and OLS. Law enforcement officers began to use the National Highway Traffic Safety Administration's (NHTSA) SFST battery in the 1970s, and they went into widespread use in the 1980s.<sup>2-3</sup> The purpose of the three tests is to assist law enforcement officers in determining whether or not an individual suspected of driving while impaired by alcohol should be arrested. In this manner, SFSTs are used as a pre-arrest screen. Limited research exists regarding baseline performance levels on these tests in a sober population. Additionally, there are numerous factors that the current battery of tests does not take into account. This research project examined the prevalence of a number of these variables, including age, sleeping habits, medical/physical history, recreational drug and alcohol use, and caffeine and nicotine intake, to determine if any correlation could be found between specific physical or physiological factors and how one performs on the SFSTs.

This research project focused on using sober volunteers to develop baseline performance levels for each test to determine if the SFSTs are valid and fit for their purpose of identifying an impaired driver. The purpose was to determine if a sober population can successfully meet the current standards and criteria used by law enforcement when evaluating the SFSTs. Participants in this study completed a questionnaire describing their medical history and various lifestyle choices. After having completed the questionnaire, the SFSTs were administered by a certified SFST practitioner to each volunteer in a controlled, isolated classroom setting to prevent any external variables from affecting the results. A group of participants underwent a second round of testing in a parking lot located next to a relatively busy road. This setting included distractions that may be present during real-life, drunk driving traffic stops. A separate cohort of individuals was also tested under two conditions: sober and after consuming alcohol. After all of the tests were completed, the results were evaluated to determine if the currently used three components of the SFSTs are fit for their purpose or if they are affected by other variables that are not commonly associated with driving impairment.

## E80 Statistical Evaluation of Latent Prints Developed by Oil Red O Solutions

Brent M. Allred, PhD\*, Defense Forensic Science Center, Forest Park, GA 30297; Amanda Kemmerer, AEOP, Forest Park, GA 30297; Mary H. Monks, BS, Defense Forensic Science Center, Forest Park, GA 30297

**Learning Overview:** This presentation will compare the relative quality of latent prints developed by the two most commonly promoted Oil Red O (ORO) solutions on numerous substrates and in sequence with other developmental techniques.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enabling latent print examiners to utilize the ORO solution that would deliver the best results when processing for latent prints on porous substrates.

While Physical Developer (PD) can develop latent prints on dry and previously wetted porous substrates, PD processing utilizes multiple components that are costly, can be destructive to paper, have a short shelf life, and are not suitable for all scenarios. Conversely, 1-[2,5-Dimethyl-4-(2,5-dimethylphenylazo)phenylazo]-2-naphthol, more commonly known as Oil Red O (ORO), is simpler, less expensive, non-destructive to paper, and has a much longer shelf life than pre-made PD solutions.

ORO has previously been suspended in either propylene glycol or with 0.23 M NaOH in 77% methanol by volume, hereafter referred to as ORO1 and ORO2, respectively.<sup>1,2</sup> The relative ability of these two solutions to develop latent prints has previously been evaluated to a limited extent. Also, ORO has been recommended to precede PD when used sequentially in series with other latent print processing techniques.<sup>2-3</sup> In a 2013 study, Frick, Fritz, Lewis, and Bronswijk contrarily noted that there was slightly better contrast when ORO was placed after PD, but still recommended PD follow ORO because of PD's "destructive potential."<sup>1</sup>

This research evaluated the two different ORO solutions on exemplars of both thermally sensitive and insensitive paper to determine which solution developed higher quality prints on each substrate for more than 20 donors. Prints developed by ORO solutions were benchmarked against those developed by PD and against those developed in sequence with 1, 2-indanedione and ninhydrin. Finally, the robustness of ORO solutions was tested using aged natural prints. Print quality was measured using the Universal Latent Workstation's (ULW) Latent Quality (LQ) Metrics overall clarity score as well as scoring by five trained latent print examiners using unenhanced grayscale images.

Overall, latent prints were sufficiently developed by both ORO solutions on most thermal and non-thermal paper exemplars. On one non-thermal paper, ORO2 provided equal or greater contrast and detail than on the thermal paper ( $p=0.01$  and  $<0.001$  as analyzed by both LQ Metric clarity and examiner scores, respectively). Contrastingly, ORO1 had equal or significantly ( $p < 0.05$  for half of the donors) better results on a thermal paper compared to the non-thermal paper. ORO2 typically produced higher quality prints than ORO1 for all substrates with only a few exceptions for some thermal papers. The relative quality of prints produced by both ORO solutions were typically of equal or higher quality than PD, except for a few donors for which the inverse was observed. Additionally, ORO was tested sequentially following 1,2 indanedione and ninhydrin, but preceding PD. Neither 1, 2-indanedione and ninhydrin inhibited ORO, but the resulting ORO prints were not of as high a quality as prints produced by only ORO. In summary, both ORO solutions developed latent prints of suitable quality for comparison, but ORO2 generally produced prints of higher contrast/clarity.

### E81 Tracking Trends Through the Peer Review Process

Jessica LeCroy, BS\*, Forest Park, GA 30297

---

**Learning Overview:** After attending this presentation, attendees will have an understanding of the unique application of the peer review process at the United States Army Criminal Investigation Laboratory (USACIL) through a simultaneous technical and administrative review of the case file and report. Attendees will also receive insight on why this new approach was needed and how it was developed. Attendees will be provided an understanding of how issues and errors detected in the peer review process can be monitored for trends and will be provided a summary of some of the trends noted during an evaluation of data gathered during calendar year 2018.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring a new peer review approach in practice in Latent Print and Footwear/Tire Track-related requests by the USACIL and how the peer review process is being utilized to track trends in the application of procedures and the mitigation of errors.

In addition to the traditional elements of administrative and technical review, the new peer review approach utilizes a specially designed checklist to rank errors detected in casework. This ranking system provides valuable insight into the critical nature of the errors and to better understand the potential impact of the error to reported results if it had not been detected. The review is categorized into several key components to better track where in the examination process issues routinely occur. The data gathered through the checklist is evaluated to look for positive and negative trends in the application of procedures or errors made in an attempt to improve case quality output and enhance the review process as a whole. Tracking of these trends allows managers and policy makers to adjust policy and resources with data to support the changes and to potentially evaluate how to prevent further review findings. This process also allows reviewers to provide suggestions, which may not be explicitly required per policy, but provides better overall collaboration between case examiner and reviewer to develop a more coherent work product. Results from an evaluation of data from 2018 will be discussed, which highlight the typical errors made and the impact of these errors to the case.

*The opinions or assertions contained herein are the private views of the authors and are not to be construed as official or as reflecting the views of the United States Department of the Army or United States Department of Defense.*

#### Peer Review, Trends, Latent Prints

## E82 Examining Drug-Related Deaths While in Custody: A Look Into the Role That Race Plays in Drug-Related Custody Deaths in Texas

*Jesus A. Campos, MS\*, Katy, TX 77449; Ashraf Mozayani, PharmD, PhD, Texas Southern University, Houston, TX 77004*

**Learning Overview:** After attending this presentation, attendees will better understand the correlation between deaths related to narcotics during custody in the state of Texas and race. The goal of this presentation is to introduce the concept of drug-related death occurrences during custody and present the data behind the association of race and specific type of drug found to contribute toward the cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of the nexus which exists between race and narcotics-related deaths of individuals in law enforcement custody. This presentation will also provide recommendations as to the necessity for thorough medical examinations of illicit drug-related deaths that occur in law enforcement custody.

Deaths of Americans in the custody of law enforcement is a widespread discussion being had in today's society. While much of the debate involves officer shootings during arrest or initial contact, drug-related deaths while in custody are a less-emphasized topic of discussion. The relationship between the race of the decedents and type of drug indicated as a cause of death by the medical examiner were tested. The results suggest that there exists a statistically significant difference between the race of the individual and type of drug associated with their death while in law enforcement custody.

As public scrutiny of law enforcement's treatment of minority citizens increases, empirical research in the fields of criminal justice and criminology increase as well. Primarily, these empirical studies seek to determine the association between citizen and police, which is most visible at the moment of initial confrontation or arrest. What is examined to a lesser extent are the occurrences between citizen and police after arrest. This report intends to examine occurrences of drug-related deaths of individuals in law enforcement custody. Specifically, it seeks to explore the relationship between race and type of narcotics that contribute to the cause of death to individuals in custody.

In understanding the current cannon of research associated with race and overdoses within custody, this report used official data gathered by the Texas Justice Initiative. The data is obtained through the mandatory reporting system between criminal justice agencies in the state of Texas and the Attorney General's Office when a death occurs in their custody. While this reporting has been in practice for decades, it was not until 2005 that it became streamlined and, in 2016, made open to the public. This study examines deaths linked to narcotic use while in law enforcement custody within the state of Texas for the period of 2015 through 2019.

Data analysis was conducted by examining the causes of death noted by medical examiners for each of the original deaths that occurred within this time frame ( $n=2,975$ ); only 3.5% ( $n=104$ ) listed a narcotic as a noted cause of death. The dataset breaks down Race by either Black, White, Hispanic, or Other. For the causes of death, this study only focused on narcotic names that were listed under the cause of death by the medical examiner. Statistical Package for the Social Sciences (SPSS), a multiple response report, is used in order to capture multiple narcotics listed in some subject's causes of death. Binary variables are created to reflect Cocaine, Methamphetamine, Amphetamine, and Other. This report then employed an uncertainty coefficient measure to determine the relationship between the race of the decedent and the form of narcotic noted as a cause of death by the medical examiner. While the Race and Drug type were too far from a uniform distribution to use chi-square, uncertainty coefficient is deployed, and the likelihood ratio between race and narcotics gave significant results.

The analysis of data conducted in this study indicates that there exists a relationship between the race of the decedent in custody and the type of narcotics associated with that individual's death. More specifically, the data finds that there exists a statistically significant relationship between Race and Cocaine ( $p=.022$ ) as well as Race and Methamphetamine ( $p=.002$ ). The results were unable to determine a significant correlation between Race and Amphetamine use and Other drug use.

The purpose of this analysis is to further the understanding of illicit drug-related deaths occurring to individuals who are placed under the supervision of a law enforcement agency. This report seeks to educate the public on the widespread occurrences of illicit drug-related deaths in custody, the types of drugs associated with these deaths, and demographics of the decedents.

### Overdose, Criminal Justice, Custody

## E83 The Application of 3D Motion Capture in the Analysis of Doubtful Forensic Cases

*Isabella Aquila, MD, PhD\**, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; *Roberto Raffaele, BE\**, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; *Giuseppe Ivan Aquila, Crotona, ITALY*; *Fabrizio Cordasco, MD\**, Università Magna Graecia CZ, Catanzaro, ITALY; *Matteo A. Sacco, MD\**, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; *Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY*; *Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY*; *Orazio Malfa, MD, University “Magna Graecia” of Catanzaro, Catanzaro ITALY*; *Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY*; *Santo Gratteri, MD, Catanzaro 88100, ITALY*; *Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY*

**Learning Overview:** After attending this presentation, attendees will know how 3D Motion Capture (MOCAP) could help forensic pathologists in recreating a crime scene closer to reality and how it can be considered very helpful in shedding light on murders cases, accidents, or suicides, making the dynamic of the events clearer.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility to help both prosecutors and detectives to understand complicated dynamics, becoming a form of judicial evidence in court. For these reasons, this presentation highlights how the correct use of the 3D MOCAP could become an essential instrument in crime investigations over the years.

During the past few years, forensic sciences have quickly developed the application of new information technologies for the reconstruction of crime scenes. The MOCAP is the recording of the movement of the human body for the immediate or deferred analysis through virtual reproduction. Presented is a virtual model created through 3D MOCAP. This method is useful for realizing a 3D video that reproduces the dynamics of the scene of doubtful forensic cases. The proposed model is not used routinely in forensics but through the analysis of these cases, its applicative utility is demonstrated. In particular, the forensic purpose is to compare the injuries analyzed at the autopsy or the inspection of the victim with the possible dynamics compatible with the environments in which the event occurred and testimonies. A judicial inspection was conducted and a planimetry of the apartment was requested for each case. The device used for the acquisition of movements was a stereophotogrammetric system, composed of infrared OptiTrack® cameras capable of capturing movements up to 100 frames per second (fps). Some objects have been modeled in 3D manually, taking into account the original measurements. Two actors mimicked the movements of the aggressor and the victim in cases 1, 2, and 3. In case 4, only one actor was used. The rendering of the frames was entrusted to Supermicro systems with multiprocessor Xeon quad and Nvidia Quadro Plex® systems for Graphics Processing Unit (GPU) rendering projects.

Reported are four forensic cases with different death modalities: two murders, an attempted murder, and a suicide.

In the first case, the scene and the injuries were analyzed for a woman found dead in her home. Death was caused by two different weapons: a knife and a stick. In this case, the dynamics, the phases of the event, and the simultaneous use of two weapons were not clear. In the second case, the death of a young boy killed at the door of his home by multiple gunshot wounds was assessed. In this case, the murderer declared a legitimate defense and the unwillingness to kill. Therefore, in this case, the use of this method was important to clarify the truthfulness of the declarations and the possible compatibility of the witnesses' stories. In the third case, a boy was evaluated who suffered a stabbing that caused cutting wounds in the pubic region. The aggressor declared his unwillingness to cause death but only the will to hurt the victim. The reconstruction with the application of the 3D model proposed by this study clarified any possible dynamics with analysis of the authenticity of the aggressor's statements. In the fourth case, the death of a man due to a firearm injury was analyzed. The analysis of the scene did not clarify the mode of death, as the body site affected was the left axillary region. Several dynamics compatible with the weapon used and the lesion analyzed were presented through the proposed experimental model.

In all cases, the dynamics were reconstructed using 3D MOCAP technology. The use of the method clarified the phases of the murder in the first case and assessed the mismatch of the aggressor's statements in the reasons for the crime of the second case. In the third case, it clarified the aggressor's intent to kill. In the fourth case, it clarified the suicide-type modality organized by the victim. In all cases, the reconstructions had a crucial role in court as tools to explain the hypothesized dynamics.

### E84 Geolocating and Protecting the Grave Sites of the Disappeared in Lebanon

*Malena Gonzalez Eichenberg, BS, Act for the Disappeared, Beirut, LEBANON; Marwan Khoury\*, University of Leicester, Leicester, Leicestershire LE1 7RH, UNITED KINGDOM*

---

**Learning Overview:** The goal of this presentation is to show how the Act for the Disappeared (ACT) started to document the fate of the missing of Lebanon, three decades after the end of the civil war. Attendees will be exposed to the methodology behind a preliminary open-source data gathering (newspapers, images, videos, official reports), the interviewing of direct sources (former fighters, witnesses, and survivors), and the crosschecking of different sources. This resulted in an investigative tool formed by a comprehensive database with interactive mapping that updates in real time as the data is modified. ACT will also share the necessary measures that it took to protect the sensitive findings, as well as a number of gravesites that were deemed at imminent risk.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by outlining how a local initiative led a serious citizen's-based investigation, after it became clear that successive governments were not prepared to undertake any meaningful action that would address the issue of the forcibly disappeared in Lebanon. ACT defied the odds that are defined by decades of post-conflict passivity resulting in data loss and grave site destruction and started collecting all remaining evidence. The methodology and the data management tools were developed with the support of the Argentine Forensic Anthropology Team (EAAF) and the International Committee of the Red Cross (ICRC), which in turn provided training on the scientific investigation of cases of political violence and the storing and archiving of sensitive confidential data.

ACT is a Lebanese human rights association founded in 2010 whose mission is to contribute to the clarification of the fate of the forcibly disappeared and missing of the Lebanese civil war. Approximately 17,415 persons went missing during this 15-year long conflict (1975–1990— as recognized by the Lebanese government. To this day, thousands of families are still waiting for information on the fate of their loved ones. In 2015, to complement the ICRC project of Ante-Disappearance Data (ADD) collection that started in 2012, and the Biological Reference Samples (BRS) collection that started in 2015, ACT started the collection of background information together with the mapping and the protection of grave sites. This work resulted in an investigative tool based on a comprehensive database with interactive mapping that updates in real time as the data is modified. The tool is built on Node.js and MongoDB following The Open Web Application Security Project (OWASP) security standards. The categories of the data include the missing person's case, checkpoints, detention centers, events related to cases of disappearances, potential grave sites, armed groups, contacts, and sources. The gravesites are ranked by three indices: risk of destruction, credibility of the information, and sensitivity of the site. Converging all these variables allows the filling of gaps and the association between individual cases and potential burial location and the location of the armed group's areas of control, checkpoints and detention centers, and links between previously unassociated cases of disappearances. Crosschecking such derived hypotheses with the ICRC's ADD and the postmortem examination results would increase the strength of the evidence and, therefore, facilitate identification. ACT also continues to work on the protection of potential gravesites to avoid their destruction.

---

#### Missing Persons, GIS Mapping, Grave Sites

## E85 The National Institute of Standards and Technology/National Institute of Justice (NIST/NIJ) Evidence Management Initiative

*Shannan Williams-Mitchem, MA\*, National Institute of Standards and Technology, Gaithersburg, MD 20899*

**Learning Overview:** After attending this presentation, attendees will learn about the activities of the NIST/NIJ Evidence Management Steering Committee (EMSC) including: the results of a national survey of evidence handlers, progress regarding the development of best practices regarding the retention and preservation of evidence types, and deliberations held at the Evidence Management Conference in October 2019.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that maintaining the integrity of physical evidence is a fundamental aspect of the administration of justice. Every day, critical decisions are made to determine outcomes in legal proceedings based on evidence and how it is managed. Once identified as evidence, the item begins a long and often complex journey until its final disposition (e.g., destruction, return to owner). Depending on the type of case, the type of evidence, the size of the item, and numerous other factors, an individual piece of evidence could be held for decades. Short- and long-term maintenance of the evidence involves a wide range of stakeholders, each with different organizational roles and responsibilities in the context of the larger system of justice.

In 2016, Congress passed the Justice for All Act calling for the “establishment of best practices for evidence retention” in consultation with federal, state, and local law enforcement agencies and federal laboratories. The NIJ commissioned the NIST to lead the development of evidence retention guidelines due to previous collaborations in the development of best practices for biological evidence published in April 2013. In March 2018, the EMSC met for the first time and developed a plan to complete its charge to: (1) develop best practices for the retention, preservation, integrity, and disposition of evidence and property; and (2) encourage adoption through education and engagement of the broad community of United States justice system stakeholders involved in the management of evidence.

Numerous studies and government-sponsored publications identify the need for best practices in the storage, preservation, and disposition of physical evidence. As the use of forensic evidence in criminal proceedings increases, the need to properly maintain the integrity of that evidence becomes pronounced. The national crises of untested sexual assault kits resulted in the passage of the SAFER Act of 2013 with revisions in subsequent years, which is symptomatic of a larger, systemic issue in the management of physical evidence. The NIST and NIJ 2013 report addressed storage issues in biological evidence, and the authors state: “Many law enforcement agencies do not recognize or support the efforts of their property rooms. Although these agencies bear ultimate responsibility for maintaining the integrity of the evidence, the real problem is a system-wide failure to properly account for evidence from collection through final disposition.”<sup>1</sup>

This presentation will include discussion of the activities that EMSC took to begin addressing the aforementioned issues. These activities include: (1) a national survey of evidence handlers and organization heads to learn more about existing gaps; (2) a review of the literature to support evidence preservation, storage, and disposition and identify gaps in the literature related to evidence handling and storage; (3) a public conference for federal, state, and local government representatives, communities of practice, and the public stakeholders to discuss, prioritize, and publicize evidence management issues and solutions; and (4) a report summarizing the findings of the previous three activities and identify best practices in evidence management in preservation, storage, and disposition.

This presentation will provide a summary of the findings of each of these activities and provide further opportunities for attendees to become engaged in the activities of EMSC.

### Evidence Management, Preservation, Stability

### E86 Challenges in Establishing an Innocence Project in the Philippines: The Innocence Project Philippines Network (IPPN) Experience

Maria Corazon A. De Ungria, PhD\*, DNA Analysis Laboratory, Natural Sciences Research, Quezon City, Metro Manila 1101, PHILIPPINES; Jose M. Jose, LLB, Jose Law Offices, San Juan City, Metro Manila 1500, PHILIPPINES

**Learning Overview:** After attending this presentation, attendees will better understand the background and history of the IPPN and the challenges it faced in organizing an Innocence Project in the Philippines.

**Impact on the Forensic Science Community:** The current Philippine administration has placed the re-imposition of the death penalty as punishment for drug trafficking and other drug-related offenses as one of its priority bills. This presentation will impact the forensic science community by exploring why an organization like the IPPN is needed now more than ever to ensure that no wrongfully convicted person is executed.

Inspired by the success of the first Innocence Project started by Peter Neufeld and Barry Scheck in 1992 at the Benjamin J. Cardozo School of Law, and the adoption by the Philippine Supreme Court in 2007 of the Rule on DNA Evidence, which provided for the first time a provision on post-conviction DNA testing, the IPPN was established in 2012 as a network of law school legal aid clinics, scientific and academic laboratories, and Non-Governmental Organizations (NGOs) that sought to make justice accessible to wrongfully convicted persons using DNA evidence.

IPPN has attracted volunteer lawyers and law and biology students from the following: (1) College of Law, Ateneo de Davao University; (2) College of Law, De La Salle University; (3) College of Law, University of Lipa; 4) College of Law, San Sebastian de Recoletos; 5) College of Law, College of Science and the DNA Analysis Laboratory, Natural Sciences Research Institute, University of the Philippines, and (4) Free Legal Assistance Group (FLAG).

The specific objectives of IPPN are: (1) to provide coordinated free legal assistance to persons wrongfully convicted; (2) to advocate reforms in policies, law, judicial procedures, criminal investigation procedures, and evidence handling; (3) to enhance capacities of justice stakeholders; and (3) to establish an independent and accurate databank on wrongful convictions in the Philippines.

After its launch in December 2012, IPPN conducted prison visits to the National Bilibid Prison and the Correctional Institute for Women where volunteer lawyers and law students interviewed prisoners who claimed to have been wrongfully convicted in order to find possible cases for post-conviction DNA testing. IPPN then conducted a Summer Internship Program in 2013 to train law student volunteers and is presently engaged in information awareness campaigns through social media and screenings of *Give Up Tomorrow*, a documentary involving a wrongful conviction case. In 2018 and 2019, IPPN conducted summer workshops with a prison visit to the minimum security compound of the National Penitentiary for volunteer interns to generate interest in the Innocence Project and to encourage the next generation of lawyers and health researchers to develop a passion for this type of advocacy.

One major challenge that IPPN discovered was the absence of properly collected and stored biological evidence in the cases where post-conviction DNA testing was being sought. Unlike other jurisdictions, there simply was no adequate and reliable system in place for the long-term preservation and collection of crime scene evidence. Thus, identifying and retrieving physical evidence for possible DNA testing proved impossible at this stage. In fact, in one celebrated case where DNA testing was ordered by the Philippine Supreme Court, no DNA test could be conducted since the biological evidence recovered from the crime scene could no longer be found several years later. A second challenge was the lack of a readily available sexual assault investigation kits so that biological evidence could be properly collected, preserved, and stored in cases of sexual assault within 72 hours post-contact. Another challenge is the absence of a law to create a forensic DNA database, which would have greatly assisted in the investigation of crimes. To date, IPPN has not yet found a single case in which the provision on post-conviction DNA testing could be applied to seek the release of a wrongfully convicted prisoner. Yet IPPN remains hopeful since the Philippine Supreme Court itself had earlier recognized and released statistics in the case of *People vs. Mateo* that showed a high judicial error rate of 71.77% in capital cases decided by the trial courts.<sup>1</sup> The need for forensic evidence such as DNA to close this gap becomes even more imperative.

#### Innocence Project, Wrongful Conviction, Forensic DNA Evidence

## E87 Terrorist Attack: The Identification of Destructive Lesions

*Lorenzo Spagnolo, MD\**, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Luigi Cipolloni, MD, PhD*, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; *Benedetta Baldari, MD*, Rome 00161, ITALY; *Livia Besi, Roma, ITALY*; *Michela Ferrara, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Stefania De Simone, MD*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Vittorio Fineschi, MD, PhD*, University of Foggia, Foggia I-71100, ITALY

**Learning Overview:** The goal of this presentation is to demonstrate the methodological approach to wound evidence that comes from different weapons used on the victims of terrorism in war zones. The focus is on the main macroscopic elements used for the preliminary distinction between different weapon injuries in order to guide the initial phases of the investigations and for the identification of problems following destructive lesions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees of the need to create a task force made up of forensic specialists, pathologists, radiologists, and dentists ready to intervene quickly in order to carry out the preliminary crime scene investigations, external examinations, and identification of the bodies in cases of death due to terrorist actions. The preventive acquisition of elements capable of allowing personal identification (fingerprints, radiographic assessments, and genetic typing) is necessary for military personnel engaged in high-risk areas.

In the past 20 years, terrorism, especially that linked to Islamic fundamentalism, has arisen all over the world and won the front pages of newspapers due to the brutality and the number of victims, including both soldiers engaged in peacekeeping missions and civilians in the West world as well as in the Middle East. A collection of cases of death by terrorist attacks will be presented.

Explosions, firearms, and air crashes are the main manner of killing. Explosions are the most frequent, causing almost 80% of the deaths, with 71% of deaths being military personnel, 22% being civilians, and 7% being hostages—both civilian and military.

In deaths due to explosions, the principal means used are cars or wagons filled with explosives, mixed with various types of metallic material added to increase the damage resulting from their projection in the space surrounding the explosion. The lesions found on the bodies of the victims vary according to the distance from the explosion: bodies found in the immediate proximity showed blast injuries with destructive lesions but also vast burns; the bodies found at greater distances showed missile injuries deriving from multiple splinters as minor as they were distant from the center; the bodies found farthest away mainly showed crushing injuries due to the collapse of buildings. The identification of the victims was often a major problem, especially for bodies found near the center of the explosions.

In deaths due to gunshot, the most used weapon is the gas-fired selective assault rifle Avtomat Kalashnikov (AK) both in the primal version (AK-47), firing the 7.62x39mm cartridge, and the next version (AKM-74), firing the 5.45x39mm cartridge. The macroscopic form of the entry wound as well as the exit wound was not regular and depended on the surface it traveled through before the impact with the body (e.g., car, doors) and during the intracorporeal trajectory (bones). Gunshots were also the usual cause of death among hostages. In these cases, the body is usually found several months after death, which often poses a problem related to the identification of the victims and to the establishment of the time of death.

Air crashes in the war zone principally refer to helicopters, which are the most-used means and, therefore, the most exposed to mechanical failures; and they are often targeted by enemy artillery or snipers. The external examination of the bodies recovered after a helicopter crash showed great precipitation trauma as well as heat lesions. In these cases, similar to explosion deaths, identification was not always possible due to the presence of destructive lesions.

During the initial phases of the investigations, the identification data of all the possible victims was preliminarily collected. These data had been crossed with the elements coming from the crime scene investigation (clothes, objects, identification plates) and the examination of the corpses (connotations, tattoos, dental prostheses). The collection of the circumstantial data, together with the external examination of the bodies with the macroscopic evaluation of the lesions, was often conclusive regarding the means of death in bodies with destructive injuries. Complete autopsies were then performed on the bodies and bone (femur) samples were taken for subsequent genetic investigations.

### Terrorist Attack, Destructive Lesions, Methodological Approach

## E88 Bovine Meat Fraud and Adulteration in Brazil: Innovative Techniques for Tamper Detection

Karen M. Nunes\*, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, BRAZIL; Marcus Vinicius de Oliveira Andrade, MSc, Brazilian Federal Police, Belo Horizonte, Minas Gerais 30441-170, BRAZIL; Marcio Talhavini, PhD, Brasilia, Distrito Federal 70736-030, BRAZIL; Mariana R. Almeida, PhD, Universidade Federal de Minas Gerais, Belo Horizonte 31270901, BRAZIL; Jose M. Amigo, PhD, University of Basque Country, Leioa, Vizcaya 48940, SPAIN; Marcelo M. Sena, PhD, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais 31270-400, BRAZIL

**Learning Overview:** After attending this presentation, attendees will understand important aspects about economically motivated food fraud in Brazil, specifically meat fraud processes, and new approaches using spectroscopic techniques combined with chemometric tools to detect illegal adulterations in bovine meat *in natura*.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing techniques with great potential for applications as a screening method, especially in regard to meat fraud identification.

World meat production has been growing at a rate of 0.64% per year. Alongside the United States, which accounted for 19.50% of total world production in 2018, Brazil is one of the world's largest meat producers (15.75% in the same year). The country accounted for 19.89% of all meat exported in the world last year, equivalent to 1.64 million tons (\$ 6.57 billion).<sup>1</sup> This corresponds to a growth of 7.9% over the previous year.

Due to the high demand for quality characteristics of fresh meat for export, concerns about the authenticity of food have been growing in recent years. In 2013 in Europe, one of the most famous incidents involving horsemeat tampering occurred.<sup>2</sup> In Brazil, the Federal Police had several scandals in recent years. In 2012, major food processors were investigated for bovine meat fraud by adding non-meat ingredients.<sup>3</sup> In 2017, the meat fraud in Brazil had the highest visibility and international impact with "Operation Weak Flesh."<sup>4</sup> The focus of this investigation was on the verification of irregularities, such as the use of animal carcasses for food production in other processing units, use of additives not permitted by law, bribes to federal inspectors and enforcement agents, and corruption.

The official methods for testing meat authenticity have employed classical techniques used for meat quality control, determining physico-chemical and microbiological parameters. However, these methods are time-consuming, laborious, and these individual parameters are inappropriate to characterize fraud due to the wide variation in the chemical composition of bovine meat, as a function of sex, cut, breed, feed intake, and slaughter age. On the other hand, the utilization of spectroscopic techniques combined with chemometric tools has shown great potential for forensic application as a screening method, because it provides fast, low-cost, minimally destructive analytical methods and requires little or no sample preparation.

In this work, the use of Raman hyperspectral imaging spectroscopy as a screening tool for fraud detection in bovine meat *in natura* by the addition of solutions of sodium salts and polysaccharides with the intention of increasing the water-holding capacity and, consequently, of obtaining economic gain. The mapped spectral range was from 2,400cm<sup>-1</sup> to 400cm<sup>-1</sup>. Data were processed using the HYPER-Tools graphical interface, and chemical maps were constructed using the Multivariate Curve Resolution (MCR) algorithm. As a result, the use of Raman imaging spectroscopy, combined with a chemometric tool, proved to be a promising method to help enforcement agencies fight against food fraud and adulterations. The use of these techniques facilitate this process, saving time and reducing costs.

### Meat Adulteration, Hyperspectral Images, Raman Spectroscopy

## E89 Multiple Implications of Postmortem Computed Tomography (PMCT) in the Forensic Approach to Charred Bodies

*Massimiliano dell'Aquila, MD\**, Sapienza University of Rome, Rome 00161, ITALY; *Aniello Maiese, MD*, Sapienza University of Rome, Rome 00185, ITALY; *Alessandra De Matteis, MD*, University Sapienza of Roma, Rome 00100, ITALY; *Raffaele La Russa, MD*, Rome, Lazio, ITALY; *Alessia Quattrocchi, Rome, ITALY*; *Mauro Arcangeli, Rome, ITALY*; *Paola Frati, PhD*, University of Roma "La Sapienza", Roma 00161, ITALY; *Vittorio Fineschi, MD, PhD*, University of Foggia, Foggia I-71100, ITALY

**Learning Overview:** The goal of this study is to carry out an operating protocol that provides the radiologist with keys to establish complete and focused reports in all cases of PMCT of burn victims. The radiological investigation will be addressed according to the specific needs of the case in order to differentiate between normal postmortem changes from heat-related changes and to help the pathologist in different issues ranging from the victim's gender identification to localization, foreign bodies, or possible sites for fluid and DNA sampling.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by using the results obtained to optimize, validate, and promote the operative protocol used in such a way that it can be consistently applied in all cases of burned/charred bodies. According to the needs, the radiologist must discern all contextual divergences with forensic history, and must be able to report all relevant elements.

Although a fire generally does not completely destroy a body, in forensic pathology the correct examination of a burned/charred body is a challenge. Over recent years, imaging methods have gained ground in all fields of forensic pathology, where PMCT prior to postmortem has proven useful as an accessible and contemporary tool for forensic investigations. By using PMCT, important information supplementary to the traditional postmortem is obtained. In addition, PMCT provides insight into areas not routinely investigated during postmortem, such as the facial skeleton, basilar skull, cervical spine, arms, and legs. Furthermore, PMCT provides many others advantages, such as objectivity, repeatability, and 3D rendering of the body surface, allowing the pathologist to choose the dissecting technique most appropriate to the characteristics of the case, avoiding improper techniques that can led to damage of the examined structures or loss of important elements. An advanced state of carbonization often complicates surgical dissection and some foreign bodies (bullets, prostheses, etc.) or bone alterations (osteosynthesis, traumatic fractures, etc.) could be missed. PMCT provides specific semiologies requiring a prudent understanding to differentiate between normal postmortem changes from heat-related changes and can help the pathologist in the victim's identification process, guiding him in the autopsy, and in the localization of possible sites for collecting DNA or fluid samples. It is also important to perform histological examinations to highlight the presence of fat embolisms in the lungs as a sign of vitality at the time of burn.

The main objective is to use the results obtained to optimize, validate, and promote the operative protocol used in such a way that it can be consistently applied in all cases of burned/charred bodies. According to the needs, the radiologist must discern all contextual divergences with forensic history and must be able to report all relevant elements, in order to answer the following questions: Are there tomographic features that could help identify the victim? Personal Identification: Point out the presence of metallic objects stuck inside the body that are highly radio-opaque and thus easily seen on the PMCT (jewelry, watches, etc.). Personal Identification: Point out the presence of internal medical devices that are useful when reported in order to correlate with the medical record of the alleged victim (vascular prosthesis, osteosynthesis equipment, dental fillings, surgical clips, pacemaker, intra-uterine device, etc.). Gender Identification: In extreme cases in which the corpse is in such a damaged state that the victim's secondary sexual characteristics are no longer distinguishable and the gender can no longer be defined. Nevertheless, the deep organs are relatively preserved from the heat by the abdominal wall or peritoneum. Thus, the uterus or prostate are generally present on PMCT, allowing a determination of the subject's gender. Is there evidence of remains of biological fluids in liquid form available for toxicological analysis and DNA sampling? (The collection of fluid samples, during the autopsy, is particularly important in the case of a charred body. In addition to the usual toxicological screening, forensic personnel would seek to ascertain the percentage of serum carboxyhemoglobin in order to determine whether death occurred before or during the fire. The availability of biological fluids is inversely related to the burning level of the body and the main risk is that the few biological fluids present could be lost during the surgical dissection. A detailed imaging analysis of the PMCT can be extremely useful to point out possible collection sites). Is there another obvious cause of death other than heat-related lesions, especially metallic foreign bodies of ballistic origin? PMCT will show the presence of foreign bodies (bullets, knives, blades, etc.) or radiological findings different from typical heat-related lesions (bone fractures different from typical heat-related fractures, epidural collections with a subdural appearance, etc.) that are capable of causing traumatic death. What are the characteristic burn-related injuries seen on the corpse that should be sought during the autopsy?

### Postmortem Computed Tomography, Charred Bodies, Forensic Science

### E90 “Giant” Aneurysm of the Right Coronary Artery—The “Fortuitous Event” in Road Traffic: The Relevance of the Judicial Autopsy

*Lorenzo Marinelli\**, AOU Arcispedale Sant’Anna, Ferrara 44124, ITALY; *Elena Lucenti, MD\**, University of Ferrara, Ferrara 44121, ITALY; *Omar Bonato, MD\**, University of Ferrara, Ferrara 44121, ITALY; *Mauro Coppone, MD\**, University of Ferrara, Ferrara 44121, ITALY; *Matteo Fabbri, MS\**, University of Ferrara, Ferrara 44121, ITALY; *Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Marianna Daniele, Ferrara 44123, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY*

**Learning Overview:** A “fortuitous event” is seen as a circumstance precluding “wrongfulness” or providing exoneration from responsibility in wrongful acts. The goal of this presentation is to report on a unusual case in which the death of a cyclist victim of a road accident was not attributable to the injurious consequences of the collision with the vehicle involved, but to a thrombosed giant right coronary artery aneurysm leading to a sudden natural death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the importance of the judicial autopsy in the event of a traffic accident fatality in order to verify the existence of a causal relationship between the accident and the death, which can lead to the recognition, or the exclusion, of any liability.

A 73-year-old man riding his bicycle was involved in a car accident, being hit by a truck. Upon arrival of the ambulance, the man was declared dead. Since there were no witnesses, the dynamic of the accident was unclear. The external examination itself, disposed by the prosecutor, showed few abrasions and lacerated/contused wounds in the right parieto-occipital region and in the left parietal region of the head, not allowing the identification of the cause of the death. Therefore a judicial autopsy was performed, which disclosed a large, tumor-like, sacular-shaped aneurysm of the right coronary artery measuring approximately 3.5cm in diameter. The internal wall of the aneurysm was covered with old thrombotic material, and the remaining lumen was obliterated by freshly clotted blood. The heart appeared dilated and weighed 530g, characterized by degenerative valvulopathy. There was significant atherosclerosis in the aorta and the large arteries, but no other aneurysms were found. Examination of the remaining internal organs revealed no other significant pathological conditions. No skull fractures nor encephalic injuries were found. The aneurysm was embedded for histology, and paraffin sections were stained with hematoxylin and eosin. Histological examination confirmed the different ages of the layers of thrombotic material. The vessel wall of the aneurysm was thinned and hyalinized with focal calcifications. Based on the detailed postmortem examination and the histopathological study of tissues, the cause of death was attributed to a thrombosed giant right coronary artery aneurysm.

Aneurysmal Coronary Artery Disease (CAD) is an abnormal dilatation of a localized or diffuse segment of the coronary artery tree. The incidence of coronary aneurysm among CAD is about 1.5% to 5%. A coronary artery aneurysm with a diameter of >2cm, which is termed a “giant aneurysm,” is even more rare. It may be congenital, or secondary to other diseases, such as atherosclerosis. Coronary artery aneurysms may exist without symptoms until a fatal event occurs.

A more common complication is thrombosis in the area of the aneurysm resulting from an alteration of blood flow or a defective endothelial layer. In case of complete luminal obstruction or when parts of the thrombus are embolized in more distant branches of the coronary artery system, acute myocardial infarction is almost inevitable. Thrombosis of the aneurysm and consecutive myocardial infarction was also responsible for death in the present case, which is remarkable for several reasons.

Primarily, the importance of judicial autopsy in the forensic medical diagnosis of death following a traffic accident emerges, and postmortem examination should always be performed, especially when there is the involvement of elderly subjects. Moreover, in road accidents characterized by modest impairment or low-speed dynamics, it is always necessary to identify the cause of the death and whether the people involved in the accident had any diseases that might be the responsible for a sudden natural death instead of a traumatic one, leading to the solution of crucial medicolegal problems.

#### **Giant Aneurysm, Fortuitous Event, Judicial Autopsy**

### E91 The Abuse and Misuse of Prescription Opioids: Is It Only an American Problem?

*Andrea Cioffi\*, Rome, ITALY; Zoe Del Fante, MD, Rome, ITALY; Nicola Di Fazio, Università La Sapienza di Roma, Rome 00161, ITALY; Gianpietro Volonnino, Roma, Lazio, ITALY; Enrica Pinchi, Roma, ITALY; Aniello Maiese, MD, Sapienza University of Rome, Rome 00185, ITALY*

**Learning Overview:** The objective of this study is to analyze the Italian context to better understand if there is the possibility of an epidemic of addiction, as is the case in the United States and Canada.

**Impact on the Forensic Science Community:** This study will impact the forensic science community as many studies have analyzed the American and Canadian “epidemic of addiction” of prescription opioids, but very little has been written on the European situation, including Italy.

Medical use of prescription opioids has been constantly increasing since the 1990s, particularly in the United States and Canada, together with the misuse and abuse of these substances, and a significant rise in the rates of dependent individuals and deaths related to prescription opioids. The situation has become so dramatic, it has led the American authorities to speak of an “epidemic of addiction” and introduce a series of countermeasures in order to better face the problem. Even in Europe, there has been an increasing use of prescription opioids and related problems, but the European context is much less dramatic than the American and Canadian ones. Nevertheless, data does not allow the exclusion of the possibility that a similar crisis will also occur in the “old continent.”

Considerable concern surrounds tramadol, whose prescription is not placed under specific control as is the case for other opioids. The objective of this study is to analyze the Italian context to better understand if, as for the United States and Canada, there’s the possibility of an epidemic of addiction. A detailed review of autopsy records and toxicology reports was conducted at the Forensic Institute of “Sapienza” University of Roma to find cases of deaths related to the use of prescription opioids. The initial list of cases was compiled based on searches including the terms “overdose,” “opioid,” and “synthetic opioid.”

More than 170 cases were reviewed based on these search parameters. Only cases involving deaths related to the use of prescription opioids were included in the final dataset. After the vetting process, 60 different case numbers were found between 2014 and 2019 that pertained to deaths related to the use of prescription opioids. It was not possible to analyze the years prior to 2014 because prescription opioids were not routinely searched.

The cases of death, following the assumption of prescription opioids, were analyzed through the preparation of toxicological samples prepared with routine methods, followed by systematic screening for substances by diverse methods. Volatile compounds were identified using Gas Chromatography/Flame Ionization Detection (GC/FID). Medical drugs and drugs of abuse were identified via the use of Gas Chromatography/Mass Spectrometry (GC/MS) and liquid chromatography/tandem mass Spectrometry (LC/MS/MS).

Of a total of 60 subjects, 44 died due to an overdose of tramadol; while 12 died due to an overdose of buprenorphine, and 4 due to fentanyl overdose. Of the deceased, most were males and the most-used drug was tramadol. In all cases, the macroscopical examinations did not reveal any organ abnormality that could explain deaths. Through histological examinations with hematoxylin/eosin, no significant findings emerged apart from widespread edema and focal sclerosis of the myocardium, and interstitial and alveolar edema of the lungs.

This work shows that attention must be paid to prescription opioids, especially those considered “safer” as tramadol and buprenorphine. The fact that there is not a full-blown epidemic concerning the deaths related to the use of these drugs does not justify a carelessness of European institutions and they must implement preventive measures that avoid the recurrence of the North American situation.

#### Opioids, Dependence, Pain

## E92 On-Going Decision Analysis (a.k.a. Black Box) Studies at the Federal Bureau of Investigation (FBI) Laboratory

Colbey Ryman\*, Woodbridge, VA 22191; Jocelyn V. Abonamah, MFS, Washington, DC 20002; Paige Riley\*, Fairfax, VA 22030; Keith L. Monson, PhD, Quantico, VA 22135; Brian Eckenrode, PhD, Quantico, VA 22135

**Learning Overview:** After attending this presentation, attendees will understand the development and purpose of the FBI's Footwear Examiner Decision Analysis Study, Handwriting Examiner Decision Analysis Study, and Firearms Decision Analysis Study, commonly known as "Black Box" studies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the concerns of the results from the Decision Analysis Studies (DAS) presented in the 2009 National Academy of Sciences (NAS) Report on "Strengthening Forensic Science in the United States" and the 2016 President's Council of Advisors on Science and Technology (PCAST) Report on "Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods" with regard to narrowing gaps within "feature-comparison" methods of footwear, handwriting, and firearms disciplines.<sup>1,2</sup>

In early 2016, the Organization of Scientific Area Committees (OSAC) Footwear and Tire Subcommittee and Forensic Document Examination Subcommittee identified a major gap in current knowledge with regard to the reliability of Forensic Footwear Examiners (FFE) and Forensic Document Examiners (FDE). The need for firearms/toolmarks examiners to support subjective opinions with logical, scientifically based explanations as the basis for their identifications was reinforced in the 1991 case of *Ramirez v. State of Florida*. Along with the needs identified by NAS, OSAC, and the courts, the PCAST study was centered on the reliability of an examiner's conclusion that an evidentiary item was likely to have been derived from the same source as a known exemplar. To date, few studies have been conducted to establish objective measures of examiner accuracy in the forensic feature comparison disciplines. Decision analysis studies are one means to test the reliability and accuracy of these disciplines. A DAS only considers the evidence provided to examiners and the conclusions reached. It does not examine the decision-making process of examiners.

Test packets were created in each study to simulate casework and were assembled so that the combination of questioned and known samples would provide participants with challenging comparisons. Known (K) and Questioned (Q) handwriting exemplars, footwear impressions, and bullet and cartridge casings were collected and used to create each QKset. The studies were all double blinded and adhered to Institutional Review Board (IRB) protocols. For example, in the footwear DAS, each examiner received 100 QKsets to examine and then submit their conclusions within a custom graphical user interface. In addition, participants in the studies were required to have been actively employed in their field within a specified amount of time (e.g., 2 years for FDEs).

The objective of decision analysis studies of FDEs, FFEs, and Forensic Toolmark Examiners (FTE) is to determine the rate at which examiners provide the appropriate forensic conclusion and, in turn, to estimate the rate of errors (accuracy). The consistency of responses between examiners (reproducibility) and their ability to reach the same conclusion when provided with the same specimens at a later time (repeatability) will be measured. When testing is concluded, accuracy, reproducibility, and repeatability will be quantified through statistical analysis. Any inter-relationships and correlations among the various factors will be explored and analyzed. Areas of improvement that warrant further study will be identified, and it will be determined what range of conclusions are appropriate. This knowledge can be leveraged by implementing a re-evaluation of examiners' suitability measures, training programs, and/or quality control methodologies. Results will be published in peer-reviewed forensic journals. These studies were administered in partnership with Ideal Innovations, Inc. and Noblis (FDE, FFE), and AMES Laboratories (FTE).

### E93 The Role of Postmortem Computed Tomography (PMCT) and Immunohistochemical Techniques in a Case of Aspiration Pneumonia in Suspected Sudden Infant Death Syndrome (SIDS)

*Gianpietro Volonnino\**, Roma, Lazio, ITALY; *Valentina Fazio*, Rome, ITALY; *Silvia Romano*, Università La Sapienza, Rome 00161, ITALY; *Alessia Quattrocchi*, Rome, ITALY; *Massimiliano dell'Aquila*, MD, Sapienza University of Rome, Rome 00161, ITALY; *Raffaele La Russa*, MD, Rome, Lazio, ITALY

---

**Learning Overview:** The goal of this study is to analyze the way in which the combined use of instrumental and immunohistochemical methods allows a correct diagnosis of aspiration pneumonia in a case of suspected SIDS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how, in SIDS cases, autopsy findings can be non-specific. The PMCT can direct the forensic pathologist toward a certain etiology. In cases of asphyxia by aspiration, immunohistochemistry is an essential technique to clarify the nature of the aspirated material, as well as its presence within inflammatory cells. The combination of these two techniques can provide a valid diagnostic aid in complex cases, such as SIDS.

SIDS is defined as the sudden and unexpected death of an infant without any apparent cause. It has major prevalence in the male sex. Etiology of SIDS is still unknown. According to numerous authors, SIDS may be due to different causes, as neurological, endocrine, metabolic, pulmonary, immune, or cardiac, and 30%–40% of cases are due to pulmonary disorders and the aspiration of gastric contents is recognized as a cause, with the consequent development of aspiration pneumonia.

Aspiration pneumonia is an inflammatory process that develops from the entry of foreign materials into the bronchial tree, often coming from the oral or gastric route, such as food or saliva. Risk factors for aspiration pneumonia include all those pathological conditions that alter the state of consciousness or create dysfunction of swallowing. Usually, aspiration pneumonia is manifested by the sudden appearance of respiratory difficulties and cough, associated with the ingestion of solid or liquid food or the regurgitation of gastric contents. Regarding SIDS, the use of PMCT in cases of sudden neonatal death is explained by the fact that SIDS never presents a certain cause of death nor possesses characteristic findings in autopsy; moreover, CT is a useful method of screening for unnatural death.

In the present case, a 2-day-old male baby (born of a diabetic mother) was pronounced dead after suffering an acute lung failure and a cardiopulmonary arrest. The previous day, the baby was in a state of hypotonia due to persistent hypoglycemia and he experienced an episode of vomiting. A total body PMCT was performed. Pulmonary scan revealed the presence of hypodense material of indeterminate nature in the main airways, from the oropharynx to the subsegmental bronchi of both lungs, with areas of pulmonary parenchyma with a “ground-glass” pattern. The remaining sectors explored appeared to be free from alterations. At autopsy, the respiratory tract revealed the presence of an edematous mucosa, which was painted with a whitish filamentous material.

Histology samples of lungs were taken and processed in Hematoxylin-Eosin (H&E) staining. A pulmonary histological study showed strong congestion of the alveolar septa capillaries, which were stacked by white blood cells. There was a widespread reduction of airspace due to collapse of the lung texture. Macrophages with cytoplasm occupied by abundant amorphous material were visualized. The same amorphous material was found in the alveolar spaces and in the bronchi, together with a great amount of white blood cells. Furthermore, an immunohistochemical study was carried out on lung samples, using antibody reaction with CD15, CD68, and alpha-lacto-globulin antibody. The study with CD15 (neutrophil cell marker) and CD68 (macrophage marker) showed clear positivity in the lung parenchyma and alveolar cavities. This finding is decisive for an inflammatory pulmonary process prior to the death, confirmed by immunohistochemical tests.

Finally, this study proceeded to the immunohistochemical research of alpha-lactoglobulin (milk protein). In this case, alpha-lactoglobulin antibody reaction showed a marked positivity in the alveolar cavity site but particularly in the macrophage cytoplasm. This latter finding attributed the development of pneumonia to an inhalation of milk.

In SIDS, autopsy findings can be non-specific. The PMCT can direct the forensic pathologist toward a certain etiology. In cases of asphyxia by aspiration, immunohistochemistry is an essential technique to clarify the nature of the aspirated material, as well as its presence within inflammatory cells. The combination of these two techniques can provide a valid diagnostic aid in complex cases, such as SIDS.

### E94 Epidural Hematoma in a Whiplash Cervical Injury: A Rare Condition

*Luca Tomassini\**, Sapienza Università degli Studi di Roma, Roma 00185, ITALY; *Andrea Cioffi*, Rome, ITALY; *Valentina Fazio*, Rome, ITALY; *Zoe Del Fante, MD*, Rome, ITALY; *Gianpietro Volonnino*, Roma, Lazio, ITALY; *Paola Santoro, MD*, Rome, ITALY; *Mauro Arcangeli*, Rome, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the dynamics of whiplash with the possible deadly consequences it can determine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how uncommon the following type of case is and how to deal with the consequences.

The name 'Whiplash Injury' (WI) derives from the etiopathogenic description of the sharp whipping movement of the head and neck, produced at the moment of a traffic accident, particularly following rear-end, head-on, or side collisions. The use of safety belts has led to a reduction in deaths derived from front-end collisions, but also to an increase in cases of typical whiplash. There are two types of force that cause WIs in rear-end car crashes: external forces applied to the body by the seat and head restraint, and internal forces generated by the activation of the body's muscles. The combination of these forces causes a differential motion between the superior and inferior tracts of the cervical spine (hyperextension-hyperflexion), which results in a strain of the neck tissues. This event can have consequences for all the neck structures: facet joints capsule, muscles, intervertebral disks, nerves, and vessels.

WI is characterized by a collection of symptoms that occur following damage to the neck, usually as a result of a sudden strain affecting the discs, muscles, nerves, or tendons of the neck caused by a sudden acceleration or deceleration of the head and neck. The head is violently thrown back, forward, or sideways, followed by reflex contraction in the opposite direction.

A condition that sometimes occurs after motor vehicle accidents are epidural hematomas. Although the pathogenesis of epidural hematomas remains widely controversial, there is a general consensus that all patients experienced the same mechanism of trauma since they were involved in a high-speed motor vehicle accident as a passenger, a pedestrian, or a bicyclist. Any deceleration, such as that occurring during cervical hyperflexion or hyperextension injuries, may result in a vascular lesion, with or without vertebral fracture

This study reports a case of a 68-year-old woman. The subject, while driving his car, hit another car head-on from the opposite direction and the woman in the hit car died immediately. During autopsy, there were no external signs consistent with fatal injuries. The only identifiable lesions were bruising in various body areas. The internal examination revealed no lesions of the head and brain; also, the organs of the abdomen had no particular alterations. There were multiple rib fractures with pulmonary laceration in the chest. When the neck organs were removed, there was evidence of infiltration of the perivertebral muscles. At the observation of the cervical vertebrae, there was a fracture of the fifth cervical vertebra. Diffuse epidural hemorrhage was also identifiable. Small hemorrhages were also found in the spinal cord.

Histological investigation confirmed the findings of the macroscopic examination. Surely the death of the subject was caused by the damage to the spinal column and spinal cord caused by the kinetic energy that developed due to a sudden acceleration followed by a deceleration. This dynamic caused vertebral fracture, epidural hemorrhage and bone marrow hemorrhage.

#### **Whiplash, Epidural Bleeding, Traumatic Injury**

### E95 Auxillary Artery Injury: A Rare Case of Death by Severe Blood Loss Due to an Accidental Fall

*Paola Santoro, MD\*, Rome, ITALY; Valentina Fazio, Rome, ITALY; Nicola Di Fazio, Università La Sapienza di Roma, Rome 00161, ITALY; Alessia Quattrocchi, Rome, ITALY; Andrea Cioffi, Rome, ITALY; Alessandra De Matteis, MD, University Sapienza of Roma, Rome 00100, ITALY*

**Learning Overview:** The goal of this presentation is to present a rare case of accidental sharp force death, showing how a thorough forensic pathology methodology, including death scene investigation, autopsy examination, and toxicological analyses, are pivotal to detect the manner of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community because of the rarity of this manner of death, regarding the epidemiological data about accidental death due to sharp forces.

Forensic pathologists are often asked to investigate deceased victims of stab wounds, as sharp force injury accounts for 10%–20% of clinical forensic examinations, and sharp force trauma represents the second most common cause of injury investigated in forensic practice. Moreover, homicide by sharp force (stabbing) is one of the most common causes of death in European countries, involving mostly domestic or interpersonal conflict. Stabbing as a suicide method constitutes a low percentage of all suicides, 2% to 3%. Accidental death due to sharp force is even rarer (0%–3%) and is usually caused by an impact or a fall into a different type of glass surface, with the victim generally being hit by a sharp-edged shard of glass, striking body parts with enough force to cause death. Death due to stabbing is usually caused by exsanguinating incisions to organs or large blood vessels, leading to hemorrhagic shock.

This study presents an unusual case of a man who was found dead at home, lying on a chair in a pool of blood with hundreds of glass fragments close by. During crime scene investigation, external examination of the body revealed a tear in the clothing at the right armpit. After removing the T-shirt, a 9cm-long wound was observed perfectly consistent with the tear. No other lesion was identified at the external examination during judiciary inspection. Analysis of the crime scene identified a shattered vase as the source of the glass fragments responsible for the armpit lesion.

Full autopsy was performed. At the external examination, the armpit wound was located 29cm away from the suprasternal notch and 40cm away from the xiphoid process; the wound presented clean-cut edges and the medial end presented a fishtail-like split. It was 3cm deep, involving pectoral muscles and surrounding fat tissue.

The internal examination did not show any gross alterations of organs. Dissection of the right arm musculocutaneous layers were performed showing hemorrhagic infiltration of the muscles, fat, and neurovascular bundle. On the posterior-lateral wall of the distal axillary artery, a 0.8cm linear full-thickness lesion was found. Histological study of the axillary artery confirmed the macroscopical finding. Further, toxicological analyses on blood, urine, and gastric fluid samples showed an alcohol concentration exceeding the toxic level, respectively 2.56 g/L, 3.55 g/L, and 2.48 g/L. Death was due to massive blood loss resulting from a lesion to the right axillary artery by glass fragments. A thorough analysis of scientific literature on death by sharp force injuries, due to axillary artery lesion, showed no results.

## E96 The “Social Web” Autopsy as an Evolution of Psychological Autopsy: The Application of the Method in Forensic Cases in Comparison

Carmen Scalise, MD\*, University of Catanzaro, Catanzaro, ITALY; Francesco Sicilia, MD\*, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Ada Maida, Vibo Valentia, ITALY; Valerio R. Aquila, Crotona 88900, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Cristoforo Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Orazio Malfa, MD, University “Magna Graecia” of Catanzaro, Catanzaro, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the evolution of the method of psychological autopsy in forensic cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the role of the web community in deaths from murder, suicide, and accident.

Psychological autopsy is a survey commonly used to study suicide deaths through the analysis of the family and social setting with the use of data collection through interviews with family members and psychological analysis of dynamics preceding death. However, to date its application has found an evolution in the era of globalization and for the diffuse presence of the web in the lives of individuals, so this study proposes its application to any forensic case whose dynamics are dubious.<sup>1,2</sup> In particular, the flow of information through telephone messages and chat and social networks has increased the means of social and environmental influence. Therefore, a web analysis can provide useful data for investigators, which may be unknown even to family members. A search of social networks is very important to investigate the victim’s psychology through the analysis of posts, images, and videos published in the weeks leading up to death. Together with the Personal Computer (PC), the mobile phone is an essential tool for the psychological autopsy.<sup>3,4</sup>

Reported here are three cases in which an evolution of the method of psychological autopsy was used. The analysis of the environmental, family, and social setting was compared with the evaluation of telephone, informatics, and social profiles of the victims. Furthermore, the data collected were compared with interviews of family members and acquaintances. The first case concerns a girl who was found dead in her home’s garden due to fall from height by suicide. The analysis of the house, in particular the girl’s room, highlighted the presence of drawings depicting stylized “souls” and other drawing proofs. Moreover, from the previously seized mobile phone, daily chats were found with obsessive virtual friendships and manipulative control not known by family members. In the second case, a boy was found dead due to an accidental railway accident. The analysis of the area allowed investigators to understand the dynamics of the event due to the use of the mobile phone to carry out a dangerous selfie with other friends who escaped. The cell phone was found two meters away from the body and was handed over to the police who subsequently analyzed the photos taken by the boy shortly before the accident. Family members did not know about the dangerous selfies, as opposed to schoolmates who did.

In the third case, researchers analyzed a double murder of a couple by firearm by the woman’s ex-boyfriend. The analysis of the social media profiles of the couple highlighted the presence of photos published on social media the day before the murder. The interrogation of the murderer revealed the motive of the crime, preceded by a story of stalking, after viewing the photos on social networks. The use of this method made it possible to answer some questions that clarified the manner, the motive, and the causes of death in all cases. Considering should be given to how much the environment can also influence the genesis of fatal events. Certainly in adolescents, the social-web is crucial in the genesis of accidental and suicidal events, as well as in the adult age group in the context of homicides, especially those with a passionate background. Currently, it is known how important it is to appear and be accepted, not only in everyday life but also on social networks, which often constitute the representation of a false self. This happens most in the adolescent age group where young people are constantly looking for a model to follow that allows them to make an idyllic escape in a parallel world.

This study proposes a method that represents a valid support to better analyze the setting, the manner (emulation), and the causes of similar events. It can be used both for investigative purposes in cases of homicide, suicide, or accidental deaths as well as for preventive purposes in the presence of explicit threats to things or people. During the investigation, it is useful to apply a multi-method approach to compensate for the limits of each and to have a broader view of the facts, thus facilitating the survey and prevention of announced fatal events.

## E97 The Role of Social Networks in the Crime of Stalking: A Case of Murder

Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Fabrizio Cordasco, MD, Università Magna Graecia CZ, Catanzaro, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Vincenzo Rania, MD, Institute of Legal Medicine, Catanzaro, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Cristoforo Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Orazio Malfa, MD, University “Magna Graecia” of Catanzaro, Catanzaro, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of social networks in investigating the crime of stalking.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the importance of applying the method of “Social-Mobile Autopsy” to prevent the crime of stalking before the stalker adopts violent behavior.

Social networks are digital platforms developed to allow communication between people who could be a great distance apart. These programs are known to also offer personal data sharing. From this point of view, social networks have become easy tools for acquiring private information via videos, geographic location, and fast methods of contacting other people. In this context, social networks may also be dangerous when are used improperly to achieve personal persecutions. The term “stalking” denotes a disturbing, threatening, unpleasant, repetitive, and/or intrusive behavior directed toward a specific person.<sup>1</sup> The victim is often linked by previous romantic relationships with the stalker, who does not accept the separation and begins an activity of controlling the victim with obsessive methods. Sometimes, the victim can be a person not known directly to the stalker but contacted through other methods, such as virtual dating sites.

A case is presented of double homicide by firearm that took place in a restaurant in a southern Italian town. The victims were a man and a woman who worked in the restaurant. Initially, the investigators had difficulty reconstructing the motive of the murder and the reason why the killer had chosen to kill only the two subjects among all the people present in the room. A crime scene investigation and an autopsy were carried out. Later, investigators listened to family members, who assumed an economic motive. Subsequently, the mobile phones of the victims and the killer and their respective personal computers were seized. The investigators focused the investigations on the social profiles of the three individuals using the Social-Mobile Autopsy method by analyzing messages, chats, public and private posts, photographs, and videos.<sup>2</sup> These investigations were carried out to understand the relationship between the victims with the killer and the motive for the murder.

The investigation revealed that the killer had used two firearms at the same time (a rifle and a gun). The woman had been struck first with both weapons for a total of 23 shots. Subsequently, the killer pursued the man on the street outside the room by hitting him only with the gun for a total of seven shots.

The analysis of the victims’ mobile phones revealed the exchange of messages between the two individuals and the existence of a hidden romantic relationship. However, the analysis of personal telephones did not highlight messages with the killer. Only the investigation of the victims’ social profiles revealed an intense stalking activity by the killer against the woman. The man sent numerous obsessive messages, photos of the victim, inserted numerous likes and comments in posts, and made video call attempts, often using fake accounts or other friends’ profiles. The murderer’s profile revealed repeated searches by typing his name several times in the search engine and publication of several posts related to the woman. The messages and photos suggested the woman’s previous relationship with the killer, who did not accept the end of their relationship.

Social networks have a fundamental role to get in touch and acquire information on the private lives of other people. In recent years, the so-called “stalker” has found in digital media the ideal tool to acquire personal information about the victim or to carry out the pursuit and oppression of the victim, specifically by sending hundreds of text messages, e-mails, and calls forwarded often using fake accounts. In the case described, the investigation carried out using the Social-Mobile Autopsy method allowed the discovery of a real crime implemented through social networks, such as stalking, and therefore allowed clarification of the motive for the murder. This case demonstrates the importance of using the Social-Mobile Autopsy method in investigating cases of suspected stalking in order to take preventive measures to ensure the safety of the victim before the stalker adopts violent behavior. Finally, this type of investigation is suggested in all cases of homicide/suicide in which the motive appears doubtful or cannot be reconstructed through circumstantial data or testimonies.

### Forensic Sciences, Stalking, Social Networks

## E98 Optimizing Sensitivity and Validating the Illumina® Infinium Assay for Genotyping of Forensically Relevant Sample Types for Investigative Lead Generation

David Russell, MS\*, Signature Science, Charlottesville, VA 22911; Elayna Moreithi, MS, Signature Science, Charlottesville, VA 22911-5844; Christina Neal, MS, Signature Science, Charlottesville, VA 22911; Mary Heaton, MS, Signature Science, Charlottesville, VA 22911; Stephen Turner, Signature Science, Charlottesville, VA 22911

**Learning Overview:** The goal of this presentation is to demonstrate a validated forensic workflow using the Illumina® Infinium assay capable of producing accurate Single Nucleotide Polymorphism (SNP) genotyping data for investigative lead generation with a higher sensitivity to lower DNA amounts and geared toward forensic-centric sample types.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by pioneering a standard validation for a forensic workflow for genome-wide SNP genotyping. Additionally, this presentation highlights the capabilities of this assay to be more sensitive, overcoming the 200ng standard input and essentially shifting the applicability of this technology from clinical laboratories to the forensic community.

Forensic genealogy applies enhanced genetic processing techniques (array-based genome-wide SNP genotyping) combined with traditional genealogical research techniques to produce new leads in cases that have gone cold or where traditional investigative means have been exhausted. The use of this technology in investigative forensics has skyrocketed since the 2018 arrest of Joseph DeAngelo as the Golden State Killer. Most microarray-based genome-wide SNP genotyping takes place under clinical research, providing services that are not adapted to forensically relevant sample types. Furthermore, Direct To Consumer (DTC) laboratory tests require high quality and quantity DNA. The Infinium assay workflow is a genome-wide microarray genotyping assay that utilizes the BeadChip platform.<sup>1</sup> This accurate and flexible microarray technology allows for the ability to interrogate a large number of SNPs through unlimited loci multiplexing.<sup>2-4</sup> However, overcoming the 200ng standard input for this assay is essential for forensic genomics as it is rare to obtain DNA at such high quantities from forensic samples.

Here is described a validation of Illumina's® Infinium assay using the Infinium Global Screening Array to show successful optimization and validation down to DNA input levels more consistent with forensic sample types and shifting the applicability from clinical laboratories to the forensic community. In an effort to set a standard for validating a forensic workflow to generate genome-wide SNP genotyping data, the validation design, where applicable, is guided by the current Federal Bureau of Investigation (FBI) Quality Assurance Standards (QAS) for DNA testing laboratories and the Scientific Working Group on DNA Analysis Methods (SWGDM) Validation Guidelines for DNA Analysis Methods.<sup>5,6</sup>

Precision and accuracy of the assay will be evaluated using the National Institute of Standards and Technology (NIST) standard reference material that have been extensively characterized.<sup>7</sup> The sensitivity study will be carried out using blood, buccal/saliva, and semen samples. These common sample types will be extracted, quantified, and diluted in a series ranging from the manufacturer-recommended input target of 200ng down to 1ng of total DNA input—an input amount more consistent to forensic samples. Currently, there are no computational methods to parse mixtures to individual genotypes. Given that mixtures are a possibility, a mixture study will be conducted to observe how data are presented at different mixture ratios. Identifying mixtures is also critical when assessing for possible contamination. Reagent blanks will be incorporated at extraction and carried throughout the workflow. Additionally, during the precision and accuracy study, the plate layout will be designed in a way to identify possible contamination during the assay. This validation will demonstrate a forensic workflow using the Illumina® Infinium assay capable of producing accurate SNP genotyping data for investigative lead generation with a higher sensitivity to lower DNA amounts and geared toward forensic-centric sample types.

### Microarray, SNP Genotyping, Investigative Lead Generation

## E99 Suicidal Cut-Throat Wounds: Elements of Differentiation From Homicidal Slaughtering

Giulia Gubinelli\*, Bari 70124, ITALY; Eloisa Maselli, MD, Bari 70122, ITALY; Valeria Bruno, MD, DIM, Bari, Puglia 70124, ITALY; Francesca Donno, MD, University of Bari, Bari 70121, ITALY; Gianni De Giorgio, Section of Legal Medicine, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will know more about the crucial features in forensic evaluation of cut-throat wounds for differentiation between suicidal and homicidal deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a complete evaluation of the crime scene investigation and the external findings of a suicidal death, underlying the distinct elements that can represent conclusive data toward the suicidal or homicidal hypothesis.

Suicide by stabbing one's own throat remains very rare and very few cases have been reported in the forensic literature. Crime scenes can often be misleading, and the direction of stab wounds, their site and number, in addition to the presence or absence of defensive wounds and hesitation marks have particular importance in helping to differentiate suicidal from homicidal deaths.<sup>1,2</sup> This study reports on the case of a 75-year-old man, found dead by his wife, with a blood-smear kitchen knife in his hand. The man had a history of psychiatric disease (mixed anxiety-depressive disorder); he was on pharmacological treatment and supervised by a psychiatrist. The morning of the discovery, he had locked himself in the bathroom and after some time, his wife, having knocked at the door several times without receiving an answer, opened it with a second key and found him lying in a prone position.

External examination of the body was performed. Findings showed an irregular transverse 14cm-long throat cut. In detail, the lesion started from the right sternocleidomastoidal region (2.5cm beneath the lower jaw angle), involving the lower part of the upper hyoidal region and the supero-medial part of the lower hyoidal region, ending at the left sternocleidomastoidal region. The underlying anatomical structures were exposed (uvula, back wall of the hypopharynx, and epiglottis). The carotid commune arteries weren't damaged. The edges of the wound were abraded and ecchymotic, and the upper part presented two epidermal flaps in its context. The right tailing was 2.5cm long and, above and below it, there were several linear, parallel cuts (three above and two below), the longest being 3cm. Another linear cut, 10cm long, 1cm above the right end, approximately parallel to the lower jaw, and four other linear abrasions, starting from the right medial part of the upper edge and going slantwise with below-upward lateral-medial and almost parallel direction, with a maximum length of 3cm, were detected. Last, another linear transversal cut of 2.5cm, starting from the upper edge of the left epidermal flap, was found. These lesions were recognized as the typical, self-inflicted suicide hesitation marks (superficial, parallel, sharp-forced skin cuts).<sup>3</sup> No significant findings were revealed on the arms, hands, back, or other parts of the body, leading to the conclusion of the absence of defensive wounds. A farewell letter was not found on the scene.

The presence of evident tentative wounds, the absence of defensive lesions, the medical history of the deceased, and the circumstantial and crime scene elements led to the conclusion of suicide. This case highlights the specific features that can help the pathologist discriminate between accident, homicide, and suicide. The complete evaluation of the crime scene, including the eventual presence of a farewell note or of elements of disturbance, and of the external findings on the body (defensive wounds, hesitation marks, lesions' typology and features) can significantly help the pathologist in correctly establishing the manner of death.

## E100 Forensic Science in the United States Court of Appeals: A Ten-Year Review (2009–2018)

*Danielle M. Crimmins, MS\*, Purdue University, West Lafayette, IN 47907; Martin Novak, MPA\*, National Institute of Justice, Washington, DC 20531*

**Learning Overview:** After attending this presentation, attendees will understand: (1) which scientific disciplines are most frequently associated with appeals relating to the introduction or exclusion of scientific evidence; (2) which forensic science disciplines are challenged; and (3) how legal issues for appeal vary by scientific discipline.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the forensic science disciplines that are appealed in the United States Courts of Appeals. In recent years, there have been efforts to look at the underlying validity and reliability of forensic science evidence from criminal and civil law and regulatory issues.<sup>1</sup> While there have been some efforts to look at legal challenges to scientific evidence, specifically surrounding the impact of the United States Supreme Court's 1993 *Daubert v. Merrell Dow Pharmaceuticals* decision, an updated effort to catalog the diversity of scientific domains that are called upon in the course of criminal law, and in what contexts, would be beneficial.<sup>2-4</sup> For instance, identifying the scientific disciplines that are most frequently associated with appeals relationship to the introduction or exclusion of scientific evidence, how do legal issues vary by scientific discipline, and are there trends or areas of law as applied to scientific disciplines that require further attention from criminal justice stakeholders, including the forensic science community, courts, and trial attorneys.

The United States Courts of Appeals records were surveyed from the past decade (2009–2018) and categorized by scientific disciplines brought up on appeal. Lexis Advance was used to identify cases, using search terms that were adapted from previous literature.<sup>2</sup> The main goal of the search was to identify cases involving admissibility, Rule 702, and Rule 703 (rules addressing expert evidence in the Federal Rules of Evidence). The search terms were designed to be overly inclusive in an effort not to miss any cases in which the opinion rendered included expert evidence. The final search included 1,775 cases. Stratified random sampling, based on the circuit size, was used to identify a sample of 350 cases.

For the 350 cases identified, case opinions were reviewed based on a 28-question codebook pertaining to information about the case (e.g., report number, circuit, data of decision, and subsequent actions); items pertaining to the basis of appeal and secondary basis of appeal; and items pertaining to the evidence type, primary scientific discipline, and a broad categorization of discipline. If there was forensic testimony, there were items related to the broad category of forensic evidence (e.g., biology, digital/multimedia) and the expert education level (e.g., PhD, MD, DDS). The codebook was reviewed individually by two attorneys and two individuals in the forensic science community. Cases were excluded if the case was a civil case that was not a writ of habeas relief, the opinion contained insufficient detail to determine the background and type of expert witness testifying (i.e., no reference as to the expert witness' profession or domain of expertise), if the appeal was about lay opinion testimony, appeals focused on a search warrant, or the result of a false search hit.

### Evidence, Appeals, Case Review

## E101 Time Between Sexual Assault and Evidence Collection: Implications for the Development of Combined DNA Index System (CODIS) -Eligible DNA Profiles

Lauren Schagel\*, Brigham Young University, Provo, UT 84604; Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Leslie Miles, DNP, Brigham Young University, Provo, UT 84602

**Learning Overview:** After attending this presentation, attendees will understand new research findings supporting that although the length of time between sexual assault and evidence collection can be five to six days post-assault, a CODIS-eligible Short Tandem Repeat (STR) DNA profile can still be developed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing victims, law enforcement, health care providers, forensic scientists, and the public with increased knowledge about the length of time in which victims can receive a Sexual Assault Forensic Examination (SAFE) to obtain an STR DNA profile of their perpetrator.

The methodology of the study is an exploratory, retrospective design of over 2,700 submitted and analyzed sexual assault kits from a Mountain West state in the United States. Findings will be compared to other research on time between sexual assault and evidence collection in the development of CODIS-eligible STR DNA profiles. Review of the current literature on time between assault and evidence collection indicate male DNA (Y-STR DNA) can be recovered up to seven days post-coitus from a cervico-vaginal swab and a Y-STR profile can be developed at eight loci.<sup>1</sup> In another study evaluating sexual assault cases, researchers found the longest time between the sexual assault and evidence collection that was positive for sperm was 169 hours (seven days).<sup>2</sup> Additional research supports possibly extending beyond the seven-day interval for DNA findings. Ballantyne and Speck discovered Y-STR DNA ten days post-coitus in a monogamous couple, demonstrating the longevity of male DNA in the cervix and vagina.<sup>3</sup>

In this large-scale, retrospective study of 2,727 sexual assault kits, probative STR DNA CODIS-eligible profiles were developed in 39% of analyzed kits. Generalized Estimating Equation (GEE) logistic regression analysis found that for every 24 hours that passed between assault and sexual assault forensic examination, there was a 10% reduction in the development of a CODIS-eligible DNA profile. The longest length of time between assault and forensic examination and development of a CODIS-eligible profile in the study was 122.5 hours, over five days from vaginal and cervical swabs. This finding supports the testing of DNA samples collected five to six days post-sexual assault due to the possibility of developing a CODIS-eligible profile.

This retrospective study is impactful due to the large sample size. The 2,727 sexual assault kits in this study are representative of sexual assault kits and findings in practice. The advancements of DNA testing paired with the research findings acquired from this study disprove the myth associated with delayed reporting and aid in educating victims, health care providers, law enforcement, forensic scientists and the public to extend evidence collection to over five days. In this study, full STR DNA probative profiles were developed from vaginal and cervical swabs obtained 122.5 hours after sexual assault.

### DNA, Sexual Assault, Evidence Collection

### E102 Does It Wash Away? The Impact of Bathing or Showering on DNA Analysis Findings From Sexual Assault Kits

Deborah Richardson\*, Brigham Young University, Provo, UT 84604; Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Leslie Miles, DNP, Brigham Young University, Provo, UT 84602

**Learning Overview:** After attending this presentation, attendees will understand the minimal effect of post-assault bathing or showering on the development of the Federal Bureau of Investigation (FBI) Combined DNA Index System (CODIS) -eligible DNA profiles from Sexual Assault Kit (SAK) evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by encouraging the submission and analysis of SAKs despite a victim history of post-assault bathing or showering.

SAK submission rates significantly decrease in cases where the victim has engaged in post-assault actions, such as bathing or showering. The belief that these actions diminish the possibility of finding prosecuting evidence heavily contributes to this decline.<sup>1</sup> This belief must now be reevaluated in light of improved DNA analysis methods that can yield CODIS-eligible DNA profiles. The post-assault action of bathing or showering has been found to be a significant negative predictor of SAK submissions by law enforcement.<sup>2</sup> However, DNA can be collected from skin and successfully analyzed regardless of victim bathing or showering.<sup>3</sup> In an effort to eradicate misbelief and improve SAK submission rates, this presentation will evaluate SAK submission rates and SAK DNA analysis findings from 5,423 SAKs and provide research findings on the effects of post-assault bathing or showering on the development of probative CODIS-eligible DNA profiles.

In this retrospective study of 5,423 SAKs, 36% of victims reported post-assault bathing or showering. Post-assault bathing or showering was found to be highly correlated with time between assault and sexual assault forensic examination. In a Generalized Estimating Equation (GEE) logistic regression analysis on SAK submission rates, victim reports of post-assault bathing or showering was a consistent predictor of law enforcement not submitting kits. Yet, bivariable statistical analysis determined that victim bathing or showering post-assault was not associated with the lack of development of a DNA probative profile from SAK evidence.

The effect of post-assault bathing or showering must be reconsidered in the forensic science and criminal justice community as DNA analysis can yield probative DNA profiles, even after a victim has bathed or showered. The presentation of these research findings will encourage the submission of SAKs by law enforcement and potentially increase SAK submission rates by eradicating any doubt regarding the minimal effect of bathing or showering on the development of CODIS-eligible DNA profiles. At the conclusion of this presentation, attendees will understand the research data that supports the submission and testing of all SAKs, especially those with a victim history of post-assault bathing or showering.

### E103 Testing Sexual Assault Kits Leads to Justice for Both Victims and Suspects

Reilly Caten, BS\*, Brigham Young University, Provo, UT 84604; Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Leslie Miles, DNP, Brigham Young University, Provo, UT 84602

**Learning Overview:** After attending this presentation, attendees will have increased knowledge and competency on the importance of testing sexual assault kits to establish justice for both victims and suspects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing research data supporting the mandatory submission of sexual assault kits to promote justice for all. Additionally, these findings can be shared with criminal justice colleagues to promote submission and testing of sexual assault kits and collection of suspects' DNA samples

In the United States, there is a push to mandate submission and testing of all sexual assault kits. A typically overlooked benefit of testing sexual assault kits is the exoneration of wrongfully accused suspects.<sup>1</sup> Sexual assault kits include DNA samples from the victim of sexual assault and occasionally are submitted with DNA samples collected from the identified suspect for comparison. Suspect samples may be taken by law enforcement personal or medical professionals in accordance with a court order.<sup>2</sup> Inclusion of suspect samples is beneficial because it can lead to a DNA match with samples collected from the victim or exclude the suspect as the source of DNA. The study methodology as an exploratory, retrospective design of submitted sexual assault kits with suspect DNA evidence samples was used to evaluate for the exclusion of suspects based upon DNA analysis findings. For a sexual assault kit to meet the criteria for "excluded the suspect," a DNA profile had to be developed from analysis of the sexual assault kit evidence that excluded the named suspect with the submitted DNA sample (either buccal swab or blood sample).

A large retrospective study of 2,727 sexual assault kits with completed DNA analysis found 66 cases in which the DNA findings excluded the suspect. Findings will be presented on descriptive data on these cases in which the named suspect was excluded: relationship between victim and suspect, victim loss of consciousness/awareness at time of assault, alcohol/drug use during the assault, suspected drug-facilitated sexual assault, and multiple perpetrator sexual assault. Each of these cases excluding a suspect represents an individual who was erroneously identified, but DNA analysis findings excluded the identified suspect.

When considering the implications for testing sexual assault kits, it is important to recognize that justice is the ultimate goal. Testing sexual assault kits uses science to aid in the establishment of justice. Sexual assault kit testing transcends accusations and labeling to provide factual evidence supporting the claims of the innocent, whether they are identified as victim or suspect. Additionally, the liberation of an unjustly accused suspect promotes the correct identification and conviction of the responsible perpetrator.<sup>3</sup> This research supports the inclusion of suspect samples in sexual assault kit testing to promote justice for all. Thus, mandated testing of sexual assault kits promotes justice for victims of sexual assault and innocent suspects alike.

#### Justice, Suspect Exclusion, Sexual Assault Kit

## E104 Giving a Voice to Male Rape Victims Through Novel Short Tandem Repeat (STR) DNA Findings

Jacob Momberger\*, Brigham Young University, Provo, UT 84602; Sam Pugh\*, Brigham Young University, Provo, UT 84602; Julie L. Valentine, PhD\*, Brigham Young University, Provo, UT 84064; Leslie Miles, DNP, Brigham Young University, Provo, UT 84602

**Learning Overview:** After attending this presentation, attendees will have increased understanding and competency on the subject of male rape victims and DNA analysis findings from sexual assault kits of male victims.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new research findings regarding male rape victims and their sexual assault kit DNA analysis findings to inform knowledge, practice, and policy for researchers, forensic examiners, forensic scientists, law enforcement, and criminal justice system professionals.

Traditionally, rape has been considered to occur between a male perpetrator and a female victim. However, sexual assault is a crime that affects all genders. Although the majority of rapes are male to female, current findings indicate that 1 in 71 men will be raped in their lifetime.<sup>1</sup> While the psychological effects of male victim rape and its underreporting are well documented, very little has been reported regarding DNA findings from sexual assault kits of male victim rapes. After an intensive search for earlier publications concerning the topic, only three articles were found to have relative correlation to this topic. Two of the three articles date back to 1978 and 1982 and the studies focused on spermatozoa findings in the anal cavities of female victims.<sup>2-4</sup> Current best practice is to obtain STR DNA profiles from sexual assault kit samples to enter into the Federal Bureau of Investigation (FBI) Combined DNA Index System (CODIS). This study methodology is an exploratory, retrospective design to identify male rape victims from a sample size of 5,442 victims who received sexual assault forensic examinations with sexual assault kit evidence collection.

Approximately 5% of the victims in this study were male ( $N=246$ ). Male victims were found to have less non-anogenital and anogenital injury, although they reported more violent acts by suspect(s). Male victims reported that ejaculation occurred less often during the assault than female victims. Male victims were found to have more physical or mental impairments, increasing their vulnerability for sexual assault. Male victims had substantially lower development of STR DNA profiles and CODIS-eligible DNA profiles of perpetrator ( $p=.007$ ). In fact, female victims were 40% more likely to develop a CODIS-eligible profile from sexual assault kit DNA analysis than male victims.

Due to low STR DNA profile yields and increased targeting of mentally impaired or otherwise vulnerable male victims, we must improve our response to male victims to ensure justice to all victims of sexual assault.

### Males, Rape, STR DNA

## **E105 Homicide by Unspecified Means: The Importance of a Forensic Pathologist and Anthropologist Teamwork Approach in Death Scene Investigation and Postmortem Analysis**

*Hailee St. Louis, BS\*, Western Michigan University School of Medicine, Kalamazoo, MI 49048; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI 48824; Theodore T. Brown, MD, Kalamazoo, MI 49008*

**Learning Overview:** After attending this presentation, attendees will recognize deaths that meet the diagnostic criteria of homicide by unspecified means and will highlight the importance of the forensic pathologist and anthropologist leading the death scene investigation and postmortem analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of a teamwork approach between the forensic pathologist and anthropologist in the medicolegal death investigation and postmortem analysis in suspected homicide by unspecified means-related deaths.

A complete medicolegal death investigation includes a death scene investigation, postmortem examination, and ancillary studies. A death that occurs under objectively suspicious circumstances, when there is no anatomic cause of death, no toxicology cause of death, no environmental, circumstantial, or historical cause of death, or when a more specific cause of death cannot be suggested, the terms “homicide by unspecified means,” “homicidal violence,” and “homicidal means” are suggested as an appropriate cause of death.<sup>1</sup> Commonly, deaths that fulfill this diagnostic criterion involve decomposed and skeletonized decedents that require additional forensic investigation and analysis. Reported here are two cases of skeletonized females that were found buried in wooded areas after their husbands killed them.

A 44-year-old female was missing for approximately five months when her husband was found dead in his residence. He hanged himself and left a confession note and map that detailed he choked the decedent to death and buried her body the next day. Based on the map, the female was found in a shallow grave in a densely wooded area. A team from the medical examiner’s office that included the forensic pathologist, two forensic anthropologists, and a medical examiner investigator led the death scene investigation of the female, which revealed predominantly skeletal remains. At the morgue, the forensic anthropologists performed a skeletal analysis, which revealed a peri-mortem defect of the right side of the skull; remote, healing, or healed fracture of the maxilla and right palate; and no fractures of the unfused hyoid bone. While the examination of the body did not demonstrate a specific cause of death, given the circumstances, the decedent’s cause of death was homicidal means, probably of asphyxia due to strangulation, and the manner of death was homicide.

A 32-year-old female was last known alive in 2010. In 2018, the decedent’s husband led law enforcement to a wooded area where he buried the decedent after killing her. He confessed he stabbed the decedent in her neck. A team from the medical examiner’s office that included the forensic pathologist, two forensic anthropologists, a forensic anthropology coordinator, and a medical examiner investigator led the death scene investigation of the female’s skeletal remains. At the morgue, the forensic anthropologists performed a skeletal analysis, which was most significant for sharp force trauma to the right sides of cervical vertebra 7 and thoracic vertebra 1, representing a minimum number of one impact, consistent with a knife cut injury of the lower aspect of the right side of the neck. Given the circumstances, the cause of death was homicidal means, including sharp force injury of the neck, and the manner of death was homicide.

When the diagnostic criteria for homicide by unspecified means under objectively suspicious circumstances of death are met, which includes a body deliberately hidden from view, attempt to conceal evidence, and scene findings suggestive of antemortem injury not verifiable by autopsy, it is recommended that the forensic pathologist and anthropologist be present and lead the death scene investigation and that a full autopsy with skeletal analysis is completed.<sup>1</sup> The presence of both the forensic pathologist and anthropologist at the death scene may serve to locate the decedent with minimal disruption if buried, preserve potential evidence, determine human remains versus non-human remains and objects, appreciate possible postmortem animal activity, and identify possible peri-mortem trauma. A full autopsy with a skeletal analysis is recommended because, as highlighted in the second case reported here, the forensic anthropologist documented sharp force trauma of the vertebrae that was consistent with the confession given, and can provide specific, scientific cause of death information in an otherwise homicide by unspecified means-related death.

## E106 Drowning: The Silent Death

*Cheyenne M. Graham\*, Beaumont, TX 77327; Roxanne Phatak, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054*

**Learning Overview:** After attending this presentation, attendees will be aware of correlations between age and drowning locations within Harris County, TX, to help bring awareness to the issue and open a discussion about drowning prevention.

**Impact on the Forensic Science Community:** This presentation will inform the forensic science community by demonstrating the prevalence of drowning, specifically pool drowning, of children aged 12 years and under. Additionally, this presentation will address how misconceptions about drowning can play a contributory role and will provide information to combat these misconceptions.

The Harris County Institute of Forensic Sciences in Houston, TX, averaged approximately 4,559 medicolegal cases each year between 2013 and 2018. Approximately 1,500 medicolegal cases each year from 2013 to 2018 had a manner of death classified as accident. Approximately 4.3% of the accidental deaths each year were drowning, which is a total of 334 drownings classified as an accident between 2013 and 2018.

To focus on the data, the 334 drownings were separated by location: bathtub, open water, and pool. Once the cases were separated by location, trends were noticed in the age of the decedents. Through further analysis, the data revealed correlations in age range and location of the drownings. When examining the age variable in pool locations, a sharp peak was noted in children aged 12 years and under. A large broad peak in open water drownings of individuals in their early 20s into their mid 30s was also observed. Last, bathtub drownings revealed a peak of individuals in their mid-50s to mid-70s. After comparing the number of drownings in each location to the ages of decedents, a pattern was noted among child drownings and location. Approximately 9% of the total 76 bathtub drownings were children and approximately 12% of the total 128 open water drownings were children. In contrast, approximately 51% of the total 130 pool drownings were children.

The data collected revealed that in Harris County, children aged 12 and under are more likely to drown in pools than in any other location, such as bathtubs or open water (i.e., bayous, rivers, ponds, or lakes). Analysis of the 469 cases classified as drownings between the years of 2013 and 2018 revealed that 130 drownings occurred in pools. Of the 130 pool drownings, 66 (approximately 51%) were children age 12 years and under. Upon further analysis of the 66 child drownings, it was noted that 48 (approximately 73%) were children age 3 years and under. The initial 51% of child drownings, age 12 years and under, is three times greater than the number of child drownings observed in bathtubs and open water combined, which was 22 (approximately 11%). Not only do the majority of child drownings occur in pools, but approximately 76% of the 66 child drownings occurred at private residences. It was also noted that of the 15 open water child drownings, 6 were in ponds or man-made bodies of water located on the property of the family.

Child drownings are more likely to occur in pools at private residences than at any other location in Harris County. To combat this, it is imperative that adults be more alert and aware of their child's location, especially when they have a pool or other body of water in their backyard. Some ways to provide protection include fencing around pools or door alarms in the house to alert someone when a door has been opened. Children are very resourceful, even at young ages, so taking extra measures goes a long way toward ensuring their safety.

---

### Drowning, Children, Accident

## E107 Let's Solve It: Designing an Interactive and Engaging Online Forensic Science Laboratory Course

Gina Londino-Smolar, MS\*, Indiana University - Purdue University Indianapolis, Indianapolis, IN 46202

**Learning Overview:** After attending this presentation, attendees will: (1) explore the design process of an online course; (2) create new learning assessments for students in an online environment; and (3) discover how online lab experiences can be formed through virtual and hands-on experiences.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by displaying the development process of an online laboratory course in forensic science. Online courses are the norm on most college campuses, even courses online in forensic science, but what about laboratory coursework online? This presentation will enable attendees to learn about the design process of a completely online laboratory course in forensic science. The course material and learning assessments will be shared, which can inspire attendees in their own online course development.

There has been a rise in the percentage of students that complete course work online. With that, there is an increase of science laboratory experiences being offered in a fully online environment. These experiences range from fully virtual laboratory exercises to kitchen chemistry kits to customized kits for traditional laboratory exercises. Fully online laboratories are developed for non-science major courses to increase enrollment. The goal of developing an online laboratory course is to offer a similar experience to that of a face-to-face course while engaging the student in the content.

Designing a hands-on online laboratory experience has advantages for both the university and the student. The university cost associated with online laboratory courses is much lower, both with space and equipment. Online laboratory courses that use at-home kits will not have the increased cost of laboratory space and teaching assistants, while virtual labs can cut costs without the extensive supply need.<sup>1</sup> Face-to-face laboratory fees can be allocated to purchase at home laboratory kits. This allows online students to have a similar experience as face-to-face students at a much lower price to the university without raising student cost.

A hands-on laboratory experience allows students to engage in their own environment. Doing hands-on experiments can enhance students' appreciation of science in their own lives.<sup>2</sup> It was also found that a virtual environment can develop a student's deeper understanding of the context through the experience.<sup>3</sup> This includes an understanding of theoretical concepts and confirming hypotheses, which leads to increasing students' motivation to learn. However, there are some disadvantages, which were a lack of skill with chemical and lab equipment as well as observation of reactions.<sup>4</sup> Therefore, as at-home labs are developed, demonstrations along with snapshots for steps throughout the lab process will be captured and shared with students. This will help students through the lab procedures and with equipment used during the lab. For more complicated labs, virtual laboratory experiences are chosen. Specific virtual labs will be highlighted along with an explanation of why these specific laboratory exercises were designed virtually.

This course was developed from a course currently being taught in the classroom and converted to be offered solely online. Students will have the same learning objectives regardless of the environment in which the course is completed. The different types of laboratory exercises specifically developed for the online course, which include virtual labs similar to the face-to-face lab experiments as well as lab experiments from a commercial kit, will be shared. Students will use a kit with equipment and specific directions or demonstrations on how to complete the laboratory exercises for the hands-on experiments. Virtual experiments were designed to simulate the same type of labs done in the face-to-face sections that could not be replicated in the kit. A comparison of the lab experiments between both environments and the design process will be shown.

Throughout the presentation, the lessons learned during the development process, how the course will be implanted at this university, and future goals of the course will be discussed. Attendees will take away useful design strategies when developing an online lab course by comparing both hands-on and virtual lab exercises and the assessment plan to have the students think critically and engage in the material.

### Education, Online, Laboratory

## E108 High-Impact Learning Within a Project-Based Learning Course

John A. Williams, PhD\*, Western Carolina University, Cullowhee, NC 28723

**Learning Overview:** After attending this presentation, attendees will understand how high-impact learning activities can be implemented into forensic science courses, even courses that are heavily activity based.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the pedagogical benefits of high-impact learning in a forensic science curriculum.

The Association of American Colleges and Universities in 2008 published a report on High-Impact educational Practices (HIP) and their importance to undergraduate education.<sup>1</sup> Effective HIP activities share several commonalities: expense of considerable time and effort, faculty and peer interaction, experience of diversity, experience feedback, and learning in different settings (i.e., outside of the traditional classroom lecture). HIP is all about focusing student engagement in their own learning. Ten proven HIP activities have been identified. Included among these are: (1) collaborative assignments and projects, and (2) undergraduate research.

In 2012, in response to a university-wide initiative, the Anthropology and Sociology Department at Western Carolina University adopted a requirement that all majors participate in an Engaged Learning Experience (ELE). This requirement could be fulfilled in a number of manners, including enrolling in an ELE-designated course. Anthropology 401, Bone Trauma and Modification, is a Project-Based Learning (PBL) themed course in the forensic anthropology curriculum.<sup>2</sup> Students engage in group activities involving the predetermined replication of bone traumas using non-human animal bone. These replications are carried out in small groups of three to five students. In 2018, this course was designated an ELE course. This meant that, in addition to the regular PBL activities performed by all students in the course, the 13 ELE participants were required to perform a separate and unique bone trauma replication project. They were also required to make a public PowerPoint® presentation of their results and submit a written report.

HIP is by its nature time- and labor-intensive not only for students but also for faculty. This creates the potential for student and especially faculty participant overload.<sup>3</sup> As Anthropology 401 is a laboratory course, introducing an added laboratory component in the form of the ELE activity compounded the logistics of time and space in the laboratory. Essentially, an HIP course had added to it a second HIP component. One solution to avoid synergistically intensifying time and space requirements was to make the ELE activity group-optional. Participants could perform their activity individually or in groups of up to four individuals. The latter was strongly encouraged and only one student chose to work on their own.

Each year, the ELE projects are internally reviewed by the department. This review process includes direct observation of the ELE public presentation as well as the physical products of the student-engaged research. Of the 13 Anthropology 401 projects submitted in 2018, 12 met and 1 exceeded expectations for quality, scientific rigor, and meeting the spirit of engaged learning. The one project that exceeded expectations was submitted by the single student participant.

## E109 Engaging Freshman Undergraduate Students in Forensic Science Research to Improve Science, Technology, Engineering, and Math (STEM) Retention

Kristi Bugajski, PhD\*, Valparaiso University, Valparaiso, IN 46383

**Learning Overview:** After attending this presentation, attendees will have been introduced to two different grant programs that are supporting forensic science undergraduate research. An outline of the programs and the types of projects students have worked on will be presented. A discussion of how other institutions could run similar programs will be part of the discussion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that there is great value in students having an authentic research experience in terms of the student's skill development and retention at a university. The impacts are intensified when students are recruited into laboratories in their freshman year.

Previous research shows there is great value in an authentic research experience for undergraduates.<sup>1</sup> Other studies have documented the importance of undergraduate research in developing student's scientific knowledge, basic laboratory skills, self-confidence, and personal motivation.<sup>2,3</sup> These improvements are even more defined in traditionally underrepresented groups, so incorporating these students in the lab helps with Valparaiso University's (VU) commitment to diversity.<sup>3</sup>

Valparaiso University has two current grant programs that are aimed at improving freshman-sophomore retention in STEM majors by incorporating students in undergraduate research labs the first semester of their freshman year. Forensic science is one of the areas that students can choose to focus their research on, and it is a subject that most find interesting and accessible. The Freshman Research Engagement in Science (FRESH) program has been funded through the Indiana Space Grant Consortium for \$14,999 annually over the past four years. The grant provides a \$1,000 research stipend to the chosen students, along with supply/travel money for their project. The students are committed to participating in a research laboratory for two semesters, both in their freshman year. The grant does not provide money for programmatic activities outside of research and conference travel. The Establishing Practices Integrating Commuters (EPIC) is a National Science Foundation (NSF) Award in the sum of \$999,991. The grant provides a sizeable four-year scholarship (average of \$5,300 annually) in addition to supply and travel money. The aim of the grant is to use research laboratories as a basis for social integration to improve retention of commuter students. EPIC has funding for program activities, such as monthly meals, field trips, industry trips, a yearly retreat, and a writing circle.

Students in both programs have participated in forensic science research projects. The projects they have worked on are: (1) diurnal oviposition of blow flies, (2) characterizing the volatiles associated with decomposition, and (3) blow fly oviposition on wounds vs. natural openings. Only one forensic science student has not continued in their research lab after their freshman year ended. These students have presented the results of their research in a multitude of venues, including departmental colloquiums, VU's undergraduate research symposium, and the Indiana Academy of Science annual meeting. They have participated in the research ideas, experimental design, data collection, insect identification, data analysis, and both written and oral presentations.

Typical freshman-sophomore retention in a student's chosen STEM major at VU is around 65%. Both the FRESH and EPIC programs have shown significant improvement in retention at the 0.05 level. FRESH has retained 87.5% of students in their discipline after their first year and EPIC has retained 87% of students in the same period. Forensic science research has had an important role in recruiting and retaining students for both of these programs.

### Forensic Science Research, Freshman, Undergraduate Research

---

## E110 Forensic Science Distance Education: Trials, Tribulations, and Triumphs

*Lerah Sutton, PhD\*, University of Florida, Gainesville, FL 32608; Jason H. Byrd, PhD, University of Florida, Gainesville, FL 32608*

---

**Learning Overview:** The goal of this presentation is to make attendees aware of the current trends in forensic science education and how the demand for online distance education within the forensic sciences is rapidly growing. After attending this presentation, attendees will better understand the fundamental difficulties associated with building a successful distance education program, learn methods to overcome these difficulties, and hear about the student successes associated with these programs. New ways to integrate scene photos, autopsy photos, and case studies within the course will be discussed as well as the implementation of new, in-person, hands-on laboratory class electives.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating attendees about the new trends in forensic science higher education. If these same concepts are applied toward continuing education for actively working professionals—a plan that is currently in progress—it will serve to improve the quality of distance-learning continuing educational opportunities available to professionals working within the forensic sciences.

Unique to Florida, but mirrored in other states, is the Earnhardt Family Protection Act, which overrides Florida's open public records laws as they relate to autopsy and crime scene photographs, preventing the copying, distribution, or viewing of these photographs. Violation of this law is a third-degree felony and violates Florida State Statute 406.135. As many of the faculty within these online programs have built their forensic careers in Florida, this law may have proved prohibitive to providing students with the type of engaging case studies needed to further their education. However, special permissions and online security techniques have been implemented to allow the use of the photographs to provide students with the highest-quality educational experience possible. Techniques that are otherwise difficult to describe online can be supplemented with optional hands-on lab classes that give students the opportunity to immerse themselves in an intensive course that complements the online course they have previously taken.

An additional component of learning is though discussion and debate with fellow students, which is often overlooked or absent in online education. Methods to encourage and stimulate discussion are integrated within each course to ensure students receive a well-rounded education. This model has, thus far, proven extremely successful as demonstrated by the online programs performing far beyond the initial market projections for student engagement. If these same concepts are applied toward continuing education for actively working professionals, a plan that is currently in progress, it will serve to improve the quality of distance-learning continuing educational opportunities available to professionals working within the forensic sciences. Offering a myriad of courses designed for the working professional (i.e., courses that may be taken on a flexible schedule from anywhere the student has computer access and an internet connection), students and participants at any level of education and experience, from the newest beginners to the seasoned professionals, may find courses tailored to their specific needs and offered either fully online or supplemented with in-person hands-on learning.

### E111 Using Online Learning and Gamification to Enhance Reasoning Skills

*Sarah R. Coffman\*, Pittsburgh, PA 15219; Lyndsie N. Ferrara, PhD\*, Duquesne University, Pittsburgh, PA 15219*

---

**Learning Overview:** After attending this presentation, attendees will understand how and why a reasoning skill curriculum was created for forensic science students.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of improving reasoning skills for forensic science students by incorporating online learning and gamification.

The goal of this research was to enhance students' reasoning skills using online content and gameplay. Curriculum used in the online modules and the modified version of Clue® were created by a student and a professor. Student involvement in curriculum design allows students to modify content to their own predisposition. Allowing students to have a say in what they learn and how may create a more engaging environment for education, increasing the motivation of students to learn. As a student, taking on the role of creating content and assessments assisted in a deeper understanding of teaching pedagogy.

Using the Online Learning Initiative (OLI) environment, modules focused on improved reasoning skills in the sciences were developed. Modules were equipped with videos, definitions, and activities to provide diversified means to grasp the content. The modules combined with the game were implemented in a flipped-classroom setting where students completed the online modules, then applied their knowledge while playing the game. Flipped-classroom models consist of lectures, online learning, and other various learning interphases outside of the classroom. This enables students to apply their knowledge in the classroom where thinking errors can be corrected and automatic feedback is feasible and encourages educators to be more of a mentor than a teacher.

Students were asked to complete the online modules at their own pace within a week timeframe. The primary analysis compared pre-test versus post-test scores to assess students' knowledge gain. Next, a group of students played a modified card-based version of Clue®. Only some of these students had completed the online modules. Students were asked to play the game once without any further instruction. For the second game, students were asked to play again and complete a worksheet to track their thoughts and identify reasoning processes. Analysis of the game included a comparison of answers between those who completed the online modules and those who did not. This research demonstrates how online learning and gamification can enhance reasoning skills.

Results indicate that students are learning the different types and modes of reasoning through the online content. Additionally, students who have completed the online modules prior to playing the Clue® game were better able to identify their own reasoning processes while playing the game. Overall, this work provides an engaging format to teach reasoning skills to forensic science students. Furthermore, the interaction between an educator and a student enhances the design process and develops new skills for the student.

#### Education, Reasoning, Learning

### **E112 Crossing the Border Between Academia and Forensic Science Practice: Managing a Successful Student Internship Program in an Integrated Medical Examiner Office and Crime Laboratory**

*Jasmine M. Jefferson, MS\*, Harris County Institute of Forensic Sciences, Houston, TX 77054-2001; Michal L. Pierce, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054*

**Learning Overview:** The goals of this presentation are to: (1) explain the mutual benefits in maintaining a student internship program at a forensic science agency; and (2) illustrate the elements in a successful internship program at an integrated medical examiner office and crime laboratory.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science program by helping attendees gain competence in explaining how a student internship program can mutually benefit a forensic science agency and forensic science students and in illustrating the system to maintain a successful student internship program.

In an effort to bridge the border between academic study and forensic science practice, there has been an observed increase in the number of collegiate programs with a student internship requirement as part of the forensic science curriculum. While many students seek a forensic science internship as an introduction into the field of forensic science, other students purposefully use internship programs as a stepping stone to future employment, establishing contacts, and creating connections for on-going research interests. Allowing students to crossover into the day-to-day functions in a laboratory discipline as part of their curriculum provides an invaluable experience to integrate their academic foundations with real-life experience and to plant seeds for relevant research. Moreover, maintaining an internship program allows eager and competent students to temporarily expand the workforce in a forensic science agency and perform work on various research projects, providing mutual benefits for both the student and the agency.

Managing a successful student internship program at an integrated medical examiner office and crime laboratory is a labor-intensive task, but is essential to exposing students to forensic science culture. As a priority, most forensic science agencies manage a large caseload and continually strive to meet turnaround time objectives. Although managers may identify areas throughout the agency that could benefit from research and development, they may be unable to dedicate lab analysts to develop validation plans or perform the research functions. This is where interns can assist. However, intern recruitment, applicant review, and mentorship require staff and a developed system. Furthermore, once students are accepted to an internship program, they require consistent oversight, a structured schedule, professional development guidance, and end-of-program activities that are critical to providing the student with a comprehensive intern experience and achieving a focused outcome for the agency.

Yearly, the Harris County Institute of Forensic Sciences (HCIFS) opens intern positions in numerous forensic science disciplines, including forensic investigations, forensic anthropology, forensic entomology, histology, forensic genetics, trace evidence, forensic toxicology, drug chemistry, firearms identification, and victim's assistance, as well as forensic imaging and administrative services. The HCIFS employs a full-time Training & Development Manager to manage the student programs, including the internship program. The Quality Management Division staffs the Training Manager, who is integral to the success of maintaining the ten-week, full-time summer internship program, and the additional intern program needs throughout the year.

The Training Manager maintains relationships with local colleges and universities as a regular source of student interns, as well as handling recruitment and outreach to a variety of schools. Application processing and screening is filtered through the Training Manager, who also tracks the applicants for each discipline and can initiate additional recruitment efforts for disciplines with multiple project needs. A trained mentor and special project is assigned to each intern once applicants are selected for and accepted into the program. Upon their arrival, the Training Manager provides an orientation to onboard all students to the agency. The Training Manager creates and maintains a formal internship program schedule with pre-scheduled professional development sessions for the interns, which has proven to be one of the most meaningful aspects of the HCIFS student-training program in further preparing students to cross over into the professional forensic science workforce. Additional activities unique to the HCIFS Internship Program, such as an autopsy viewing or forensic investigations field call ride-along, may also be scheduled to enhance the intern experience. At the end of the program, each intern provides a formal presentation to HCIFS managers and staff to summarize the project completed during the program. Finally, the HCIFS Training Manager facilitates the intern performance evaluation process and periodic progress reports with each mentor to ensure administrative documentation is maintained as part of the internship program. In 2019, the HCIFS received 35 intern applications from qualified students; 13 interns were selected for the summer internship program from six different universities.

### E113 Forensic Sciences Learning for Victims of Enforced Disappearances

*Carlos A. Gutierrez, MS\*, Chaminade University of Honolulu, Honolulu, HI 96816*

---

**Learning Overview:** The goal of this presentation is for attendees to learn about an innovative teaching program in basic forensic sciences and crime scene investigation developed for the relatives of victims of enforced disappearances that happened in Sinaloa State, Mexico. This program has been developed to be offered online from Chaminade University of Honolulu, HI, to its recipients in Culiacan, Sinaloa State, Mexico, in Spanish.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that people without any background or knowledge of the forensic sciences and crime scene investigation field can have the ability to address and process a crime scene. This educational program can be utilized for other groups of victims of enforced disappearances around the world, in different languages.

Enforced disappearances are a major issue that several nations have faced throughout history and that have left a problematic number of people declared “missing” around the world. An enforced disappearance is the kidnapping process of a person by an unknown individual/organization with the purpose of acting outside the margins of the law. Oftentimes, enforced disappearances entail the assassination of the kidnapped person, whose body is usually discarded, leaving the feeling that the victim has faded away from the face of the earth. Enforced disappearances have occurred in different contexts throughout history; some of the most remarkable contexts are dictatorships, armed conflicts, and drug trafficking. These illegal actions have been used to spread terror in countries and regions around the world, such as Sri Lanka, Syria, and Mexico, countries where enforced disappearances have become a serious problem not only for the victim and governments but also for close relatives.

Currently, drug trafficking is considered one of the most important contexts in which numerous people are declared “missing,” and Mexico ranks among the countries with the highest number of enforced disappearances. Groups of close relatives of enforced disappeared people have formed throughout Mexico, initially with the main goal of supporting the close relatives of the “missing,” but subsequently with the purpose of searching for any kind of physical evidence that can be provided to the prosecutor’s office to help with the investigation of these cases. One of these groups is Sabuesos Guerreras (Warrior Hounds), a not-for-profit organization from the city of Culiacan, in Sinaloa, Mexico. This group is composed mainly of women whose beloved husbands and/or sons have been victims of enforced disappearances, who for years, in addition to supporting each other sociologically and economically, have searched for physical evidence in different open fields of the state.

These acts have inspired the creation of an innovative training program in basic forensic science with the goal of being able to use the knowledge acquired through this program in their own relatives’ cases. This training program consists of a ten-class online course, focusing on: “Crime Scene Investigation,” “Analysis and Preservation of Physical Evidence,” and “Management of an Organization for Victims of Enforced Disappearances.” In this program, participants are assessed before the course begins and after it ends using the same evaluation instrument.

## E114 Curriculum and Accreditation Pertaining to Crime Scene Investigation Education

*Mark Vecellio, MFS\*, Methodist University, Fayetteville, NC 28311; Erick P. Bryant, MFS\*, Colorado Bureau of Investigation, Arvada, CO 80002*

---

**Learning Overview:** After attending this presentation, attendees will have gained insight into the current state of accreditation relating to crime scene investigation education and ideas concerning development of a model program.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through discussion of potential benefits of accreditation and oversight of university crime scene investigation programs. Additionally, a proposed framework supporting an effective educational Crime Scene Investigator (CSI) program will be presented.

Traditional university forensic science programs generally prepare students for work in forensic laboratories. Such programs may be accredited through the Forensic Science Education Programs Accreditation Commission (FEPAC), thus helping to standardize and maintain assurance of quality and relevant education. FEPAC accreditation, logically, focuses on the sciences. CSI work, however, is often completed by investigators who are not formally trained scientists nor have completed degrees in a scientific field. Many universities have developed programs focusing on preparing students for CSI or general investigative work; however, these programs are quite variable in terms of curriculum, the methods in which educational content is delivered, and quality.

The primary objective of this presentation is to raise awareness and initiate dialogue relating to accreditation of CSI educational programs. Though CSI work, especially at entry level, does not require the same depth of understanding of the sciences as does forensic laboratory work, it does require thorough knowledge and technique mastery of identification, collection, initial processing, and storage of physical evidence, as well as the ability to request relevant forensic exams of physical evidence that is recovered. Some research, and a wealth of professional anecdotal experience, suggests that evidence is routinely overlooked, improperly processed, or not submitted to forensic laboratories for appropriate testing, thus severely limiting the full capabilities of forensic science. It is thought that quality college education would naturally help correct this problem. Accreditation would help ensure students receive quality, rigorous education.

The second objective of this program is to encourage dialog concerning program objectives and coursework for CSI-related curriculum. A model program will be discussed. This program has undergone over ten years of refinement and development and is based upon training methods used by federal and state law enforcement training centers. The program grounds students in the basic science and the necessary hands-on skills to expertly locate, document, identify, process, collect, protect, and analyze many types of forensic evidence in support of felony investigations. This education/training prepares students for the potential to pursue advanced degrees as well as employment within the forensic science and law enforcement/investigative professions. In addition, the curriculum content is consistent with the primary national certification program.

Program coursework, in addition to general education requirements including life and physical science, consists of a theoretical foundation of courses, including the Introduction to Forensic Science, the Investigative Process, Drugs of Abuse, Homicide and Death Investigations, Forensic Profiling, and Forensic Firearms. Students also complete a series of lab-based courses, including Forensic Photography, CSI, Advanced CSI, and Crime Scene Reconstruction. Students engage in approximately 100 hours of practical exercises in addition to hands-on experience in internships.

---

### Education, Accreditation, Crime Scene Investigation

### E115 Taking Science Behind the Walls: Side-by-Side Learning With Students and Incarcerated Individuals

Susan M. Gurney, PhD\*, Drexel University, Philadelphia, PA

**Learning Overview:** After attending this presentation, attendees will have greater insight into the Inside-Out pedagogy and how it can be used to enhance learning and understanding within a science course taught in a correctional facility.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a novel pedagogical approach that may be incorporated into an undergraduate or graduate forensic science curriculum and which juxtaposes the course content with a criminal justice context.

Inside-Out is a national program that brings together college students and incarcerated individuals to learn side-by-side through facilitated discussion. The first Inside-Out class started in 1997, Temple University in Philadelphia, PA, and as of 2019, more than 200 correctional facilities have hosted over 35,000 inside and outside students.<sup>1</sup>

Initially, the Inside-Out courses addressed topics surrounding criminal justice, but have expanded to cover many topics within the humanities and social sciences. In 2019, Drexel University taught the first science-based Inside-Out course, The Science of Science Fiction, bringing together 12 outside students from different majors (Biology, Biomedical Engineering, and Communications) with 14 inside students from Curran-Fromhold Correctional Facility. The course met for two hours weekly, during the ten-week quarter term. The topic of science fiction was specifically selected to ensure that it was accessible to students from different educational and scientific backgrounds. It also allowed discussions on many different aspects of science, including evolution, the physics of time travel, and editing of genomic DNA, while also allowing discussions on such themes as societal structure, prejudice, and justice.

The role of the instructor in the classroom setting is as a facilitator to the discussions and learning. Through group work and class discussions, the aim of the program is for the students to learn from each other entirely through discussion, without any traditional lecturing. This was adapted slightly to introduce some more complex scientific concepts, to introduce recent scientific advances. The course was designed around two novels, *The Time Machine* and *The Genius Plague*; one comic, *Astounding X-Men*; and one television show, an episode of *Doctor Who*. Students were given weekly reading and assignments to complete. In class, students would start by working together to outline the scientific concepts covered in the assigned reading from that week. From the concept, they would select two or three for further discussion. The instructor prepared “pop-up” lectures lasting three to five minutes on two or three of the main themes, providing more context for the science content and the current understanding. Group activities allowed students to work together to draw images of characters, design technology that may have been used in the reading, or to discuss specific quotes in more detail. Class discussion allowed students to share their views and their own understanding and insights of science with each other. Over the course of the ten weeks, it was evident that the Inside-Out model works well with a science-based curriculum. The students were fully engaged in the pre-class readings and very active within the classroom. The most successful part of the class was the class discussions, which were varied in their topics, but were always focused on science and the themes within the readings. This course helped to break down the barriers between inside and outside students, generating an active learning community over the course of just ten class meetings.

### E116 The Lessons Learned in Teaching Forensic Toxicology From “Wet Lab” to “Lab Bench”

*Michelle R. Peace, PhD\**, Virginia Commonwealth University, Richmond, VA 23284; *David Nigro, BS*, Virginia Commonwealth University, Richmond, VA 23219; *Aaron Lavigne, BS*, Virginia Commonwealth University, Richmond, VA 23219; *John Venuti, BS*, Virginia Commonwealth University, Richmond, VA 23219; *Justin L. Poklis, BS*, Virginia Commonwealth University, Richmond, VA 23219-0613

**Learning Overview:** The goal of this presentation is to identify the elements and challenges in developing the full arc of an experiment from the field to the bench that involves human participants and the regulatory requirements.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying solutions to challenges in developing robust, engaged, field-to-bench education modules for students learning the practice of forensic toxicology.

The Forensic Science Education Programs Accreditation Commission (FEPAC) -accredited Department of Forensic Science (DFS) at Virginia Commonwealth University (VCU) has a three-year average of 320 undergraduate majors and 20 masters-level graduate students. Since the inception of the DFS as a stand-alone academic unit in 2000, a three-credit graduate lecture course in forensic toxicology has been a requirement for master students on the Drugs and Toxicology Track. An accompanying laboratory course was established Spring 2019 as a result of policy shifts that enabled faculty to build and teach this course. The laboratory course focused on standard analytical techniques encountered in the forensic toxicology sub-disciplines of urine drug testing, postmortem toxicology, and Driving Under the Influence (DUI) testing. The course was co-taught and utilized the combined experience of both faculty members to develop the laboratory module as the course was being implemented. In a collaboration with the course faculty and with the generous help of VCU's Police Department (VCU PD), a laboratory module was developed that would take the student from the field to the laboratory. The purpose of this laboratory module was to have students perform the analysis of blood for volatile compounds, including ethanol, improve their understanding of the effects of ethanol and of zero order elimination, and to observe the Standardized Field Sobriety Test (SFST) by trained Law Enforcement Officers (LEO) in a safe environment to facilitate questions and engagement.

The development of this laboratory module involved VCU PD running a wet laboratory re-training session for their officers to review and practice SFSTs. The wet laboratory was conducted as required by the accreditation standards for the law enforcement academy. Volunteer drinkers were enlisted. The volunteers were given Preliminary Breath Alcohol Test (PBAT) at routine intervals before and after the SFST was administered. An on-site registered nurse collected blood from the volunteers prior to drinking and immediately before the SFST was conducted in compliance with requirements of the DFS's Institutional Review Board (IRB) protocol (HM20002931 CR3) for de-identified collections. Students were provided a lecture prior to the wet laboratory regarding DUI laws and the SFST by an instructor in the VCU PD Police Academy. The student observed the SFST performed by LEO as re-training and review. The collected PBT, blood specimens, and the SFST results recorded by the LEO were de-identified and given to the students for bench analysis. The student used the PBT results to generate an ethanol elimination curve, and they analyzed the blood samples by headspace Gas Chromatograph with Flame Ionization Detectors (GC/FID). The students then correlated the results of the PBT, Blood Alcohol Concentration (BAC), and the SFST results.

#### Education, Toxicology, Wet Lab

### **E117 High Tech, High Touch Learning for High School and Undergraduate Forensic- and Crime Scene-Related Fields of Study**

*Charla Skinner Perdue, MS, MFS\*, Florida State University Panama City Campus, Panama City, FL 32405*

---

**Learning Overview:** The goal of this presentation is to demonstrate a model in which experiential learning can be utilized in high school and undergraduate forensic- and crime scene-related fields of study by integrating traditional classroom and online learning for a tech-enhanced learning modality.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the benefits of educators developing experiential learning courses and of students participating in career-building experiences before graduation.

Online education is beneficial and continues to grow in popularity. Graduates from forensic and crime scene-related online programs frequently leave with an understanding of key concepts but with little ability to demonstrate the skills and techniques they can explain. By requiring experiential learning courses in a mostly distance-learning program, students graduate with relevant real-world experience on their resume and are better prepared for the job hunt and workplace. Students are buoyed by the ability to point out to potential employers that they know about a particular subject and have completed the processing, testing, analysis, etc.

There are many challenges when it comes to incorporating hands-on learning into a mostly online educational program. This presentation will detail how the Florida State University (FSU) faculty have developed curriculum for the Crime Scene Investigation Major that uses technology to deliver lectures and labs live, online for distance learners and uses accelerated on-campus summer semesters to further develop skills. With proper planning, this strategy can be emulated by interested institutions.

This presentation will detail how students at FSU participate in introductory course work that is lecture-based to gain understating of a particular forensic discipline. This is done traditionally for face-to-face students in the classroom and Using Blackboard Collaborate Ultra, distance learners join the classroom remotely from their laptop or other mobile device. Distance-learning students are able to join in in the discussion using their microphone or the built-in chat feature.

During hands-on labs, traditional students are in the laboratory with the instructor. For the online student, a box is mailed at the start of the semester with the materials needed to participate in the lab. Like the lecture, distance learners join with traditional students from wherever they are located and participate in the lab using their own lab in a box. These technology-enhanced courses provide the underpinnings of the more intensive on-campus summer labs.

Summer labs are held in an accelerated summer semester on campus only and are required. Students travel and stay on campus for one week and attend lab Monday through Friday from 9:00 a.m.–5:00 p.m. daily. During this week-long, 40-hour lab, students receive the full lab credit that would normally be taught over a traditional 13-week summer semester. During this time, the traditional and online students have the opportunity to get to know one another personally and work together in small groups, problem solving and completing casework.

At the end of the program, students are required to participate in a Capstone internship program. This is done with a crime scene-related agency in the student's area and does not require relocation. Students must apply for the Capstone and have their agency and position approved by the program. While working at the agency, students complete weekly assignments highlighting what they are learning. Results from this program, which had its first graduates in the summer of 2017, have been obtained in post-graduation surveys and reveal alumni are at certain hands-on labs and the required internship gave them an advantage in hiring.

### E118 Chemical Murder Mystery: Two Decades of Experiences of Forensic Science Education in Delivering a Hands-On Event for 15- and 16-Year-Old Students at a University

*Stewart Walker, PhD\*, Flinders University, Adelaide, South Australia 5001, AUSTRALIA*

---

**Learning Overview:** The goal of this presentation is to present experiences of writing and presenting hands-on forensic science events for school students between the ages of 15 and 16 years old. Some of the problems and pitfalls will be discussed along with some of activities that worked. Consideration will also be given to changes that have been made over the two decades of running these events and of what students expect from these events in 2020.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relating experiences to attendees who may have undertaken, or plan to participate in, forensic science school outreach programs.

The Chemical Murder Mystery (CMM), a hands-on, day-long activity for 15- to 16-year-old students, has been run at the South Australian Branch of the Royal Australian Chemical Institute ([RACI; the equivalent of American Chemical Society) and The School of Chemistry, Physics and Earth Sciences at Flinders University, Adelaide, South Australia, over the past two decades. The basic format has been to gather the students (up to 144 per day) and split them into 12 teams with different colored T-shirts. The students then gather in a lecture theater for a presentation, “CSI: Adelaide. Forensic Fact or Forensic Fiction,” that illustrates the breadth of forensic investigations from DNA, drugs, fingerprints, soil, toxicology, etc. The presentation is interrupted by a policeman or security guard who says that the head has been found dead. The students then become crime scene investigators and go to the (reconstructed) crime scene. Two representatives from each team collect evidence from the car, the tires, the shoes, and the body of the deceased. After a short overview of the evidence collected, they go to the lab and analyze the evidence at 1 of 12 stations, then rotate stations. After the evidence has been analyzed, they congregate in the theater again, which serves as a court room. One representative from each team comes to the stand and presents what they did and what they found. The different evidence is then placed on the white boards under the appropriate suspects. At the conclusion, the students vote on who they think “dunnit” and how. This has proven popular with local schools and some who travel in from the country. At peak, there were 850 students enrolled for six days with 500 on the waiting list. This is a major event for a small department and small RACI group.

Over the two decades of training, many changes have taken place and the CMM has developed and changed to: keep relevance with the changing school curriculum; enable more students to attend; adapt to changes in students’ expectations; include input from new forensic staff; and keep up with changes in Health and Safety requirements. The initial aim of the Chemical Murder Mystery was not to attract students to Flinders University’s Forensic Program (BSc, BSc[Hons], MSc, and PhD in Forensic and Analytical Chemistry and Biology/DNA), but to encourage students to choose to continue studying science in the last two years of school by having a day of fun using science to solve a crime. This presentation will discuss some of hands-on activities that worked well with this age group but will also indicate some of the problems and pitfalls for discussion with others doing such forensic science outreach activities. It will also discuss additional potential forensic science outreach.

#### Education, Schools, Outreach

**E119 Deceased Children Due to Trauma and the Evaluation of Non-Accidental Injuries: A Dutch Retrospective Level-1 Trauma Unit Study**

Marie-Louise Loos, Amsterdam, Noord-Holland 1105 AZ, NETHERLANDS; Steven Kooiker, MD, Emma Children’s Hospital, Amsterdam University Medical Center, Amsterdam 1105 AZ, NETHERLANDS; Rick R. Van Rijn, MD, PhD\*, Amsterdam University Medical Center & Netherlands Forensic Institute, Amsterdam, Noord Holland 1105AZ, NETHERLANDS; Roel Bakx, MD, PhD, Emma Children’s Hospital, Amsterdam University Medical Center, Amsterdam 1105 AZ, NETHERLANDS

**Learning Overview:** After attending this presentation, attendees will know the incidence of child abuse and neglect in deceased children presented at a Level-I trauma center.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing knowledge on non-accidental trauma and causes of death in the pediatric population.

Child maltreatment is a worldwide health problem. Previous studies have, depending on the patient population, shown significant differences in the incidence of Child Abuse and Neglect (CAN) at the emergency department. There is little evidence on the incidence of CAN in children admitted to a shockroom of a Level-1 trauma center. Children admitted to the shockroom suffer from severe injuries with a possible fatal outcome. Death resulting from CAN is the most severe outcome, which should be recognized not only to identify a potential perpetrator but also to protect siblings.

The objective of the current study was to identify the extent of non-accidental trauma in deceased Dutch children who were admitted to the shockroom of a Level-1 trauma center and to determine indicators of CAN. Medical and forensic files of all deceased children admitted between January 1, 2014, and December 31, 2018, in one of six university hospitals were retrospectively reviewed. Eligible for inclusion were children aged between 0 and 17 years admitted to the shockroom and who died due to traumatic injuries, suicide, or drowning. Excluded were children who died of natural causes. Non-accidental trauma was confirmed after evaluation of the multidisciplinary team (the Suspected Child Abuse and Neglect [SCAN] team), after forensic medical evaluation (using information of postmortem images, forensic autopsy), and/or confirmation in the courtroom. The following data was collected; age (years), gender, trauma mechanism, injuries, Injury Severity Score (ISS), medical history, family composition, and cause of death as established by the forensic physician. To determine significant differences in characteristics between cases with CAN and Accidental Trauma (AT), the Mann-Whitney U test was used for a skewed distribution, the unpaired *t*-test for a normal distribution for numerical data, and the chi-square test was used for discrete data. A factor was considered statistically significant when the *p*-value did not exceed 0.05.

In all, 137 children were included, with a median age of 5 years (IQR 1–13), and 87 (64%) were boys. CAN was confirmed in 13 (9.5%) cases, 21 cases remained undetermined and accidental trauma (AT) was confirmed in 103 cases. In young children (< 5 years of age) CAN was confirmed in a number of cases. The median age of CAN cases was 0 years (Interquartile Range [IQR] 0–2.5 years) versus a median age of 8.5 years (IQR 2–15) in the AT group (*p* < 0.001). An overview of the trauma mechanisms is shown in Table 1. In all deceased children, fractures (47/137) and Traumatic Brain Injury (TBI) (85/137) were often found, followed by injuries to the chest or abdomen due to blunt trauma (45/137). TBI was significantly associated with CAN (CAN 12/13 versus AT 64/103; *p* = 0.031). Children in the CAN group had a median ISS of 20.5 (IQR 13.75–28.75) versus a median ISS of 34 (IQR 25–50) in the AT group (*p* = 0.084). Postmortem investigations were performed in 11 CAN cases and 24 AT cases, total body Computed Tomography (CT) scan (CAN 1 vs. AT 12 children), autopsy (CAN 9 vs. AT 3 children). Additional injuries were found in 2 (18%) CAN children and 2 (8%) AT children (*p* = 0.001). In the undetermined group, 11 of 21 (52%) cases were drowning cases, 4 (19%) cases were “found dead” in their home. These cases were not evaluated by the SCAN team and did not undergo postmortem investigations other than the physical exam of the forensic specialist.

The incidence of CAN in deceased children in this cohort is 9.5%, and TBI was significantly associated with CAN. Postmortem investigations usually consist of a total body physical exam by the forensic physician. Postmortem imaging studies and a forensic autopsy are seldom reported, especially in drowning cases. Therefore, the incidence of CAN may be underestimated. Based on these findings, it is recommended that a thorough work-up in all young (<5 years of age) children be conducted to detect additional injuries, as injuries in these children are easily missed during the postmortem physical exam.

Table 1. Reported trauma mechanism.

Causes of Trauma	No. of Cases	%
Traffic Incident	38	27.7
Drowning	31	22.6
Found Dead	19	13.9
Suffocation	16	11.7
Fall from Height	8	5.8
Suicide	7	5.1
Other	7	5.1
Blunt Trauma	6	4.4
Sharp Trauma	2	1.5
Shooting Incident	2	1.5
Burn Incident	1	0.7

### E120 Scene Inspection in a Harsh High Mountain Environment: The Valle d'Aosta Pilot Program

*Pasquale Beltempo, MD\**, Azienda USL Valle d'Aosta, Quart, Valle d'Aosta 11020, ITALY; *Serena Maria Curti, MD\**, Azienda USL Valle d'Aosta, Quart 11020, ITALY; *Maurizio Castelli, MD*, Azienda USL Valle d'Aosta-SC Medicina Legale, Quart 11020, ITALY; *Mirella Gherardi, MD, SC Medicina Legale, Aosta 11100, ITALY*

**Learning Overview:** After attending this presentation, attendees will be informed regarding the challenging task of performing a thorough crime scene inspection in a harsh high mountain environment such as Valle d'Aosta (VDA).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by outlining the VDA's model of cooperation between the VDA Office of Medical Examiner and the rescuers of the emergency department in order to gather proper documentation of the death scene, even in hostile conditions.

VDA is the smallest and least densely populated region of Italy, with a density of just 39 residents per square kilometer. However, the presence of 16 mountains in the region—among them are Mont Blanc, Monte Rosa, and the Matterhorn—whose peaks are higher than 4,000 meters, with nearly 200 glaciers, represents an attraction for tourists in search of high-altitude activities, such as skiing, and rock and ice climbing. Every year, nearly 800,000 tourists arrive in VDA to spend the holidays. Research and rescue interventions of missing people in natural disasters, extreme sports accidents, and motor vehicle/air crashes in such a harsh environment with suddenly changing weather conditions require well-established protocols between Armed Forces alpine rescuers, emergency department first aid teams, and hospital physicians. Forensic activities during these emergencies are not always feasible by the VDA Office of Medical Examiner, due to safety regulations, operative statutory requirements for high altitudes, the limited seating capacity of rescue helicopters, and the survivor's need for prompt response.

Since 2018, the VDA emergency department physicians certified for high-altitude first aid have attended informal training by medical examiners. During classes, the health care professionals were provided with forensic pathology knowledge and operative instructions, including forensic photography skills. A crime scene inspection form was introduced and attendees were taught proper compiling. During the second phase of the program, the first aid team was encouraged to provide feedback to the learning curve by practical experience. The feedback was evaluated and corrections have been discussed for each case with the attendees. Continuous feedback was guaranteed by on-call consultations and recurring meetings.

The results of the training course were tested in the field on January 25, 2019. An aerial collision occurred between an Italian helicopter and a French light aircraft over the Rutor glacier, at an altitude of 2,700 meters, close to the northern Italian border with France and Switzerland. The helicopter was carrying six people: the pilot, an alpine guide, and four passengers who were heli-skiing. There were three passengers on the light aircraft, all pilots who were training in mountain flying. All six passengers of the helicopter were killed in the accident; two of the three passengers of the light aircraft were found alive by rescuers. The remains of the helicopter were spread over a 400-meter area, with bodies recovered from about 50 meters from the wreckage site.

Despite the complexity of the rescue, the trained emergency team was able to accurately geolocate the seven corpses and the survivors, while collecting viable data for accident reconstruction and documenting the scene of the rescue. The bodies underwent external examination, Computed Tomography (CT) scans, and a complete autopsy at Aosta Regional Hospital. The results will be presented and discussed. The confluence of data resulting from scene inspection and from the autopsies allowed the team to reconstruct the accident as a mid-air impact during vertical take off of the helicopter and on-glacier landing of the light aircraft. The pilots of the aircraft were prosecuted for crossing into Italian territory without communicating a flight plan to Italian air traffic control. The preliminary results of the program have been discussed with authorities and a regional training program for emergency physicians is set to start in the fall of 2019. The goal of the program is also to prepare a regional protocol for scene inspection in harsh high mountain environments that could be applied in regional systems with comparable geographical characteristics.

#### High Mountain, Harsh Environment, Scene Inspection

## E121 Alternate Light Wavelength and Filter Detection of Inflicted Cutaneous Bruises

*Katherine N. Scafide, PhD\**, George Mason University, Fairfax, VA 22030; *Matthew J. Hayat, PhD*, Georgia State University, Atlanta, GA 30303; *Yesser Sebeh, DMD, MPH*, Georgia State University, Atlanta, GA 30303; *Nancy R. Downing, PhD*, Texas A&M College of Nursing, Bryan, TX 77803; *Daniel J. Sheridan, PhD*, Texas A&M University College of Nursing, Bryan, TX 77807

**Learning Overview:** After attending this presentation, attendees will understand which alternate light wavelengths and filters are most likely to be effective in the detection of potential bruises.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by potentially improving the likelihood of cutaneous bruise detection during the clinical assessment of victims of violence.

Forensic clinicians often struggle with identifying and documenting bruises on victims of physical violence, particularly on those with older injuries or darker skin. The Department of Justice has recommended the use of alternate light as a tool to enhance visualization.<sup>1</sup> However, rigorous scientific evidence is lacking to broadly support the adoption of this technology for this purpose. It is also unclear how bruise age may impact the specific wavelength performance. The aim of this randomized controlled trial was to determine whether certain wavelengths of alternate light with the ultraviolet and visible spectrums are effective at improving detection of likely bruises over time.

A sample of 157 healthy adults received a bruise inflicted to the lateral deltoid using the controlled application of a paintball pellet. Quota sampling was used to ensure equal representation of six skin color categories determined by spectrophotometer. Bruises were assessed at 21 timepoints over four weeks. The order of assessment in this crossover study was randomized with assignment to alternate light (treatment) and white light (control). Alternate light bandwidths evaluated included 365nm, 415nm, 450nm, 475nm, 495nm, 515nm, and 535nm with observations made using yellow, orange, and red long-pass filters. Multilevel modeling was used to account for the correlated data structure. The multilevel structure entailed wavelength measurements nested within assessments for each subject. Marginal models were used with fixed effects to control for the following variables: skin color, gender, arm fat, age, bruise age, and observer.

The retention rate of this longitudinal study was high (95%). The sample was primarily young ( $M=24$ ,  $SD=7.6$  years) and dominantly female (73%), with an average Body Mass Index (BMI) of 26 ( $SD=6.7$ ). A total of 2,903 bruise assessments were completed resulting in more frequent bruise detection under alternate light (98.6%) compared to white light (85.7%). The odds of detection were greatest compared to white light for 415nm and 450nm using a yellow filter (OR=5.3, 95% CI: 4.3–6.5,  $p < .0001$ ; OR=4.1, 95% CI: 3.3–4.9,  $p < .0001$ , respectively), followed by the orange filter under the same wavelengths. All of the remaining bandwidths had significantly lower odds of bruise detection compared to white light. Based on these results, recommendations can be made for clinical forensic units to invest in alternate light technology to improve the detection of potential bruises.

*This research was funded by a National Institute of Justice (NIJ) Grant. Opinions, points of view expressed in this research, and products discussed represent a consensus of the authors and do not necessarily represent the official position, policies, or endorsement of the United States Department of Justice or the NIJ.*

### Bruise, Alternate Light, Detection

## F1 Brazil's Forensic Science: How Could It Be Helped (and Improved) by American and European Guidelines?

Maria Eduarda A. Amaral\*, Porto Alegre, Rio Grande do Sul 90440001, BRAZIL; Nereu J. Giacomolli, Porto Alegre 90619-900, BRAZIL

**Learning Overview:** The objective of this study is to analyze how the North American and European guidelines can help in the development of Brazil's forensic sciences. This will bring to the public the knowledge regarding the forensic sciences in Brazil, as well as bring to the public's attention the standard guidelines pointed out by the United States and Europe.

**Impact on the Forensic Science Community:** This presentation will have a significant positive impact on the forensic community, demonstrating important characteristics of forensic science that have been pointed out by the major forensic agencies worldwide. In addition, this presentation will promote a connection between what is studied in Europe and what is researched in the United States, making a parallel between the Brazilian and world forensic sciences in addition to bringing improvements to both.

In recent years, Brazil's courts have seen a dramatic increase in the use of scientific evidence. This forensic evidence often is assumed to be reliable by the courts. However, just because evidence is scientific in nature does not mean that it should not also be scrutinized before use. From the collection of the evidentiary material to the issuance of the final report, it is important that procedures be carefully established and carried out before the evidence can be presented to a fact finder. The newness of the Brazilian practice makes it ideal for pointing out ways to improve early on. To be sure, the Brazilian forensic practice has some deficiencies that must be overcome in order to have more reliable forensic evidentiary conclusions.

This study aims to evaluate two reports that were published worldwide in the field of forensic sciences and to identify how these reports could help in the development of forensic sciences in Brazil. The two reports, *Strengthening Forensic Science in the United States: A Path Forward*, and the European Network of Forensic Science Institutes (ENFSI) *Guideline for Evaluative Reporting in Forensic Science: Strengthening the Evaluation of Forensic Results Across Europe (STEOFRAE)*, were published by American and European forensic science researchers, respectively.<sup>1,2</sup> Viewed through the lens of a developing national forensic service provider, these reports demonstrate important areas of international consensus. Parallels between the two reports and Brazil's nascent practice promote border-crossing connections and elevate the field of forensic science.

The two reports each add different insight into Brazil's developing field of forensic science. *Strengthening Forensic Science in the United States: A Path Forward* provides a comprehensive view of forensic sciences and explains the general characteristics of the disciplines and how they can best be used in court.<sup>1</sup> ENFSI's report, meanwhile, focuses more on the characteristics of how to interpret scientific evidence and how to issue an expert report.<sup>2</sup> Together, they are both extremely important and relevant to the legal-forensic-criminal context.

Specific takeaways to be discussed in this study are the importance to Brazil's developing forensic practice accreditations, certifications, standards, and guidelines for quality control and the code of ethics. In 2014, two laboratories in Brazil received the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17025:2005 seal, both from the National Institute of Criminalistics of the Federal Police, being the Laboratory of Forensic Genetics Expertise, and the Laboratory Expertise Service. Currently, the accreditation is being redone and both laboratories are accredited.

Another point of discussion is the usefulness of the ENFSI report in guiding Brazilian forensic scientists on the communication of scientific findings in expert reports. Among these requirements, there is balance, logic, robustness, and transparency. These are essential characteristics of a good expert report and must not be missing at the time of scientific evidence production.

Thus, both publications have much to contribute to the forensic field. Standardizing forensic practice is extremely important so that basic principles of criminal procedure are assured and, especially, that innocent people are not imprisoned based on evidence produced without minimum scientific requirements. Brazil needs to improve its forensic practices; the analysis of both reports is an important initiative for the country.

### Strengthening Forensic Science, Penal Process, Scientific Evidence

## F2 Deaths During Law Enforcement Encounters

*Michael M. Baden, MD\*, New York, NY 10019*

**Learning Overview:** After attending this presentation, attendees will better understand the difficulties in identifying and investigating deaths that occur during police encounters.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the need to better determine the extent of the problem of police-encountered deaths in order to develop strategies to reduce such deaths.

Deaths during law enforcement encounters usually occur from shooting or while someone is being restrained. When someone is shot, the cause of death is usually clear and intended. The issues are whether the shooting was justified. When death occurs during physical restraint, the cause of death is not clear and the death is almost always unintended.

This presentation will address the roles excited delirium, Tasers<sup>®</sup>, drugs of abuse, acute psychotic behavior, pre-existing natural disease, and physical interference with breathing may have in causing or contributing to such deaths. The politics that are often involved in deciding what to do with such information will also be addressed.

The investigation into the death of Eric Garner illustrates many of the above issues. Mr. Garner was a 43-year-old Black male who collapsed and died in the early afternoon of July 17, 2014, while being restrained on his sidewalk by New York City Police in Staten Island. He was being arrested for selling individual cigarettes in his neighborhood. The initial confrontation, his takedown, and his death were captured on a neighbor's iPhone<sup>®</sup>. He is heard in the video saying, "I can't breathe," 11 times during the 50 seconds of struggle while pressure was placed on his neck, back, face, and nose. The video will be shown and examined.

At autopsy, Mr. Garner was 74" tall and weighed 395 pounds. There were petechial hemorrhages in his eyelids, hemorrhages in his neck muscles, and evidence of neck compression. He also had evidence of hypertensive cardiovascular disease with cardiomegaly (660 grams) and acute and chronic bronchial asthma. Toxicology was negative. The medical examiner listed the Cause of Death as "Compression of neck (choke hold), compression of chest and prone positioning during physical restraint by police. Contributory conditions: Acute and chronic bronchial asthma; obesity; and hypertensive cardiovascular disease. Manner of Death: Homicide." Other jurisdictions might have listed the cause of death in this case as excited delirium, asthma, heart disease, or acute psychosis without including the police encounter in the cause of death. Some pathologists may conclude that the death would have occurred even without police involvement. If a drug of abuse were present, it may be called a drug overdose. The manner of death may be listed as accident, natural, or even suicide if a drug is present. This makes identification of such deaths difficult.

The five-year statute of limitations relative to Mr. Garner's death expired in July of 2019 without any charge being brought after city and federal government evaluations. The ability to address this national problem of deaths during law enforcement encounters—and the community disruptions they cause—begins by knowing how frequent such deaths are, who are the victims, when they occur, and the circumstances of such deaths to be able to develop strategies to reduce them. However, no such national statistics of deaths during police encounters are kept by any agency locally or nationally. Some newspapers try to keep daily records of shooting deaths by examination of newspaper mentions and death certificates. However, there is no attempt to maintain such statistics on non-shooting deaths.

This presentation is intended to raise awareness among forensic scientists that it is necessary to address the societal calamity of deaths that occur during law enforcement encounters.

### **Custody, Excited Delirium, Restraints**

## F3 Litigating the Admissibility of Black Box Forensic Software

*Kevin Riach, JD\*, Fredrikson & Byron, PA, Minneapolis, MN 55402; Charles A. Ramsay, JD\*, Ramsay Law Firm, PLLC, Roseville, MN 55113*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the practical issues unique to *Frye* and *Daubert* litigation regarding the admissibility black box forensic software and will have learned practical strategies to deal with those issues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the competence of lawyers and expert witnesses who face the challenge of litigating the reliability and admissibility of evidence generated by black box forensic science software.

The universe of “black box” forensic software has expanded rapidly in the past several years. From probabilistic genotyping to breath alcohol measurements to facial recognition, and more, a new wave of computer-generated evidence is becoming commonplace in criminal prosecutions. But the need for transparency in the forensic sciences and in criminal law is in tension with software developers’ desire to protect the “special sauce” behind their programs. Not surprisingly, this tension has generated new challenges for lawyers and experts. Source code review, evaluation of software testing documentation, and wrangling over disclosure of proprietary technology are increasingly critical aspects of litigating the admissibility of forensic evidence in criminal cases.

This presentation will discuss the practical difficulties with litigating the admissibility of evidence generated by black box software, including the use of protective orders and Non-Disclosure Agreements (NDAs) by software developers, the need to evaluate and challenge computer-generated evidence from not just a forensic science but also a software engineering perspective, and how non-scientists can begin to approach understanding the mechanisms employed by complex software systems sufficiently to challenge those systems in court. The presenters will share their experiences litigating the admissibility of evidence generated by probabilistic genotyping software and computerized BrAC systems, and the lessons gained from those experiences.

Attendees will learn strategies for propounding discovery to the third-party companies that develop and sell black box forensic software, as well as strategies for litigating the inevitable disputes that arise from these discovery requests. Attendees will also learn how the discipline of software engineering applies when evaluating the admissibility of black box forensic software. This presentation will address specific validation and verification standards commonly applied in the software industry and relevant to forensic software, ways to incorporate those standards into a *Frye/Daubert* proceeding, and what objections lawyers can expect from forensic software developers to the use of these standards to evaluate a software program’s reliability. This presentation will discuss resources available to lawyers to advance their understanding and obtain expert assistance with respect to these standards. Finally, attendees will gain insight into the trends in black box forensic software—what disciplines are likely to see a rise in the use of such software and how courts’ views regarding the admissibility of such software have been changing over time.

---

### Black Box, Litigate, Software

## F4 The Defense Lawyer Perspective on Uncertainty in Probabilistic Genotyping

*Jessica Goldthwaite, JD\**, *The Legal Aid Society, New York, NY 10038*; *Tamara Giwa\**, *New York, NY 10038*

**Learning Overview:** After attending this presentation, attendees will better understand: (1) why the sources of uncertainty in probabilistic genotyping may mean different things to defense attorneys than to lab analysts; (2) the various sources of uncertainty that defense lawyers must incorporate into their understanding of forensic DNA case results; and (3) the importance of clear communication and transparency about the sources of uncertainty in promoting just outcomes in the criminal justice system.

**Impact on the Forensic Science Community:** This presentation will increase awareness among attorneys about the sources of uncertainty in probabilistic genotyping and encourage laboratories to adopt practices to better communicate uncertainty in their results.

In the criminal justice system, defense attorneys are always the last to know. They typically meet their clients after an investigation and arrest has occurred, and they receive the DNA casefile and reports at the end of the testing and interpretation process—once prosecutors have put together their case against the accused, and labs have examined and interpreted the forensic evidence. The defense is almost always excluded from the process of scientific interpretation and has to try to make sense of the already-completed forensic product. On the path to generating the final likelihood ratio results, laboratories may encounter various sources of uncertainty inherent in probabilistic genotyping systems. These include: (1) communicating the meaning and limitations of likelihood ratios; (2) different results among software programs; (3) unexpected occurrences in the results; (4) proposition setting and other user-defined choices in running probabilistic genotyping software; (5) the modeling of relatedness; and (6) bugs in the software. Sometimes these uncertainties are explicitly disclosed in the casefile, but sometimes they are not. Sometimes they are disclosed but buried deep in the casefile, and would escape the notice of even the most diligent attorney.

In this new scientific frontier, defense lawyers should be aware of and understand the reality of these uncertainties in order to mount a vigorous defense of the accused. Thorough investigation, case preparation, and courtroom litigation requires lawyers to first recognize the uncertainty and then decide what questions to ask. This presentation will encourage lawyers to ask some essential questions: Is uncertainty from the defense perspective the same as uncertainty from the laboratory's perspective? What are the causes and effects of uncertainty that defense attorneys must consider? What is the relationship between scientific uncertainty and the presumption of innocence?

This presentation will also advocate for greater transparency and communication by laboratories around points of uncertainty. It will encourage laboratories to ask some essential questions: What if communication with defense attorneys was frequent and open? What if error was immediately disclosed without fear? What might best practices around communicating uncertainty look like?

### Uncertainty, Probabilistic Genotyping, Communication

## F5 Bioethics and Emerging Trends in Texas for Mirandizing Juveniles

Jennifer Bennett, JD\*, 265th Judicial District Court, Dallas, TX 75207

**Learning Overview:** The goal of this presentation is for attendees to better understand how Texas has taken steps to protect the rights of juvenile suspects without creating an undue burden on law enforcement. Attendees will also have a greater understanding of emerging trends in courts that provide more protections to persons who are deemed to be in need.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by detailing the progressive measures Texas has taken to protect the rights of juvenile defendants.

The purpose of this presentation is to educate attendees about trends in juvenile interrogations within the Criminal Justice System. This presentation will help the audience understand the differences in juvenile interrogations across the United States, specifically related to confession admissibility. The progressive, more protective standard that Texas follows will be highlighted in contrast with the other jurisdictions that Mirandize juveniles similarly to adults.

Unlike most states, Texas has statutorily protected the rights of juveniles and set out requirements for law enforcement to follow in order to admit the statement of a juvenile in court. As a result, Texas law provides greater protections for juveniles than most jurisdictions, as well as more safeguards than the United States Supreme Court, which ruled most recently on issues pertaining to custodial juvenile statements in *J.D.B. v. North Carolina*.<sup>1</sup> In *J.D.B.*, the Supreme Court applied a totality of circumstances test for juvenile statement admissibility; a test which the Court decided permits consideration of a juvenile's age.<sup>2</sup>

Today, most states follow the totality of circumstances standard, which incorporates Miranda warnings and the consideration of age; however, other than implementing those requirements, each state has the discretion to apply their own standards regarding the admissibility of juvenile statements gathered by law enforcement. As the Supreme Court has yet to add a universal standard, there is a large discrepancy in how jurisdictions handle Mirandizing juveniles.

While all states have policies in place, very few are as progressive as Texas. For example, in *U.S. v. Guzman*, the Court applied a totality of circumstances test for juvenile statement admissibility, but declined to expand juvenile protections to require the presence or notification of a parent or guardian for police questioning.<sup>3</sup>

Texas is considered more conservative when handling matters of legislation, but the policies concerning Mirandizing juveniles are forward-thinking. In Family Code 51.095, the State of Texas requires juvenile suspects be given warnings by a magistrate outside the presence of law enforcement. That being said, Texas allows for the protection of the rights of the juvenile without imposing an undue burden on law enforcement.<sup>4</sup>

Furthermore, while most states follow a totality of circumstances test, it can be very subjective. West Virginia is an exception to this standard and requires juveniles in custody be immediately taken before a magistrate, circuit judge, or referee before any statements given to law enforcement be admissible in court.<sup>5</sup>

### Juvenile, Protection, Statement

### F6 “I thought if I Told Them I Did It, They Would Let Me Go ...” and the Unintended Consequences of *Miller v. Alabama*

Antoinette E. Kavanaugh, PHD\*, Chicago, IL 60647

**Learning Overview:** The goal of this presentation is to educate attorneys, judges, and other criminal justice stakeholders how unreliable Miranda waivers and false/involuntary confessions create undue financial burdens on the justice system and violate an individual’s constitutional rights and the changes needed after the United States Supreme Court decision of *Miller v. Alabama*.<sup>1</sup>

**Impact on the Forensic Science Community:** Attendees will be able to describe and identify factors that contribute to youth providing unreliable Miranda waivers and false confessions and will also be able to identify unintended consequences of *Miller v. Alabama* in their respective jurisdictions.<sup>1</sup> This presentation impact the forensic science community by assisting attendees in identifying systemic changes needed in response to *Miller v. Alabama*.<sup>1</sup>

Better education among the legal stakeholders relating to the science behind juvenile Miranda waivers and juvenile involuntary confessions will lead to more reliable statements and better outcomes for juveniles and the integrity of the criminal justice system following the decision of *Miller v. Alabama*.<sup>1</sup>

Unreliable Miranda waivers and false/unreliable confessions create undue financial burdens on the justice system and violate an individual's constitutional rights. There often seems to be a disconnect between the knowledge of stake holders in the criminal justice system (law enforcement, prosecutors, defense attorneys, and judges) and the scientific research relating to vulnerabilities unique to juveniles and the need for special protections for juveniles who are being interrogated. Courts appear to frequently admit statements made by juveniles based on interrogation processes that were intended for adults and do not take into account the vulnerabilities associated with being a youth. At the conclusion of this presentation, attendees will have a better understanding of the factors that make youth vulnerable to providing unreliable waivers and confessions. By understanding the factors that make youth vulnerable, there can be a better ability to identify cases where statements made by youths are not reliable based on the findings within the scientific research. By being able to better identify improper techniques based on the scientific research and the unique vulnerabilities associated with youth, the criminal justice system can make further reforms relating to juveniles.

Regardless of the severity or actual participation in the alleged offense, many juvenile suspects believe this statement: “I thought if I told them I did it, they would let me go ....” Research findings will be presented that explain how this belief: (1) is related to vulnerabilities associated with being a youth; (2) contributes to an inability to provide a voluntary, knowing, and intelligent waiver; and (3) contributes to youths providing unreliable or false confessions.

The Criminal Justice System has started to take notice at the sentencing stage that youths are different than adults. The Supreme Court ruled in *Miller v. Alabama* that before a defendant who committed a charged crime before their 18<sup>th</sup> birthday is sentenced to Life Without Parole (LWOP), the court must consider the defendant’s: (1) home life and environment; (2) age and characteristics associated with youth; (3) the circumstances of the offense, including the defendant’s role in the offense; and (4) the possibility for rehabilitation.<sup>1</sup> While some saw this as a victory, the decision caused many unintended consequences. This presentation will discuss the following four consequences that have become especially problematic after the decision in *Miller v. Alabama*: (1) the lack of individuality of some of the responses to *Miller*; (2) the implication for the parole board systems; (3) implications for the adult prison and parole system; and (4) the procedure for obtaining a forensic mental health evaluation.<sup>1</sup>

### F7 “The Worst of Both Worlds”: Neurodevelopment of the Transitional Age Brain

Sandra Antoniak, MD\*, *Impavida Forensic Consulting, LLC, Fishkill, NY 12524*

**Learning Overview:** After attending this presentation, attendees will appreciate the major neurodevelopmental processes present in adolescents and young adults and its impact on their behaviors and decision-making abilities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a basic introduction to neurodevelopmental processes present in youth and young adults. Knowledge regarding the neurodevelopmental basis for behavior will enhance the legal practitioner’s ability to understand and communicate with their adolescent and young adult clients, as well as enhance advocacy efforts.

In the decades between *In Re Gault* and *Miller v. Alabama*, the legal system in the United States has sought to develop legal processes and remedies that reflect our evolving societal values while maintaining the due process rights of children and adolescents accused of major crimes.<sup>1,2</sup> In 1966, Justice Fortas famously captured the gestalt of this legal quandary when he wrote, in the majority opinion for *Kent v. United States*, that, “The child receives the worst of both worlds ... neither the protection accorded to adults nor the solicitous care and regenerative treatment postulated for children.”<sup>3</sup>

During the past two decades, the concept of the “transitional age brain,” occurring between ages 13 and 25, has become part of the child and adolescent psychological and neurodevelopmental canons. The transitional age brain, and the behaviors it produces, is precariously balanced between the surging development of subcortical regions of the brain that drive risk-taking behavior and the gradually emerging prefrontal regions that enhance behavioral restraint. Simultaneously, the novelty-seeking circuitry is primed, but the reward response is quiescent, thereby driving the adolescent or young adult to impulsively seek more extreme stimuli to feel the psychological and physical reward of the behavior (e.g., binge drinking, impulsive drug use, multiple sexual partners, sexting).

This neurodevelopmental period is also marked by significant increases in psychiatric and physical morbidity (e.g., depression, Sexually Transmitted Diseases [STDs]), high risk social behaviors such as drug and alcohol use, risky sexual practices), and mortality from violence, accidents, or suicide. To complicate matters further, intellectual disabilities, developmental delays (e.g., autism spectrum disorders), chronic medical conditions (e.g., epilepsy), trauma due to abuse and neglect, and psychosocial stressors can alter the time course, and ultimate outcome, of the individual’s neurodevelopment. These physiological or environmental effects can be exerted directly, such as occurs with brain injury, or indirectly, as mediated by hormonal systems and environmental impact on genetic expression (e.g., G x E interactions). Regardless of etiology, the above factors can impact the form and function of the transition age brain and can impact the individual’s life course.

This presentation will provide the legal practitioner with a plain language explanation of the neurodevelopmental basis of impulse-control difficulties and risk-seeking behavior that often bring adolescents and young adults before the court. Utilizing a neurodevelopmental lens will aid the legal practitioner to understand complicated issues surrounding the adolescent’s or young adult’s legal decision-making capacity, their ability to meaningfully participate in legal proceedings, and their susceptibility to peer influences and coercion.

### F8 Is Communication Between the Surgeon and the Anesthesiologist Really Necessary? What Are the Medicolegal Implications?

*Lucia Nardelli\**, Francavilla Fontana, Provincia Brindisi-Regione Puglia 72021, ITALY; *Alessandra Stellacci*, Bari, Puglia 70124, ITALY; *Claudia Perrone, MD*, Legal Medicine, Department of Public Health Sciences, Bari 70124, ITALY; *Salvatore Moliterno, MD*, Section of Legal Medicine University of Bari, Bari 70124, ITALY; *Francesco Vinci, MD*, Bari 70124, ITALY

**Learning Overview:** The goal of this presentation is to evaluate the existence of bad communication between doctors in the operating room in a clinical case of professional responsibility.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees how a lack of or bad communication between an anesthesiologist and an ear surgeon prevented correct management of the clinical case, determining the fatal outcome.

**Background:** Ineffective team communication is often the cause of medical errors. This story begins with a serious error by an anesthesiologist.

**Clinical Case:** The incident, which occurred in December 2007 at the Hospital of Vibo Valentia (Calabria), is inherent in the death of a 16-year-old girl hospitalized with a peritonsillar abscess with edema.

On December 1, 2007, the girl was visited by the family doctor who diagnosed tonsillar abscess and prescribed an antibiotic and cortisone. This was followed by hospitalization after a few days. The patient was visited by the head of the Otorhinolaryngology department of the aforementioned hospital. Peritonsillar abscess with edema was diagnosed. Therapy with intravenous and cortisone cephalosporins was prescribed but did not prevent the progression of the disease. The morning after admission, the young woman was taken to the operating room for a tracheotomy, which was necessary due to the disease progression, which compromised the airways.

The anesthesiologist tried twice to give general anesthesia with curare and intubation; but without results. The myorelaxant effect of the curare caused paralysis of the respiratory muscles with consequent total occlusion of the respiratory tract. Anoxia occurred with desaturation. In this dramatic contingency, the anesthesiologist tried to perform an emergency tracheotomy, but without success. Death from cardiocirculatory arrest occurred following pharmacologically induced asphyxia. The autopsy conducted on the girl's body showed that the scalpel had also caused a lesion on the esophagus and a lesion of the large neck vessels.

At the end of the judicial procedure, the six doctors, including otolaryngologists and anesthesiologists, accused of manslaughter were sentenced.

**Conclusions:** The sentence of the Cassation of May 5, 2015, states that bad teamwork has given way to human error responsible for the death of the girl.

The Court of Cassation observes that, "Teamwork sees the institutional cooperation of different subjects, often bearers of distinct competences," placing itself perfectly in line with its own jurisprudence and of previous merit. It adds, however, that, "This activity must be integrated and coordinated, it must be removed from anarchism." For the first time in memory, the Supreme Court used this term referring to teamwork and drew the following conclusion: "For this reason the role of guide of the head of the work group is relevant," which "cannot disregard the whole activity of the other therapists, but must instead direct it, coordinate it."

Therefore, when the anesthesiologist makes choices related to his role as a medical specialist in his own specialty, he is personally responsible for the choices made. When, on the other hand, he proposes choices that belong to a context of common knowledge of other doctors, he re-emerges from the past role of head of the surgeon's first operator who, in the face of the refusal to adhere to the directives given by the anesthesiologist "well may suspend the activity," or, using the words of the judges of merit, dismiss the anesthesiologist.

In this case, regarding the specific multidisciplinary anesthetic question and in the face of decisions that interfered with the surgical choices of edema control, the Roman judges specify that it was up to the surgeon to decide the "weighting of the implications of curative anesthesia" with the consequence of "preventing anesthesia."

This was so true that he expressed his point of view, which turned out to be correct, but he did not draw the necessary consequence; that is, the duty to prevent anesthesia by possibly suspending the execution of the surgical procedure which, as was seen, was urgent but was not treated as such.

The lack of or bad communication between the anesthesiologist and ear surgeon prevented the correct management of the clinical case, determining the fatal outcome.

## F9 Recent National Institute of Standards and Technology (NIST) Activities in Forensic Science: Examining Scientific Foundations and Innovation-to-Implementation Issues

John M. Butler, PhD\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Robert M. Thompson, MFS\*, National Institute of Standards and Technology, Gaithersburg, MD 20899

**Learning Overview:** The goal of this presentation is to discuss recent efforts at NIST to strengthen forensic science through examining scientific foundations of methods and through studying challenges with implementing new research innovations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the importance of having documented research and validation studies to support measurement and interpretation claims in forensic science. This presentation will also review a recent innovation-to-implementation meeting held at NIST.

Involvement of the NIST in forensic science spans almost a century. Wilmer Souder, a physicist at the then National Bureau of Standards (1911–1913, 1917–1954), performed handwriting, typewriting, and ballistics analysis on more than 800 cases for dozens of Federal agencies beginning in the 1920s.<sup>1</sup> After the 2009 National Research Council Report, *Strengthening Forensic Science in the United States: A Path Forward*, NIST increased its involvement in the field. A partnership initiated in 2013 with the Department of Justice (DOJ) launched the Organization of Scientific Area Committees for Forensic Science (OSAC) and established the National Commission on Forensic Science (NCFS) as a federal advisory committee to DOJ.<sup>2,3</sup> While NCFS closed after its second two-year term in April 2017, OSAC continues with Congressional-funding and participation of more than 500 members of the forensic community.<sup>4,5</sup>

Today, NIST conducts collaborative research, partners with the community to strengthen policies and practices, convenes meetings to examine issues, and explores scientific foundations of forensic disciplines.<sup>6</sup> NIST maintains active research programs in fingerprints and other pattern evidence, including firearms and tool marks, forensic DNA, digital evidence, forensic statistics, drug analysis, and trace evidence. NIST creates forensic-specific reference materials and data sets to enable traceable measurements. NIST also funds the Center for Statistics and Applications in Forensic Evidence (CSAFE) to improve statistical support for pattern and digital evidence.

At the request of Congress, NIST has begun scientific foundation reviews of various forensic disciplines.<sup>7</sup> The first review covers DNA mixture interpretation and explores issues of relevance and reliability when testing complex mixtures involving small amounts of DNA. Additional reviews are planned to cover bitmark analysis, digital evidence, and firearms and tool marks. These reviews should increase trust in forensic methods that have a strong scientific foundation and provide strategic direction for future research in areas that need further strengthening.

In June 2019, NIST convened a Forensic Science Research Innovation-to-Implementation (RI2I) Symposium to examine challenges with moving research ideas and projects into routine use in forensic laboratories.<sup>8</sup> Presentations and discussions came from a broad range of stakeholder perspectives: academic researchers, practitioners, public and private laboratory directors, lawyers, judges, and business product managers. The United Kingdom Forensic Science Regulator and a senior project officer from the Australian National Institute of Forensic Science provided important overseas experience and perspectives. Two RI2I breakout sessions gathered additional insights from each perspective and explored implementation challenges for introducing a new technique into a toxicology laboratory.

This presentation will provide a summary of these recent activities at NIST.

### F10 The Elusive Holy Grail of Simple Yet Adequate DNA Mixture Evaluation Method, or How to Frame a Suspect?

Charles H. Brenner, PhD\*, DNA-VIEW, Oakland, CA 94611-1336

**Learning Overview:** After attending this presentation, attendees will appreciate that highly prosecution-biased DNA mixture analysis is still thriving and dangerous.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by alerting it the existence of an ongoing subversion of justice via misrepresentation in the court of DNA evidence, leading some suspects to be unfairly convicted based on inadequate evidence, likely including some who are factually innocent.

For 25 years, the forensic community has sought a simple but adequate method for evaluating mixtures. Some folks promoted Combined Probability of Inclusion—the idea of distilling the DNA data down to an unfortunately elusive concept of “inclusion” or not—as filling the bill. For several reasons, it was never good; finally the general understanding of the necessity of dealing with dropout turned the tide against it. The essence of “dealing with dropout” is being able to calculate the probability of some suspect allele to be missing from the mixture data even while hypothesizing that the suspect did contribute.

At present, the general consensus is to confront dropout head-on with a “continuous” approach modeling the phenomenon of peak height stochastic uncertainty. This presentation argues that a continuous model can be simple and elegant in concept, but recognizes that it is tedious to compute. It needs a computer. Hence the less comprehensive “semi-continuous” approach has its adherents and perhaps provides a useful compromise dropout capability.

At a recent murder trial, a Dr. X, expert witness for the prosecution, presented a surprising and unfamiliar mixture calculation method that purports to be the long-sought holy grail of adequate but simple. Dr. X deems a mixture locus to be “informative” if all expected alleles, especially those of the suspect, are observed. Simple binary Likelihood Ratios (LRs) are computed and accumulated across the “informative” loci. The remaining loci are discarded (conveniently evading the difficulty of a dropout calculation); Dr. X testified that omitting them is to omit further evidence against the suspect, hence omitting them favors the suspect.

That is, of course, well-known to be too good to be true. The truth is the opposite. The so-called “non-informative” loci are where the strong exculpatory evidence for an innocent suspect comes from. (Not seeing a suspect’s bootprints on the burgled property is evidence he wasn’t there.) Omitting them is cherry-picking that frames the suspect. Dr. X’s computation will *never* produce a suspect-benefitting  $LR < 1$ . It can only deliver a number that, to a small or large extent, hurts any suspect.

This is notable because, per Dr. X, Dr. X has testified upward of 1,000 times. If 50 out of each 100 cases rested significantly on the DNA evidence and had less than 100% of the suspect’s profile recorded in the mixture, then those 50 cases need re-evaluation. A handful will be actually innocent. It is likely that numerous innocent people are in prison because courts were gulled by this enticing but anti-mathematical method

---

#### DNA, Injustice, Frame

## F11 DNA Confronts Bayes and There's Trouble

Charles H. Brenner, PhD\*, DNA-VIEW, Oakland, CA 94611-1336

**Learning Overview:** After attending this presentation, attendees will have learned that mathematics applied to the real world has its limitations, which we are beginning to come up against with some of the advanced problems that recent DNA methods try to deal with.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting humility, modesty, and some disappointment.

DNA evidence enters legal decision-making via a Bayesian framework. The framework has two components: an objective calculation of the evidentiary strength of the DNA, and a step in which the decision-maker (the court, judge, or jury) incorporates that information to sway their subjective opinion. Whether the swaying occurs according to Bayes Theorem, or whether that's a convenient fiction and a vain hope, is irrelevant to the present discussion. The only relevant point here is that the mathematical calculation is an objective process. Everything subjective or otherwise outside the knowledge of the DNA analyst is relegated to the domain of the court where it sensibly belongs.

This framework has served well historically. The evidential value of DNA data is a Likelihood Ratio (LR) computed by mathematical calculation based on a model. "Model" means a mathematical model of reality—a quantitative theory as simplified as reasonable but as complicated as necessary—that describes how the DNA data comes about. A model that deals only with measurements—allele sizes, allele population frequencies—lies within the DNA analyst's proper purview.

A dilemma arises when the DNA analysis model requires a prior probability assumption about something that can't be thought of probabilistically, or which current scientific knowledge cannot provide.

Two examples arise mostly from advanced (i.e., continuous model) mixture analysis. The analysis requires assumptions about the number of contributors, and there is no mathematically sound way to choose. Deciding how to weigh among different numbers of contributors requires assuming for example that a three-person mixture is *à priori* (i.e., without even looking) more probable than a four-person, but it is hard to imagine data that allows such an inference. All one can do is hope that the choice does not matter much. Another vexing problem arises when adjusting a "degradation" parameter in the model in order that the calculation be correct, assuming degraded contribution from the suspect. If that substantially increases the LR, one has created a more satisfying explanation of the mixture—but that end doesn't justify the means. Even if the suspect happens to be connected to the mixture, that doesn't justify framing him to prove it.

Parentage attribution can be problematic. Suppose a child shares alleles with an alleged father at all but two or three Short Tandem Repeat (STR) loci. Three hypotheses stand out: (1)  $H_p$ =man is the father and there are a few mutations; (2)  $H_a$ =man is the uncle ("a" for "avuncular"); or (3)  $H_0$ =man is unrelated to the child.

When  $H_a$  isn't under consideration, a reasonable DNA analysis reports the LR supporting  $H_p$  over  $H_0$ , properly leaving the question of the prior probabilities for  $H_p$  versus  $H_0$  to the court. With two different versions of non-paternity— $H_a$  and  $H_0$ —similar could be done only by making an assumption as to the relative prior probabilities of  $H_a$  versus  $H_0$ , but, at least for the DNA laboratory, that is not possible.

Further examples can be listed.

The conclusion from these problematic situations is not that we need better mathematics; the traditional Bayesian framework is the principled mathematical approach. Some mathematical-seeming problems simply don't have a clean solution.

---

### Bayes, DNA Evidence, Limitations

### F12 Probabilistic Genotyping in the Courtroom: Admissibility, Families, Secondary Transfer, and Competing Statistics

Rachel H. Oefelein, MSc\*, DNA Labs International, Deerfield Beach, FL 33441; Alicia M. Cadenas, MS, DNA Labs International, Deerfield Beach, FL 33441; Samantha Orans Wandzek, MS, Pompano Beach, FL; Cristina L. Rentas, MFS, DNA Labs International, Deerfield Beach, FL 33441; Daniel I. Aguilar, MS, DNA Labs International, Deerfield Beach, FL 33441

**Learning Overview:** The goal of this presentation is to convey the difference between different statistics, specifically Random Match Probabilities (RMPs) and likelihood ratios for the purpose of expert witness testimony, the importance and nuances of admissibility hearings for probabilistic genotyping, and the use of the familial diagnostic in casework and the courtroom.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how probabilistic genotyping is changing the way the forensic DNA expert testifies in the courtroom, as well as the way counsel presents their case. It is important for attorneys and scientists to be provided with the background information on applications and limitations of expert witness testimony on probabilistic genotyping.

STRmix™ went live for casework in the first United States laboratory in 2014. Since 2014, more than 40 additional laboratories have also gone live for casework with many additional United States laboratories in various stages of validation and implementation.<sup>1</sup> This presentation will discuss the differences between the RMP versus the Likelihood Ratio (LR) and how transitioning to LRs changes the way DNA evidence must be offered in court. The initial difficulties facing forensic DNA experts and attorneys working in the United States court system were primarily regarding admissibility and how to explain this new technology to a jury. The admissibility of probabilistic genotyping in the courtroom is currently making its way throughout all levels of the legal system. A discussion on filing motions *in limine*, in addition to responses to these motions, from jurisdictions with and without previous admissibility rulings will be addressed.

Nearly five years later, new challenges are emerging regarding testimony on probabilistic genotyping. What is the difference between different probabilistic systems? Is this case covered by this past admissibility hearing? What information can be garnered from these types of analyses other than a statistic? Can this analysis provide any support for or against a secondary transfer argument? What does this mean for relatives of the victim and/or person of interest? The familial diagnostic has been employed at DNA Labs International (DLI). This tool is utilized by DNA analysts to help evaluate probabilistic genotyping results and determine when reference standards from primary relatives may be requested. The effects of the use of this diagnostic in the courtroom will be examined.

Probabilistic genotyping has evolved how forensic DNA evidence is presented to the jury from the forensic DNA expert and the attorneys. Training, care, and consideration must be applied for the prosecution and defense attorneys and the respective DNA experts. There are probative applications to this testimony as well as limitations. As always, it is important to not overstate or understate the evidence at hand. Professional responsibility on presenting probabilistic genotyping evidence is paramount with the implementation of any new technology.

#### Probabilistic Genotyping, Likelihood Ratio, Expert Testimony

### F13 Scientific Transparency vs. Trade Secret: Issues Surrounding Disclosure of Computer Software Programs, User Manuals, and Source Codes

Jennifer Friedman, JD\*, Los Angeles, CA 90068

**Learning Overview:** The goal of this presentation is to provide an opportunity for a robust discussion about the legal and practical issues surrounding access to proprietary software programs, user manuals, and source codes of programs used in criminal prosecutions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing attendees' knowledge of the law on trade secrets and the relationship between the trade secret privilege and a defendant's constitutional rights, specifically as they relate to access probabilistic genotyping software programs, user manuals, and source codes.

**Proposition:** There is a tension between a defendant's Constitutional right to due process and confrontation and a software developer's proprietary interest in his software that has not yet been resolved by the courts.

The use of computer software programs in criminal prosecutions and, in particular, in the interpretation of DNA evidence has become ubiquitous. Indeed, the majority of laboratories in this country now use some type of probabilistic genotyping program for interpreting DNA results. DNA is not the only area in which computer software programs are used to prosecute, and in some cases exculpate, suspects. Computer software is used to help determine blood alcohol concentrations, risk assessments, and facial recognition, among other issues. Some probabilistic genotyping programs are open source, meaning scientists may review the software and source code and learn how the program operates. However, the two most widely used probabilistic genotyping programs are largely unavailable for review because their developers claim a proprietary interest. Access to their source codes has been thwarted by claims of trade secrets made by developers of the computer software program and arguments that access is unnecessary. While trial courts have generally accepted such claims, there remain no published Court of Appeals rulings specifically addressing the issue of whether upon a showing of necessity, a criminal defendant should have unfettered access to a computer program, its source code, and its user manual when results obtained from the program are being used to prosecute him.

In *People v. Superior Court (Dominquez)*, a California Court of Appeals held that the trial court had erroneously granted the defendant's motion for access to the computer program, the user manual, and the source code for the STRmix™ program and sent the case back to the trial court for further proceedings. Presumably, the defendant will attempt to make a stronger showing as to why the computer software program, source code, and user manual are necessary, and why access should be ordered. The computer software developer will have an opportunity to explain why he believes the trade secret privilege trumps the defendant's right to access.

A different California Court of Appeals, in an unpublished opinion, acknowledged the importance of this issue, but nevertheless failed to address it. "This court recognizes the important disputes underlying appellant's evidence-based positions and the amicus briefing submitted. Clarifying the circumstances necessary to trigger production of source code related to mathematically complicated and machine-derived DNA evidence and the scope of testimony from experts discussing such methodology when used to support a conviction is a matter of great concern in future cases."

While this presentation will be presented from the perspective of a defense attorney, the goal is to facilitate a discussion between prosecutors, judges, and criminalists about the role transparency plays in forensic science, the importance or lack of importance of gaining open access to the underpinnings of computer software used in criminal prosecutions, as well as the legal and constitutional implications of granting or denying disclosure.

The focus of this discussion will on probabilistic genotyping programs, but this discussion will have implications for other types of computer software and source codes used in breathalyzers, risk assessment tools, facial recognition programs, and programs used by the government to track computer use.

---

#### Probabilistic Genotyping, Source Code, Access

### F14 The Fast and the Furious

*Matthew J. Marvin, BS\*, Ron Smith and Associates, Inc, Collinsville, MS 39325; Sarah Chu, MS\*, Innocence Project, New York, NY 10013*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the risks and costs of the limited examination procedures that are currently being implemented to address crime laboratory backlogs.

**Impact on the Forensic Science Community:** Limited examination procedures carry risks and costs and have considerable criminal justice impacts. This presentation will impact the forensic science community by describing each type of procedure, articulate the costs and risks, and provide recommendations for moving forward.

The 2014 Census of Public Funded Forensic Crime Laboratories estimated that public forensic science service providers possessed a backlog of 570,100 requests. In 2014, 63 public forensic science service providers conducted latent print functions for a total of 67% of federal, 53% of state, 62% of county, and 88% of municipal jurisdictions. Backlogs of latent print requests grew from 6% in 2009 to 12% of latent print requests in 2014. Consequently, public forensic science service providers have been seeking ways to increase casework efficiency and reduce their backlogs. A myriad of different solutions to address latent print backlogs have been implemented across the United States. Limited examinations, eliminating verifications, set rules on exclusions, and incomplete searches for prints are just a few of the methods that have been proposed and implemented. While these procedures may be effective means to reduce backlogs, they may also produce a different set of risks and costs, and should not be considered as a best practice.

This presentation poses the question: What is the cost of these policies? This presentation will include case examples of missed evidence due to incomplete or rushed examinations, with an emphasis on the long-term impact of shortcuts in friction ridge examination. Consequences include the collateral consequences of pre-trial detention, not collecting or not analyzing relevant evidence in a case, reducing the latent print examiner's exposure to complex cases, or having no record of evidence that may turn out to be important in a case post-conviction. Although identifications and inclusions are typically the focus of latent print examinations, ensuring that exclusions are properly called is also critical to identifying the person who committed the crime and freeing the innocent.

This report submits that when evidence is not processed and analyzed in full, the forensic scientists cannot tell the whole story the evidence can tell. Additionally, quality assurance methods, such as increased documentation, are not a panacea when evidence has not been collected or analyzed. Ultimately, every one of these strategies carries risks and criminal justice costs and this presentation declares that the best practice is to collect, document, and analyze all prints at a crime scene. Finally, the question is posed: "What is the role of a forensic science laboratory in the criminal justice system?" as a guiding question for forensic science service providers as they contemplate whether they will engage in backlog reduction strategies. This presentation will conclude with recommended approaches or policies to address the potential risks of limited examination and other backlog reductions strategies if they must be applied.

---

#### **Latent Print, Risk Management, Criminal Justice Outcomes**

### F15 The Nose Knows? Residual Odor and Cadaver Dogs: A Review

*Dana Delger, JD\*, The Innocence Project, New York, NY 10013*

---

**Learning Overview:** After attending this presentation, attendees will understand some of the scientific problems faced when using dogs to detect places where human remains once were and the current state of the law regarding the admissibility of dogs for this purpose.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining the current state of the science involving cadaver dogs, particularly as it relates to so-called “residual odor,” and how that science has been understood, or misunderstood, by courts. This presentation will provide an overview for the historical uses for cadaver dogs and the trajectory toward their current use to detect residual odor. Specifically, the presentation will discuss the science (and lack thereof) supporting these determinations and other problems with using dogs in this manner, including cognitive bias and prejudice.

Dogs have long been used by human beings for their superior scenting abilities, with reports of dogs finding missing or absconded people going back to medieval times. Dogs, as natural scavengers, also have a long history of being used to find deceased human remains. In 1809 Bavaria, a court clerk used his own dog to ostensibly find the victims of the “Bavarian Ripper,” and in 1974, the first purposely trained dog—a Golden Retriever named Pearl—recovered the remains of a deceased college student in upstate New York.

This use, and the use of dogs to find the extant remains of other deceased persons (such as after a natural disaster), is relatively non-controversial; remains are either found or they are not. However, there has been a rise in the use of dogs to ostensibly detect places not where human remains *are*, but where human remains *have been*—days, weeks, months, or even years after those remains have been removed. There is, however, little empirical evidence that dogs are capable of such feats. There is also no evidence about how long such odors could last, and how that may vary with differing environmental conditions. Nor is it understood what, in particular, dogs are detecting when they alert to human remains, and how that may differ when those remains are no longer present. The extremely limited research in this area will be discussed. This presentation will also cover how cognitive bias may play an outsize role in these cases, given the evolutionary relationship between humans and dogs. Scientific research showing how jurors credit and understand dog evidence will also be examined.

Despite these issues, the use of this evidence is on the rise, with at least a half-a-dozen active cases at various stages of litigation in the first half of 2019 alone. Yet courts have failed to fully grapple with these and other problems with using dogs in this manner; many are refusing to subject the claimed abilities of the dogs to the scrutiny demanded of scientific evidence. These decisions and the law underlying the admissibility of this evidence will be examined.

### F16 The Evolution of Wrongful Convictions in Fire Cases

Terry-Dawn Hewitt, LLM\*, McKenna Hewitt, Denver, CO 80224-3703; Wayne J. McKenna, LLB, McKenna Hewitt, Denver, CO 80224-3703

**Learning Overview:** After attending this presentation, attendees will have learned of the growing problem of wrongful convictions in fire cases resulting from faulty fire science. Attendees will learn to recognize the issues that most often cause wrongful convictions in fire crime cases and how these issues are evolving, in part due to steps being taken to implement the National Academy of Sciences/National Research Council (NAS/NRC) Report.<sup>1</sup> Recognizing these issues is the critical first step to avoiding the pitfalls that lead to wrongful convictions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a wake-up call to fire investigators, prosecutors, defense attorneys, and others involved with criminal fire cases. This wake-up call comes as people become sensitized to the common issues running through wrongful conviction cases that arise from misapplied fire science. From examining these common issues, those involved in prosecuting, defending, or testifying in a fire crime case can learn lessons that reduce the likelihood of being involved in a wrongful conviction.

Post-conviction relief in fire crime cases began slowly to emerge in the 1990s, largely coinciding with early editions of National Fire Protection Association (NFPA) 921 *Guide to Fire and Explosion Investigations*, which publicized misconceptions in commonly held beliefs about fire behavior and fire patterns that were simply wrong.<sup>2</sup> Over time, NFPA 921 and its companion, NFPA 1033 *Standard for Professional Qualifications for Fire Investigator*, have together raised the bar for fire investigations by incorporating information about reliable fire investigation methodology along with developments in the knowledge base of fire science.<sup>3</sup> These two documents have long ago become entrenched in the fire investigation community. They form the basis of the two international fire investigator certification programs, play a significant role in fire investigator training, and have become widely accepted as foundational works for fire investigators. NFPA 921 has also become a favorite tool in *Daubert* challenges of fire investigation experts across America.

One would think that by now, almost 30 years after NFPA 921 was first published, cases of post-conviction relief and exonerations based on faulty fire science would be abating, at least after cases from the pre-NFPA 921 days were adjudicated to finality. Not so. Post-conviction relief for fire crime cases resulting from misleading or bad fire science continue to grow. This presentation will identify the common issues that arise from examining the court decisions in such cases. The way in which the issues in post-conviction relief or *habeas corpus* applications are evolving in response to initiatives flowing from the NAS/NRC Report will also be explored. Finally, the impact on wrongful conviction cases of the two industry standards governing fire investigations, NFPA 921 and NFPA 1033, will be analyzed.

### **F17 Post-Conviction DNA Testing: A Law School and University Collaboration as a Model to Identify and Evaluate Post-Conviction Cases**

*Katherine A. Roberts, PhD\**, Hertzberg-Davis Forensic Science Center, Los Angeles, CA 90032-4210; *Paula Mitchell, JD*, Loyola Law School, Los Angeles, CA 90015; *Cassandra Olsen, JD*, Loyola Law School, Los Angeles, CA 90015; *Nikki Herst-Cook, JD*, Loyola Law School, Los Angeles, CA 90015; *Mehul B. Anjaria, MS, MBA DNA Consulting LLC*, Los Angeles, CA 90071

**Learning Overview:** After attending this presentation, attendees will understand the California Forensic Science Institute-Loyola Project for the Innocent (CFSI-LPI) case review model, with particular emphasis on case prioritization, filing, and arguing motions requesting DNA testing, and strategic approaches to case resolution.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a Law School-University collaboration model to tackle the logistical challenges related to post-conviction DNA testing.

The Postconviction DNA Testing Law (Senate Bill 1342) was passed in California in 2001. This law provides a mechanism for inmates to seek post-conviction DNA testing of evidence to ensure those wrongly convicted are able to prove their innocence through the use of newly developed technology. SB 1342 states that in felony conviction cases, government agencies must retain evidence for potential post-conviction DNA testing. With respect to retention of biological evidence, SB 1342 specifies agencies should retain all items that have a “reasonable likelihood” of containing biological evidence. However, it is virtually impossible for persons seeking to exonerate themselves through post-conviction DNA testing to meet the requirements of California’s statutory scheme without some legal and expert assistance. Under California’s DNA testing statute (Penal Code §1405), a request for DNA testing must comprise several criteria. These include a claim of innocence; the details regarding every reasonable attempt made to identify both the evidence to be tested; and, the specific type of DNA testing sought. Further, the statute requires an explanation as to how, in light of all the evidence, the requested DNA testing would raise a reasonable probability that the convicted person’s verdict or sentence would be more favorable if the results of DNA testing had been available at the time of conviction.

In 2019, the CFSI within the School of Criminal Justice and Criminalistics at California State University, Los Angeles, established a partnership with Loyola Law School’s LPI in order to review cases and locate and test evidence related to violent felony offenses where actual innocence may be demonstrated. The CFSI-LPI team was awarded Department of Justice (DOJ) funding under the 2019 Postconviction Testing of DNA Evidence solicitation to provide critical assistance to individuals convicted of a serious felony that meet specific criteria. Collectively, the CFSI-LPI team reviews violent felony cases to locate biological evidence for submission to a forensic laboratory for DNA testing to demonstrate their innocence or assist in their exoneration.

This presentation will provide an overview of the CFSI-LPI case review model, with particular emphasis on the identification and evaluation of cases that meet the criteria under CA Penal Code §1405 for post-conviction DNA testing. This presentation will also include a discussion of the prevalence of skewed eyewitness testimony, false or misleading forensic evidence, inadequate crime scene investigations, and false confessions among cases under review by LPI. Further, there will be debate that these long-standing issues in criminal investigation may be exacerbated when coupled with the pervasive, if unintentional, bias that recent literature shows may alter an investigator’s perception of the evidence. This presentation will also describe obstacles to this project design during the first year of the grant award and will demonstrate how the CFSI-LPI model provides an invaluable forensic science experiential learning experience where graduate students participate in a service-learning social justice project. Exposing forensic science graduate students to actual innocence cases provides them with a clearer understanding of how the justice system can sometimes make mistakes that lead to dire consequences.

#### **Post-Conviction, DNA Testing, Law School-University Collaboration**

### F18 An Evaluation of Sample Preparation Techniques for Cannabis and Cannabis Products

*Kelsey Cagle\**, State College, PA 16801; *Jessica Westland*, MPS, Agilent Technologies, Inc, Wilmington, DE 19808; *Frank Dorman*, PhD, University Park, PA 16802-4500

---

**Learning Overview:** This presentation will discuss the results from a consolidated sample preparation technique for cannabis and cannabis products that will allow for the analysis of incurred pesticides residues and potency evaluations, ideally from the same sample preparation process. Data from both Gas Chromatography/Tandem Mass Spectrometry (GC/MS/MS) and High-Performance Liquid Chromatography (HPLC) will be shown to demonstrate the effectiveness of this approach. Furthermore, the cannabinoid profiles for the samples will be determined and the incurred pesticides residues will be measured for each sample as a result of proper sample preparation methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a more comprehensive overview of sample preparation techniques that can be used for a host of analyses using a complicated matrix like cannabis or cannabis product that will demonstrate to users the effectiveness of the sample preparation techniques but also the ease the expense of the technique.

Sample preparation is an essential part of method development that is critical to successful analytical measurements. In short, the goal for organics analysis is to reduce and simplify the complex sample matrices to a form that is applicable for instrumental analysis without bias to potential target and desired non-target compounds. With cannabis and cannabis products, however, the analyst is faced with a very challenging matrix and targets that may range from trace level through percent level, thus placing considerable demands on the sample preparation techniques. The most effective sample preparation techniques will allow for a precise and accurate analytical measurement of both cannabinoids and incurred pesticides present within the samples. Cannabinoid profiling has been utilized in the field for some time now due to the legal aspects associated with cannabis and cannabis products; however, incurred pesticide recovery analysis is currently a hot-button topic and growing in popularity. The need to perform pesticide analyses on cannabis and cannabis products is rising because of safety concerns for the users and growers that are present due to the lack of regulations in place in regard to pesticides and the cultivation of cannabis plants. Cannabinoid profiling alongside incurred pesticide analyses could also be useful to law enforcement in order to track where the cannabis and cannabis products came from, including dealer and grower, if any patterns were to be detected. Those patterns could be of importance to law enforcement when trying to investigate cannabis cases.

Recently, sample preparation for cannabis and cannabis products has moved toward Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS)-like procedures due to their high throughput and lower costs. QuEChERS-like procedures provide a more generic approach that is well suited for a variety of products and also provides sample cleanup that increases compatibility for both GC and LC separations. QuEChERS' appeal to cannabis work is its ability to be modified in order to deal with matrix effects commonly associated with cannabis.

#### Cannabis, HPLC, GC/MS

## F19 How Should Uncertainty Be Expressed and Communicated?

Veronica Scotti, LL.M.\*, Politecnico Di Milano, DEIB, Milano 20133, ITALY; Alessandro M. Ferrero, M.Sc., Politecnico di Milano, DEIB, Milano 20133, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the role played by forensic metrology in providing a universal method for expressing and communicating uncertainty. The method, originally thought for expressing uncertainty in measurement, can be applied to express and communicate uncertainty related to scientific theories and data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a better awareness that uncertainty can be expressed and communicated in a universal way, independently of the mathematical tool used to evaluate it. The methods of metrology can be usefully applied to express and communicate uncertainty also when non-physical quantities are considered, such as expert testimonies.

An important outcome of the 2009 National Academy of Sciences (NAS) and 2016 President's Council of Advisors on Science and Technology (PCAST) Reports is a greater awareness that any scientific method is inherently uncertain, and the provided results are consequently affected by uncertainty that must be expressed and communicated to avoid presenting incomplete or even misleading evidence to the trier of fact.<sup>1,2</sup>

These documents have opened the discussion not only on how to assess the scientific validity of forensic science methods in terms of uncertainty, but also on how to communicate it.<sup>3,4</sup> In particular, the discussion focused on who is communicating, what is being communicated, in what form is uncertainty communicated, to whom it is communicated, and to what effect.<sup>4</sup>

While some of these points involve psychological issues that must be considered, especially when communicating uncertainty to individuals and communities without a proper technical background to avoid undesired negative perceptions, other points, namely what and in what form is communicated, involve technical issues.

In this respect, the fundamental concepts of metrology, as defined by the International Vocabulary of Metrology (VIM) and the Guide to the Expression of Uncertainty in Measurement (GUM), provide a helpful background to communicate uncertainty in a scientifically sound way, encompassed by the international Standards.<sup>5,6</sup>

It is worth quoting clause 0.3 in the Introduction section of the GUM: “*just as the nearly universal use of the International System of Units (SI) has brought coherence to all scientific and technological measurements, a worldwide consensus on the evaluation and expression of uncertainty in measurement would permit the significance of a vast spectrum of measurement results in science, engineering, commerce, industry, and regulation to be readily understood and properly interpreted.*”<sup>6</sup>

Moreover, the proposed method is *universal*, that is: “*the method should be applicable to all kinds of measurements and to all types of input data used in measurements*” (clause 0.4).<sup>6</sup>

This presentation seeks to show that the uncertainty definition proposed by the GUM is indeed universal and can be usefully employed in evaluating, expressing, and communicating uncertainty also when non-physical quantities have to be measured (the so-called *soft measurements*).<sup>6</sup>

It will be shown that the method for quantitatively evaluating uncertainty is presently based on the mathematical theory of probability. It will be shown as well that this mathematical approach has some limitations, due to the required mathematical assumptions on the way limited information is modeled, and that more recent mathematical theories are available, such as the theory of evidence, to model limited information in a more general way than probability, thus leading to the ability to also express, evaluate, and communicate uncertainty on non-physical quantities, such as human reasoning, in a strict and scientifically sound way.

### Methods, Data, Uncertainty

## F20 Breath—A Bodily Fluid: Semantics, Syntax, Syllogisms, Euphemisms, and Science

*Dennis C. Hilliard, MS\*, RI State Crime Laboratory, Kingston, RI 02881-1966; Gil Sapir, JD, Chicago, IL 60680*

**Learning Overview:** After attending this presentation, attendees will understand how a novel definition of breath as a bodily fluid affects the applicability of breath alcohol testing in the workplace.

**Impact on the Forensic Science Community:** The presentation will impact the forensic science community by discussing practical aspects of breath sample testing in non-regulated workplace testing as a gas versus a bodily fluid.

Employers have developed drug-free workplace policies. Nationally, 46 states have laws imposing drug-testing restrictions specifying testing methodologies, use of test results, and privacy issues.<sup>1</sup>

Statutory workplace testing of controlled substances permit urine, blood, tissues, or other bodily fluids and may include alcohol. Analysis is by a federally certified laboratory (common body fluids are: saliva [oral fluid], vitreous humor, cerebral spinal fluid, synovial fluid, urine, blood, bile, semen, etc.). Frequently, blood is initially analyzed using the Enzyme-Multiplied Immunoassay Technique (EMIT) and Ultraviolet (UV) analysis. Positive test results require confirmation testing employing Gas Chromatography/Mass Spectrometry (GC/MS) or technology recognized as being at least as scientifically accurate (e.g., Liquid Chromatography/Mass Spectrometry [LC/MS] or UV/Infrared [UV/IR] spectroscopy). Labor statutes usually entail “controlled substances” and may include alcohol.<sup>2</sup>

Driving Under the Influence (DUI) statutes mandate blood, urine, or breath for drug and alcohol (ethanol and low molecular-weight alcohols) testing. Breath alcohol testing is conducted with a preliminary or evidential testing device using expired alveolar air.<sup>3</sup> Breath alcohol testing devices do not directly test for alcohol in blood. If blood or any liquid is placed into the unit, it will malfunction.

Breath alcohol testing devices are not considered laboratory clinical-grade instrumentation and are not commensurate with GC/MS’s accuracy and reliability for determination of blood alcohol concentration. If a blood test for alcohol determination is required, then blood is drawn (serum, plasma, whole) and analyzed with GC/MS head space analysis procedures.

Statutes are constructed for clarity. Testing for drugs and alcohol is inconsistent. In many states, breath alcohol testing in non-regulated workplaces statutes is not mentioned. Urine testing for alcohol is allowed for easy sample collection without any question of accuracy. States need to change arcane statutory language with an understanding of scientific nuances necessary to clearly define appropriate terminology with its intended implementation. Otherwise confusion and imaginative nonsense exists.

A creative interpretation for workplace alcohol intoxication testing, absent designated statutory or contractual language, seeks to define breath as a “bodily fluid” for statutory testing compliance.

Matter exists as a solid, liquid, or gas. A liquid describes a state of matter, whereas a fluid is any substance that flows. Liquid is a substance that flows in a natural state, flowing neither solid nor gaseous. A fluid is a liquid or gas, composed of elements or particles that freely change their relative positions without separating.<sup>4</sup>

Blood, with oxygen, carbon dioxide, nitrogen, and alcohol, is a liquid fluid. However, components in the blood are actively exchanged between the blood and the air in the lungs and they become a “gas” component within the breath.

Breath is a derivative factor of blood. The air people breathe is a gas. It is compartmentalized in the lungs for an exchange of oxygen and carbon dioxide, which is essential for life. The breath/gas expired from the respiratory system should be considered a bodily fluid—a technical distinction due to practical methods of measurement. However, common sense is paramount. Bodily liquids cannot replace breath and breath cannot replace bodily liquids in living organisms. Creatively contrived attempts to circumvent and redefine basic fundamental science are specious and problematic. If legislators or employers want to employ breath alcohol intoxication for termination under a drug-free workplace policy, then labor statutes or contracts should be amended specifying the use of breath as a testing specimen (consult the statute’s history and committee comments for legislative intent).

Semantics, syntax, syllogism, and euphemisms are irrelevant to breath alcohol as a bodily fluid. Common sense should prevail—statutory construction and the novel interpretation of breath alcohol analysis for workplace termination is at issue, not the science.

### Breath Alcohol, Bodily Fluid, Workplace

## F21 Secure Continuous Remote Alcohol Monitor (SCRAM): Judicial Liaison As Expert Witness Controverted

Donald J. Ramsell, JD\*, Wheaton, IL 60187; Gil Sapir, JD, Chicago, IL 60680; Raul Ayala, JD, Los Angeles, CA 90012

**Learning Overview:** After attending this presentation, attendees will appreciate the necessity of questioning credentials, qualifications, and competency of SCRAM's crafted expert witness.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through recognition and understanding of an expert witness pursuant to Federal Rules of Evidence and *Daubert* criteria.<sup>2,3</sup>

SCRAM has problems with its product, marketing, and usage, which appear compounded through its expert witnesses.<sup>1</sup> The expert witness' existence is created and perpetuated by the legal system. But for the Rules of Evidence, consulting and testimonial evidence would not exist. Expert witnesses are derived from five general categories of expertise: lay people; technician/examiner; practitioner; specialist; and scientist based upon their knowledge, education, skill, practical experience, and training.<sup>4</sup> They are hired in anticipation of litigation. Experts have an ethical duty of candor and full disclosure. Omissions and misrepresentations may be considered ethical violations. Judges control the determination of good science, evidential reliability, expert witness qualifications, and competency under *Daubert*.<sup>3</sup> The expert may be qualified but not competent to testify and offer their opinion. However, as litigation support professionals, they are responsible for the losses they cause to foreseeable plaintiffs, including violations of a person's civil rights.<sup>5-9</sup>

SCRAM is designed to measure alcohol content while it diffuses through a person's skin as insensible perspiration.<sup>10</sup> It is manufactured by Alcohol Monitoring Systems, Inc. The device, worn as an ankle bracelet, is commercially available to law enforcement agencies and privately operated correctional institutions. It is primarily designed and marketed for court-ordered alcohol monitoring of Transdermal Alcohol Concentration (TAC) readings.<sup>11</sup>

SCRAMs have limitations. TAC does not directly correlate to blood alcohol concentration in a SCRAM.<sup>12</sup> SCRAMs are useful in general population biomonitoring of self-induced alcohol consumption as a passive preliminary testing device. The manufacturer's criteria conveys SCRAM can reliably detect the consumption of five or more standard beers or drinks, and 45.9% of all occasions of drinking one to three beers went undetected when using SCRAM's 0.02g/dl as a threshold.<sup>13-15</sup>

SCRAM offers litigation support to consumers of its products through expert witness services. SCRAM's "judicial liaison" testified as an expert witness concerning the credibility and reliability of SCRAM CAM SMO2 results in *U.S. v. Colby*.<sup>16,17</sup>

Based on the *Colby* record, SCRAM's "judicial services liaison" possess controvertible expert witness qualifications consisting of: being an attorney; in-house administrative experience as a business product manager; conducting product service and promotional lectures; and completing two SCRAM operator training courses. SCRAM's expert severely lacks expected credentials: a formal science education; specialized knowledge; demonstrable expertise; any publications; scientific memberships; and published subject research.

Selected random *Colby* issues include: (1) limited knowledge of the fuel cell; (2) calibration standards and procedure not subjected to scientific scrutinization and criticism; (3) questionable basis of published analytical tolerance; (4) yearly calibration standards not maintained; (5) asserting average fuel cell life span is less than a year conflicts with SCRAMS annual calibration; (6) device diagnostics being irrelevant to calibration; (7) fuel cell and pump degradation only issues adversely affecting accuracy; (8) exhaust/contamination test conducted without supporting data; (9) misdirected authentic peer-review studies and topics (transdermal studies not SCRAM studies); (10) false positive authenticity rate less than 1%; (11) SCRAM studies conducted on earlier generation devices or not using SCRAM analytical software or analysts to determine positives and negatives; and (12) SCRAM lowered testing standards for confirmed positives several times over the years. Missing were relevant peer-review studies discussing revised methodology requirements, false positive rates, current cited cases, controlled testing for false positives, and actual situations with double-blind testing.

Initial concern is whether the SCRAM device is accurate and reliable to identify and measure TAC.<sup>18,19</sup> SCRAM seemingly presents tenuous and dubious expert witnesses and selective marketing data without adhering to governmental or industry reliability standards. The perceived lack of quality, candor, and competent expert witness testimony reasonably corroborates SCRAM's diminished product stature, controversial evidential value, and invites professional sanctions for its expert witness. Competent oversight and greater scrutiny should be used.

Limitations of SCRAM devices and TAC data is arguably skewed or specious through marketing and other claims, including shaped and shaded judicial liaison testimony. Apparently, public policy against alcohol intoxication cases continues to detrimentally transcend expert witness ethics, qualifications, and competency.

### F23 The Significance of Informed Consent in Workers' Compensation Forensic Blood Toxicology Testing

Helen D. O'Connor, LLM\*, Robert O'Connor, Jr., Houston, TX 77056-8187

**Learning Overview:** This presentation will inform attendees of the significance of informed consent in drug/alcohol forensic testing with relation to workers' compensation statutes, state and federal constitutional privacy protections, the United States Health Insurance Portability and Accountability Act (HIPAA) statute, and also the medical ethical principle of *primum non nocere* in the preparation and disclosure of a workers' compensation forensic science expert report.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the legal and ethical support for the requisite of informed consent of blood samples used in workplace injury forensic science analysis.

Informed consent is a process by which a patient (who is legally of the age of majority) and medical care providers document the agreement under which medical care, treatment, or services are provided to the patient. If an adult patient is competent, then consent for treatment must be obtained by the medical care provider and documented in writing. In emergency situations, when the patient does not have the legal competency to properly give consent for medical treatment, the consent is implied to protect the emergency medical provider under the "Good Samaritan" laws. In the case of minors, the authorized legal representatives (usually the custodial parent/s), are authorized to give consent for the medical care and treatment of the minor patient.

Under workers' compensation statutes, there is a defense/bar for the insurer of the subscriber to provide benefits to the injured worker if the circumstances of the workplace injury occurred when the worker was "intoxicated," whether under the influence of alcohol or other drugs. The legal definition of "intoxication" is set forth under the relevant workers' compensation statute and is proven by forensic science testing of either urine or blood samples from the worker at the time of the injury incident. The focus of this presentation is on blood sampling forensic science expert reports, with analogous principles applicable in urine testing. The effect of forensic science testing of worker blood samples can foreclose the possibility of treatment and monetary benefits to the worker for his workplace injury if the incident occurred while the worker was in a state of "intoxication." An analogy is the criminal sanction for drivers who operate vehicles while in a state of "intoxication," which can include confinement, loss of driving privileges, and/or monetary penalties.

The worker/patient's blood testing is part of the Protected Health Information (PHI) under the United States HIPAA statute. The United States HIPAA statute requires health care providers to protect PHI from unauthorized disclosure, including drug testing in any patient/injured worker, and mandates documentation of consent by the worker/patient for any disclosure.

The PHI information of the worker/patient involves state and federal constitutional guarantees of "privacy," which require that the worker/patient must have executed a proper consent for the "intoxication" testing to be performed by the medical care provider, including: the sampling, the laboratory processing of the specimen, the toxicology analysis, and the disclosure of such forensic science results in an expert report.

The consent requirements ensure statutory and constitutional protections for workers/patients for their medical care and treatment—including forensic science analysis and reporting of blood sampling to workers' compensation subscribers and their insurers. Informed consent also encompasses the medical ethical principle of *primum non nocere* because the worker/patient will be harmed by deprivation of treatment and compensation if informed consent is absent for the forensic science analysis disclosure in the workers' compensation case. Hospital toxicology lab testing routinely notes the limitation of its use "for medical purposes only."

The principles of informed consent in the workers' compensation worker/patient scenario are discussed with specific relevant Texas statutes and constitution, and United States Constitution privacy protection in reported case law.

In the United States, proper consent must be in place for disclosure of the worker/patient blood alcohol/drug forensic science expert analysis in court/administrative hearings.

---

#### Consent, Jurisprudence, Ethics

### F24 Genetic Genealogy and Law Enforcement: New Bedfellows

*Donald E. Shelton, JD, PhD\*, University of Michigan-Dearborn, Dearborn, MI 48128-2406*

**Learning Overview:** After attending this session, attendees will have a better understanding of how genetics and genealogy have come together to solve crimes and will also learn how recent developments raise both legality and ethical issues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making practitioners aware of how genetics and genealogy can now be used by law enforcement, as well as the legal and ethical issues that are presented by the process.

Since the identification and arrest of the suspect in the “Golden State Killer” investigation in early 2018 using novel DNA and genealogy tools, dozens of law enforcement investigators in North America have effectively used such methods in high-profile cold cases. A combination of advanced DNA methods, using thousands of Single Nucleotide Polymorphisms (SNPs) along with searching of ancestry databases, has allowed genealogists to assist investigators in identifying possible persons of interest as suspects in unsolved crimes. A free website database called GEDMatch allows comparison of suspect DNA to any of the millions of persons who have voluntarily submitted their DNA to that website database to accurately identify distant relatives of the suspect. In the past year, some of the more general direct-to-consumer genealogy websites, such as FamilyTree® and 23andMe®, have also indicated that they will release information to law enforcement under certain conditions. These tools have significantly changed the face of genealogical searching, and those changes now offer new investigative methods of crime solving.

Police can submit raw data from crime scene DNA to one of the new genealogy databases to find relatives of the person who left the specimen. While the suspect may not be in the Combined DNA Index System (CODIS), and may not have submitted his or her DNA to the genealogy site, the DNA of any of his or her relatives who have innocently submitted their data for genealogy search purposes can lead police to a range of suspects. The results of DNA-based genealogy searching allows follow-up investigation by police to further narrow the range of suspects based on age, locale, and other factors associated with the crime. Once a possible suspect has been identified, police can obtain a known DNA sample from the suspect. This can be done using discarded DNA without a warrant (for example, a discarded tissue from a garbage can in the “Golden State Killer” case). After that DNA profile is related to the crime scene specimen, the police have the basis for a warrant.

The entire process may raise potential admissibility issues that have yet to be decided by the courts. These admissibility issues involve questions such as legal standing and waiver doctrines, as well as the more basic issue of whether the ancestral leads generated by the process are even relevant to introduction of the eventual DNA comparison of the crime scene DNA to the defendant’s DNA. The waiver issue has recently become more prominent since GEDMatch and some of the more general ancestry searching sites have now required an “opt-in” consent before data will be shared with law enforcement.

Notwithstanding the legality issues, the use of genealogical data raises ethical and policy issues. There is a significant debate about whether individuals who submit their DNA for personal genealogy research understand that it may expose their relatives to potential criminal prosecution. The recent “opt-in” requirements are attempts to insure that true “informed consent” is obtained before the information is released to law enforcement. Furthermore, some argue that the very concept of genealogical searching by law enforcement is the beginning of a “slippery slope” leading to a “police state” mass identification of the populace that violates basic societal notions of privacy. Others, however, maintain that consensual submission of DNA data that may lead to the apprehension of a dangerous criminal is an entirely ethical and individual decision.

#### Genetic Genealogy, Genetic Genealogy Admissibility, Genetic Genealogy Ethics

### F25 You Are the Judges: An Interactive Session on Cutting Edge Issues at the Intersection of Law and Science

W. Milton Nuzum III, JD\*, Supreme Court of Ohio, Columbus, OH 43215; Stephanie Domitrovich, JD, PhD\*, Sixth Judicial District of PA, Erie, PA 16501

**Learning Overview:** After attending this presentation, attendees will better understand the role of judges as gatekeepers when cutting edge science arrives at the court's doorsteps and be able to apply rules of evidence to scientific issues in actual court cases involving expert witnesses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with learning opportunities to be able to apply and understand rules of evidence involving their roles as expert witnesses in the courts through the use of actual court cases.

This presentation will first provide a quick primer on the evolution of admissible scientific expert testimony. This presentation will review how judges make critical admissibility decisions as gatekeepers of scientific evidence in their courtrooms. State jurisdictions can range from *Frye* to *Daubert* jurisdictions. *Frye v. U.S.* is a one-page decision that still exists in several state jurisdictions.<sup>1</sup> Under the *Frye* test, expert opinions based on scientific techniques are admissible only when the techniques are generally accepted as reliable in the relevant scientific community. *Daubert v. Merrell Dow Pharmaceuticals, Inc.* is the leading case regarding this gatekeeper role of admissibility decision making.<sup>2</sup> The United States Supreme Court in *Daubert* defined the judge's role as a gatekeeper to admit relevant and reliable scientific knowledge by reviewing a non-exclusive list of questions for "Gatekeepers": Has theory or technique been tested? Has it been subjected to peer review and publication? Is there known or potential rate of error in technique? Is it generally accepted in the relevant scientific community (the *Frye* test)? Federal Rule of Evidence 702 permits witnesses qualified by knowledge, skill, experience, training, or education to testify if: (1) the expert's scientific, technical, or other specialized knowledge will help the trier of fact to understand the evidence or to determine a fact in issue; (2) the testimony is based on sufficient facts or data; (3) the testimony is the product of reliable principles and methods; and (4) the expert has reliably applied the principles and methods to the facts of the case.

This presentation will also review actual cases with attendees through an interactive PowerPoint® vehicle for attendees to respond to on admissibility issues. This presentation has selected various state and federal cases to review the admissibility considerations as to various cutting edge issues. How do courts determine the admissibility of cutting edge issues, such as cases involving the STRmix™ program? What are the considerations in discovery? Is the program in the exclusive control of the prosecution team? Can the prosecutor be compelled to produce the STRmix™ software program, the program source code, and internal validation studies? Can computer algorithms be compelled to testify? This presentation will review recent cases involving pathology, toxicology, and chemistry. This presentation will review cases involving qualifying experts. What are the considerations that courts find important in qualifying experts? What about the methodology of the expert? Does Forensic Statistical Tool (FST) testing of DNA meet the *Daubert* standard of admissible evidence? In the case of hypergeometric testing, when is the scientific mythology sufficiently reliable to admit? What about authenticating Facebook® postings where the case relies solely on Facebook® postings? Are these postings admissible when an expert has been qualified? What proof is necessary to authenticate social media evidence, such as Facebook® postings and communications? Additional cases will be reviewed as time permits.

## F26 The Importance of Evidence in Proof of Accusation in Criminal Procedure Law in Turkey

*Hatice Yilmaz, BS\*, Üsküdar University, Forensic Sciences, Istanbul 34662, TURKEY; Tugba Ünsal, PhD, Üsküdar University, Forensic Sciences, Istanbul 34662, TURKEY; Sevil Atasoy, PhD, Uskudar Universitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY*

**Learning Overview:** The goal of this presentation is to propose a solution to the problems in the judicial process that are encountered in obtaining evidence for Proof of Accusation in Criminal Procedure Law in Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how the crime is not rendered suspect when the issue of proof comes into play. The function of the Law of Criminal Procedure, criminal and criminal norms by showing the offender in return of actual execution of the application if it has been exercised to determine by whom it is handled. Essentially, the goal is to investigate material facts. In order to achieve this goal, it must be proven that a crime was committed by acts as shown.

In the legal sense, a crime, criminal, or legal enforcement of security is measured by the institutions of a society. The person who performs the crime is called a criminal. The history of crime is as old as the history of humanity. Throughout history, governments and society are required by the dynamics of the committed criminal action that perpetrators be judged and it is concluded through the trial of the perpetrator that, if guilty, is subject to sanctions in various ways. If it is concluded he did not commit the crime, he is acquitted.

That the crime is not rendered suspect by the issue of proof comes into play. Thus, the suspect is innocent or prove to himself that will be hard to prove that the party who claims to have committed a crime. In Roman law, put some money in our legal system as it is the party that has to prove the claim. In medieval Europe, he had to prove that the suspect is innocent. The function of the Law of Criminal Procedure, criminal and criminal norms by showing the offender in return of actual execution of the application if it has been exercised to determine by whom it is handled. Essentially the goal is to investigate material facts. In order to achieve this goal, it must be proved that a crime was committed by who acts as shown. For punishment to follow authority who has the authority, by whom the crime does not have the authority to decide that arbitrarily, the proof of this must be done in accordance with the law. Truth is relative. Naturally, we go ways to influence the court, the parties, the judicial authority, he would go the way of finding the truth by examining the evidence. In criminal proceedings, the Turkish Criminal Procedure article 217/2 of the law to regulate the discretion of the judge as the “alleged crime, it can be proven with any evidence obtained in accordance with the law” in the form of are arranged. The judgment of events that have occurred during the criminal procedure shall be proved before the time of the event and the conditions of the emergence of prior knowledge for reasons such as lack of freedom of evidence in criminal procedure was adopted that principle asserts. In this presentation, the problem of evaluation of evidence that is required for proof of the allegations will be discussed.

Therefore, search for truth cannot be executed at all costs. This process should take into consideration the rights that human beings intrinsically have. The thesis therefore consist of the parts as follows: purpose of the criminal process and historical evolution of it; definition, gathering, and reviewing process of evidences.

### **Criminal Process, Juveniles, Evidence Law**

## F27 The Need for a Full Specification for Digital Forensic Tool Validation

Nicolas R. Hughes, JD\*, Harris County Public Defender's Office, Houston, TX 77002-1957

**Learning Overview:** After attending this presentation, attendees will better understand the definition and process of validating digital forensic tools.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for a fully specified definition of the validation of digital forensic tools.

Digital forensics encompasses the acquisition and analysis of digital data. Digital forensic examiners collect and analyze evidence pertinent to the investigation of traditional crime, cybercrime, or civil matters. Examiners routinely rely on software- and hardware-based tools to analyze otherwise unmanageable amounts of data.

Tool validation is the recognized process for evaluating the accuracy and reliability of an instrument. Validation requires the "provision of objective evidence that a given item fulfills specified requirements, where the specified requirements are adequate for an intended use."<sup>1</sup> The discipline of digital forensics provides a definition of validation that does not fully capture the intent of the formal definition: "[a]n evaluation to determine if a tool, technique or procedure functions correctly and as intended."<sup>2</sup>

In digital forensics, confusion about what "validation" means results in the use of the term to describe a wide range of methodologies. The term may describe manufacturer's internal studies, manual verification of data, and fitness-for-purpose testing conducted by the Computer Forensics Tool Testing Program or laboratories.<sup>3</sup> Non-public or limited manufacturer studies do not provide the empirical data needed to justify reliance upon the tool. Fitness-for-purpose testing and manual verification may demonstrate that a forensic tool operated successfully in one scenario, but typically fails to demonstrate performance over a full range of realistic conditions.

Validating digital forensic tools is inherently difficult. One difficulty is accounting for the number of variables affecting digital investigations. Many tools perform multiple functions—for example, correlating text messages, Global Positioning System (GPS) data, and photo metadata. Tools may accommodate different operating systems, devices, and hardware configurations. Tools and software often receive updates. Each different function, hardware configuration, and version represents a variable that may affect a tool's operation. Additionally, collecting digital forensic reference samples is difficult. The sensitive personal information present on digital devices poses privacy and legal concerns, making it challenging to use real samples.

The discipline should provide a functional, low-level specification of tool validation defining the requirements, reference samples, and methodologies used during tool validation. First, the discipline should enumerate the specifications and requirements for tool validation. These should include the range of conditions expected during analysis, a detailed hierarchy of functionality possible for each forensic process, and any known anomalies expected to affect a given forensic process.<sup>1,4,5</sup> Second, the discipline should curate appropriate validation methods and reference samples. The discipline should specify the appropriate use of a validation method, the provenance of reference samples, how to generate synthetic evidence, and should specify how to structure data generated during the study. Finally, the discipline should identify remaining gaps in the assurance methodology. The gaps mark the limitations of present knowledge about forensic tools and should direct future efforts.

Fully specifying the definition of digital forensic tool validation is beneficial. A fully specified definition permits researchers, experts, and developers to make independent, incremental contributions to a common body of assurance methodology. It establishes a common definition of tool validation. Finally, a full specification encourages the generation of public, transparent data used to justify conclusions about tool performance. By fully specifying the definition of tool validation, the discipline strengthens the foundation of digital evidence.

### Digital Forensics, Tool Validation, Specification

## F28 #Datastories

*Paul Reedy\*, 4th Street Global, Washington, DC 20003*

**Learning Overview:** After attending this presentation, attendees will understand the increased challenges of digital evidence and hear an alternative approach to meet the challenge.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternative approach to meet the increasing challenge of digital evidence as new technologies and applications become available in the consumer and business marketplaces.

As the volume of forensic data continues to grow, alternative approaches to assessing and interpreting the data are required. One alternative is presented that attendees may wish to adopt.

A different approach to looking at data is required. All forensic information is data, no matter from where it is derived. The most obvious is digital evidence obtained from data storage devices; however, in many investigations, this now includes network and internet logs. But what are we to make of DNA, or images of latent fingerprints, or those related to firearms? How does one consider financial transaction records? Gone are the days of the digital forensics and other experts looking at the data in isolation. A different approach is the use of multidisciplinary teams looking at the whole of digital evidence, but also interpreting other forensic data when available. Teams comprising expert individuals who bring a range of skills and knowledge to bear on the question(s) at hand, who can read and interpret different forms of data from multiple sources. In collaboration, the data story can be revealed.

Every person has a unique digital identity and, as technology evolves, this identity will become more specific and more informative. Historically, the challenge has been about getting hold of the data. Where is it located? Is it encrypted? Is it hidden? Can we look at all of it?

It is no longer just the phone and computer. Now, as the Internet of Things becomes ubiquitous, every individual is part of the digital mesh, permanently integrated into the system 24 hours per day, 7 days per week. An individual's every thought, behavior, relationship, decision, and action is captured digitally. Now, there is too much to look at all of it, and it is all in different formats, from different sources, different devices, and generated for different purposes.

4G telecommunications brought innovations that were unanticipated. Initial marketing was for more reliable phone calls and faster data transfers. What was not expected was the explosion in social media; Netflix®, Hulu®, and other streaming services; the beginning of autonomous vehicles. Although not directly related to 4G, technological evolution has resulted in the appearance of deep fakes and the weaponization of social media has real-world impacts. Is the data real?

As 5G telecommunications with increased speed (download a high-definition movie in less than five seconds), improved latency to almost assure autonomous vehicle safety, and improved reliability, what will be the challenges for those of us who are looking at digital evidence to ascertain the course of events and the person involved in an incident. New applications that can be anticipated will include telemedicine with implanted devices and monitors, building access and control management, public transport management, and motor vehicle monitoring and management. The total volume of data will continue to grow incrementally as 5G is rolled out, the infrastructure is upgraded and new, yet to be conceived, applications are developed and marketed. To illustrate the point, BEBO was the largest social networking site in the United Kingdom with 10.7 million users and sold to AOL® for \$850 million in 2008. In 2010, AOL® decided to either sell it or close it down as it was losing users to Facebook®. That was just ten years ago. This was around the same time as the advent of 4G.

## F29 Spotting Stingrays: The Legal Issues of Covert Cell Phone Location Surveillance

*Michael Buresh, JD\*, Cook County Public Defender, Chicago, IL 60602*

---

**Learning Overview:** The goal of this presentation is to introduce attendees to cell-site simulators, a covert cell phone location tracking device commonly referred to as a “stingray.” The presentation aims to teach attorneys how to identify when a stingray has been used against their clients and how to seek legal recourse. This presentation will also cover the current state of search-and-seizure law on stingrays. Two real-life case examples in which law enforcement utilized stingrays will be presented to provide specific examples and to contextualize the presentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how attorneys can identify cases in which a stingray may have been used and how to uncover evidence of stingrays.

Cell phones communicate via stationary cellular antennae (cell sites, also commonly referred to as “cell towers”) that relay phones’ radio signals over long distances. Law enforcement can exploit this technology to conduct covert surveillance of citizens and their locations via a device called a cell-site simulator (a.k.a. “stingray”). Like “Kleenex<sup>®</sup>” or “iPad<sup>®</sup>,” the term “stingray” derives from a specific brand of cell-site simulator manufactured by Harris Corporation. A stingray impersonates a real, carrier-operated cell site and forces all phones in the immediate vicinity to connect to it. The stingray then acts as a go-between, relaying signals between those target phones and the true, carrier-operated cell sites. These stingrays can decode these signals to reveal the identifying information of the phone (the International Mobile Equipment Identifier [IMEI]) and the identifying information of the customer (the International Mobile Subscriber Identifier [IMSI]). A stingray can act as a pen register/trap and trace device by intercepting all incoming and outgoing phone numbers to and from the target phone. A stingray also acts as a wiretap by intercepting the content of voice calls and text messages to and from the target phone. However, the most commonly used ability of a stingray is its ability to track the location of the target phone by measuring signal direction and strength. Stingrays can track multiple phones simultaneously and identify a specific individual’s phone by the process of elimination.

As a covert surveillance device, law enforcement’s use of these devices has been shrouded in mystery. Law enforcement agencies obtain these devices under strict Non-Disclosure Agreements (NDAs) with the Federal Bureau of Investigation (FBI). These NDAs prohibit local police from disclosing the existence or use of their stingray without the express permission of the FBI. The NDAs even commit local law enforcement to dismiss cases at the direction of the FBI if backed into a corner by a court. Police use vague language, parallel construction, legal fictions, and even outright lies to conceal their use of stingrays in criminal investigations.

The presentation will cover the current state of the law on stingrays. While there is no directly applicable United States Supreme Court opinion on the specific topic of stingrays, several lower courts and state legislatures have weighed in on the issue. This presentation will also cover two specific case examples in which clients of the presenter were “stung” and in which law enforcement went to great lengths to conceal their warrantless use of stingrays. In these cases, it was ultimately the work of independent government accountability and transparency activists (and their attorneys) that uncovered Chicago law enforcement’s ownership and use of stingrays and secured justice for the clients.

---

### Stingray, Cell Phone, Surveillance

## F30 Historical Cell-Site Location Basics

Michael Buresh, JD\*, Cook County Public Defender, Chicago, IL 60602

**Learning Overview:** The goal of this presentation is to teach attendees the basic principles of historical cell-site location information and the current state of the law on cell-site location. This presentation will introduce attendees to various types of cell-site location data, the various records that comprise cell-site location data, and the legal issues implicated by the introduction of cell-site location into evidence in court.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by spreading knowledge of, and building competence in, a relatively unknown field of forensic science. The case example will serve as a cautionary tale for both cell phone location surveillance practitioners and attorneys as to the potential consequences of not fully understanding this discipline.

Cell phones rely on stationary cellular antennae (cell sites, also commonly referred to as “cell towers”) that relay phones’ radio signals over long distances. Cellular service providers keep records of which specific cell sites transmit their subscriber’s calls and text messages for the purposes of both billing and network analysis. Law enforcement can obtain these records via warrant to determine individuals’ past locations for use in investigation or prosecution. These records include Call Detail Records (CDRs), tower lists, and CDR keys, and are commonly referred to as Historical Cell-Site Location Information (HCSLI). Inadequately trained law enforcement officers can make errors in their analysis and often overstate the precision and, therefore, the probative value, of this evidence. It is important that practitioners and attorneys are aware of these potential pitfalls in order to avoid miscarriages of justice.

The legal landscape of HCSLI is evolving rapidly. Prior to June 2018, law enforcement commonly obtained HCSLI via a “d-order” under the federal Stored Communications Act (SCA). This statute allowed law enforcement to obtain these records with a court order issued on an evidentiary standard lower than probable cause. In a landmark ruling, *Carpenter v. United States*, the United States Supreme Court declared that individuals possess a reasonable expectation of privacy in their past locations as revealed through HCSLI.<sup>1</sup> The Supreme Court also held the SCA procedure for obtaining HCSLI to be invalid and ruled that law enforcement must generally get a warrant to obtain these records. While the privacy interest in these records is now established, the lower federal courts and state courts are still developing the law around other aspects of cell-site location, such as the exclusionary rule, real-time cell-site location, and tower dumps.

In 2016, while investigating a near-fatal shooting, Evanston, IL, police officers obtained the HCSLI of a suspect, C.L., by his consent. In analyzing C.L.’s HCSLI, a detective made a crucial error that resulted in C.L. being arrested and charged with attempted murder. C.L.’s defense attorneys were able to identify this error and referred the case to an independent expert who was able to refute the erroneous analysis. This presentation will explain the error made in C.L.’s case, discuss other common errors in cell-site location analysis, and prepare attorneys to identify and counteract these errors.

### F31 Drone Laws: The Imminent Quandry

Corey A. Bauer, JD\*, *Bauer Law, Pittsburgh, PA 15222*; Victor W. Weedn, MD, JD\*, *The George Washington University, Washington, DC 20007*; Anthony M. Hallett\*, *Unmanned Response, Inc, Beaver, PA 15009*

**Learning Overview:** After attending this presentation, attendees will understand: (1) the early stages of development of the civil and criminal law of Unmanned Aerial Vehicles (UAVs); (2) the conflicts between federal and local laws; and (3) how privacy implications are substantial.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an awareness of the issues that are developing from the proliferation of drones.

The civil and criminal law of UAVs is in an early stage of development. Federal and local laws often conflict. Privacy implications are substantial. The Federal Administration (FAA) has adopted the term Unmanned Aircraft (UA) for aircraft systems without a flight crew on board, but they are more popularly known as UAS, or simply drones. UAS are approaching ubiquity in America's skies and, as is typical of technological innovation and diffusion, the law lags behind. The FAA currently permits drones under 55 pounds to be operated for two distinct purposes—recreational or commercial—each of which must follow a different set of rules that periodically change. Also, it is against federal law for anyone, including local law enforcement, to shoot down or disable any manned or unmanned aircraft. Can the FAA enforce their UAS laws, or do they have to rely on local law enforcement? The FAA has been attempting to assert itself as the sole regulator of the airspace—*field preemption*, but state laws and local ordinances proliferate in the face of unenforced federal preemption. States press their historic police powers, reserved to them by the United States Constitution, as well as primary land use, zoning, privacy, and trespass jurisdiction of launch/landing sites. Most of the federal regulations involve air safety, and most local laws involve privacy, but the proposed and enacted local laws vary widely. An example state law is 18 Pa.C.S. § 3505, which criminalizes the use of drones to: (1) conduct surveillance upon people in a private place; (2) operate so as to place another in reasonable fear of bodily harm; or (c) deliver, provide, transmit, or furnish contraband to convicts in prison or inmates in a mental hospital. Outside of breaking the aviation rules themselves, drones are primarily used in ways that may invade our privacy.

Beyond the small toy drones, most UAS are equipped with cameras. The United States Supreme Court has already ruled in *California v. Ciraolo* and *Florida v. Riley* that there is no reasonable expectation of privacy from the air.<sup>1,2</sup> Even if aerial observation was considered a privacy infringement, would merely racing over the property with a camera at 20mph be a violation? A recent criminal case from northwest Pennsylvania (among the first in the country) illustrates the current problematic state of affairs. This case involves the attempted prosecution of a recreational drone operator for allegedly disturbing dogs at a K-9 training kennel. The drone log was used by the defense to challenge the assertions of the local authorities. In 2017, the FAA launched the UAS Integration Pilot Program (IPP), a collaboration of local, state, and federal government agencies and private-sector vendors and operators. The intent is to promote cooperative oversight of the national airspace. Progress has been encouraging, but is universal agreement and adoption even possible? Furthermore, consider the American National Standards Institute's Roadmap for UAS, an ongoing collaboration that has identified 60 "gaps" in UAS oversight that must be remedied through new regulations issued by dozens of federal agencies. Even the FAA will soon add another layer of complexity when drones are widely approved to fly beyond the operator's visual line of sight. Ambiguities, preemption conflict, and the inherent intrusive nature of drones will almost certainly provoke a flood of unwarranted cases in the months and years ahead.

#### UAVs, Drones, Privacy Law

## G1 The Applicability of the “Dimodent” Sex Predictive Equation Assessed in a Senegalese Population

Khalifa Dieng, DDS, PhD\*, Dakar, SENEGAL; Sankoung Soumboundou\*, University Cheikh Anta Diop, Dakar, 99000, SENEGAL

**Learning Overview:** After attending this presentation, attendees will gain a method to achieve a sexual dimorphism using odontometric data specific to each population. The purpose of this study is establish the degree of this dental dimorphism within the population.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the determination of gender is one of the most important and crucial steps in identification using the Dimodent method described by Fronty.<sup>1</sup>

**Materials and Methods:** A total of 104 subjects (52 males and 52 females) aged 20 to 60 years were included in this study. Mesiodistal and vestibulo diameters, lingual of the mandibular lateral incisor and canine, were measured with a digital caliper on plaster models. The measurements obtained were integrated into the sexual prediction equation:  $P=1/(1 e^y)+Y$ . Y is evaluated based on measurements of mesiodistal and buccolingual diameters. The Mesiodistal Dimension (MD) was defined as the largest distance between the contact points on the proximal surfaces of the dental crown.

$P=1/(1 e^y)+Y$  is evaluated according to measurements of mesiodistal and vestibulo diameters.  $Y=+24.2 (1.54*+I MD) (1.92*-I VL) (2.84* C-MD) (3.38*C VL)$  (I=Incisor, VL=Vestibulo-Lingual, C=Canine). The equations and P and Y were created on Excel<sup>®</sup> thanks to the inter- and intra-observer variabilities that were evaluated with the Kappa Cohen test.

After casting alginate (irreversible hydro-colloid) impressions with hard plaster, the measurements were taken along the long axis of each tooth, with a digital caliper with a digital display of precision of 0.01mm according to the method described by Dimodent.

This study included 104 Senegalese melanoderm subjects, including 52 women and 52 men randomly selected, with an average age of 41.22 years  $\pm$  12.58. The study of inter- and intra-writing of the functions  $P=1/(1 e^y)+$  where P expresses the probability of being in the presence of a feminine or masculine dentition. According to Dimodent: if P is between 50% and 100%, the teeth are probably female. If P is between 0% and 49%, the teeth are likely to be male. Depending on the value of P found, the samples were ranked according to the pattern.

The collected data were analyzed using Microsoft<sup>®</sup> Excel<sup>®</sup> (version 2013) software. The comparison of the data was made with the Chi-square Xtests2 and Pearson and a significance level  $p \leq 0.05$  was retained.

**Results:** The study of inter- and intra-examiner variability yielded a satisfactory kappa of 0.70. A statistically significant difference was found in the medial-distal ( $p<0.0001$ ) and vestibul-lingual ( $p<0.0001$ ) diameter of the canine. The measurements obtained on the lateral incisor, mesiodistal diameter, are not discriminate.

In this study, the overall positive prediction rate is 86.53%. The success rate was higher for men (90.38%) than for women (82.69%).

**Conclusion:** The method used in this study is simple and inexpensive to conduct and therefore can be applied in forensic odontology to establish an individual's sexual identity.

## G2 A Case of Great East Japan Earthquake Human Remains for Which Digital Imaging Analysis of Dentures Helped in Identification

*Akiko Kumagi, DDS, PhD\*, Iwate Medical University, Shiwa-gun, Iwate 028-3694, JAPAN; Mitsuru Izumisawa, PhD, Iwate Medical University, Morioka 020-8505, JAPAN; Noriaki Takahashi, PhD, Iwate Medical University, Morioka 020-8505, JAPAN; Yutaro Oyamada, PhD, Iwate Medical University, Morioka 020-8505, JAPAN; Takuya Kobayashi, PhD, Iwate Medical University, Morioka 020-8505, JAPAN*

**Learning Overview:** After attending this presentation, attendees will have acquired a new dental identification technique.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that judgment of a case report of comparison was based on very little evidence utilizing artificial teeth from dentures.

Human remains were discovered immediately after the Great East Japan Earthquake and were cremated, although the person was not identified. The full set of dentures in the mouth at the time of discovery of the remains were kept as possessions of the victim in the municipality. Possible identification of the remains emerged through collation with a DNA database, but an additional personal identification method was desired for a more reliable identification. Eight years later, the dental clinic that the candidate attended during his lifetime was identified, and it was revealed that the dental clinic prepared the upper and lower full dentures. Moreover, it was revealed that the dentures the candidate wore had rare artificial teeth in the molar regions.

Demonstration of wearing the dentures prepared with the rare artificial teeth by the unidentified remains may be a big help in judging the comparison. Thus, this study tried to increase the possibility that the remains were the patient (candidate) who attended the dental clinic by analyzing whether the artificial teeth of the dentures worn by the remains were the rare artificial teeth.

Images of the dentures belonging to the unidentified body were acquired using cone beam Computed Tomography (CT) and Stereolithography (STL). Then, the artificial teeth used in the dentures worn by the candidate, Livedent FB20 Plastic 108, and hard resin teeth used about 40% of the time in Japan (frequently used in general dentures prepared within the coverage by national health insurance and used in the anterior tooth region of the dentures prepared by the dental clinic), and ENDURA S28 A3, used as a control material, were imaged using a desktop scanner for dental technicians and STL was constructed. These were superimposed on STL of the bilateral upper and lower first molars of the artificial teeth in each of aforementioned images. The software used for superimposing the images was spGauge. As a result, it was determined that the artificial teeth of the dentures worn by the unidentified body were very likely to be identical to those used by the candidate.

Component analysis was also a measure for this case, but items left behind by an as-yet unidentified individual cannot be destroyed, so non-destructive analysis was required. In the analytical results, large differences were noted in the functional palatal- and lingual-side cusp between the artificial teeth of the dentures worn by the remains (candidate) because the morphology of these is likely to have changed due to being ground for occlusal adjustment by a dentist when new dentures are attached and attrition by mastication, but almost no difference was noted on the non-functional buccal surface or fissure of the occlusal surface of the cusp; these useful results helped in obtaining a judgment of the comparison.

### Disaster Victim Identification, Forensic Odontology, Stereolithography

### G3 Should Facial Marks Created Because of Tooth Loss Be Considered as Hard Evidence?

*Huseyin Afsin, PhD\*, Istanbul 3400, TURKEY; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104*

**Learning Overview:** After attending this presentation, attendees will be familiar with different views on using facial marks due to tooth loss.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing another way to use facial marks due to tooth loss in forensic cases.

Opinions on using facial marks resulting from tooth loss as hard evidence vary. This study attempts to evaluate different opinions on using facial marks due to tooth loss as evidence according to Turkish penal code.

This study brings together opinions and applications of facial marks due to tooth loss by forensic experts, dentists, and jury members as a piece of evidence used in a usual course of their practice. Data has been analyzed and evaluated by a statistical program.

A total of 162 people participated in this study, which included 103 forensic experts/assistants, 38 jurists, and 21 dentists. Of these, 38.8% of the forensic experts/assistants, 90.5% of the dentists, and 34% of the jurist participants in the study were professionals practicing in three big cities of Istanbul, Ankara, and Izmir. Just over 60% (61.1%) of participants had less than 10 years of experience, while 38.5% had more than 11 years of experience in their respective professions. Even though the number of participants with less than 10 years of experience in the study is statistically higher, the majority of the dental participants had more than 11 years of experience ( $p < 0.05$ ). Thirteen percent of the study subjects were categorized as having no face marks because of tooth loss and 87% had definite facial marks as a result of tooth loss. In categorizing study subjects, there was no statistical significance among participants according to their areas of expertise or years of experience ( $p < 0.05$ ). Participants were grouped according to their area of expertise and written opinions.

Tooth loss can be repaired close to its original aesthetic appearance with today's dental technologies that are available to dentists. Despite this advance in dentistry, people with tooth loss have to live the rest of their lives with dentures or without replacing the tooth/teeth at all. There are several reasons that contribute to one's decision to not seek dentist's help; major contributors include fear of dental treatment, economic reasons, lack of access to dental services, and transportation problems. The importance of evaluation of facial marks due to tooth loss and its application are what this study hopes to highlight.

#### **Tooth Loss, Facial Marks, Evidence**

### G4 Paradise Lost: The Camp Fire

*Mark D. Porco, DDS\*, Lincoln, CA 95648*

---

**Learning Overview:** After attending this presentation, attendees will be acquainted with information regarding the Camp Fire in, and around, Paradise, CA, which started on November 8, 2018.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing details of the disaster and the importance of a working relationship between forensic odontologists and the coroner's office, as well as other members of the forensic team.

On November 8, 2018, a wildfire started in rural Butte County, in northern California. The Camp Fire's name came from the place of origin: Camp Creek Road. This fire was the deadliest and most destructive wildfire in California history. Also, it was the deadliest wildfire in the United States since 1918, and ranked as the sixth-deadliest United States wildfire overall. The fire caused more than 80 civilian fatalities. It covered more than 153,000 acres and destroyed 18,804 structures. Most of the damage occurred in the first four hours.

Due to the nature of the wildfire, the victims ranged from being visibly recognizable to near-cremation. This necessitated the need for multiple forensic sciences working together. This presentation will show how several of the forensic science disciplines worked together to attain the goal of victim identification. Anthropology, pathology, odontology, fingerprints, and DNA were some of the forensic sciences represented at the morgue. Reportedly, this was the first time "Rapid DNA" was used in a mass disaster such as this.

While the fire and its victims were located in Butte County, the decision was made to send all victims to the Sacramento County Coroner's Office, which is approximately 90 miles from Paradise. Sacramento was better able to accommodate the anticipated number of potential victims. Thus, the Sacramento County Coroner's Office facilitated the victims and the workers, while Butte County remained the authorizing agency.

As many of the local dental offices were destroyed by the fire, retrieving antemortem records necessitated an alternative method. With the help of the local dental society, emails were sent out to all of the dental office in surrounding towns and cities for requests of records of reported missing persons. The records that were sent in by the surrounding dental offices were then screened by the coroner and the lead odontologist.

Early on, it was discussed that this disaster could potentially become a Disaster Mortuary Operational Response Team (DMORT) event. This led to the decision to input all data in to the WinID program. Even though this would prove to be unnecessary, it still proved to be beneficial by allowing part of the team to work remotely on the antemortem data gathering and input.

---

### Wildfire, Odontology, DVI

### **G5 National Crime Information Center (NCIC) Dental Coding: Washington State Patrol's Missing/Wanted and Unidentified Persons Unit (WSP/MUPU) Cold Case Hit**

*Kyle C. Tanaka, DDS\*, Lynwood, WA 98036; Gary L. Bell, DDS, WA State Patrol Missing/Unidentified, Seattle, WA 98115*

**Learning Overview:** After attending this presentation, attendees will understand, through case examples, how the NCIC dental coding system is used to identify unidentified human remains. Additionally, attendees will gain insight into how an agency is structured to have success utilizing the NCIC system.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how the NCIC dental coding system can aid in the identification of unidentified human remains. WSP/MUPU has a developed protocol to effectively utilize the NCIC dental coding system, and the unit has a long-standing working relationship with appropriately trained forensic odontologists.

On Thursday, January 30, 2019, human skeletal remains were discovered in Snohomish County, WA, by Forest Service personnel. A dental examination was completed on Friday, February 1, 2019. The following Monday, February 4, 2019, the dental information, including an NCIC-coded Unidentified Persons (UP) Digital Wide Dynamic Range (DWDR) image was forwarded to WSP/MUPU. This dental information was entered into the NCIC system on February 5, 2019, and a dental Across Matching Ranking (\$M) report was generated on February 6. That same day, the comparison report was reviewed by a trained forensic odontologist. The UP dental information was compared to the Missing Persons (MP) information in the NCIC \$M report, and a match identifying the unidentified remains was made. The Snohomish County medical examiner was notified of the identification on February 6.

A similar sequence occurred in August of 2018 when human remains were recovered in the town of Mill Creek, WA.

Again a dental examination of the remains was performed, the UP information entered into the NCIC database by the Washington State Patrol, a \$M report was generated and reviewed by a forensic odontologist, a match was confirmed, and the local medical examiner was notified.

In 2013, a review of an NCIC \$M cross match report yielded a match between an individual who was reported missing since March 31, 1992, and unidentified human remains recovered on April 29, 1992.

Washington State has state laws that designates the WSP as a central repository for all dental records for Washington States' missing/wanted and unidentified individuals. These laws (Revised Code of Washington (RCW)) include a requirement for entry of the dental information for MPs and unidentified remains into a system linked to other statewide and national systems. There are also requirements for law enforcement, coroners, or medical examiners involved in an MP investigation to collect dental information for submission to WSP/MUPU. The RCWs also include a protocol for the dental information of unidentified human remains to be submitted to the WSP/MUPU.

The protocol Washington State has established to aid in their missing/wanted and UP cases is able to utilize the NCIC dental coding system due to the WSP/MUPU's relationship with trained forensic odontologists.

This working relationship ensures that the NCIC dental coding is accurate and that the NCIC \$M cross match reports are reviewed. Law enforcement, coroners, and medical examiners can consult with the State Patrol's unit if ever aid is needed in the collection of dental data. Washington's system is a *de facto* centralized repository for the entire state.

---

#### **Dental Identification, NCIC Dental Coding, Missing/Wanted/Unidentified Persons**

## G6 Exhumed Remains: A Historic United Kingdom Case Review

*Camilla George, BDS\*, DentArtWork Dental Care, Lechlade, Gloucestershire GL7 3AX, UNITED KINGDOM; Gaille MacKinnon, MSc, Alecto Forensic Services, Watchfield, Oxfordshire SN6 8TZ, UNITED KINGDOM*

**Learning Overview:** After attending this presentation, attendees will understand the importance of working in an interdisciplinary forensic team. This historic United Kingdom case of exhumed remains used an interdisciplinary approach. Attendees will also learn about the application of technology in this particular odontology case report and how this could be applied in future forensic human identification. The goals of this presentation include: (1) introducing an interdisciplinary forensic case from an odontologist's point of view; (2) recording of information at the postmortem (dental, anthropology, radiology, and pathology); (3) radiography in a mortuary (dental and full body); (4) a review of the odontology report; (5) how report writing for odontology in the United Kingdom has changed; and (6) lessons learned (from the perspective of a young odontologist).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the need for consistency in documenting dental and anthropological evidence, the importance of working with other forensic disciplines, and the application of technology in forensic reports during cases that involve human identification.

In June 2018, a major crime review team of a United Kingdom police force enlisted forensic anthropologists/archaeologists to exhume the body of an unidentified male. New evidence led to a second postmortem as the unidentified male was believed to be associated with an attempted murder in 1993. Human identification of these remains used anthropology, pathology, and odontology, along with other supporting disciplines, such as radiology. Hard tissue and dental samples were sent for DNA analysis, which subsequently confirmed his identity and confirmed that he was indeed the suspect the police were seeking.

In 1993, a man was wanted in connection with a horrific attack on a woman. The woman suffered severe head injuries, to the extent that surgeons had to rebuild her face. The suspect subsequently fled the scene using the woman's car. The police issued a number of appeals. Advice was sought from the National Missing Persons Bureau and the International Criminal Police Organization (INTERPOL). Appeals were also made on the BBC television show *Crimewatch*. No proof of life was established following the suspect's disappearance. All attempts to trace him were unsuccessful, and the case remained open.

In 1995, the body of an unidentified male was recovered from the weir of a river near the locality of the attempted murder. The unidentified body underwent a postmortem examination and was subsequently buried as a "John Doe." In 2011, the car the suspect was believed to have been driving was found in the river. The front and rear windcreens were broken. The driver's seat was pushed back and a length of wood matching the length to the foot pedals was found. No body was found in the vehicle.

In June 2018, the body of an unidentified male was exhumed by forensic anthropologists/archaeologists from Alecto Forensics. The remains were thought to be the suspect. A forensic team was assembled. A home office forensic pathologist and an accredited anthropologist examined the remains. Radiographers and police photographers assisted in the capture and collection of information. Samples for DNA analysis were taken from one molar and a section of long bone. A positive identification that matched the suspect was achieved by DNA analysis.

The forensic odontology examination was a comparison to the first odontologist's chart by Dr. Bernard (Bernie) Grant Sims at the first postmortem in January 1995. Bernie was known as the father figure of forensic odontology in the United Kingdom. His expertise was utilized in many United Kingdom major crime investigations and mass disasters such as the King's Cross Underground Fire (London, 1987), the Pam Am plane crash (Lockerbie, 1988), and the Marchioness Riverboat (London, 1989).

This case will look at the biological information that was collected during the odontology and anthropology examinations conducted during the postmortem. Reflection on how we can further improve the method of collection and recording information through the use of technology will also be explored. This odontology report showcases a simple and effective way to demonstrate antemortem and postmortem comparison dental charting.

---

### Exhumed Remains, Forensic Odontology, Odontology Report

## G7 “Oscar”: The Final Chapter

Warren D. Tewes, DDS\*, Queenstown, MD 21658-1101

**Learning Overview:** After attending this presentation, attendees will understand some principles of homicide investigations that are within the usual, and beyond the usual, time and technique expectations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating action-orientated perseverance in cold case investigations. Specifically, as forensic science techniques advance in accuracy and application, the science can return to decades-old cases and bring new insight to light which, as in this case, identifies a 34-year-old unknown homicide victim, who is a 57-year-old missing person.

The identification of missing and unknown persons has been an effort since the beginning of time. It has been documented in forensic odontology from the Roman Agrippina and Lollia Paulina. The science made a quantum leap in the “Bazar de la Charite” fire disaster in Paris 1897. Dr. Oscar Amoedo coordinated colleagues in collecting and comparing antemortem/postmortem victims’ dental records for identification. In recent decades, the same is modeled in DNA comparisons.

The unknown homicide subject of this presentation was found in a galvanized trash can during the excavation of a mall site and hence nicknamed “Oscar” by scene investigators because at the time he had no name. The year was 1985 in Maryland, and evidence materials found with the remains have been analyzed repeatedly by all disciplines of forensic sciences over the decades as new techniques developed.

This case has been presented twice to the Academy in an effort to generate new leads. Serious as homicide is, this unknown was continually referenced in local media as “Oscar” and, therefore, was presented this way at the AAFS Bring Your Own Slides session in 2003. The hope was that there may be a pattern of other homicidal dispositions via galvanized trash cans. No positive outcome resulted.

With perseverance and advancing technologies, “Oscar’s” jurisdictional law enforcement agency engaged Parabon® Nanolabs to generate and publicize his phenotypic, biometric profile to facilitate new leads in a cold case. This included illustrations in *National Geographic* magazine. In 2017, these latest scientific advances on “Oscar” were again presented to the Academy for easier identification, and for encouraging young investigators to persevere by applying the newest technologies to their own cold cases.

In recent years, familial DNA research has been applied to the criminal world. In concert with law enforcement holding “Oscar’s” DNA, these newest technologies were applied. During the last week of June 2019, the Anne Arundel Police Department Maryland publicly announced their success in a press conference and revealed the identity of this long-term 1985 unknown person.

Frequently, the process of investigating missing and unidentified person homicides is to presume that the time of death is somewhat near the abduction or body recovery time, or within a year of the cycle of seasons and advancing decomposition. In this case, the 1985 autopsy report read, “. . . strands of skin were still present on the body . . .” and “Minimal remnants of soft tissue are noted in the trunk and they are not recognizable.” This suggested a reasonably recent death, and his postmortem age assessment was about 20 years.

However, he is now identified. He was a local resident, a 1961 graduate of the local high school, and according to the family, voluntarily left home in 1962. Applying postmortem time-of-death assessments to this new family history, the time of death is not early 1980s per the time of body recovery, but early 1960s. The investigation continues to determine a motive and perpetrator.

---

### Cold Case, Identification, DNA

## G8 The Drowning of 26 Koreans in the Danube in Budapest

*Armin A. Farid, DMD\*, London N1 9RA, UNITED KINGDOM*

**Learning Overview:** After attending this presentation, attendees will be aware that the success of a Disaster Victim Identification (DVI) mission is founded on the unity of all national and international agencies involved; in a spirit of learning and collaboration, these agencies can provide their very best to serve society by recovering the dead and ensuring a dignified handling of their remains, as well as ensuring closure for the victims' loved ones and the survivors of any tragic event.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring the recovery and identification process, according to the International Criminal Police Organization (INTERPOL) standards, of the victims of a ship collision disaster on the Danube river in Budapest at the end of May 2019. This presentation seeks to point out that each DVI operation is unique in its nature and provides a large variety of challenges that need to be overcome in a relatively short period of time.

On May 28, 2019, at 10:00 p.m. in the evening during heavy rainfall, a sightseeing ship named “Hableány” (Mermaid), fully booked by 31 South Korean tourists, accompanied by two South Korean tour guides, with a Hungarian captain and one other crew member on board, collided against a much bigger cruise ship and sank within seven seconds. Seven tourists survived the accident and were rescued from the 10°C–15°C cold water. Consequently, seven other victims were found dead and were removed from the water under very difficult circumstances. The rescue operation, which already faced massive challenges due to the high tide, the heavy rainfall, lack of light, low water temperature, and dirty conditions, was unsuccessful in the recovery of the remaining 21 persons, who were either on the deck or inside the ship at the moment of the accident. While South Korean officials dispatched fingerprint specialists, divers, and logistical personnel, the Hungarian DVI team received its first mission to register and identify the dead bodies that were found at different spots of the Danube, the furthest 120km away. Over the following two weeks, 19 bodies were recovered from the Danube.

The mission itself stood out by the great level of cooperation between the different agencies, such as the Hungarian Counter Terror Unit, which supervised the entire operation, the Budapest Police Department, the Catastrophe Rescue Department, and the National Bureau of Investigation's DVI team. In addition to that, a very close collaboration was established with the South Korean Crime Scene Investigator (CSI) fingerprint specialists and their respective INTERPOL liaisons, the Austrian Counter Terror Unit Cobra, and foreign diving specialists.

---

### DVI, Korea, Disaster

## G9 A Measurement of Morphological Features of Maxillary First Molar Crowns for Human Dental Identification

Ana M. Milheiro, PhD\*, KULeuven, Leuven B3000, BELGIUM; Cezar Capitaneanu, DMD, PhD, KULeuven, Leuven B3000, BELGIUM; Emmy Shaheem, PhD, KULeuven, Leuven B3000, BELGIUM; Steffen Fieuws, Leuven, VB, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will be aware of the potential to include specific measurements of maxillary first molar crowns in human dental identification protocols.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a method for the ranking of quantified uniqueness of specific measurements of maxillary first molar crowns and a proposition of its inclusion in protocols for human dental identification.

Improvements in oral health and the trend for minimally invasive, computer-aided dentistry makes classical protocols for human identification redundant. Morphological comparison, using 2D or 3D imaging and registration techniques, is becoming an important identification tool. This research aims to measure specific morphologic features of maxillary first molars, registered on 3D images, and to quantify their identifying power, separately and in combination.

One hundred sixty-four upper first molars were isolated from 3D digitally scanned, dental cast models and standardized dimension measurements were registered using the 3D modelling software 3-Matic Medical. Fifteen measurements were classified in four groups: tooth depth ( $n=1$ ), measurement between the cusps ( $n=6$ ), measurement between the cusps and the core of the tooth ( $n=4$ ), and angles between cusps ( $n=4$ ). All measurements were registered by the first examiner ( $n=2,460$ ). After a month, a subset ( $n=600$ ) was re-analyzed by the first examiner and by a second examiner. The distance between each subject in the subset and the subjects in the sample was quantified for each measurement to establish a Mean Potential Set (MPS) of candidate matches. The MPS, expressed as the amount of possible matches that would not exclude the correct subject in the sample, was determinant in the quantification of uniqueness of each specific measurement (univariate) and measurement combinations (multivariate). Intra-class Correlation Coefficient (ICC) was calculated to quantify inter- and intra-observer reliability. Differences and agreement between right and left measurements were evaluated.

The most unique measurement was tooth depth (ICC=0.879, MPS=17.1%), followed by the measurement between distal cusps and the measurement between the core of the tooth and the disto-palatinal cusp (ICC=0.855, MPS=19.9% and ICC=0.840, MPS=20.9%, respectively). The measurement between the mesio-buccal and disto-palatinal cusps (ICC=0.524, MPS=32.3%) was the least unique. The angles between cusps ( $n=4$ ) was the most unique measurement combination (MPS=3.911%). The intra- and inter-observer ICC (over all measures) were 0.75 and 0.78, respectively. The measurement between the mesio-palatinal and disto-buccal cusps was the only measurement revealing a statistically significant difference between the right and left side (mean difference -0.25,  $p=0.0008$ ). For this measurement, there is a clinically unimportant average discrepancy with narrow limits between the right and the left measurement. All other measurements showed a variable degree of right/left agreement.

Digital measurements of morphological features of maxillary first molars present a useful tool to integrate in human identification protocols. However, validation in forensic practice is required.

### Forensic Odontology, Human Dental Identification, 3D Morphometrics

## G10 The Uniqueness of Human Teeth: A Systematic Review and Meta-Analysis

Cezar Capitaneanu, DMD, PhD\*, KULeuven, Leuven B3000, BELGIUM; Guy Willems, PhD, Katholieke Universiteit Leuven, Leuven B-3000, BELGIUM; Patrick W. Thevissen, PhD, KULeuven, Leuven, Vlaams-Brabant B-3000, BELGIUM

**Learning Overview:** After attending this presentation, attendees will be informed about current literature status regarding the proof of uniqueness of the human dentition in the forensic context. This will be outlined in a systematic review and meta-analyses of publications considering the uniqueness of human teeth and dentitions.

**Impact on the Forensic Science Community:** There is still a lack of proof regarding the uniqueness of human teeth, despite diverse research attempts. A systematic review will reveal that a small number of related studies have been conducted, mainly allied to bitemark analysis. This presentation will impact the forensic science community by demonstrating the need for future research on uniqueness of human teeth, in particular as it relates to human dental identification.

**Background:** Attempts to prove uniqueness of human teeth in a forensic context have been undertaken. Related research addressed two different forensic areas: human dental identification and human bitemark analysis. A systematic review will identify and synthesize papers considering uniqueness of human teeth and dentitions.

**Goal:** To perform a systematic literature review in order to evaluate the proof of uniqueness of human teeth and dentition morphology in a forensic context.

**Research Question:** Was uniqueness of human teeth and dentition morphology proven in a forensic context?

**Search Methods:** An electronic search was performed in six databases: MEDLINE/PubMed®, Cochrane, EMBASE®, SciELO, LILACS, and Web of Science. Additionally, reference lists of included articles and study registers were searched. There were no restrictions related to country of publication, language, or publication date.

The systematic review complied with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement.<sup>1,2</sup> The review protocol was developed according to the Cochrane Guidelines for review protocols, and was registered in Prospero, the international prospective register of systematic reviews.<sup>3,4</sup>

**Selection Criteria:** To avoid bias, two reviewers independently selected articles based on titles and abstracts. Study populations, including living/deceased subjects, were considered. Review articles and pilot studies of included main studies were excluded. To check eligibility, both reviewers evaluated the full text papers independently. In case of disagreement, a consensus decision was made.

**Data Extraction and Analysis:** Data extraction and study characteristic tables have been developed. A tool for the risk of bias and paper quality assessment was developed, based on the Effective Practice and Organization of Care (EPOC) overview and Quality Assessment of Diagnostic Accuracy Studies (QUADAS)-2.<sup>5,6</sup> If data were unclear, not reported, or in a format unsuitable for the systematic review analysis, authors were contacted for further details. The articles were divided into two groups according to the area of investigation: human identification and bitemark analysis. Both groups were assessed based on the studied parameters (sample size, considered tooth/tooth part/tooth groups, registration technique for data collection, methods for data analysis, and study outcomes), and a comparison was conducted in each group and between groups.

**Results:** It was hypothesized that according to the electronic search, a small number of eligible published papers investigating uniqueness of human teeth in forensic context (approximate  $n=20$ ) will be detected. A low quality of diagnostic accuracy in these studies is expected and the extracted data comparisons will highlight that the uniqueness of human teeth in forensic context was not scientifically proven. The results will be used to address the research question.

### Forensic Odontology, Human Dentition, Dental Morphology

## G11 Sex Estimation Using Enamel and Dentin Proportions of Human Mandibular Canines

Zama Moosvi, MDS, MS\*, University of Dundee, Forensic Odontology, Dundee, Scotland DD1 4DZ, UNITED KINGDOM; Scheila Manica, PhD, University of Dundee, Dundee, UNITED KINGDOM; Gavin F. Revie, PhD, University of Dundee School of Dentistry, Dundee, Scotland, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand sexual dimorphism in enamel and dentin proportions of mandibular canines and their possible role as a tool in sex determination in the future. Apart from age estimation from teeth, the use of ImageJ in sex determination from Radiovisuographs (RVGs) can also be appreciated. Attendees will learn that employing ratios in tissue proportions compensates for variation in tooth size across populations and overcomes difficulties encountered in radiographic standardization.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting a non-invasive method in sex determination using RVGs of teeth.

**Background:** Sex determination of fragmented human remains poses a challenge in archaeological excavations of mass graves, forensic anthropology, and identification of severely destroyed bodies in disaster sites.<sup>1</sup> Biological analysis of hard tissues provides nearly 100% sex identification of fragmented remains but, unfortunately, results in destruction of prime evidentiary material.<sup>2</sup> In such cases, teeth offer as non-invasive alternatives for sex determination. Dental sexual dimorphism between males and females is seen in overall size of teeth as well as in enamel and dentin proportions.<sup>3</sup> Studies on tissue proportions showed more enamel in females and greater dentin in males.<sup>4-6</sup> These studies explored tissue proportions by employing linear measurements on radiographs or area measurements on tooth sections.<sup>4-8</sup> While linear measurements are regarded as less ideal representatives of total tissue volumes, area measurements are considered accurate sex predictors but require invasive procedures.<sup>5,6</sup>

**Goals:** This study aimed to investigate sexual dimorphism in enamel and dentin proportions of human mandibular canines using both linear and area measurements by employing a non-invasive method using RVGs.

**Materials and Methods:** The study sample consisted of 85 uncalibrated RVGs (44, females and 41 males) of sound permanent mandibular canines of South Indian population in the age group of 17–35 years. All RVGs were taken earlier for diagnostic purposes and retrieved from centers with informed consent. Using ImageJ1.52a, four linear measurements (Maximum Mesiodistal Width (MMD), mesial-enamel, distal-enamel, and dentin) and three area measurements (Tooth Area (TA), Enamel Area (EA), and Pulp Area (PA)) were performed. Ratios were determined to compensate for lack of standardization of radiographs. Two ratios were determined from linear measurements (enamel/MMD and) and three ratios from area measurements (EA/TA, DA/TA, and PA/TA). Measurements were performed by a single observer. Twenty samples were randomly selected for inter- and intra-observer reliability. Data was analyzed using intra-class correlation and logistic regression analysis, and regression models were developed for sex prediction.

**Results:** Both linear and area enamel ratios were significantly higher in females than males, indicating more enamel in females. Similarly, both dentin ratios (linear and area) were greater in males indicating more dentin in males. No difference was seen in pulp ratios. A regression model using EA ratio correctly predicted sex in 69.4% of the cases, and a model using dentin linear ratio correctly predicted sex in 61.2% of the cases. The area method showed excellent intra- and inter-observer agreement. However, the linear method showed excellent intra- and poor inter-observer reliability.

**Conclusion:** Sexual dimorphism in mandibular canines is due to differences in both enamel and dentin proportions, with females showing more enamel and males more dentin. Regression models developed using enamel and dentin ratios can be utilized for sex prediction. The area method shows good reliability and sex prediction rates in comparison to the linear method.

### Sexual Dimorphism, Mandibular Canine, Enamel/Dentin Proportions

## G12 Sexual Dimorphism in Mandibles and Permanent Mandibular Canines in a Brazilian Population: A Pilot Study

Gabriel C. Dias\*, Recife, Pernambuco 50670901, BRAZIL; Macelle V. Campos, Recife, Pernambuco, BRAZIL; Carolina P. Magalhães, Vitória de Santo Antão, Pernambuco 55608680, BRAZIL; Renata C.F. Campina, Recife, Pernambuco 50670901, BRAZIL; Jaciel B. Oliveira, Recife, Pernambuco 50670901, BRAZIL

**Learning Overview:** After attending this presentation, attendees will understand that Brazilian mandibles and permanent mandibular canines, despite the great miscegenation of its population, have a good potential for sexual diagnosis through odontometric and morphologic analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that, even with the high miscegenation of the Brazilian population, the permanent mandibular canine, and especially the mandibles, have significant degrees of sexual dimorphism, which can help in sex determination of unknown individuals when the pelvis and skull are missing.

Sex determination has a major role in the reconstruction of the biological profile of unknown individuals in a forensic context. The most reliable results for this question are obtained from morphological and metric analyses of the pelvis and skull. However, in certain cases, these bone segments are not available for analysis, which makes the forensic anthropologist capable of determinate sex from other bones. The teeth and the mandible have been widely studied as auxiliaries in sexual determination: the teeth for being resistant to high temperatures and taphonomic effects, and the mandible for being, as is the entire skull, pretty sensitive to genetic and environmental influences. Existent studies show a high sexual dimorphism in European individuals, which can be justified by the presence of a more homogenous population and a lack of significant influences of other populations. The same does not happen with South American populations, due to their distinct degrees of miscegenation.

Certainly, the use of a specific population database brings better results since the sexual dimorphism varies between the populations. Currently, there are no odontometric or morphologic standards for Brazilian individuals. Therefore, this project aims to analyze the sexual dimorphism in mandibles and permanent mandibular canines from the populations of Recife, Pernambuco, Brazil and of Vitória de Santo Antão, Pernambuco, Brazil. In Recife, 15 male mandibles, 6 female mandibles, 19 male permanent mandibular canines, and 4 female permanent mandibular canines were analyzed. In Vitória de Santo Antão, 13 male mandibles and 8 female mandibles were analyzed. In the mandibles, morphological analysis of the bone and measurement of Intercanine Distance (ID) of the mandibular canines was done with a virtual Vernier caliper. In the canines, the Mesiodistal Diameter (MD) was measured with the same caliper. All the bones and teeth are from the Contemporary Human Bones Collection from the Federal University of Pernambuco. This project was approved by the Ethics Committee CCS/UFPE n°43228015.0.0000.520.

In Recife, sexual dimorphism percentages of 16.56% for mandibles and 7.98% for right permanent mandibular canines (formula by Garn et al.) were found.<sup>1</sup> In addition, the male MD proved to be larger than the female MD; with a difference of 0.5mm to 1.0mm. In Vitória de Santo Antão, the sexual dimorphism percentage was of 6.07%. This suggests that even proximate populations have different degrees of sexual dimorphism. Other measurements were not collected due to the high rate of edentulous individuals, a problem of public health in Brazil caused by the population's lack of access to quality health. Further studies may broach the sexual determination in other teeth to avoid this problem.

This preliminary study suggests that permanent mandibular canines, and mainly mandibles, have significant sexual dimorphism and can be helpful in determining the individual's sex in a forensic context. The sexual dimorphism of more than 16% found in Recife mandibles allows an interpretation in which, contrary to previous research, an extremely mixed population may have a high degree of sexual dimorphism, but analyses with larger numbers of individuals of this population is necessary. The opposition of Recife's population to the results of other populations from South American perhaps can be explained by the populations that were mixed in the Northeast region of Brazil, primarily Portuguese (European) and Africans. This is a pilot study, with few analyzed individuals, in which future studies are needed to improve the regional population database.

### Sexual Dimorphism, Odontometry, Mandible

## G13 Forensic Dental Identification: Using Computerized Tomographic (CT) Scans to Identify Human Remains

*Iris L. Shields, DDS\*, Bel Air, MD 21014; Patrick A. Murray, DDS, Office of the Chief Medical Examiner, State of Maryland, Frederick, MD 21701*

**Learning Overview:** After attending this presentation, attendees will have learned how postmortem CT scans may be used in forensic odontology, in conjunction with fingerprint analysis, DNA profiling, and clinically used radiological documentation techniques such as dental periapical radiographs, bitewing films, and panoramic X-rays. CT scans may be used when these forensic methodologies are unavailable or impossible to perform on human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring how postmortem CT scans may reduce the need for jaw resections by aiding in the dental identification of human remains.

This presentation will introduce attendees to an alternative tool in aiding in the identification of a decedent, by comparing antemortem and postmortem radiographs, which is currently being used by the Office of the Chief Medical Examiner (OCME) in Maryland. This presentation will also explore the advantages and marked disadvantages of using CT scans when other methods are unavailable.

Radiography can play an important part in forensic odontology, mainly to establish identification. This may take the precise form of comparison between antemortem and postmortem radiographs. Radiographs may also be taken to determine the age of a minor victim and even help in the assessment of the sex and ethnic group.<sup>1</sup> Along with dental and DNA analysis, radiographic images are used to identify unknown individuals. This requires the securing of pre-mortem examination (e.g., CT scan or radiograph) of the suspect individual and the matching of specific anatomical details with similar postmortem studies.<sup>1</sup> Anatomical details such as the shape of the teeth, roots, supernumerary teeth, missing and present teeth, attrition, abrasion, coronal fracture, signs of bone resorption resulting from periodontal disease, bone pathology, diastemas, dental cavities, endodontic treatment, interradicular and intracoronal posts, implants, extraction socket(s), and dental prostheses can be used for identification purposes.<sup>2</sup>

Data examined will show that use of CT scans may prove remarkable because positive identification of a decedent has been accomplished by performing a CT scan on an unidentified cranium and comparing multiple landmarks and images with corresponding features in an antemortem CT scan.<sup>3</sup> Conventional CT is a useful imaging method in the process of human identification and presents innumerable advantages in this field compared to traditional radiographic projection.<sup>4</sup> CT has been utilized in the study of skulls and, in the forensic context, as an additional resource in the process of identification.

The use of CT scans may increase the quantity and quality of information involved in the death of the person examined.<sup>5</sup> Overall, there is an emphasis that the use of the CT scan may contribute significantly to forensic purposes, allowing the exploration of dental identification in cases where traditional fingerprint analysis, and classic radiographical methodologies, are not available or conclusive.

### Computerized Tomographic (CT) Scans, Postmortem Identifications, Dental Identification

## G14 A Study of Non-Metric Dental Traits of a North Indian Population: Forensic Aspects

*Kewal Krishan, PhD\*, Panjab University, Chandigarh 160014, INDIA; Sandeep Kaur, PhD, Forensic Science Laboratory, Moahli 160059, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand the usefulness of non-metric characteristics of the teeth in the identification of individuals and in forensic examinations, especially with reference to sexual dimorphism and ethnicity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the utility of morphological characteristics of the teeth in the identification of human remains, especially in a genetically disparate population.

Teeth are the hardest part of the body and can withstand even the most extreme situations, such as very high temperatures, corrosion, fire, putrefaction and decomposition, explosions and thermal trauma, as compared to the other elements of the human skeleton. Therefore, in these situations, the teeth are the most available and favored skeletal elements for the identification of the unknown human remains. Basically, there are two methods by which the teeth could be used in the identification process. The first method involves a comparison of Antemortem (AM) and Postmortem (PM) dental records of the deceased. The second method deals with making a PM dental profile in which the individualistic features of the teeth are recorded, which can ultimately help in narrowing the possible victim matches in the investigation process. The present study focuses on the variations in the morphological characteristics of the teeth, which may not only help in establishing the uniqueness and identity of the deceased in forensic examinations after comparing the AM and PM records, but also may help to estimate the sex and ethnicity/ancestry of the deceased.

The present study was conducted to examine the non-metric and morphological traits of the teeth among a North Indian population. The data were collected from a genetically disparate population of the Punjab State of North India (150 males and 150 females). Dental casts of the subjects were made by the standard procedure. These casts were studied for non-metric and morphological characteristics of the teeth. The subjects with abnormalities of the palate and lips, such as a cleft palate and cleft lip, and the subjects who were wearing partial dentures and braces were excluded from sample selection. The morphological features consist of shovel-shaped tooth, Carabelli's cusp (single-cusp, bicuspid, and multi-cusp), occlusion (normal bite and open bite), anterior cross bite, posterior cross bite, crowding, abrasion, supernumerary teeth, erosion, diastemas, crowns, peg-shaped lateral incisors, grooves, twinned, hyperdontia, abnormal crowns, crown wear, hypocones, central ridges, protostylids, distal trigonid crests, and hypoconulids. The frequencies of occurrence of these characteristic features were noted.

The statistically significant sex differences were observed in the morphological features of teeth. The most common morphological features of teeth found in males and females are Carabelli's cusp (male 90% and females 98.7%), occlusion I (male 90.7% and female 86.7%), normal bite (male 75.3% and female 72%), grooves (male 96.7% and female 73.3%), hypocone (male 98% and female 96%), central ridge (male 96.7% and female 90%), and hypoconulid (male 90.7% and females 87.3%). The least occurring morphological features of teeth found in both the sexes are shovel shaped tooth (male 23% and female 29.3%), occlusion II (male 12.7% and female 11.3%), open bite (male 4% and female 3.3%), anterior cross bite (male 2% and females 2.7%), posterior cross bite (male 5.3% and females 1.3%), crowding (male 44.7% and females 40%), supernumerary teeth (male 0.7% and female 0%), diastema (male 8.7% and female 7.3%), crowning (male 1.3% and female 0.7%), caries (male 21.3% and female 18.7%), fracture (male 4% and female 3.3%), peg-shaped lateral incisor (male 6% and female 4%), and crown wear (male 0% and female 0.7%). The study may be of great help to forensic scientists and Disaster Victim Identification (DVI) team to identify the human remains on the basis of very rare and common morphological features of the teeth. The study further cites an example for linking up certain dental traits with a particular community, especially an endogamous group.

### Forensic Odontology, Personal Identification, Non-Metric Traits

### G15 Hurricane Michael: The Role of the Forensic Odontologist

*Lisa M. Hofstad, DMD\*, Quincy, FL 32351*

**Learning Overview:** After attending this presentation, attendees will understand the role of the forensic odontologist as a responding member of the Florida Emergency Mortuary Operations Response System (FEMORS) during the Hurricane Michael mass disaster.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the significant role of mass disaster teams. Attendees will learn the mission of FEMORS and the assistance that the team was able to provide to the local district medical examiner's office during a declared disaster.

On October 10, 2018, Hurricane Michael made landfall in the Florida Panhandle as a Category 5 hurricane. Panama City, Mexico Beach, and surrounding towns suffered catastrophic destruction. Hurricane Michael caused in excess of \$25 billion dollars in damage and more than forty-five lives were lost in Florida.

The FEMORS was formed in July 2002. It is a portable morgue with a team of professionals that train annually with the mission of assisting and supporting the local district medical examiner's office during a mass incident. The state of Florida and the William Maples Center for Forensic Medicine have implemented protocols to respond to these disasters. A mission assignment was activated from the Florida Department of Health, and the FEMORS team prepared to deploy from the State Emergency Operations Center in Tallahassee on October 11, 2018. The FEMORS commander managed the deployment from the Emergency Operations Center in Tallahassee, FL. The retired FEMORS commander deployed with the activated team members to Panama City, FL.

The Disaster Portable Morgue Units (DPMU) arrived first and prepared to set up the morgue in Defuniak Springs, FL. The FEMORS team worked with the Air National Guard Search and Recovery Team. The District 14 medical examiner's office in Panama City began preparing for mass fatalities.

Despite the overwhelming destruction and devastation to areas of Panama City, Mexico Beach, and surrounding areas, the medical examiner's office in Panama City remained relatively unscathed. There was the immediate loss of power, water, and technological resources. Florida's death toll from Hurricane Michael was greater than 40 as of November 2018. The fatalities were reported in Bay, Gadsden, Franklin, Liberty, Jackson, Leon, Gulf, and Washington counties. The majority of the decedents were elderly. There were deaths as a result of storm surge, collapsed structures, crushing trees, post-storm cleanup, inability to access medical care, and homicidal/suicidal violence. The numbers continue to rise as a result of post-storm cleanup and reconstruction.

The Odontology section of FEMORS is composed of dentists, hygienists, and dental assistants. The volume of fatalities were not overwhelming for the local medical examiner's office and since the decedents were arriving slowly over several days, the entire FEMORS team was not deployed. The activated forensic odontologist worked with the Air National Guard, medical examiner, medical examiner staff, and other FEMORS team members. Some team members slept at the morgue due to generalized destruction of infrastructure, downed trees, and long transportation times to the community center facilities. During the deployment, postmortem radiographs were obtained on incoming decedents. Antemortem records were initially difficult to access due to lack of power, closed/damaged dental offices, lack of cellular phone service, etc. Upon receipt of antemortem radiographs, dental identifications were made.

---

#### Mass Disaster, Medical Examiner, Odontologist

### **G16 The Incorporation of Both Community and Forensic Dentistry in the Child Abuse and Neglect Clinic in Turin, Italy**

*Emilio Nuzzolese, PhD, DSSPP, Sez. Medicina Legale, Università di Torino, Torino 10126, ITALY; Elena Coppo, MD\*, Department of Pediatric Emergency, Turin, Metropolitan City of Turin, ITALY; Francesco Lupariello, MD\*, University of Torino, Torino 10126, ITALY; Caterina Bosco, MD, Department of Public Health and Pediatrics, Torino 10126, ITALY; Luana Bonaccorso, MD, University of Turin, Turin 10126, ITALY; Ilaria Cavecchia, MD, A.O.U. "Città della Salute e della Scienza," Turin 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY*

**Learning Overview:** After attending this presentation, attendees will possess a deeper understanding of how a dentist with experience in pediatric dentistry and a knowledge of forensic odontology can become a valuable resource in child abuse and dental neglect diagnoses and the promotion of oral health.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the added value offered by including odontologists in the multidisciplinary teams involved in investigating child abuse and in the recognition and reporting of neglect, helping to close the circle relating to child protection.

In 2002, Dr. Fulvia Negro, a pediatric physician at the "Regina Margherita" pediatric hospital in Turin, Italy, created a specific hospital clinic called "Bambi." This clinic was initially composed of pediatricians, psychologists, and social workers with the purpose of assessing and monitoring children coming from the emergency unit with a diagnosis of physical or sexual abuse. In 2013, medical examiners with a forensic background were incorporated into this unit to enhance the medicolegal evaluation and also in consideration of the judicial aspects related to the involvement with the Juvenile Court in Turin.

In 2019, a forensic odontologist with experience in community dentistry and humanitarian work was also incorporated into the "Bambi" clinic, thereby creating a full multidisciplinary approach, and introduced oral health promotion and *pro bono* dental treatments.

A specific dental form was developed to record a dental history as well as tooth and soft tissue conditions, together with any signs of physical abuse on the head and neck. Thanks to the presence of a dentist, it was possible to assess the parent's or guardian's knowledge of oral hygiene and identify any eating habits that could be harmful to the correct growth of the child. This also allowed for a dental examination to assess any potential dental neglect, which was followed by specific prescription and treatment plans, when appropriate.

Since 2002, more than 2,100 children have been seen in this unit, with physical abuse as the most distributed finding. The incorporation of a forensic odontologist was generally accepted by all the families. This allowed for a greater recognition of dental neglect cases and also enhanced the forensic evidence collection of physical signs of abuse on the mouth, face, and neck.

A specific oral health promotion program was also implemented, as the odontologist involved acted as a volunteer in community dentistry services with other volunteers.

A dentist with a forensic background and humanitarian pediatric dentistry experience can represent an additional resource in the recognition, assessment, and collection of forensic evidence in child abuse and child neglect cases. This also offers the contextual benefit of safeguarding children's oral health and well being.

---

#### **Child Abuse, Forensic Odontology, Community Dentistry**

## G17 A Forensic Age Estimation From the Pulp/Tooth Area Ratio (PTR) of the Canines: A Forensic Odontological Study

Jagmahender Singh Sehrawat, PhD\*, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA

**Learning Overview:** After attending this presentation, attendees will be more aware of the crucial role of radiological methods in forensic age estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by scrutinizing the role of radiological techniques in forensic odontological identification.

Teeth are among the hardest structures of human body that remain well preserved for forensic investigations for comparatively longer periods of time as they can resist all sorts of physical, chemical, biological, and taphonomic destructions or traumatic insults. The formative, degenerative, and histological changes in human dentition after death make teeth the most reliable and significant forensic anthropological evidence for establishing identity of the deceased, such as age, sex, ethnicity, or pathological status of the deceased. For age estimations, a number of methods have been suggested by different researchers, based either on gross tooth specimens or the radiographs of the deciduous or permanent teeth, either fitted in the jaw sockets or dislocated. Radiological analysis is a non-invasive technique that has played a pivotal role in forensic age estimations of both living and dead individuals required for various purposes. The radiographic method has its own advantages, being less time-consuming, non-destructive in nature, and providing precise estimates.

The present study used radiographs of human canines recovered from human skeletal remains, exhumed from a unused well present underneath a religious structure at Ajnala, Amritsar, in April 2014.<sup>1</sup> From more than 6,000 human teeth of different types, anatomically sound canines were selected for the present investigation. Though there are some historically written versions about the identity of these non-scientifically excavated human remains, this study scrutinized the scientific validity and authenticity of various hypotheses put forth by various amateur historians and other stakeholders in an attempt to endorse or refute the written facts about the remains from their forensic anthropological examinations. The unscientific excavations have seriously challenged forensic identifications of these remains; still, there are some sound opportunities and analyses that can help to establish their identity.

The present study was conducted with the goal of estimating the age of Ajnala victims from their Pulp Tooth area Ratio (PTR) calculated from the area of the tooth surface and its pulp chamber. The morphologically intact dislocated canines were radiographed at the university health center with Siemens' digital X-ray machine and the images were stored digitally. The outline surface area of each canine and its pulp cavity was marked with the help of the computer-aided drafting program ImageJ, and their ratios were calculated. The calculated values were put into the regression equations proposed by previous researchers for PTR among different population groups.<sup>2</sup> Analysis of results and their comparisons showed that only a very few Indian studies could provide positive results when PTR values of the present study were put into their regression equations. It was found that the average age of the majority of teeth was 17–30 years or more; only 14 teeth were found to be subadults (below 14 years of age) when compared with previous studies.<sup>3</sup>

### Forensic Odontology, Age Estimation, Pulp-to-Tooth Area Ratio

## G18 Fractalyse Software—The Analysis of the Trabecular Bone in Identification (The Continuation)

Sylvain Desranleau, DMD\*, *Ordre des dentistes du Québec, Montreal, PQ H3B 1X9, CANADA*

**Learning Overview:** After attending this presentation, attendees will have acquired new information regarding the use of mandibular trabecular bone patterns to establish positive identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing a method of calculating the significance of mandibular trabecular bone patterns in arriving at a positive identification.

According to Berkeley's Orthopaedic Biomechanics Research, the trabecular bone can be classified as a porous cellular solid, consisting of an irregular 3D array of bony rods and plates, called trabeculae, which are composed of a calcified matrix. Bone marrow fills the spaces of the pores. In addition, because all free bone surfaces are covered with bone cells, bone is a living tissue that is self-healing and has the ability to adjust its morphology in response to changes in its mechanical environment, the so-called but poorly understood phenomenon of bone remodeling. As such, the mechanical complexity of this two-phase biological tissue surpasses any engineering material, making it a fascinating subject of study regardless of clinical applications.

The process of dental identification compares postmortem to antemortem data. It involves the analysis of different factors such as: the presence and absence of teeth, crown and root morphology and their interrelationships; the evaluation of the periodontal status; the type and extent of restorative, endodontic, fixed, removable, and implanted materials; tori and sinus configuration; and anomalies and pathologies of teeth and bone, as well as trabecular pattern morphology.

Few studies have been conducted on the statistical reliability of trabecular bone patterns for identification purpose. Some deal with algorithms, a mathematical expression that produces the answer to a question or the solution to a problem in a finite number of steps. Others deal with fractal analysis consisting of assigning a fractal dimension or other fractal characteristic to a dataset. The theoretical dataset, pattern, or signal extracted from a phenomenon can include natural geometric objects, sound, market fluctuations, heart rates, digital images, molecular motion, networks, etc.

Some of the studies apply fractal geometric techniques to the study of trabecular bone, to fractal analysis of radiographs by the assessment of trabecular bone structure and prediction of elastic modulus and strength, to methodological principles for fractal analysis of trabecular bone, to digital image analysis of cadaver mandibular trabecular bone patterns, to fractal dimension and lacunarity analysis of dental radiographs, to technical factors in fractal analysis of periapical radiographs, to the morphodigital study of the mandibular trabecular bone in panoramic radiographs, to fractal analysis of mandibular trabecular bone using the tile counting method, to the anatomical variations of trabecular bone structure in intraoral radiographs using fractal and particles count analyses, to the analysis of trabecular bone using site-specific fractal values calculated from cone beam Computed Tomography (CT) images, and finally to the fractal dimension of the mandibular trabecular bone measured on digital and digitized images.<sup>1-11</sup>

As a continuation of the previous research projects, *The Trabecular Bone in Identification*, *The Trabecular Bone in Identification—Algorithms and Fractal Analysis*, and *Fractalyse Software—The Analysis of the Trabecular Bone in Identification*, the current research is a continuation of the multifunctional uses of Fractalyse software, a free open source software, as an aid and noteworthy tool for trabecular bone pattern morphometric analysis and comparison.<sup>12-16</sup> Outcomes suggest that the development of a new software with a revolutionary approach to handling human trabecular jaw bone patterns for identification purposes could be possible. This approach would be especially practical in mass disaster situations involving large numbers of edentulous victims and/or with fragmented remains.

### Forensic Odontology, Trabecular Bone Patterns, Fractal Analysis

### **G19 An Innovative Approach to the Importation and Conversion of Antemortem (AM) Dental Data to Blockchain-Protected Forensic Data for Utilization in Disaster Victim Identification (DVI)**

*Shada Alsalamah, PhD\**, King Saud University, Riyadh 11545, SAUDI ARABIA; *Ala'a Alimam, BS*, King Saud University, Riyadh, SAUDI ARABIA; *Ahad Alabdullatif, BS*, King Saud University, Riyadh, SAUDI ARABIA; *Maram Alamri, BS*, King Saud University, Riyadh, SAUDI ARABIA; *Miral Althaqeb, BS*, King Saud University, Riyadh, SAUDI ARABIA; *Sara Alqahtani, BS*, King Saud University, Riyadh, SAUDI ARABIA; *Kenneth W. Aschheim, DDS\**, New York, NY 10065; *Sakher J. AlQahtani, PhD\**, College of Dentistry, Riyadh 11545, SAUDI ARABIA

**Learning Overview:** After attending this presentation, attendees will better understand the potential value of integrating blockchain technology into the field of forensic odontology. By automating the conversion and importation of a patient's dental records into a standardized AM dental database, the data can then be stored in an immutable ledger using blockchain-based architecture. This will allow the information to be securely stored and shared among DVI teams from around the world.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, and especially the forensic odontology community, by demonstrating how blockchain technology adoption should create a universal trustworthy ecosystem for DVI teams to identify global victims more accurately and in a more timely manner than traditional methods.

Disasters are difficult to predict, and, in most cases, cannot be prevented. The number of casualties involved varies depending on the type and location of the disaster. Such disasters leave behind thousands of victims from many nations, making the process of identifying multinational victims a challenging task for the international DVI team. Collecting AM dental records from multiple nations is the key requirement in the reconciliation process with Postmortem (PM) data.

Forensic odontologists face key issues when dealing with AM dental records, which can hamper the identification process. First, the readability and quality of the recorded AM data in their original dental charts and their accessibility to the DVI team requires a solution that provides up-to-date accurate information at a minimally acceptable standardized format that can be readily understood by multiple nations. Second, dental codes are inconsistent across countries, and this requires manual conversion of dentists' codes into the standardized format for forensic odontologists used by DVI teams. This manual conversion process risks the introduction of human errors that can inadvertently introduce irreconcilable discrepancies that will hinder the reconciliation process.

This study proposes a Universal blockchain-based Dental record & Translator (UDenT) for multinational disaster victim identification. UDenT aims to automatically convert incompatibly formatted primary dental records into a unified dental record coded using standardized DVI codes such as those recommended by the International Criminal Police Organization (INTERPOL). In addition, it stores the converted dental records into an immutable distributed ledger on a blockchain-based architecture to be shared among worldwide DVI teams. This would allow for immediate access, at any time, in any place, of any victim's AM dental records in a readily understood universal format. UDenT's goal is to build the right ecosystem for DVI teams to identify global victims accurately and in a timely manner and, by creating this ecosystem, preserve their human rights along with their families.

#### **Dental Records, Disaster Victim Identification, Blockchain Technology**

## G20 The Identification of Skeletal Remains After Nearly Two Decades

Robert C. Walcott, DDS\*, Moraga, CA 94556

**Learning Overview:** After attending this presentation, attendees will understand the identification of skeletal remains with no antemortem records.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating key investigatory techniques to identify skeletal remains using search and rescue personnel with technicians, forensic odontology, anthropological human Identification (ID) laboratory, the Missing and Unidentified Persons Unit of the Department of Justice (MUPS of DOJ), news publications, DOJ DNA laboratory, and the Federal Bureau of Investigation (FBI) Combined DNA Index System (CODIS) DNA database profiles.

On March 16, 2017, a hiker discovered a skull and remains near a seasonal creek on a secluded steep hillside near the Moraga Lafayette border in California. The hiker returned to the area with Moraga police, field officers, and Contra Costa Sheriffs, including technicians equipped with dogs and metal detectors. Global Positioning System (GPS) coordinates were recorded at the site. The remains were documented at the coroner's office for determination of cause of death and identification. This office requested a forensic odontology examination. The skull, mandible, and restorations were cleaned, and the teeth were placed in their respective sockets, including a four-unit maxillary anterior fixed bridge. The dentition was charted on the DOJ Unidentified Deceased Report. A digital radiographic survey was completed utilizing DEXIS™ software with a NOMAD™ hand-held portable unit. The radiographs and completed charting were emailed to the DOJ MUPS Section in Sacramento. A search of the dental data base did not produce a comparison.

The examination revealed that there were 21 teeth present. The four third molars, maxillary left lateral incisor, and mandibular left first bicuspid were missing antemortem. Five maxillary teeth were missing postmortem. The four mandibular incisors, the right mandibular cuspid, and right first bicuspid all exhibited trauma, which may have been peri-mortem. Four of these had extensive crown fractures, both vertical and horizontal, and the other two exhibited enamel cracks. The right anterior maxillary bone above the right first bicuspid, cuspid, and lateral was missing, possibly peri-mortem, as were these teeth. Five molars had amalgam restorations and four molars had composites. A maxillary, porcelain-to-metal, four-unit fixed bridge replaced the left lateral incisor. The left central incisor had a root canal and post present. The missing mandibular left first bicuspid was also replaced by a porcelain-to-metal three-unit fixed bridge.

Two prosthodontists, six dentists, and four experienced laboratory technicians in four local cities examined the bridges. Two bay area broadcasting stations reported on this case, the *Contra Costa Times* and local newspapers published articles asking anyone with information to contact the Moraga Police Department. The Contra Costa Dental Society's monthly newsletter with photographs and radiographs published an article asking if members could assist with records. Concurrently, the coroner sent a femur bone to the California State University Chico Human Identification Laboratory. This lab provides forensic anthropology services to assist the legal system in resolving criminal cases, missing person cases, and in providing closure to families. The skeletal analysis determined that the remains were most likely a middle-aged Caucasian male approximately 70 inches in height. Subsequently, the coroner sent a femur bone to the California DOJ Bureau of Forensic Sciences, Richmond DNA laboratory. Here, extraction and purification techniques were utilized for the analyzation of the mitochondrial DNA. This lab sent their profile to CODIS, which resulted in a hit. CODIS sent this DNA type profile back to the Richmond DNA lab to be reviewed and confirmed. This positive identification was sent to DOJ MUPS, Contra Costa coroner, and the Moraga Police Department.

The identified was Richard Allen Saimons, who was reported to the Lafayette Police Department as a missing person on August 2, 1998. Saimons had lived in Lafayette and left his home on that day but never returned. He was 37 years old. On July 18, 2017, his parents were notified by the Moraga Police Department.

This case study demonstrates the application of several key techniques to identify skeletonized remains without antemortem records.

### Skeletonized, Techniques, Identification

### **G21 The Odontologist Relationship With Medicolegal Death Investigators in the Setting of the Medical Examiner's Office and Their Role in Obtaining Antemortem Dental Records for Identification**

*Christen C. Eggers, MS\*, Phoenix, AZ 85007; John A. Piakis, DDS, Forensic Science Center, Phoenix, AZ 85007; Leigh-Ann Schuerman, DMD, Cave Creek, AZ 85327*

**Learning Overview:** After attending this presentation, attendees will have an understanding of the importance of identification coordination and the process of obtaining antemortem dental records for comparison to postmortem radiographs for scientific identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a comprehensive overview of identification policies and protocols that can be accepted by other medical examiner offices.

The Maricopa County Medical Examiner's Office is located in Phoenix, AZ. The jurisdiction for the medical examiner's office covers more than 9,200 square miles with a population of 4.3 million people. Maricopa County is the fourth-largest and fastest-growing county, in population, in the United States. In 2018, this office received more than 10,000 reported deaths. The high case load is due to extreme heat, vast desert area, being a border state, large transient population, and winter visitors.

With nearly 700 unidentified cases admitted each year, this office implemented a comprehensive identification policy to ensure the validity of the identifications. Due to the large amount of identification cases, this office has an identification team that consists of the Identification Coordinator/Sr. Medicolegal Death Investigator, Investigator Trainer/Sr. Medicolegal Death Investigator, scene/field Medicolegal Death Investigator, odontologist, anthropologist, and advanced fingerprint technicians. The identification policy is three-fold: the decedent is either admitted as identified, as a.k.a. (tentative identification), or unidentified. The Identification Coordinator or designee assesses each case and will request an odontology consultation for cases in need of postmortem dental examinations. The consultation request is predicated by the scene investigation information. While at the scene, the Medicolegal Death Investigators attempt to locate dental information such as dental appointment cards, medications prescribed by dentists, and even toothbrushes that have a dentist's name. The Identification Coordinator or designee will subpoena the dental radiographs and written records. This is usually done with ease, but complications do occur, such as the dental office not being willing to release their records. Outreach to consular offices is essential and has been successful in obtaining dental study models and records from other countries. Additionally, there has been great success achieved by reaching out to the Arizona State Dental Association for assistance on cases that have no known dental information.

It is policy that a full mouth series of dental radiographs and dental charting is completed on all dental consultation requests. For the past five years, the odontologist has completed more than 200 cases per year. This consists of predominately identification cases, but also age estimation and bitemark cases. This office converted from conventional dental film to digital radiography approximately ten years ago and it has been highly efficient in identification cases. The image software in addition to the hand-held radiation source has been very cost effective for this county. The images are captured on a laptop, then downloaded to the county medical examiner's database. A written dental chart and an odontogram is created and also downloaded to the database.

Upon receiving the antemortem dental records, a dental identification can be made. Once the identification is completed, a formal dental report is sent to the assigned medical examiner and this report, in addition to the antemortem records, are also downloaded to the medical examiner's database. If a case remains as unidentified, these dental records are added to a local database and national database that can be compared to missing persons.

This presentation will showcase study examples of the policy in contacting private practice dentists and obtaining antemortem dental records. The presentation will also show the collaborative effort with the Arizona State Dental Association and consular offices of Mexico and Central America. The importance of having a comprehensive identification policy can be used as a guideline by other medical examiner's offices.

---

#### **Dental Identification, Identification Coordinator, Medical Examiner's Office**

## G22 The Performance of Forensic Craniofacial Identification in Surgically Altered Faces

*Petra Urbanová, PhD\**, Masaryk University, Brno 611 37, CZECH REPUBLIC; *Hana Eliasova, PhD*, Prague 170 89, CZECH REPUBLIC; *Tatjana Dostalova, MD, PhD*, Motol University Hospital, Prague 150 06, CZECH REPUBLIC

**Learning Overview:** After attending this presentation, attendees will be acquainted with the basic principles of forensic craniofacial identification and its technical and methodological shortcomings when applied to persons whose craniofacial region was altered in the course of a maxillofacial surgical treatment. Attendees will be presented with performance rates acquired using a sizeable study sample.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an insight into state-of-the-art forensic craniofacial identification and its pitfalls related to the processing of surgically altered faces.

Forensic craniofacial identification is a set of techniques that allows forensic practitioners to establish a person's identity by comparing morphological characteristics of facial features in an unknown person (e.g., victim, perpetrator, or witness) with the physical appearance of a target or an array of candidates. Identification can be conducted in real time or off-line, based on various visual recordings via image processing (e.g., photographs, surveillance videos, medical images, etc.). Generally, image identification requires a trained professional who examines identity-coding facial features or runs computer-aided algorithms. There are fundamental differences between expert-based and computer-based image identification procedures. However, in both cases, forensic identification is known to be highly dependent on a variety of technical factors (image quality and resolution) as well as other behavioral and biological determinants (aging, pose, facial expression, postmortem modifications). Recently, surgical facial alterations performed for esthetical or other purposes (e.g., functional, trauma-related) at lower costs have become very abundant and emerged as a new covariate of craniofacial processing. However, to date there has been little scientific evidence specifying practical consequences of such artificial interventions in forensics.

The present study explores the effect of maxillofacial surgeries in forensic craniofacial identification. The tested sample consisted of 50 individuals of European ancestry aged between 17 and 44 years (average of 22.6 years) who underwent a maxillofacial surgical procedure. For each individual, pre- and post-operative image were acquired using a Cone Beam Computed Tomography (CBCT) unit and a 3D stereophotogrammetry device (Vectra M3). In addition, a control subset ( $N=500$ ) was sampled randomly from the FIDENTIS 3D Face Database ( $N\sim 3,000$  subjects; [www.fidentis.cz](http://www.fidentis.cz)).

Two basic quantitative matching techniques, landmark-based and surface-based, were employed. The landmark-based approach was based on 26 discrete facial points collected manually on 3D images, whereas the surface-based approach processed 3D meshes in their totality. For each tested individual, the post-op record was taken for a probe and superimposed, then compared in the one-to-many fashion against an array of targets composed of the individual's pre-op record and the control subset. A sum of squared distances between corresponding points (landmarks) and closest points (surfaces) were taken as the measures of dissimilarity.

The results expressed in terms of rank-1 identification rates, Receiver Operator Curves (ROCs), and likelihood ratios showed that the presence of surgical modifications raised challenges for the tested identification approaches. For the landmark approach, the accuracy rates ranged from 66% to 92%, depending on the combination of input points. The surface-based performance was likewise affected, falling to 64% of correctly matched pairs. The improvements in accuracy were observed once the mid-face and lower face regions were given a lower priority in the processing. However, in all tested instances, the acquired results fell short of the identification rates reported for similar types of face identification processing.

Similar to other scientific approaches in forensics, the primary concern for conclusions derived using craniofacial identification techniques is to be based on sound scientific principles. This requires questioning conditions, under which the employed techniques can yield accurate and reliable results. The purpose of this presentation is to raise awareness of the examined conditions to the forensic community.

---

### Forensic Identification, Surgical Alterations, Craniofacial Region

### G23 The Recent Identification of a World War II Canadian Soldier: A Multidisciplinary Teamwork Approach

*Melanie Dumas, DMD\**, Royal Canadian Dental Corps, Ottawa, ON K1A 0K2, CANADA; *Trenna M. Reeve, DMD\**, University of Manitoba, College of Dentistry, Winnipeg, MB R3E 0W2, CANADA; *Sarah Lockyer, PhD\**, Department of National Defence, Ottawa, ON K1A 0K2, CANADA

**Learning Overview:** After attending this presentation, attendees will better understand the skills, knowledge, and techniques involved in the identification via forensic odontology of the skeletal remains of a Canadian soldier killed in action during World War II. This presentation will also discuss the challenges encountered when using forensic odontology for historical cases within the context of war.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing the ongoing responsibility and commitment by the Canadian Armed Forces (CAF) to honor its war dead. Applying current forensic science principles to historical cases allows CAF to identify recently discovered skeletal remains of Canadian soldiers and provide their families with peace of mind that their loved ones now have a proper final resting place and a headstone with their name.

The CAF, Canadian Army Dental Corps, was established on May 13, 1915. Its time-honored tradition of operationally focused dental care, both at home and abroad, has ensured that troops, past and present, have sustained the highest level of dental fitness for virtually every military operation in peace and war. As such, the present day Royal Canadian Dental Corps (RCDC) has served overseas in both the First and Second World Wars, the Korean Conflict, and in Afghanistan, as well as during peace making, peacekeeping, humanitarian, and forensic operations.

As catastrophes are of varying degrees of magnitude, Disaster Victim Identification (DVI) resources are often rapidly exhausted. Therefore, the RCDC was called upon by the Royal Canadian Mounted Police (RCMP) to aid in the DVI for catastrophes such as the Swiss Air Flight 111 crash in 1998, the earthquake in Haiti in 2010, and the First Air Flight crash 6560 in 2011. Following these disasters, the formation of the Canadian Forces Forensic Odontology Response Team (CF FORT) was created under the Canadian Forces Expeditionary Command as part of the Humanitarian Operations and Disaster Relief Contingency Plan.

The Department of National Defence's Director of History and Heritage (DHH) also relies upon the CF FORT to aid in the identification of Canadian soldiers discovered worldwide from former battlefields. DHH was founded in 1996 and is mandated to preserve and communicate Canada's military history and foster pride in a Canadian military heritage. Canada has a legal and moral obligation to care for newly discovered remains of servicemen and women from 20<sup>th</sup>-century wars.

The Casualty Identification Program was formally established in 2007 to respond to an increasing number of discovered human remains of the more than 27,000 Canadian war dead with no known grave from the First and Second World Wars and the Korean Conflict. The program's mandate is to identify these remains, whenever possible, through historic and scientific analytical techniques, and bury these remains. When the Casualty Identification Program's investigation is successful, identified human remains are buried with a name, by their unit, and in the presence of their family. Since its inception, the Casualty Identification Program has successfully identified 31 Canadians and helped with the identification of 19 foreign nationals.

On June 7, 2019, the partial remains of Sergeant John Albert Collis, discovered in January 2017, were reunited with his grave during a Government of Canada ceremony at the Commonwealth War Graves Commission's Bretteville-sur-Laize Canadian War Cemetery commemorating the 75<sup>th</sup> anniversary of D-Day and the Battle of Normandy. Sergeant Collis's immense sacrifice was recognized with his grandson, nephews, and other family members in attendance. Veterans from the Second World War, the Commander of the Canadian Army, as well as Canadian and local French dignitaries were also present to witness the interment. This positive outcome was made possible due to the strong collaborative commitment of CF FORT and the Casualty Identification Program.

#### Canada, Soldiers, Honor

## G24 Automated Identification From Dental Data (AutoIDD): A New Development in Digital Forensics

Gowri V. Reesu\*, University of Dundee-Level 8, PhD Hub-1, Dundee, Scotland DD1 4HR, UNITED KINGDOM; Brenainn D. Woodsend, BS, University of Dundee, Dundee, Angus DD1 4HN, UNITED KINGDOM; Scheila Manica, PhD, University of Dundee, Dundee, UNITED KINGDOM; Gavin F. Revie, PhD, University of Dundee School of Dentistry, Dundee, Scotland, UNITED KINGDOM; Peter A. Mossey, PhD, University of Dundee School of Dentistry, Dundee DD1 4HR, UNITED KINGDOM; Nathan L. Brown, PhD, Dundee University, Scotland, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand new developments in the automation of forensic identification using 3D dental images and will appreciate the functionality of this automatic program in identifying significant changes in an individual's dentition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring a novel identification system in dentistry and its application in the field of forensic dental identification and how this supports further research in the field.

**Background:** Various techniques have been proposed for automating the identification process using dental records. The use of 3D dental images has widely expanded in recent years. An efficient automatic identification program would enhance the identification process. This study proposes a novel technique to assist the forensic expert in identifying deceased individuals using an automated system, provided Antemortem (AM) records are available. This has been implemented in a newly developed AutoIDD.

**Goal:** To design a new method in Digital Forensics for accurate identification by comparing 3D dental models.

**Materials and Methods:** A new automated software was designed that uses a combination of techniques, including Iterative Closest Point (ICP) and Principal Component Analysis (PCA) for accurate identification using 3D images.

The total study sample consisted of 240 3D maxillary and mandibular dental data. The data was divided into two groups: Group A ( $n=120$ ) and Group B ( $n=120$ ).

Group A was composed of 3D-scanned orthodontic patient models from the Dundee Dental School (30 maxillary and 30 mandibular). This data was considered as AM digital data. To generate an identical sample, the dental casts of the same patients were retrieved and laser scanned to create indirect 3D dental models and considered as Postmortem (PM) digital data. This was to test the software for correct identification of all identical 3D models which validates the function of AutoIDD.

Group B consisted of 120 Intra-Oral Scans (IOS). To reconstruct a dental identification scenario, 30 maxillary and 30 mandibular IOS were obtained from 30 volunteers in the dental school and were considered as IOS-AM. After a year's interval, another 30 maxillary and 30 mandibular IOS were acquired from the same volunteers and considered as IOS-PM. This was to determine the sensitivity of AutoIDD toward any variations in an individual's dentition.

This study hypothesizes an accurate dental identification can be facilitated through the use of AutoIDD. The identification process is based on shape and alignment of the 3D dental arches, which can comprise a unique set.

A user-interface was designed to import digital dental data into Reference section (AM) and Unknown section (PM), which allows the operator to align the entire datasets to produce results—match percentage and mean distances.

**Results:** Group A Data: 30 AM and 30 PM maxillary 3D models were aligned followed by 30 AM and 30 PM mandibular 3D models. The results indicate that the system is able to correctly distinguish the matching models from the non-matches. In both the experimental studies, 100% matching results were produced.

Group B data: 30 AM and 30 PM maxillary IOS were aligned, followed by 30 AM and 30 PM mandibular IOS. The results indicate that the AutoIDD was able to accurately identify the matching AM-PM IOS from the non-matches. The match percentage ranged from 64% to 100% with a mean of 95.5% for maxillary scans and 87% to 100% with a mean of 96.5% for mandibular scans.

In summary, AutoIDD was able to demonstrate the identification of correct matches with a match percentage that clearly differentiates the matches from non-matches. This system also enables recognition of the changes in the human dentition, such as restorations and missing teeth. The match percentage is a combination of the best fit alignment and the changes identified by the system. A low match percentage may also infer that there has been significant changes to that individual's dentition, usually due to dental or orthodontic intervention.

This study presents a novel method for automatic human dental identification using 3D images and the performance of this software using digital dental data.

### Automatic Dental Identification, 3D Models, Intra-Oral Scans

### G25 Helpful Hints for a Variety of Dental Autopsy Situations and a Compilation of “Interesting” Cases

*Veronique F. Delattre, DDS\*, University of Texas School of Dentistry, Houston, TX 77054*

**Learning Overview:** After attending this presentation, attendees will have viewed a number of forensic dental identification cases, have a better understanding of methods to manage a variety of dental autopsy situations, and have viewed a selection of interesting cases. Helpful hints and methods indicated for a wide variety of dental autopsy situations, body conditions, and dental evidence will be presented through a storytelling format. Additionally, a compilation of “interesting” cases will be presented to demonstrate the types of cases a forensic dentist may be asked to consult on, and knowledge to help make the decision on whether or not to accept each “interesting” case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information that will help provide budding forensic dentists with tools to aid their community by enhancing their readiness to serve as a consultant in dental identification cases.

The dental autopsy cases to be presented will also demonstrate the variety of “Degrees of Certainty” in dental identification cases. Positive Identification cases will be presented in which the antemortem and postmortem data match in sufficient detail to establish that they are from the same individual, within a reasonable dental probability, and there are no irreconcilable discrepancies. Insufficient Evidence cases will be viewed in which the available information, antemortem or postmortem, is insufficient to form the basis for a conclusion. Unidentified cases will be presented that demonstrate that, in some instances, there is no antemortem evidence or insufficient evidence to perform a dental comparison. Exclusion cases will demonstrate that, at times, the antemortem and postmortem data are clearly inconsistent.

Medical examiner and coroner offices often request the expertise of a forensic dental consultant to achieve the positive scientific identification that is necessary for the issuance of a death certificate. The death certificate in turn facilitates the funeral arrangements, burial or cremation of the individual, life insurance benefits, social security benefits, disposition of instructions in the decedent’s last will and testament, and matters of inheritance.

This presentation will prepare those who are in the early stages of experiencing or performing actual dental autopsies with information about situations they may encounter. Attendees will learn processes to facilitate their success as Forensic Dental Consultants. Additionally addressed during the session will be the topics of professionalism and collegiality with other forensic professionals interacted with on dental identification cases, as appropriate for the cases presented during the session.

Some of the topics to be addressed include: the recently deceased, skeletal remains, charred remains, incinerated remains, mangled remains, beaten remains, blunt force trauma remains, gunshot-to-the-head remains, decomposing remains, fragmented remains, dental evidence found at the scene that could belong to either the assailant or the victim, dental identification issues in removable prosthetics, and orthodontic evidence.

---

#### **Forensic Science, Forensic Odontology, Dental Identification**

### G26 A Dental Malpractice Case Involving a Potentially Broken Dental Bur

*Cheri Lewis, DDS\*, Beverly Hills, CA 90211-3106*

---

**Learning Overview:** After attending this session, attendees will have reviewed organizational requirements for an expert witness in a malpractice case. Additionally, attendees will have reviewed skills required for preparation of both depositions and expert trial testimony. Attendees will be learning a systematic approach for preparing materials in a malpractice case. Included will be preparation for a deposition and/or trial, as well as how and when a research project can assist in this preparation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reviewing the need for a detailed review of materials provided by attorneys, checking for disparities in records, and the potential use of research projects to validate opinions to be presented in both deposition and trial testimony.

This case review of a dental malpractice lawsuit involves an aspirated dental bur. The case was sent for review based on a paralegal's internet search related to aspiration cases. Guidelines for evaluation of the case will be reviewed, including, but not limited, to the information provided by the attorney. The original information provided included the patient's age and health status. Records requested and later obtained included dental radiographs of the patient along with defendant dentist treatment notes. Hospital records were ultimately provided in addition to a photograph of an aspirated surgical dental bur adjacent a ruler. The photograph provided of the aspirated dental bur was compared to the measurements of a new surgical dental bur.

The dental radiographs, in addition to the defendant dentist records, will be discussed, as will alternate treatments that legally should have been presented to the patient. The technique utilized to review the dental records from the defendant dentist, including his radiographs, his depositions, and hospital records, will be discussed. Inconsistencies within the records provided will be brought forth. Safety measures that were available and should have been provided to protect the patient's airway from the aspiration of the dental bur will be discussed.

Ultimately, a research project was conducted to clarify the standard of care among oral surgeons regarding patient protection against aspiration of foreign objects during surgical dental extraction procedures. The technique for setting up this research project will be reviewed, and the findings and value will be discussed. Preparation for expert depositions will be reviewed, including disclosures of exhibits required. The need to provide all exhibits at the time of the deposition will be reviewed.

Also discussed will be the need for the expert to review the case with the plaintiff attorney, the expert's responsibility for assisting in setting forth questions for the plaintiff attorney, the type of questions that should be provided for the plaintiff attorney to be used with the defendant dentist and his experts at the time of their depositions and later in the courtroom, and questions relating to the standard of care for oral surgeons providing surgical extractions and the requirements of a general dentist to adhere to the same standards.

#### **Malpractice, Dental, Research**

## G27 Thresholding Adulthood: What Are We Doing?

James F. Goodrich, FFOMP\*, Cambridge, Waikato 3496, NEW ZEALAND

**Learning Overview:** The goal of this presentation is to describe the current application of dental age estimation procedures with respect to thresholding adulthood in many parts of the world and provide estimates of the number of errors made. The forensic odontologist engaged in providing opinion to any authority around thresholding adulthood should be aware of the limitations of the science that they employ and the implications to the individual concerned.

**Impact on the Forensic Science Community:** The role of forensic scientists in advising policy makers is important to the outcome of the application of that branch of science. If mistakes are being made in the area of thresholding of adulthood, solutions need to be discussed and efforts made to reduce or eliminate those mistakes. This presentation will impact the forensic science community by informing attendees of some of the challenges faced in this area of science, and some possible solutions to help them maintain a role as a responsible forensic practitioner.

The idea of an age at which adulthood is reached is a common notion worldwide. This chronological marker varies, and has different implications, in different parts of the world. This threshold age of adulthood is almost invariably an inflexible and meaningful border between being a child and being considered by the law, as well as by society, as an adult. The threshold age itself may well be viewed as an arbitrary value, given the variability in human maturation, but it is nonetheless a strict and binary judge between childhood and adulthood. It is a breach of the human rights of any child to be treated under the law incorrectly as an adult.

In many cases, the chronological age of an individual is not known. In such cases, the law often requires an age to be ascribed to these individuals, along with the rights and responsibilities of that age group. This process often occurs when undocumented people are crossing borders. Many methods have been employed to aid with this determination of age, all of which are based on a system of estimation.

Dental maturity is widely regarded as one of the most reliable indicators of chronological age estimation.<sup>1</sup> Unfortunately, the accuracy of dental age estimation varies with the age and stage of the individual concerned. As a general rule, dental aging methods tend to be more accurate the younger the individual in question is, and thresholding adulthood, if that age is 18 years, is difficult.

Dental age estimation around 18 years of age tends to rely on the development of the third molar teeth. Famously, in 1993 Harry Mincer et al. published the results of a study of 823 individuals and he found that "... the association between chronological age and the formation of the third molar is, at best, moderate," and that with intermediate indicators only, he described it as a "coin-toss" if the individual had reached 18 years of age.<sup>2</sup> Since that time, many researchers have strived to improve on our ability to reliably threshold a given individual as an 18-year-old using dental maturation.

Forensic odontologists have a responsibility to examine the methods they are using, and how the information that they are providing is being used. As a group, we should always be considering our role in any forum for which we provide information. In this case, the question that may need to be discussed is "despite us being the best at age estimation around thresholding adulthood, what level of inaccuracy is acceptable to us before we shouldn't be doing it at all?" The justification that we are not the judge, and we are simply supplying information to a decision maker, may or may not be ethically satisfying.

Simply put, despite best intentions and skillful application of the known science, because of the limitations of our current methods, forensic odontologists may be involved in a process that sometimes wrongly thresholds a child as an adult and visa versa.

Our role as forensic odontologists also includes educating policy makers around the functional application of our science. If there is a problem with the way our expert opinion is being used, then we should be actively engaged in providing a solution.

## G28 Method Differences, Population Differences, or Examiner Differences: Which Affects the Age Estimation the Most?

Sakher J. AlQahtani, PhD\*, College of Dentistry, Riyadh 11545, SAUDI ARABIA

**Learning Overview:** After attending this presentation, attendees will be able to take a more critical look at the concepts of accuracy and precision as they relate to dental age estimation. In addition, attendees will be able to understand that method selection, utilization of population-specific databases, and failure to calibrate examiners have different effects on the accuracy in reporting of age estimation interval.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of not only applying the correct testing methodology on dental age assessment technique, but this presentation will also encourage the community to take a more critical look at comparing the effects of examiner calibration versus the use of population-specific databases in the reporting of an accurate age estimation interval.

Although dental age assessment methodologies have been extensively researched, tested on different populations, and modified throughout the years, there is still contradictory evidence as to what are the key parameters to consider when selecting the appropriate reference database to use on an individual case. One area of concern is that there is a belief that there are significant differences between different geographic and ancestral populations, and it is critical that population-specific databases be utilized by age assessment techniques. In the past, differences expressed by researchers between test groups have universally been interpreted as proof that population differences exist. Unfortunately, most researchers have failed to look critically at the possibility that other factors, such as examiner calibration and bias, and not population or sex differences, may have had a greater influence on these differences.

The goal of this study was to compare the interpretation of results and particularly differences between three dental age estimation methods, Moorrees, Fanning, and Hunt's stages of dental development, Demirjian's dental development scores, and the London Atlas of Human Tooth Development and Eruption, to determine the sources of variances when taking into account subjectivity and user bias.<sup>1-3</sup> An additional goal was to take a more critical look at the concepts of accuracy and precision as they relate to dental age estimation when a technique is tested.

**Conclusion:** Differences in most published research between dental age techniques and population differences actually falsely attribute these differences to population variance when they should be attributed to the testing methodology of that technique. Measures of performance, study design, and reporting of results when a technique of dental age assessment is being tested need to be revised, especially when measuring population variance.

### Dental Age Estimation, Accuracy, Population Variance

## G29 Forensic Age Estimation Based on the London Atlas of Human Tooth Development and Eruption Assessment in a Population With Systemic Disorders: A Pilot Study

*Cristiana M.P. Pereira, PhD\*, Department of Pharmacology and Therapeutics, Lisboa 1649-003, PORTUGAL; Lucianna P. Russell, MD, Rua Professora Teresa Ambrósio, Lisboa 1600-277, PORTUGAL; Maria Pádua, DDS, University of Ribeirão Preto, Ribeirão Preto, BRAZIL; Ricardo H.A. Silva, PhD, University of Sao Paulo, School of Dentistry of Ribeirao Preto, Ribeirao Preto, Sao Paulo 14040-904, BRAZIL; Rui Filipe Vargas de Sousa Santos, PhD, School of Technology and Management, Leiria, PORTUGAL*

**Learning Overview:** After attending this presentation, attendees will understand why using the London Atlas of Human Tooth Development and Eruption on panoramic radiographs is of limited value for age estimation in children and subadults with special needs, such as with systemic disorders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing why using the London Atlas is of limited value for age estimation in a special needs population, for example, those with systemic disorders.

**Introduction:** The forensic estimation of chronological age has played an increasingly important role, not only in the identification of human remains, but also in living individuals due to the phenomenon of immigration and sexual abuse of undocumented trafficked children.

**Goal:** The goal of this research was to validate the use of the London Atlas, an atlas already used in the normal population, in estimating chronological age in a population with special needs and/or with systemic disorders.

**Materials and Methods:** A sample of 163 orthopantomograms from two independent medical institutions were collected from 133 patients, between 4 and 23 years of age, with systemic disorders in the appointment of patients with special needs. The orthopantomograms were divided into two groups, 95 from patients with systemic pathologies that have repercussions on dental development and 68 with systemic pathologies without dental repercussions. Dental ages were estimated by the London Atlas using the left side, then independently using the right side of the maxilla. The intra- and inter-observer agreements were evaluated. The difference between the dental age estimates and the chronological age and its absolute value were computed and analyzed.

**Results/Discussion:** Statistically significant differences were obtained between estimates and chronological age, revealing a general prevalence for underestimation; except for ages less than 12 years. Nevertheless, the underestimation in individuals less than 16 years of age was not significant (with an average of less than one month), while the underestimation was quite significant for patients at least 16 years of age (with an average over 26 months). Furthermore, for those patients with systemic diseases with dental repercussions, a greater error in underestimation was obtained, which indicates that the midpoint values should be reassessed in patients with Down's syndrome, chromosomal alterations, syndromes, and central nervous system disorders.

**Conclusions:** Hence, this Atlas can be potentially used as a tool for age estimation, but we suggest further studies with larger samples to create adequate atlases for all the required scenarios, in particular, diagrams for patients with special needs development who are more than 12 years old and, specifically, for those more than 16 years of age.

---

### Forensic Age Estimation, London Atlas, Systemic Disorders

## G30 Dental Age and Odds Probability at the 18-Year Threshold

Graham J. Roberts, MDS\*, King's College London, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, London SE1 9RT, UNITED KINGDOM; Fiona Warburton, MS, King's College London, London SE1 9RT, UNITED KINGDOM; Victoria S. Lucas, PhD\*, King's College London Dental Institute, London SE1 9RT, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand different strategies for presenting data in forensic age estimation reports based on expert witness reports in the United Kingdom Immigration Court in relation to the 18-year threshold.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how the former legal threshold of Preponderance of the Evidence (which in Europe is referred to as "Balance of Probability" (> or < 50%)) has transmogrified into 100% Certainty as the level of proof. The Minimum Value Threshold (beyond reasonable doubt) is the level of proof recommended in Europe as promoted by the European Commission.<sup>1</sup>

**Issues for Consideration:** Use of teeth as an indicator of age is the most reliable method for estimating chronological age using human biological growth markers based on Normal distribution summary statistics.<sup>2</sup> Arising from this is Simple Probability (SP), which provides a neat technique to estimating the probability that a subject is more than 18 years of age.<sup>3</sup>

There are four possible approaches to expressing uncertainty in relation to the 18-year threshold and the lower left third molar.

Simple probability—this requires the full raw dataset.<sup>4</sup> Results for over 18 years old are: United Kingdom-Whites,  $p=0.7920$ ; Iran,  $p=0.9483$ ; and for Southern Chinese,  $p=0.9991$ .

Odds—this also requires the full raw dataset.<sup>5</sup> *Specificity* and *Sensitivity* are calculated. This enables estimation of the Odds. In this context, the Odds of a subject with a mature 3<sup>rd</sup> molar for United Kingdom subjects is (approximately) 1:4; for Iranian subjects, 9,483:1; and for Southern Chinese subjects, the Odds are 9,991:1.

Likelihood Ratio (LR)—this also requires the full raw dataset.<sup>6</sup> For United Kingdom subjects, this is given by  $0.792/0.208=3.82$ . This is weak support for the view that the subject is more than 18 years old. For Iranian subjects, the LR is given by  $0.9483/0.0517$ , which gives the LR as 18.34. This is moderate evidence to support the contention that an Iranian subject is more than 18 years old. For Southern Chinese subjects, the LR is given by  $0.9991/0.0009$ , which is 1110.1. This is compelling evidence that a Southern Chinese subject with a mature 3<sup>rd</sup> molar is more than 18 years of age.

Minimum Threshold Value (MTV)—this comes from European Commission Guidelines.<sup>1,7</sup> It is a robust marker for age and provides a 100% probability that a subject is below the minimum age of the Tooth Development Stage used for assessment. The MTV has the advantage that values from summary statistics in published papers can be used to make the assessments. It is not necessary to have access to the raw data.

**Concluding Remarks:** The MTV is an unambiguous technique for indicating whether or not a subject is under (or over) the 18-year threshold.

### Dental Age Estimation, Minimum Threshold Value, Odds Values and Likelihood Ratio

## G31 Calculating the Standard Deviation: An Innovative Approach for Utilizing Historical Databases

Sakher J. AlQahtani, PhD\*, College of Dentistry, Riyadh 11545, SAUDI ARABIA; Kenneth W. Aschheim, DDS\*, New York, NY 10065

**Learning Overview:** After attending this presentation, attendees will understand how a new, proposed method in the calculation of standard deviation combining historical databases with modern populations' databases in the reporting of a dental age assessment can greatly improve the reporting of the age interval.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and legal community by improving the accuracy of dental age assessment techniques by combining traditional methods of calculating an age estimation interval using a new, proposed method. A step-by-step process of calculating standard deviation using three different methodologies will be detailed.

Age estimation remains one of the more complicated and difficult aspects of the human biological profile to assess. In addition, when used on living individuals, a dental age assessment has the potential to greatly affect their future and, if done improperly, can potentially violate their human rights. Given the risk involved with flawed reporting, concerns raised over the accuracy of the age estimation interval are justifiable, and scrutiny over its reporting understandable. Finding the most accurate method of calculating the standard deviation for a dental age assessment technique is essential to allow for a precise range calculation, and that the technique will apply an appropriate age interval to an individual. The calculation of a standard deviation is particularly complicated because not only there is variability in the historic dental developmental tables but variability in the rate of development of each of an individual's tooth buds as well. Numerous factors have been hypothesized to influence the rate of dental tooth bud development; however, for many of these factors, there has been no appropriate studies to verify that the effect and, if it exists, its magnitude.

Because of the complexity of these calculations as well as the lack of consensus on calculating of the standard deviation, many dental age estimation techniques, each with its own standard deviation calculation methodology, exist. In this study, different traditional methodologies of calculating a standard deviation, as well as a new innovative approach utilizing both a traditional database as well as a secondary population-specific database, was tested on a Saudi population using three dental age estimation techniques: Moorrees, Fanning, and Hunt's stages, Cameriere's open apices formula, and the London Atlas of tooth development.<sup>1-3</sup> A step-by-step process of calculating standard deviation using these different methodologies will be detailed, and the test results will be explained.

### Dental Age Estimation, Accuracy, Standard Deviation

## G32 Third Molar Development in Caucasian and Chinese Populations and Its Implication in Dental Age Estimation

Jayakumar Jayaraman, PhD\*, University of Texas Health School of Dentistry, San Antonio, TX 78240; Graham J. Roberts, MDS, King's College London, London SE1 9RT, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will be able to appreciate the variations observed in the development of third molars between two distinct ethnic populations. This will be presented in the form of a research study that sought to compare each stage of development of third molars in a large sample of Caucasian and Chinese populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of ethnic variations in the development of third molars. Attendees will learn how these variations could influence the accuracy of estimated age, particularly in the 18-year-old threshold.

Evaluation of dental development is useful in forensic dentistry to estimate the age of subjects without authentic birth documentation or those involved in falsified age claims. The 18-year-old threshold is important in forensic age estimation as in most countries, this age differentiates child from an adult. For this purpose, investigators rely on the development of third molars as they are the most reliable teeth for age estimation at this threshold. Variation in dental maturation has been shown in ethnically different populations.

This study aimed to evaluate the dental development of third molars in Caucasian and Chinese populations. Dental panoramic radiographs of 1,670 subjects constituting 898 females and 772 males aged 14 to 23 years were obtained from the archives of teaching hospitals in London and Hong Kong representing Caucasian and Chinese populations, respectively. The maxillary and mandibular right third molars were scored according to Demirjian's classification for the root development stages (E to H). The number (n), mean age ( $\bar{x}$ ), and Standard Deviation (SD) of the mean age was derived for each tooth development stage for females and males separately in both populations. Statistical significance was set at  $p < 0.05$  and an independent sample  $t$ -test was used to compare the mean age for each stage of development between the Caucasian and Chinese populations. In all the stages, the Caucasians were more dentally advanced than the Chinese. The mean age difference between Chinese and Caucasian females ranged from 1.18 years to 3.50 years, and in males it ranged from 0.63 years to 2.71 years ( $p < 0.05$ ). It is concluded that the Caucasian subjects demonstrated significantly advanced dental maturation of both maxillary and mandibular third molars in both sexes compared to the Chinese subjects and this emphasises the utilization of appropriate population-specific data for age estimation.

### Third Molar, Dental Maturity, Age Estimation

## G33 Minimum Values for Mandibular Maturity Markers

Victoria S. Lucas, PhD\*, King's College London Dental Institute, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, London SE1 9RT, UNITED KINGDOM; Graham J. Roberts, MDS, King's College London, London SE1 9RT, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand that for clinical dental age estimation in Europe, there is a prevailing view that only the minimum value of age at assessment reference data is the legally acceptable threshold in Europe. This applies at all ages, but particularly at the 18-year threshold.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that for the European Union, the legal burden of proof is 100% certainty for determining whether or not a subject is below or above 18 years of age. This has considerable impact because in the United Kingdom and European Courts, the civil burden of proof of "greater or less than 50%" no longer applies. In the United States, this is called the "preponderance of the evidence."

**Introduction:** The use of human biological growth markers to help estimate chronological age has undergone a shift from the use of normal distribution statistics with the "preponderance of the evidence" to the rigorous use of age marker-based assessment criteria using the minimum value (0th%ile) of an age marker as the criterion.<sup>1,2</sup> The purpose of this report is to review published data to determine if the variability of the age at assessment for the minimum value of Root Pulp Visibility (RPV) discriminates between <18 years and >18 years.

**Materials and Methods:** The data used as the starting point are from a previously presented paper.<sup>3</sup>

The summary statistics for males only in decimal years are shown in Table 1.

	n-tds	$\bar{x}$ -tds	sd-tds	Minimum	25th%ile-	50th%ile	75%ile	Maximum
RPV-Am	213	21.27	2.05	17.16	19.67	20.91	22.80	25.49
RPV-Bm	272	22.61	2.15	17.71	21.06	22.77	24.38	25.93
RPV-Cm	66	23.34	1.98	18.16	22.13	23.76	25.05	25.96
RPV-Dm	9	23.46	1.67	20.19	22.41	23.47	24.87	25.19

It can be seen that the minimum values for RPV-Am and RPV-Bm are below the 18 year threshold whereas the minimum values for RPV-Cm and RPV-Dm are above the 18 year threshold.

This is offered as compelling evidence that the mandibular maturity marker of RPV discriminates between a juvenile and an adult.

This was rejected by the United Kingdom Court of Immigration as it was "too novel" and needed confirmation from other studies. Further support has been provided by studies in Germany-2, Portugal, Western China, the United Kingdom, and Malta.

**Results:** The minimum values for RPV-Cm and RPV-Dm for the seven countries are shown in Table 2 (decimal years).

Stage	Germany -1	Portugal	United Kingdom	Germany-2	Northern China	Malta
RPV-Cm	24.70	18.80	18.58	22.10	24.68	18.23
RPV-Dm	25.20	21.20	22.45	25.10	27.66	23.99

**Discussion:** These multi-ethnic data from several disparate countries, but using the same methods, provide similar results. All the studies provide satisfactory assessments of between assessor and within assessor performance.

**Conclusion:** RPV stages C and D at the minimum value demonstrates the validity of using this age-related growth marker to determine in legal terms whether a subject is a juvenile or an adult.

### Mandibular Maturity Markers, Root Pulp Visibility, Minimum Age Threshold

## G34 Demirjian 2.0

*Corinne D'Anjou, DMD\*, Saint-Lambert, PQ J4P 1Y2, CANADA; Derek M. Draft, DDS\*, Grandville, MI 49418; Arto Demirjian, DMD, Outremont, QC H2V 3A1, CANADA; Sigrid I. Kvaal, Institute of Clinical Odontology, Oslo 0317, NORWAY; Normand Bach, DMD, Faculté de Médecine Dentaire, Université de Montr, Montreal, PQ H3C 3J7, CANADA*

**Learning Overview:** After attending this presentation, attendees will have gained a basic understanding of the historical significance of the original Demirjian dental age estimation studies and their impact on current dental age estimation cases routinely performed by forensic odontologists. Attendees will also learn about the current status of the historical Demirjian data collection and its availability for future research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reviewing the significance of the historical Demirjian dental age estimation studies and discussing the limitations of the original study and calculations and how the original data will be managed and utilized in new modern studies.

The forensic odontologist is often called upon by agencies to estimate the age of both living and deceased individuals. The forensic odontologist often applies published studies that provide a method to analyze the dentition of an individual as well as a mathematical formula and/or a table of reference data to calculate the estimated age.

Some of the more significant historical studies for dental age estimation were conducted by Demirjian, et. al, in the 1970s. Dr. Demirjian conducted several longitudinal studies of children and adolescents over the span of 20 years utilizing dental models and radiographs of the developing dentition along with radiographs of the hand and wrist. Their data was published in several studies, which set the standard for future age estimations cases.

One of the major critiques of the original study as used for dental age estimation was the calculation and utilization of a maturity score index. The method of calculation has never been fully understood and in practical use was found to consistently underestimate the age of the studied individual. Another critique is the reporting of the age interval in a graphical format in percentiles making it difficult to accurately report the age and associated interval. The current common accepted method of reporting the age interval is in standard deviations.

With Dr. Arto Demirjian's assistance, the archives of the original data have been located. Dr. Demirjian has graciously made the original data available through the University of Montreal. The data is currently being digitized, and it is the intention of the University of Montreal to make the data available to qualified researchers for future studies.

This study in conjunction with the University of Montreal also intends to redo the original studies and provide forensic odontologists and other disciplines with a modernized study for dental age estimation cases, including standard deviations to report the age interval.

---

### Age Assessment, Demirjian, Standard Deviation

### G35 A Comparison of Dental Age Estimations From Two Radiographic Methods of Metric Analysis in North Indian Young Adults

Deeksha Sankhyan, Panjab University, Chandigarh, INDIA; Jagmahender Singh Sehrawat, PhD\*, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA

**Learning Overview:** After attending this presentation, attendees will better understand the comparison between the efficiency and accuracy of two methods for age estimation based on the same factor/principle but with different forms of measurement of the pulp chamber area. This presentation will also apprise attendees of the population-specific variations present in the reduction of the pulp chamber with age.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring the variations in the deposition of secondary dentine, believed to be genetic-based and population-specific. This would also encourage scientists to formulate a standard formula/method suitable for all populations, which is a need of the hour due to the admixture of races and globalization.

Age estimation is one of the important components of the biological profile of an individual. Numerous dental age estimation methods have been suggested by different researchers, based either on gross tooth specimens or the radiographs of the deciduous or permanent teeth, either fitted in the jaw sockets or dislodged ones. Radiological analysis is a non-invasive technique that has played a very crucial role in forensic age estimations of both living and dead individuals required for various purposes. The radiographic method has its own advantages, being less time consuming, non-destructive in nature, and providing precise estimates. Forensic age estimation is no longer limited to the identification of the dead or skeletonized remains, but has been commonly warranted by law enforcement agencies for age estimation of even living individuals in cases such as age-related frauds, crimes to avail certain social or legal benefits, etc. Teeth are the ideal evidence in most of such forensic scenarios due to their slow rate of decomposition and higher resistance to morphological or taphonomic degradations compared to other osseous parts of human body.<sup>1</sup> They are the reservoirs of biological information of the individuals, being least affected by external factors. Radiographical assessment of teeth, a non-invasive technique, further augments their significance for age evaluation in the living individuals as well.<sup>2</sup> Estimating age in children is an easier task since the development stages follow more or less a definite pattern, unlike adults, whose teeth undergo degenerative changes at a much slower rate than the formation stage and depict wide variations due to environmental, nutritional, and genetic factors.

This present study is based on radiographic quantification of the intrinsic changes occurring in the teeth in the form of deposition of secondary dentin in the pulp chamber with advancing age, thus leading to area reduction in the latter.<sup>3</sup> Such variations in pulp width is measured using two radio-metric methods, namely the Tooth Coronal Index (TCI) and Pulp Chamber Tooth Height Ratio (PCTHR). Most of the studies conducted for estimating age using these methods have indicated the need for population-specific standards for more accuracy.<sup>4,5</sup> This study proposes estimating the age of 300 adults (aged 21 to 50 years) belonging to a North Indian population, comprised of individuals belonging to Himachal Pradesh, Punjab, Haryana, and Chandigarh. No such study has been conducted on this population, per research.

The digital panoramic radiographs of the subjects were collected after their written informed consent and ethical clearance from Institutional Ethics Committee of the Government Medical College and Hospital (GMCH), Chandigarh. Collected images were analyzed using ImageJ software. The goal of the present study is to compare the validity and precision of the above-mentioned two radiographic methods in estimating the age of North Indian individuals. The preliminary results based on 102 samples indicated the error range of the TCI and PCTHR methods in age estimation as  $\pm 5$  and  $\pm 6$  years, respectively. The conclusive analysis of the present study is underway and the results and their interpretations, along with the comparative efficiency of these two dental age estimation methods, will be presented.

Sally E. Andrews, MS\*, University of Cambridge, Great Maze Pond, London SE1 9RT, UNITED KINGDOM; Graham J. Roberts, MDS, King's College London, London SE1 9RT, UNITED KINGDOM; Fraser McDonald, PhD, King's College London, London SE1 9RT, UNITED KINGDOM; Pat Set, FRCR, University of Cambridge, Cambridge CB2 0QQ; Fiona Gilbert, FRCR, University of Cambridge, Cambridge CB2 0QQ, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand that ethnic-specific reference data are essential for dental age estimation, especially around the 18-year-old threshold.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing ethnic differences in third molar development between Black British and White British subjects. The attainment of Demirjian tooth development stages in third molars occurs earlier in Black British subjects compared with White British subjects.<sup>1</sup>

The aim of the research was to test the null hypothesis that there is no ethnic difference in the timing of tooth development in Black British and White British children and young adults.

This study (IRAS Project ID 239922) is relevant because ethnic or ancestral differences in dental maturation have been inadequately studied. Data was collected from digitized Dental Panoramic Tomographs (DPTs) from the archives of a teaching hospital. This convenience sample compared dental maturation of Black British and White British ethnic groups residing in and around London. The main inclusion criterion was a self-assigned ethnicity in the hospital records. All those reporting Black ethnicity were included in the Black British group. For both Black British and White British ethnicities, a DPT for up to 50 male and 50 female subjects in half-year age bands in the age range of 11 to 24 years was examined. The current sample totals 3,675 subjects. The Anglo-Canadian eight-stage scoring system was used.<sup>1</sup> Datasets for females and males of the two ethnic groups were compared. Nearly all stages of third molars developed earlier in the Black British group compared to the White British group, the difference being greater in females. For Demirjian Stages D, E, F, and G of all four third molars, with the exception of Stage D in the right-sided third molars in females, Student's *t*-tests demonstrated a significant difference ( $p < 0.03$ ).

The table below shows results for the lower left third molar (LL8) Stages A-H<sup>1</sup> in males aged 11-24 years.

Results for lower left third molar (LL8) Stages A-H for males (Ages in decimal years)												
TDS	Black British					Difference between		White British				
	<i>n</i>	Mean	SD	Min	Max	Means	<i>p</i> value	<i>n</i>	Mean	SD	Min	Max
LL8A	0							24	12.41	1.21	11.01	15.09
LL8B	3	13.20	0.45	12.71	13.62	-0.40	0.5570	62	12.81	1.15	11.05	16.70
LL8C	30	13.09	1.19	11.61	15.69	0.37	0.1739	149	13.47	1.40	11.05	17.87
LL8D	47	13.34	1.29	11.15	16.36	1.10	0.0001	65	14.44	1.54	11.74	19.28
LL8E	65	14.38	1.52	11.44	19.53	1.45	<0.0001	131	15.83	1.78	11.50	21.57
LL8F	48	16.11	1.14	14.19	18.73	1.32	<0.0001	87	17.42	1.51	13.15	20.83
LL8G	46	17.52	1.36	14.93	20.71	1.28	<0.0001	80	18.80	1.50	15.76	23.41
LL8H	74			14.13	20.69		<0.0001	330			16.28	23.39

Ages compared using Student's *t*-test for Stages A-G and Mann Whitney Test for Stage H (censored)

Censoring the ages at 20.71 years for Black British and 23.41 years for White British (i.e., the maximum ages for LL8 at Stage G), a Mann Whitney test showed significant difference ( $p < 0.0001$ ) between the two ethnic groups for Stage H of the LL8.<sup>2</sup>

The following table shows percentages of all assessable third molars at Stages A-H in 17- and 18-year-old males, illustrating earlier development in Black British compared to White British subjects.

TDS	TDS A-H of all assessable third molars (%)			
	18-year-old males		17-year-old males	
	Black British	White British	Black British	White British
A	0	0	0	0
B	0	0	0	0
C	0	0	0	1
D	0	0	0	4
E	4	13	3	20
F	10	26	21	32
G	38	21	38	26
H	48	40	38	17
Total	100	100	100	100

In conclusion, differences between Black British and White British ethnic groups from a London population indicate that ethnically appropriate reference datasets are essential for age assessment throughout childhood and young adulthood in skeletal remains as well as the living but may be particularly important when decision-making regarding the 18-year-old threshold.

The data demonstrate that there are highly significant differences in dental development between Black and White ethnic groups in a United Kingdom population.

## G37 An Analysis of a Dental Prosthesis Technique in Korean War Casualties

*Seoum Oh\**, Ministry of National Defense Agency, Seoul 06984, SOUTH KOREA; *Hyejin Lee*, Ministry of National Defense Agency, Seoul 06984, SOUTH KOREA; *Seokdong Oh*, Ministry of National Defense Agency, Seoul 06984, SOUTH KOREA; *Kyoungmin Koh*, Ministry of National Defense Agency, Seoul 06984, SOUTH KOREA; *Yu Ryang Jang, PhD, MAKRI, Seoul 156-080, SOUTH KOREA*

**Learning Overview:** After attending this presentation, attendees will understand the differences in materials used in dental prosthetic manufacture between Korean and Chinese dentistry in the 1950s.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by employing an unusual attempt to analyze the materials used in dental prosthesis through Laser-Induced Breakdown Spectroscopy (LIBS).

During three-year Korean War (1950-1953), numerous soldiers were killed or went missing. In 2007, the Korean government established a special organization, the Ministry of National Defense Agency for KIA (Killed in Action) Recovery and Identification (MAKRI), to recover and identify the remains of unaccounted-for casualties. However, due to the fact that most of casualties are of Asian origin, determining the nationality based on the DNA haplotype is sometimes very challenging. Therefore, various studies have been attempted to overcome those limitations. Analysis of prosthetic materials by nation is one of those efforts. In addition, due to the lack of previous studies, it was important to compare the results and accumulate a database.

The 35 dental remains with dental prosthesis, determined to be those of Korean and Chinese service members from the Korean War collected at the MAKRI Central Identification Laboratory (CIL) during the period from 2015 to June 2019, were assessed. All samples were analyzed using LIBS equipment to contrast atomic emission peak results by nation and prosthesis type.

In the results of LIBS, it was observed that metal crowns confirmed specific atomic emissions, such as Al, Mg, Zn, Fe, and Cu, in Korean and Chinese prosthesis. All silver-colored crowns were confirmed to contain specific atomic emissions, such as Ni, Al, Cu, Ag, Cu. Furthermore, it was observed that there were similar spectral peak values on Ni, Au and Ag. However, silver-colored crowns were not observed among the Chinese dental remains. It seems that this dental technique is not shared in both countries. This study indicates that the results of dental prosthesis comparison has considerable utility in cases of the same Asian ancestry in which is difficult to estimate the ancestry.

In conclusion, Korea's dental technique was very similar to the Chinese dental technique, such as full-coverage crowns and full-coverage crowns with a cantilever pontic, but was not similar as regards silver-colored crowns at the time of Korean War.

### Korean War, Nationality Determination, Dental Restoration

### G38 The Advantages and Limitations of Various Dental Age Estimation Methods in Forensic Odontology: A Systematic Review

*Jagmahender Singh Sehwat, PhD\*, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA*

**Learning Overview:** After attending this presentation, attendees will be informed about the utility and shortcomings of various age estimation methods used by forensic anthropologists.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the use of different age estimation methods in different contexts and their usefulness and limitations.

Teeth, along with associated oral structures, play an important role in the identification of an individual as they are considered storehouses of invaluable information for biological, physical, chemical, and medical sciences and may provide vital information about the identity, provenance, migration history, dietary status, trauma, etc. Dental structures are the hardest and most well-protected structures of the human body and can resist decompositions, incinerations, and other degradations.

Age is an important aspect of the biological profile that is estimated from human skeletal remains retrieved from forensic scenarios, such as disasters, accidents, or crime scenes. Age is also an important factor in clinical practice, research endeavors and courts of law. In addition to some administrative and judicial reasons, forensic age estimations have become vital for checking illegal population migrations, fraudulent old-age pensions, and asylum seekers. The lifetime biological changes and events occurring in the human body are impregnated in the hard tissues (bones and teeth), which are directly related with the biological age of an individual. Statistically significant correlation exists between the chronological age and the growth and development status of an individual.

Forensic odontology is playing a very important role in the age estimation of an individual. Dental age estimates are considered more reliable than bone age estimates as dental tissues show less vulnerability to taphonomic destructions and remodeling events. Different morphological stages of dental mineralization status correlate with the different developmental phases of life. Various age estimation methods such as Demirjian, Nolla, Willems, Cameriere, Kvaal, and others have been proposed in dental anthropology to be used with appropriate modifications for individuals of different age groups in different populations. However, each such method has its own advantages and disadvantages to be considered differently in bioarchaeological and forensic age estimations. This presentation will highlight various aspects of morphological, biochemical, and radiological methods in forensic dental age estimations, as will their scopes, accuracy levels, and limitations.

### G39 Disaster Victims Identification (DVI) Using Digital Radiology: A Case Report of a Brumadinho Victim Identification by the Dental Comparative Method

Sandra G.G. da Silva\*, Belo Horizonte, Minas Gerais 31980-320, BRAZIL; Luciene M. Corradi, MS, Medical Legal Institute of Minas Gerais, Belo Horizonte 30510160; Denise V. Travassos, Universidade Federal de Minas Gerais, Belo Horizonte, BRAZIL

**Learning Overview:** The goal of this presentation is to demonstrate, through a literature review and case report, the importance of the presence of a digital X-ray device for the comparative dental study within the Legal Medical Institutes and how the method is relevant in DVI, plus the benefit of using this instead of other identification methods.

**Impact on the Forensic Science Community:** The scrapping of Legal Medical Institutes is a known reality in Brazil. Lack of equipment and the devaluation of coroners is a barrier to the successful identification of dead bodies. Bringing this problem to the center of the discussion can be decisive in revising the amount of investment in this sector. In this context, this presentation will impact the forensic science community by revealing the importance of an X-ray machine in the work of the dental professional and how it can directly impact the rapid and accurate identification of bodies in mass accidents.

A mass disaster is a sudden natural or man-made event that sets in motion multiple work teams. The identification of corpses in these disasters is a process that involves, in addition to technical and scientific procedures, affective issues related to the families involved, legal procedures, and other activities.<sup>1</sup>

Dental structures are highly resistant to destruction, but dental identification also depends on relying on all available Antemortem (AM) dental documentation of the missing person. The role played by dentists in Postmortem (PM) dental examinations is extremely objective, and the use of dental radiology is an absolute need. AM radiographs can be easily compared with PM radiographic images, because even in the absence of dentistry or prosthesis work, the images offer very personal anatomical details.<sup>2</sup> The advancement of microelectronics and informatics, allied to the reduction of the cost of equipment, allowed the development of new, more powerful, and reliable techniques for comparing radiological images with forensic dentistry application.<sup>3</sup> Radiological scanning with digital X-ray before the necroscopic examination is useful for a quick overview of the remains and provides an easy method to record the data found in their *in situ* state.<sup>4</sup>

Dentists from the Forensic Anthropology Sector of the Legal Medical Institute of Belo Horizonte (LMI-BH) were assigned to perform a dental anthropological examination of an unknown corpse from the region where the Feijão Mine dam was ruptured, located in the city of Brumadinho in Minas Gerais, on January 25, 2019. After due expert procedures, dental data were collected and recorded in an expert report. Digital radiographs of the mandibular remnant were taken and archived at the LMI Forensic Radiology Service. Based on the comparative study of the occurrences and dental work present in the radiographic images of the mandibular remnant with the AM radiographic images, it was found that there was compatibility between AM and PM data. The characteristics revealed were sufficient, in isolation, for the effective recognition of the screen. Thus, it was concluded there is express need for the existence of digital X-ray devices for forensic purposes within the Legal Medical Institutes. Human identification by dental techniques is effective, more agile, and less expensive; however, in cases of cadavers without AM dental parameters for comparison, it is not possible.<sup>5</sup>

### G40 A Data-Driven Process, Prediction, and Reporting Model to Improve Human Identification Using the Mobile Application Intelligent System in Automation of Legitimated Examination Methods (iSALEM)

*Salem Altalie, FACLM\*, Abu Dhabi Police GHQ, Abu Dhabi, UNITED ARAB EMIRATES*

**Learning Overview:** After attending this presentation, attendees will be informed about the development of the new innovative mobile application iSALEM. This will assist in the use of legitimate age estimation methods in a systematic form using digital automation as integrative new conceptual models to estimate and identify the age of the individual.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by acknowledging the challenge of clarity in the standard procedure to acquire estimated age. The iSALEM application is the response to usability and also the adequacy of using both the sciences and expertise to deliver a quality evaluation record.

The innovative application is part of the plan presented at the International Organization for Forensic Odonto-Stomatology (IOFOS) Conference titled “A Roadmap Plan of Developing Forensic Odontology in UAE” in 2017. Presently, the conversion of medicolegal data into a useful tool is essential to improve the process of analysis and outcome prediction by building a unique structural platform. The platform conveys tested models, techniques with specific formulas, tables of statistical values, and diagrams and X-ray films to create an impactful innovated application. iSALEM has two developing phases. In the first phase, an algorithm is used to automate the data from international practice of age estimation methods. In the second phase, a specific algorithm is intended to detect specific tooth development in medical images called image-recognition. Machine learning allows decision making to detect specific tooth development. Experts will be able to have access to a deep-learning Artificial Intelligence (AI) system for detecting developmental tooth stages.

Dealing with the many details of morphological tooth characteristics and numerous age estimation methods, iSALEM simplified the process to predict the age. The iSALEM application contains some of the most validated methods with technical procedures to narrow the search parameters and thereby assist in human identification of the deceased and living persons. Minimizing invasive assessment is essential to preserve the evidence and to reproduce the test. Therefore, radiological imaging in this process is a vital tool for iSALEM application. The new design is not only reducing the variation of error, but also enhancing accurate reporting. This paperless operation can protect case integrity of misfiling and prevents loss of immediate information by enhancing the use in the clinic, morgue, laboratory, and the area of disasters for DVI purposes. The new model’s results in the application were verified and validated for the intra-examiner by comparing the results of the age estimation model from iSALEM mobile application against the classic age estimation from experts in the field.

Authors of peer review publications set out age estimation methods for specific age phases and defined minimum requirements to perform an evaluation and reference to data and studies. Examiners should handle these necessities by allocating a case for a specific examination technique and interpreting its results. It is crucial to explain the method in the submitted report and its significance to the competent authorities. The model established in iSALEM using a mobile application is verified by the referees of the original paper, which makes it unique and the only data analyst program of its kind. It helps in reducing the subjective assessment of tooth development of the conducted subject and a comparison of the following criteria.

Dental age estimation narrows the scope in identifying unknown persons, which plays a significant role in many aspects of humanity, medicine, security, and sport. Using the iSALEM application, which is accessible software any time or place using smart phones, allows the consensus of experts internationally for improvements in methods and approaches. Furthermore, the great advantage of the process in the application is helping to calibrate examiners through exercise on solved cases before conducting a real case, which increases the examiners’ competences. Because of each methodology’s disadvantages as well as the advantages, it is essential to reduce the variation of errors in using these methods with communication technologies. The iSALEM application follows an already verified technique to produce a reliable and accurate dental age estimation report.

## G41 The Estimation of Sex From Dental Arch Dimensions: An Odontometric Analysis

*Tanuj Kanchan, MD\*, All India Institute of Medical Sciences, Jodhpur, Jodhpur, Rajasthan 342 005, INDIA; Rutwik D. Shedge, MSc, All India Institute of Medical Sciences, Jodhpur 342005, INDIA; Vinay Kumar Chugh, MDS, All India Institute of Medical Sciences, Jodhpur 342005, INDIA; Ankita Chugh, MDS, All India Institute of Medical Sciences, Jodhpur 342005, INDIA*

**Learning Overview:** The goal of this presentation is to educate attendees concerning the applicability of dental arch dimensions in sex estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing attendees to estimate sex from dental arch dimensions in the absence or extreme decimation of more reliable parameters or in association with other criteria.

Identification process is the backbone of crime investigation. Lack of sophisticated facilities such as DNA profiling in the developing countries make anthropometric and odontometric techniques a popular and useful choice for identification among the experts.

Estimation of sex is a part of the identification process and is an essential investigation in medicolegal examinations, especially those involving dismembered and skeletal remains. Principle determination of sex is based on well-established size differences between males and females. These differences are dependent on a variety of factors, such as genetics, environmental influences, etc. Traditional methods of determination of sex include observation of differences in morphological features of males and females. Most of these differences are somewhat subjective and are not measurable. However, owing to the reliable results derived in the research involving metric analysis, experts rely more on the methods which involve measurements.

Teeth are one of the most durable and well-protected parts of the human body that resist decay and destruction even in cases of extensive fire and can be used to determine the sex of an individual. Though a lot of research has been conducted on correlation of sex and tooth size, not much emphasis has been given to the use of dental arch dimensions for estimating sex. Even among the few studies that have conducted some research using dental arch dimensions, focus has been singularly on the inter-canine distance and not the distances between the premolars and molars, which are more likely to be found intact in decomposed and skeletonized remains. Also, the majority of such studies have been conducted only on the mandible. Measurements of maxillary arches assume importance, considering that the mandible may not always be recovered in extreme decay and dismemberment, and when only skull is brought for examination.

This present study was conducted to analyze the differences between males and females based on all the dental arch dimensions of both of the jaws in an Indian population. The dental arch dimensions of the canines, premolars, and the molars of both the jaws were recorded in dental casts of 307 participants. Comparison of the dental arch dimensions of males and females was performed and logistic regression models were generated to estimate sex. Receiver Operator Curve (ROC) analysis was performed to find out the potential to estimate sex for all the dental arch dimensions in both sexes. It was observed that maxillary inter-molar II distance gave the best results in estimating the sex. The sexing accuracy is seen to increase as one goes distally from canines to molars in each jaw; minimum for inter-canine distance and maximum for distance between the 2<sup>nd</sup> molars. The development of models for estimation of sex from dental arch dimensions will enable sexing in cases of dismembered skeletal remains too.

### Dental Arch Dimensions, Sex Estimation, Forensic Odontometry

## G42 Cementum Annuli: Technique, Microscopy, and Assessment of Age

*Michael Clay, DMD\*, Foley, AL 36535; Murray K. Marks, PhD, University of Tennessee, Knoxville, TN 37920; James M. Lewis, DMD, Madison, AL 35758; Paula C. Brumit, DDS, Nocona, TX 76255*

**Learning Overview:** After attending this presentation, attendees will understand: (1) the method of dental cementum thin section preparation of forensic teeth; (2) the microscopic analysis necessary to assess age via band qualification and quantification; and (3) age assessment methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of the techniques and methods. Attendees will be able to initiate the cementum annuli age assessment technique using microscopy in cases of partial representation of the dentition and skeleton.

Mineralized tissue, particularly the dentition, possess superb postmortem longevity. In certain wildlife such as bears and wolves, cementum annuli counts have been considered one of the most accurate indicators of age. While cementum annuli studies of zooarchaeological and modern wildlife are well documented, application to human teeth has been histologically and methodologically far less successful, preventing standardization and utilization. However, recent research indicates that cementum annuli may be used more reliably than any other part of skeletal remains to accurately determine age.

This study documents the laboratory preparation and enumeration of cementum structure on all tooth types and root locations using dissecting, light, and scanning electron microscopy. Teeth that were extracted because of periodontal disease, orthodontic, and prosthetic reasons were used in this study. The extractions ( $n=108$ ) from several general dental and oral and maxillofacial practices were documented with age, sex, and ancestry. All deciduous and permanent tooth types were embedded, thin sectioned (whole tooth, labiolingual and root, transverse, and mesio-distal), ground, polished, and etched or stained. Select intra- and inter-root locations (i.e., cervical, mid-root, apical, and inter-radicular) were examined. At low magnification, the dissecting microscope at 5X–10X was utilized to assess cementum quality, thickness, and root coverage. At high magnification, the scanning electron microscope at 100X–200X documented the structural reality of annuli and not for the counting procedure for age estimation. The light microscope at 25X–50X provides the tool for annuli counting in assessment of age.

Light microscopy of the mid-root area, regardless of the molar's mesial or distal root or tooth type, revealed the most easily visualized annuli for quantification. The cervical region is many times damaged or thinned from periodontal events, and the thickened apical region display a more "confusing" and unassignable array of annuli.

Countable cementum annuli are present in human teeth. Images of the annuli in the form of dark and transparent bands were counted using image analysis software to arrive at an age estimation. The average number of years of eruption for each tooth were added to the annuli count. Results helped determine the best methods to count the cementum annuli while also showing a significant correlation between the annuli count, predicted age, and actual chronologic age of each individual. Further studies are needed to help determine the environmental effects such as climate, temperature, and length of day on the production of the annuli in different populations.

### Cementum, Age, Microscopy

## G43 Morphological Examinations of the Teeth and Jaw Fragments Retrieved From an Ajnala Skeletal Assemblage: A Forensic Odontological Study

Jagmahender Singh Sehrawat, PhD\*, Panjab University, Department of Anthropology, Chandigarh 160014, INDIA; Ashith B. Acharya, GDFO, Sri Dharmasthala Manjunatheshwara College of Dental Sciences & Hospital, Dharwad, Karnataka 580009, INDIA

**Learning Overview:** After attending this presentation, attendees will be sensitized regarding the postmortem longevity of dental remains and the significant contributions teeth and jaw fragments make toward identification of badly damaged and commingled human remains found in forensic situations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees how teeth serve as crucial markers of identity of the victims whose badly challenged human remains were excavated by amateur archaeologists or curiosity-seekers.

Bones and teeth have been increasingly used to figure out the biological profile of an individual(s) who lived in the past as they have the longest postmortem longevity to serve as crucial markers of human form and identity after death. Fragmented and commingled skeletal remains retrieved during mass disasters, archaeological excavations, construction activities, criminal submissions, forensic contexts, etc., pose a serious challenge for their identification endeavors in forensic anthropology. Odontology has contributed significantly in identification strategies of such unknown human remains as teeth remain minimally affected by biological, physical, or taphonomic destructions such as fire, chemicals, trauma, burial environments, etc.<sup>1</sup> Teeth contain invaluable biological, physical, and chemical information, crucially needed for responding to various forensic anthropological parameters such as provenance, biological identity establishment, exposure to pollutants or taphonomic/traumatic insults, estimation of dietary practices and subsistence patterns, paleopathology, etc. It is the small size and mineralized status of human teeth that impart their resistance against most types of decompositions and degradations.

Mankind has witnessed several heinous crimes against humanity, and some pre-existing structures such as abandoned wells, waterways, sewage systems, potholes, caves, pits, natural ravines, and roadside trenches have been commonly used as preferred burial sites for the clandestine disposal of human cadavers to avoid the attention of human rights watch-groups. In one such incident, thousands of badly damaged and commingled human remains, along with numerous contextual items of personal identity, were excavated non-scientifically by amateur archaeologists from a disused well found underneath a religious structure at Ajnala, India, in April, 2014.<sup>2-3</sup> The written records mention that the exhumed human remains belonged to 282 Indian-origin soldiers killed in August 1857 whose corpses were immediately dumped into a bricked well due to the contemporary socio-political situation in the area. Only teeth and a few jaw fragments could survive the taphonomic destructions during the hurriedly carried-out excavation of the site by the local curiosity seekers.

In this presentation, 1,527 teeth (1,200 dislodged and 327 present in 93 jaw fragments) collected from Ajnala skeletal assemblage were assessed for their age at death, sex characteristics, population attributes, traumatic and pathological signatures, occupation markers, health conditions, and other attributes. The application of three methods of adult age-at-death estimations (Johanson attrition grades, Average Stage Attrition (ASA), and Pulp-to-Tooth area Ratio (PTR)) found that the Ajnala remains belonged to individuals who were most likely from 32 years to 53 years of age (approximately). Johanson and PTR methods provided higher and lower age estimates, respectively, whereas the ASA method gave age estimates in-between the two other methods.<sup>4,5</sup> The anatomical discrete dental traits of jaw fragments revealed that at least 84% of them belonged to males, suggesting the vast majority of remains exhibit very prominent and obvious male characteristics. The odontometric values of dislodged teeth were substituted in the available logistic regression formulas generated from tooth metrics of known biological credentials, and it was found that about 78% of tooth measurements were categorized as males. Eleven non-metric dental traits, as defined by Scott and Turner, were evaluated following Arizona State University (ASU) Dental Anthropology System to estimate their population affinity.<sup>6</sup> It reaffirmed that predominance of relatively unique non-metric dental traits in Ajnala teeth allude them to be of Indians.<sup>7</sup> Only 4.2% of the dislodged teeth and 14% of the jaw fragments exhibited dental caries, which is in stark contrast to the 78% caries in present-day Indian populations; 4.9% of the teeth exhibited fracture of the crown or root, probably owing to their prolonged burial and possible ambient pressure exerted by soil and its components. The tooth wear in anterior teeth and premolars of jaw fragments may be attributed to some influence of biting of cartridges for probable loading into rifles/muskets (perhaps). Extrinsic blackish-brown or reddish staining on a few teeth were suggestive of nicotine consumption, smoking of any form, or betel-nut chewing/eating habits.<sup>8</sup> These observations correspond to the biological and geographic identity of the Ajnala skeletal remains as described in the written records. The detailed results will be presented in the textual, graphical, tabular, and diagrammatic forms.

### G44 The Importance of Bitemarks in Child Abuse Cases in Turkey

*Huseyin Afsin, PhD\*, Istanbul 3400, TURKEY; Sermet Koc, Adli Tip Kurumu Morg Dairesi Baskanligi, Istanbul 34196, TURKEY; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104*

**Learning Overview:** After attending this presentation, attendees will have learned about the challenges in collecting and reporting child abuse cases in Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing some of the injury types in child abuse cases.

Child physical abuse is a major cause of pediatric morbidity and mortality that is associated with physical and mental health problems and can last until adulthood. There are limited numbers of reported child abuse cases in Turkey. Some of the reasons for this lack of reporting child abuse cases include a lack of adequate training of health workers, hesitance to interfere with family issues, the belief that a parent cannot hurt their own children, a lack of official centers for reporting child abuse, and inadequate record keeping and reporting of these types of abuse cases. Turkey is a country that bridges Asia and Europe, acts as a passageway for immigrants, and is also a place for their settlement. Due to the increase of immigrants in recent years, the importance of reporting and the correct handling of child abuse cases has taken more prominent place in the country's justice system.

Child abuse case injuries include facial injuries caused by slapping, patterned injuries, lip lacerations, scaring of the corners of the mouth due to gag use, bruises, human bitemarks, electrical, chemical, or thermal burns, maxillary or mandibular fractures, intraoral injuries, mobilized or broken teeth, torn frenilumlar, other intraoral lacerations, and bruising and injuries to the hard and soft oral palate from forced oral sex.

**Case 1:** A 3-year-old boy—a forensic report prepared by an emergency room doctor was sent to legal authorities. Upon further examination of the boy, an official report of a child abuse complaint was filed. Examination revealed fracture of the right tibia proximal, bruises on the left lower quadrant of the left breast and right kidney area, a circular pattern of bitemarks on the left gluteal area, scars measuring 2cm x 1cm on the left index finger, swelling of the right arm, and swelling and bruises on the left leg. The report included a list of 25 different injuries. It also concluded that the scars and bruises resulted from repeated blunt trauma and human bites. A forensic bitemark analysis performed by the Istanbul Forensic Medicine's Dental Department was included in the report and used in identifying the defendant.

**Case 2:** A 2-year-old boy—death resulted from child abuse. According to toxicological analysis, there was no evidence of any chemical or substances that were sought in the analysis. There were numerous nail marks and bruises on the neck, and evidence of continual physical abuse were present on the trunk and victim's back. The cause of death was blunt head trauma that caused cerebral hemorrhage and brain tissue damage. The victim also had rib fracture, internal organ, and abdominal injuries. Upon examination of the bitemarks, the child's father was a match for this closed case.

## G45 A 3D Analysis of Bitemarks: A Validation Study Using an Intraoral Scanner

*Géromine Fournier, DDS\*, Faculty of Odontology, Toulouse 31400, FRANCE; Frederic Savall, Service de Médecine Légale, Toulouse Cedex 9 31059, FRANCE; Norbert Telmon, PhD, MD, Service Medico-Judiciare, Toulouse F-31054, FRANCE; Delphine Maret, PhD, Faculty of Odontology, Toulouse 31400, FRANCE*

**Learning Overview:** After attending this presentation, attendees will have learned a new 3D approach to human bitemark analysis using an intraoral scanner. With this approach, the feasibility, reproducibility, and reliability of comparisons were established.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how a 3D analysis optimizes and facilitates bitemark analysis.

**Purpose:** Conservation of the 3D aspect of bitemarks improves their analysis. In clinical dentistry, intraoral scanners are used as an alternative to conventional dental impressions for prosthetic design. Digital impressions are accurate, editable, and stable. In forensic odontology, an intraoral scanner could be used to record the bitemarks and a suspect's dentition. Then a 3D point processing software could compare these two objects.

The goal of this presentation is to assess the feasibility, the reproducibility, and the reliability of this new approach to bitemark analysis.

**Materials:** Twenty-seven volunteers bit into four materials: a triple thickness of dental wax, a hard cheese (Gouda or similar), a bar of milk chocolate, and an apple. The intraoral digital scanner PlanMeca® Emerald scanned dentitions and bitemarks. The scans obtained were exported into the mesh comparison software CloudCompare®, which can generate overlays automatically. For this purpose, dentitions were aligned and compared with the indentations. Meshing and non-meshing were visualized using a colorimetric scale.

**Methods:** First, the same blinded observer analyzed 256 comparisons for each material in order to compare the bitten supports. Second, 50 comparisons of bitemarks from wax were analyzed in a randomized blinded study involving four observers (dentist, dental student, forensic scientist, and police officer). None of the observers were trained before making these comparisons. Descriptive statistics, such as predictive value analysis and Cohen's kappa coefficient, were carried out in order to study the reproducibility of comparisons.

**Results:** For all materials, the rate of correct classifications was higher than 90%, and misclassification was rare. After calculation of predictive values, the wax support obtained the best result (positive predictive value: 87.1%, negative predictive value: 100%) and the apple the worst (positive predictive value: 57.1%, negative value predictive: 98.6%). Moreover, for each observer, negative predictive value was near 100%. Positive predictive values were more variable but higher than 70%. Cohen's Kappa coefficients showed a better concordance (almost perfect agreement) between the two observers whose training included odontology. For the other observers, the coefficient was substantial or agreement was perfect. Positive predictive values were better for the dentist and dental student than for the forensic scientist and police officer. Thus, the work clearly highlighted the importance of experience in odontology.

**Conclusion:** The 3D aspect of bitemarks was preserved, which facilitated analysis and reduced bias. Thus, 3D analysis was more objective than a photographic method. Dentitions not implicated by bitemarks could be excluded with certainty. Moreover, dental experience was fundamental to obtaining the best values.

## G46 3D Dental Digital Study Models in Bitemark Comparison

Robert B.J. Dorion, DDS\*, Laboratoire S.J.M.L., Montreal, PQ H2K 3S7, CANADA

**Learning Overview:** After attending this presentation, attendees will have acquired information regarding the role that 3D dental digital study models have in bitemark comparisons.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that 3D dental digital study models are as accurate as original dental stone casts and have the distinct advantage of being unbreakable, cost-effective substitutes for the original dental stone casts and can easily be securely transferred to forensic dental experts and other interested parties by the internet.

A male adult defendant was sent to trial on charges of first-degree murder, aggravated sexual assault, and sexual interference in connection with the death of a three-year-old female. There were 13 human bitemarks on the torso and limbs, in addition to three scarred/healing human bitemarks to the buttocks and right forearm.

The case went to preliminary inquiry in 2010 and to trial in 2012. A Board-certified forensic dentist testified for the prosecution in both events. The trial court judge acquitted the accused, and the Court of Appeal ordered a new trial on the basis of judicial error. There was no dental expert witness for the defense, neither at the preliminary inquiry nor at trial. For both the preliminary inquiry and for the trial, the case was considered a “closed population” event. However, for the retrial, further investigation discovered that more persons had been in contact with the child than had originally been thought, thus it became an “open population” case. A forensic dental expert witness for the defense was appointed for the scheduled retrial in 2014.

For the retrial, a judge ordered the duplication of original dental stone casts of six suspect dentitions to be constructed in another jurisdiction and ordered that the duplicate dental stone casts be sent to all experts in the case. The pairs of duplicate dental stone casts received by the forensic dental expert witness for the defense were defective in one form or another. One dental stone cast contained three broken anterior teeth on the stone models, which the suspect dentition did not have. Others had air bubbles on the incisal edges of anterior teeth.<sup>1</sup> In the absence of the original dental stone models, it was not possible to determine if the defects were artifact on the original or the duplicate models. Either way, air bubbles do not exist on human teeth, and the models cannot be used for comparison.

The use of digital files representing 3D objects is currently accepted for diagnostic and comparison purposes and are recognized for judicial purposes. Had 3D dental digital study models been made from defect-free dental stone casts and transferred to the interested parties, this dilemma would not have occurred.

This presentation will include the use of different views of 3D dental digital study models, 3D measurement tools, cross section properties, and cast “highlights” of the ORTHOpix™ 3D dental digital study models for comparison purposes.

In conclusion, 3D dental digital study models can play an important role in bitemark comparison and can substitute for the original dental stone casts of suspect dentitions.

## G47 Non-Bitemarks That I Have Known

Robert E. Wood, DDS, PhD\*, Ontario Forensic Pathology Service, Brighton, ON K0K1H0, CANADA; Yolanda Nerkowski, BA\*, Ontario Forensic Pathology Service, Toronto, ON M8W 3X4, CANADA; Taylor L. Gardner, BFS\*, Ontario Forensic Pathology Service, Toronto, ON M3M 0B1, CANADA

**Learning Overview:** The goal of this presentation is to focus on the first step of a three-step process outlined by the American Board of Forensic Odontology (ABFO) with respect to new bitemark guidelines and a bitemark decision tree/algorithm, the first step being whether a patterned injury is in fact a bitemark. Several cases will be presented in which a patterned injury looked to someone to be a bitemark that later was determined to not be a bitemark and the motivation that led some investigators to believe that a pattern injury was a bitemark.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by postulating that if the decision tree proposed by the ABFO is used appropriately, far fewer cases will advance beyond the first step of the suggested guidelines, ultimately preventing costly judicial errors.

The long and winding road of bitemarks began with *Doyle v. the State of Texas* in the 1950s—a bite in cheese<sup>1</sup>. Over the ensuing years, the ability to “match” the teeth of an individual, not to cheese but to a human dermal bitemark was, if not the stated goal, the unstated goal of both bitemark analysis and comparison. It was also considered, as many forensic disciplines were, both straightforward and scientifically valid. It was not scientifically validated—and many think scientifically invalidated. In the years since *Doyle v. the State of Texas*, there have been numerous cases in which bitemark analysis and comparison resulted in convictions of persons that were later overturned. In excess of 30 people, wrongfully convicted of crimes in which bitemark evidence was used, have been re-adjudicated. Finally, bitemark evaluation, analysis, and comparison is only a small part of many forensic odontologists’ case work, with the largest part of most forensic odontologist practices being comprised of the identification of human remains.

In 2018, the American Board of Forensic Odontology published new bitemark guidelines and a bitemark decision tree/algorithm. The goal of this endeavor was to guide the profession with respect to the three-step process by which an investigator first decides whether a patterned injury is a bitemark, second whether a mark that is deemed to be a bitemark possesses evidentiary value sufficient to warrant further investigation, and third, having passed the previous two hurdles, whether a suspect dentition or dentitions can be excluded or not excluded as having produced the bitemark.

This presentation intends to focus only on the first step, since often the question before an investigator or even before the courts is not always “whose bitemark is it?” but “is it a human bitemark at all?” Several cases will be presented in which the first fork in the road was reached (i.e., a patterned injury looked to someone to be a bitemark that later was determined to not be a bitemark). It is postulated that if the decision tree proposed by the ABFO is used appropriately, that far fewer cases will pass the bar of even being a bitemark and certainly for evaluation for evidentiary value sufficient to warrant further investigation; and even fewer will reach the stage of comparison to a suspect. This will be accomplished by examining non-bitemarks that were thought to be bitemarks, the motivation that lead some investigators to believe that a pattern injury is a bitemark, and an assessment of some of the clinical cases in which a pattern of contusions, lacerations, incisions, or abrasions led to someone at the very early stage of an investigation to diagnose a patterned injury as a bitemark.

With the human cost of a wrongful conviction being terrible enough, even from a monetary standpoint of the cost of a jury trial, the post-conviction appellate costs, and monetary awards to those wrongfully convicted, there is a strong argument for applying the 2018 algorithm effectively since it seems prudent to look at a decision-point where at least some of these cases can be filtered from the judicial system.

### Bitemark, ABFO, Wrongful Conviction

## G48 A Historic Perspective of Bitemark Analysis and Bitemark Comparison

Robert B.J. Dorion, DDS\*, Laboratoire S.J.M.L., Montreal, PQ H2K 3S7, CANADA

**Learning Overview:** After attending this presentation, attendees will possess a historic perspective of bitemark analysis and bitemark comparison.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the myriad of changes that have occurred from the 1970s to today. These include, but are not limited to, the American Board of Forensic Odontology (ABFO) establishing a Research Committee, the Standards, Methods, and Procedures Committee, the Bitemark Evidence and Patterned Injury Committee, the Certification and Examination Committee, and Bitemark Workshops.<sup>1</sup> As well, the American Society of Forensic Odontology (ASFO), the American Academy of Forensic Sciences (AAFS) Odontology Section, and the ABFO are all involved in continuing education for their members.

The influence of 2009 National Academy of Sciences (NAS) recommendations, the National Institute of Justice (NIJ), the President's Council of Advisors on Science and Technology (PCAST) conclusions, the Texas Forensic Science Commission report, and finally the National Institute of Standards and Technology (NIST) Organization of Scientific Area Committees (OSAC) efforts to open dialogue and promote consensus are discussed.<sup>2-5</sup>

The role that universities worldwide have contributed, the textbooks and scientific articles published, and the research in the field since the 1970s is ever expansive and contributes to the advancement of bitemark evidence.

For some, bitemark analysis was synonymous with bitemark comparison in the 1970s, and wrongful convictions resulted. For others, the exaggeration of claims of certainty of identification were not justified. Fortunately to date, there have been no reported, nor cited, wrongful convictions involving bitemark evidence anywhere else in the world other than in the United States. This suggests that a multitude of domestic systemic problems contributed to wrongful convictions of bitemark evidence in the past.<sup>6</sup>

If class and individual characteristics exist, and both sufficient quality and quantity of information is present (evidentiary value), a diagnosis can be made that the pattern was created by teeth or was not. On the other hand, there may be insufficient information to arrive at a diagnosis. Bitemark comparison may or may not follow, depending on circumstance.

In conclusion, bitemark analysis and bitemark comparison are two different topics requiring individual assessment. With the advent of DNA, and the new algorithms for bitemark analysis and for bitemark comparison, a completely different paradigm exists from that of the 1970s.

### Forensic Odontology, Bitemark Analysis, Bitemark Comparison

### H1 Circumstances and Injuries in Female Homicide Victims of Strangulation: A Four-Decade Review of 143 Cases in King County, Washington

*Robert Johnston, DO\**, King County Medical Examiner's Office, Seattle, WA 98115; *Richard C. Harruff, MD, PhD*, King County Medical Examiner's Office, Seattle, WA 98104; *Micheline Lubin, MD*, King County Medical Examiner's Office, Seattle, WA 98104; *Cloyd Steigerr*, Washington State Attorney General's Office, Seattle, WA 98104; *Nicole Siver*, Washington State Attorney General's Office, Seattle, WA 98104

**Learning Overview:** After attending this presentation, attendees will be able to: (1) describe the circumstances surrounding homicides of female victims of strangulation, (2) list the most reliable physical evidence supporting a diagnosis of strangulation, and (3) explain why females are especially vulnerable to this modality of violent death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data from a large case series of female homicide victims that can help in identifying circumstances and physical evidence characterizing this modality of death of which females are especially vulnerable.

Strangulation is a cause of death that is often challenging to establish because of relatively minor anatomic injuries, obscuring postmortem changes, and coexisting injuries, natural disease, or intoxication. Previous studies have identified characteristic findings in both decedents and surviving victims, demonstrating considerable variation in the anatomic findings, as well as the difficulties in proving death or injury in strangulation. Thus, it is important to review a large series of cases to more completely understand the complexities inherent in making a diagnosis of strangulation.

This study is a retrospective review of homicidal strangulation of female homicide victims examined in the King County Medical Examiner's Office (KCMEO) from January 1979 to December 2016. For the cases identified, demographic information was collected from the medical examiner files, investigative reports were used to assemble circumstantial information, and autopsy reports were abstracted to compile anatomic injuries. Data from the Washington Attorney General's Office Homicide Investigation Tracking System supplemented the medical examiner information regarding perpetrator and circumstances. The current KCMEO electronic database was queried to compare the number of female strangulation homicide victims relative to those of males from 2000 to July 2019.

Over the time period of 1979 to 2016, there were 143 female homicide victims of strangulation used for this study. In the later time period used to compare the number of male to female strangulation victims, there were 30 females and 9 males. In the 143 cases of female victims, the highest proportion of cases (29%) were in the age range of 20–29 years; 14% of cases were in ages older than 70 years. Sexual motivation was prevalent in the younger age group, whereas robbery prevailed in the older age group. The majority of deaths were in private places (65%) and the perpetrator was known to the victim in 80% of cases. Of the known circumstances surrounding the homicide, 25% were related to domestic violence; sexual assault was evident in at least 25%. Overall, manual strangulation was the predominant method of strangulation; however, in cases with sexual motivation, ligature strangulation predominated. In approximately 73% of cases, strangulation alone was responsible for death; other modalities of injuries were present in the remainder, most commonly blunt force injury.

Petechiae were documented in more than 80% of the cases, nearly always in the conjunctivae; postmortem decomposition likely obscured their appearance in other cases. Internal neck injuries were evident in about 92% of the cases, mostly in the form of soft tissue and strap muscle hemorrhages (86%); thyroid cartilage fractures were noted in 38% of the cases, and hyoid fractures occurred in 25%. The latter especially were highly correlated with ages older than 40 years.

The results of this study are largely consistent with previous studies, showing that female victims of strangulation outnumber those of males by a ratio of at least 3:1. Circumstances and venues of domestic violence account for a substantial proportion of female homicidal strangulations, and sexual motivation is also a major factor, readily explaining why females are especially vulnerable to this modality of death. Conjunctival petechiae and soft tissue/muscle neck injuries remain the best evidence supporting a diagnosis of strangulation, while cartilaginous or hyoid fractures are much less common, especially in younger victims.

#### Strangulation, Female, Injury Patterns

### H2 A Fistful of Dollars: An Unexpected Delayed Development and Rupture of a Traumatic Fusiform Posterior Inferior Cerebellar Artery (PICA) Aneurysm

*Maria Silvestre, MD, Section of Legal Medicine, University of Foggia, Foggia 71122, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Michela Ferrara, MD, Department of Forensic Pathology, Foggia 71122, ITALY; Lorenzo Spagnolo, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Stefania De Simone, MD, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the importance of suspecting and evaluating vascular lesions of the posterior cranial fossa following closed head trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that a craniocervical trauma that creates acceleration and deceleration of the cerebellum inside the skull affecting PICA at its origin can lead to the formation of intracranial traumatic aneurysms, causing ischemic processes and death of the affected subject.

Intracranial traumatic aneurysms are extremely rare, representing less than 1% of all intracranial aneurysms. Traumatic aneurysms should be suspected in the context of acute neurological deterioration following any type of closed head injury. Most of these lesions develop in the anterior circulation (i.e., in the middle cerebral artery, in the anterior cerebral artery, or in the internal carotid artery). Less than 10% of them occur in the posterior circulation. Delayed rupture occurs in about 50% of cases; the interval between injury and rupture ranges from a few hours to ten years, with an average interval of 14–21 days. The mortality rate is high, ranging between 32%–54%. As far as pathogenesis is concerned, it is suspected that the head trauma produces acceleration and deceleration of the cerebellum within the skull, tearing the PICA at its origin.

A 26-year-old man was brutally punched in the face in a disco. He was admitted to the emergency department unconscious, with a lacerated-contused eyebrow wound, and with several vital sign parameters that were severely altered. No skull fractures were evident. A head Computed Tomography (CT) scan revealed extensive subarachnoid hemorrhage, cerebral edema, intraventricular hemorrhage, and post-traumatic endocranial hypertension. Based on these diagnostic findings, the patient underwent bilateral decompressive neurosurgery. There were no complications until postoperative day ten, when suddenly the patient's hemodynamic status and neurologic condition began to worsen. Head CT scan and CT angiogram were performed showing a fusiform aneurysm measuring approximately 3.6 x 4.5mm located in the proximal portion of the left PICA. This aneurysmal dilatation showed homogeneous enhancement in the arterial phase and presented irregular profiles on the anterolateral side due to apparent rupture. Associated hypodensity of the brainstem due to vasospasm phenomena was identified, as was a vasospasm-associated filiform aspect to the arteries of the Circle of Willis. Overall, the described findings were compatible with a ruptured post-traumatic intracranial aneurysm, a rare but recognized complication of closed head trauma. Despite neurosurgical attempts to repair the vessel, the patient died after a few months following multiple episodes of massive rebleeding.

Diagnostic features useful to distinguish a traumatic aneurysm from a natural fusiform aneurysm include age and sex (i.e., traumatic aneurysms are more frequent in young males) and a history of closed head trauma with typical angiographic aneurysm characteristics, including peripheral position. Other supportive traumatic aneurysm features include aneurysm location away from a branching point with irregular contour of the aneurysmal sac, absence of an aneurysmal neck, and delayed filling and emptying with position adjacent to the edge of the sicle. The radiological images obtained in the case described above fully reflected these characteristics.

In conclusion, this case report demonstrates that a history of a closed traumatic brain injury causing intraventricular hemorrhage with massive subarachnoid bleeding in the posterior cranial fossa should raise concern for significant vascular lesions, such as a ruptured aneurysm or other rupture/dissection of the vertebro-basilar arterial system. Unfortunately, it is not possible to precisely predict the timing for development nor rupture of a post-traumatic intracranial aneurysm; the relatively few cases presented in the literature, anatomical variability of the subjects involved, and multiplicity of other involved factors preclude standardized timing. Currently, careful monitoring of patients at risk seems the only option to detect intracranial traumatic fusiform aneurysms, a rare but potentially lethal consequence of closed head traumatic injury.

#### TBI, Subarachnoid Hemorrhage, Traumatic PICA Aneurysm

### H3 An Accidental Death Caused by Blunt Force Injuries Resulting in Multiple Fractures and a Pulmonary Fat Embolism

Juliana Molosky\*, Kalamazoo, MI 49004; Stephen Peltier, BS, Kalamazoo, MI 49004; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be familiar with the pathophysiology and microscopic appearance of pulmonary fat embolism, a known cause of death following trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a case of accidental death related to multiple fractures and pulmonary fat embolism caused by traumatic blunt force injuries in a man with a known clinical diagnosis of coronary artery disease and hypertension.

A 71-year-old Caucasian male, with additional history of hypertension, coronary artery disease, and obesity, was the driver of a vehicle that crossed the centerline and collided head-on with a semi-truck. His legs were trapped, requiring extrication. Diagnostic imaging revealed a left iliac crest fracture extending into the sacrum with bilateral superior and inferior pubic rami fractures, left tibial plateau fracture, and right olecranon fracture. Although he was initially alert upon arrival, he experienced cardiac arrest while on the operating table and was pronounced dead.

A complete medicolegal autopsy was performed, which revealed an obese (Body Mass Index [BMI]=38) adult male with numerous blunt force injuries to the head, neck, trunk, and extremities. Internal examination disclosed multiple fractures involving the pelvis, ribs, and sternum, a 200mL right hemothorax, and a 100mL left hemothorax, but no other significant injuries. Cardiomegaly (800 grams) with marked biventricular dilatation was noted along with other findings consistent with hypertensive and atherosclerotic cardiovascular disease. Microscopic examination of the lungs included extensive intravascular fat emboli, which were also visualized with Oil Red O on frozen section. The cause of death was ruled as multiple blunt force injuries with multiple fractures and pulmonary fat embolism, with underlying hypertensive and atherosclerotic cardiovascular disease and obesity considered contributing causes of death. The manner of death was accidental.

Although a less common cause of death than pulmonary thromboemboli, fat emboli are an exceedingly common pathologic process known to occur in traumatic femur and pelvic fractures.<sup>1</sup> Mechanistically, fat globules are released from the bone medullary space into the venous circulation, which return to the heart and subsequently the lungs. Although their occurrence in association with traumatic fractures is common, symptoms related to traumatic fat embolism are less common; acute right heart failure can occur in fulminant cases, resulting in death.<sup>2</sup> Fat emboli are present in the microcirculation, which must be distinguished from the clinical manifestations of the so-called fat embolism syndrome. This syndrome includes common systemic signs, such as respiratory distress, altered mental status, and petechial rash, but strict diagnostic criteria are not agreed upon.<sup>3</sup> Autopsy diagnosis of pulmonary fat emboli can be accomplished with histologic examination of tissue samples, which may allow for postmortem diagnosis of fat embolism syndrome.<sup>4</sup> In certain cases of death related to injury, fractures with associated extensive fat embolism may be the major (or only) serious manifestations of trauma. Fat embolism, with or without contribution from underlying natural disease, is sufficient to explain death in such cases.

#### Fat Embolism, Blunt Force Trauma, Death

## H4 Carbon Dioxide Asphyxiation Due to Pulmonary Embolism: A Case Report

Katherine Cochran, MD\*, Knoxville, TN 37920; Darinka Mileusnic-Polchan, MD, PhD, Knox County Regional Forensic Center, Knoxville, TN 37919

**Learning Overview:** After attending this presentation, attendees will be familiar with the findings in confined space carbon dioxide asphyxiation and understand the importance of autopsy findings and death scene investigation in determining cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing an unusual case of confined space asphyxiation as the result of pulmonary embolism and the importance of collaboration between death scene investigators, police, and the forensic pathologist for an accurate evaluation of these fatalities.

A 38-year-old man working as a special effects technician using a commercial Carbon Dioxide (CO<sub>2</sub>) tank to create a fog effect within a theatre was operating the shut-off valve in a contained room under the stage when he was unable to be contacted via portable radio for 12–13 minutes. He was found unresponsive with seizure-like activity by two coworkers, who also became unresponsive. A third coworker was able to turn off the CO<sub>2</sub>, allowing the removal of the three victims from the room. Both coworkers were revived and transported to the hospital along with the primary patient, who remained unresponsive. Arterial blood gas performed en route to the hospital revealed a CO<sub>2</sub> level of greater than 100mm Hg with the level decreasing to 40mm Hg upon arrival at the hospital. Therapeutic hypothermia protocol was initiated due to continued unresponsiveness and seizure-like activity. Upon rewarming, Computed Tomography (CT) of the head revealed severe encephalopathy, diffuse cerebral edema, and downward herniation. Brain death was declared, care was withdrawn, and death was pronounced four days after the incident.

Autopsy performed the following day revealed a thromboembolus within the main trunk of the pulmonary artery and completely obstructing the right pulmonary artery. A healing hemorrhagic pulmonary infarct, as well as multiple deeper shower thromboemboli and dilated cardiomyopathy, were also present. The right lower extremity was swollen and a massive residual organizing thrombus adherent to the deep vein endothelium was found. Microscopic examination of the pulmonary thromboembolus demonstrated interlacing gray fibrinous bands indicative of a long-standing organizing blood clot consistent with at least a week-long process. The deep vein thrombus from the right leg was similar in appearance. Further investigation of the decedent's history revealed a recent lower extremity injury. Based on the autopsy findings, it was concluded that the collapse at work was due to an episode of pulmonary embolization by deep vein thrombi, which partially occluded the pulmonary artery tree. The sudden incapacitation and collapse prevented the decedent from operating the shut-off valve on the CO<sub>2</sub> tank. The unencumbered release of CO<sub>2</sub> from the tank led to an exclusion of oxygen, resulting in confined space asphyxia and, ultimately, death due to anoxic encephalopathy.

CO<sub>2</sub> is a colorless, odorless gas present in low percentages in normal room air (0.02%–0.04%). At low concentrations, it has little toxicological effect.<sup>1</sup> At higher concentrations, it leads to increased blood pressure, tachypnea, tachycardia, respiratory acidosis, and cardiac arrhythmias.<sup>1,2</sup> It acts as both an asphyxiant and toxicant, causing neurological changes, such as headaches, clouded awareness, and impaired consciousness.<sup>1,2</sup> Seizure, coma, and death occur at concentrations greater than 10%.<sup>1,3</sup> At levels above 20%, there is a high risk of fatality.<sup>4</sup> At such high levels, loss of consciousness can occur within seconds, which can lead to severe accidents also involving rescuers, as in this case.<sup>4</sup> Deaths due to CO<sub>2</sub> often involve storage tanks or wine cellars as CO<sub>2</sub> is a by-product of fermentation, and the enclosed spaces allow the accumulation of high concentrations.<sup>2</sup> CO<sub>2</sub> has a greater density than oxygen, causing it to accumulate near the ground and displace oxygen from the area.<sup>1</sup> Asphyxiation occurs in the confined space as a consequence of an oxygen-deficient atmosphere.<sup>1</sup> Toxicity may be expedited by the body's failure to eliminate CO<sub>2</sub> resulting from respiratory failure or obstruction, such as pulmonary embolism as in this case. Autopsy findings are non-specific and the rapid accumulation of CO<sub>2</sub> after death renders postmortem CO<sub>2</sub> levels of little diagnostic value.<sup>5</sup> Therefore, the diagnosis of CO<sub>2</sub> intoxication is based on the scene investigation and circumstances of the death with the exclusion of other possible causes.<sup>1</sup> This is an unusual but not to miss diagnosis where close communication among all parties is critical, especially those participants at the scene.

### H5 Autopsy Findings in Dog Attacks in Mississippi

*Katie C. Donohue\**, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *Heather M. McLendon\**, Mississippi State Medical Examiner's Office, Pearl, MS 39208

**Learning Overview:** After attending this presentation, attendees will understand the affects the human body can suffer after experiencing a severe dog attack.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a series of five different deaths in which the victims went through the extensive trauma of a dog attack and will provide an insight into multiple ways a dog attack can lead to a decisive cause of death.

The intent of this presentation is to better characterize the injuries victims may sustain in cases of severe dog attacks. A series of five cases in which victims sustained extensive traumatic dog attack injuries are described and help provide insight into the multiple ways a dog attack may factor into cause-of-death determination.

**Case 1:** A 70-year-old White female was found in her backyard by a neighbor after discussing with him that his dogs had gotten out of his fence. Autopsy examination revealed multiple cuts and claw marks noted on the anterior and posterior of her body, along with nearly a complete stripping of the skin from each arm. This case presented the challenge of determining whether the victim had died of natural causes in her backyard prior to the attack or whether she died as a direct result of trauma from the attack.

**Case 2:** A 75-year-old African American female was known to have had an agreement with many of her neighbors to collect cans. It is believed that she knocked on the door of a house whose owners often had cans for her, and when she found them not home, she wandered into their backyard. She was found in the yard with the owner's two dogs who had attacked her and dragged her body to the back of the yard against the fence. Autopsy examination revealed the majority of her facial tissue to be missing, including both ears. It was determined that the intense trauma to her neck was most likely the ultimate cause of death.

**Case 3:** A 3-year-old African American male was found at autopsy to have severe lacerations of his face and throat, as well as lacerations and gnawing injuries to both ears and jugular veins. Additionally, he had puncture wounds on the backs of his thighs as well as on the back of his head and neck. In this case, the attack was so powerful that he was found to have a dislocation of the C1/C2 vertebrae.

**Case 4:** A 45-year-old African American male was transported to the medical examiner's office with no known history other than that the victim was found lying deceased in the street. The decedent's body was covered in irregular lacerations and tears and had been castrated. There was evidence of multiple sharp force and blunt force injuries. Due to lack of further conclusive investigative findings, the death was ruled a homicide due to homicidal violence.

**Case 5:** A 50-year-old African American male stated before arriving at the hospital that a neighbor's dogs had attacked him and chased him down the street. At autopsy, there were numerous puncture wounds of the body, particularly on the left side and extremities. There was tearing and ripping of almost the entirety of the inner arms. Law enforcement investigation—in conjunction with the medical examiner's office findings—subsequently revealed that the victims in Cases 4 and 5 were killed by the same set of dogs. The dogs' owner was later charged with manslaughter with culpable negligence for both attacks.

#### Trauma, Dog, Laceration

### H6 Frangible Ammunition in Gunshot Wound Suicides in the Hampton Roads Region of Virginia: An Upward Trend?

Catherine G. Wilson, BS\*, Eastern Virginia Medical School, Norfolk, VA 23510; Gary M. Zientek, MD, Office of the Chief Medical Examiner, Virginia, Norfolk, VA 23510; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will be familiar with frangible ammunition effects on imaging and at autopsy of gunshot wound suicides and will elevate their index of clinical suspicion for an upward trend in its use.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of a possible trend in the use of frangible ammunition in gunshot wound suicides and by recognizing that frangible ammunition, although intended to cause less bystander damage, inflicts devastating injuries at contact range and may produce exit wounds.

Frangible ammunition has historically been used by law enforcement for training and for domestic and Special Weapons And Tactics (SWAT) team interventions, as it is more likely than conventional ammunition to wound only the intended target. This report reviews three recent gunshot wound suicides with frangible ammunition in the Hampton Roads area of Virginia (a catchment area covering a population approaching one million).

Within a span of three days, three unrelated persons committed suicide by gunshot wound to the head with frangible ammunition. A 25-year-old man with a family-reported history of psychiatric problems shot himself in the side of the head with a .40 caliber pistol, after first shooting and killing another victim with conventional ammunition in a homicide-suicide event. A 70-year-old male hunter, with a history of traumatic brain injury and anger management issues, shot himself in the side of the head with a .38 caliber revolver. In the third case, a 38-year-old woman with a significant psychiatric history shot herself in the forehead using a 9mm handgun loaded with 50-grain lightweight bullets carrying an increased gunpowder load. The first two decedents were proficient in knowledge of guns and ammunition (i.e., the younger man from military service and the older man from hunting experience). The third decedent used ammunition found at the scene.

On radiographic imaging of each decedent, there were radiating fractures from the entrance wound and frangible fragments scattered throughout the cranial cavity; the intact base of the frangible bullet was always identified. Autopsy of the first two cases demonstrated characteristic pulpified gunshot wound tracks through the brain, accompanied by multiple smaller tracks from ammunition and disrupted bone fragments. Fragments were also found in the scalp and dura. The first case had no exit wound. The second case had a partial exit wound from escaping fragments. The third case, with a central forehead entrance, had a continuous entrance-exit wound of the entire frontal skull and scalp, with radiating fractures throughout the calvarium and base of the skull; this case had some characteristics of a high-velocity gunshot wound, due to the ammunition type.

**Discussion:** Gunshot wounds comprise the most common method of suicide in the United States for both men and women. Standard ammunition is generally used (fully or partially jacketed lead-core bullets). Such bullets may be stripped into fragments during passage through bone from shearing forces, or they may remain intact. In contrast, frangible ammunition is manufactured to break apart into smaller pieces upon impact with hard surfaces. This enables law enforcement to reduce the risk of any ricochet damage.<sup>1</sup> Frangible ammunition can be differentiated from sheared standard ammunition on X-ray films by the granular-appearing borders of the fragments, the intact base, and the absence of standard core and jacket fragments.<sup>2</sup>

Studies have found that the damage caused by frangible ammunition is similarly severe to the damage caused by standard ammunition; these three cases illustrate the extent of damage caused by frangible ammunition in hard-contact gunshot wound suicides, and demonstrate that fragments may exit.<sup>3</sup> These cases also illustrate that frangible ammunition can be recognized by its characteristic appearance on radiographs and at autopsy, and that there may be increasing use of frangible ammunition in gunshot wound suicides.

### H7 The Feasibility of an Enteroclysis Pump for Postmortem Computed Tomography Angiography (PMCTA)

*Marloes E.M. Vester, MD, Amsterdam UMC, Location Academic Medical Center, Amsterdam, North-Holland 1105AZ, NETHERLANDS; Ellen Servaas, MSc, University of Applied Science Haarlem, Haarlem, Noord Holland 2015 CE, NETHERLANDS; Ludo F.M. Beenen, MD, Amsterdam UMC, Location Academic Medical Center, Amsterdam 1105AZ, NETHERLANDS; Mara Clerkx, Amsterdam UMC, Location Academic Medical Center, Amsterdam 1105 AZ, NETHERLANDS; Astrid De La Rie, MS, Amsterdam UMC, Location Academic Medical Center, Amsterdam 1105AZ, NETHERLANDS; Nick Lobé, Amsterdam UMC, Location Academic Medical Center, Amsterdam 1105AZ, NETHERLANDS; Maaike J. Vogel, Amsterdam UMC, Location Academic Medical Center, Amsterdam 1105AZ, NETHERLANDS; Rick R. Van Rijn, MD, PhD\*, Amsterdam UMC & Netherlands Forensic Institute, Amsterdam, Noord Holland 1105AZ, NETHERLANDS; Roelof-Jan G. Oostra, PhD, Academic Medical Center, Amsterdam 1100 AZ, NETHERLANDS*

**Learning Overview:** After attending this presentation, attendees will be better informed regarding the use of an easy-to-use, inexpensive enteroclysis pump to acquire an accuracy of PMCTA in a clinical setting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a new PMCTA method for daily use in their own clinical practices.

PMCT is an established method utilized to diagnose disease, detect complications, and assist in determining cause of death in both clinical and forensic cases. By adding intravascular infusion of contrast medium, PMCTA can provide additional information regarding vascular structures and hemorrhage. If easy to operate and low in cost, this technique would likely be more frequently utilized and of additional value for clinical and educational purposes, particularly in the forensic scientific context. As in the Netherlands, all postmortem imaging is performed in a hospital setting, this study developed a new alternative technique using materials readily available in a clinical setting. As an alternative pump, this study chose an enteroclysis pump, as these are readily available and yet not in continuous use in clinical practice.

PMCTA was performed on ten decedents obtained via the anatomy department. First, a metal T-piece was inserted into the femoral artery as part of the standard practice for conservation. Second, surplus contrast medium with sodium chloride was infused into the body through a catheter tube set attached to the metal T-piece, using an enteroclysis pump obtained from the radiology department.

To assess PMCTA quality, the body was divided into nine regions as follows: head-circle of Willis (COW), carotid arteries, aortic arch, thoracic aorta, abdominal aorta, upper arms (brachial artery), lower arms (radial and ulnar arteries), upper legs (femoral artery), and lower legs (tibia artery and peroneal artery). The regions were assessed for arterial vascular opacification by two independent researchers on a scale from 0 to 2, with 0 meaning no opacification, 1 meaning partial opacification, and 2 meaning complete opacification of the arteries. Results were analyzed utilizing Fisher's exact test for left and right artery opacification comparison.

With added costs of approximately €66 (approximately \$297), including personnel and materials, and an additional procedure time of 15–20 minutes, successful infusion of contrast mixture was achieved with the enteroclysis pump. Visualization of amount and extensiveness of structures, such as tumors in soft tissues, improved with PMCTA, along with improved identification of thrombi. Partial or complete opacification was measured in 89% of arteries. For arteries with both a left and right component, there was no significant difference between sides.

This study successfully evaluated an inexpensive and easy-to-use method to perform PMCTA for clinical postmortem investigations. This study presents a novel approach to PMCTA, increasing the technical arsenal of the autopsy pathologist and radiologist. With more and cheaper methods becoming available, this could help increase the acceptance of PMCTA by a wider audience.

## H8 The Utility of Routine Histological Sampling in the Assessment of Cause and Manner of Death in Medicolegal Autopsies—Fire, Immersion, and Traffic-Related Deaths

Björn Bäckström, MD\*, Umeå, AC, SWEDEN; Staffan Finn, Umeå University, Forensic Medicine, Umeå SE-907 12, SWEDEN; Peter Lydig, Umeå University, Forensic Medicine, Umeå SE-907 12, SWEDEN; Oscar Sandberg, Umeå University, Forensic Medicine, Umeå SE-907 12, SWEDEN; Anders Eriksson, MD, PhD, Umeå University, Umeå SE-907 12, SWEDEN; Torfinn Gustafsson, MD, Umeå University, Forensic Medicine, Umeå SE-907 12 Umeå, SWEDEN

**Learning Overview:** The goal of this presentation is to reveal the value of routine histological sampling in deaths related to traffic, fire, and immersion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing ethical standards and effectiveness and lowering costs.

In 1999, the European (EU) Committee of Ministers recommended histological sampling of “major organs” in medicolegal autopsies.<sup>1</sup> Also because of local routines, histological examination is often routinely included in the autopsy, although the scientific evidence regarding its value is disputed. Previous studies using mixed populations have shown inconsistent results, some highly favorable and others dismissing its utility.<sup>2-7</sup>

In order to allow practical applicable conclusions regarding the necessity of routine histological sampling, it seems necessary to analyze specific Cause Of Death (COD) groups separately. This study focused on deaths related to traffic, fire, and immersion, with the intent of analyzing the value of histology to determine COD and/or Manner Of Death (MOD).

Autopsy protocols, including toxicologic and histopathologic analyses, were acquired from the national database of the Swedish National Board of Forensic Medicine. Study cases were selected based on information available *before* autopsy, suggesting traffic-related, fire-related, or immersion-related deaths. Fifty cases in each study group were selected from the years 2017 and 2018. Any information connected to the decedent, the forensic pathologist, the forensic medicine unit, original assessments regarding COD and MOD, and histological analyses, was masked out. The study was performed in two steps, and there were four reviewers, with two reviewers participating in each subgroup analysis.

**Step 1:** The de-identified autopsy protocols (excluding histological analyses) were sent to two independent, board-certified forensic pathologists who independently reviewed the macroscopic and toxicologic findings. The reviewers determined the COD and the MOD and graded the certainty of their assessments using an incremental scale.

**Step 2:** After reporting the results of Step 1, the reviewers were given access to the histologic analysis in each case, then reevaluated their previous assessments, including the degree of certainty. Any discrepancy between ante-histology and post-histology assessments regarding COD and MOD was analyzed.

Cases were classified on a 1–5 scale as to the extent of agreement ante- vs. post-histology, and the underlying COD was registered in all cases, both ante- and post-histology. Ordered-logistic and logistic Bayesian generalized linear models were used to model the effect of histology on underlying COD, MOD, and agreement.

**Agreement:** In all groups the inter-observer agreement was high both ante- and post-histology. There were minor shifts in agreement in the immersion and traffic-related deaths but none in the fire group. The effect of histopathology on agreement was credibly 0 (-0.4, 0.4 95% Highest Posterior Density Interval [HPDI]) in all groups.

**Underlying COD:** The probability of changing COD for an average observer was small in all groups; in fire cases 0.0038 ( $1.02 \times 10^{-26}$ , 0.016 95% HPDI), in immersion 0.018 ( $9.02 \times 10^{-12}$ , 0.068 95% HPDI), and in traffic cases 0.032 ( $1.38 \times 10^{-13}$ , 0.13 95% HPDI).

**MOD:** The probability of changing MOD for an average observer was small in all groups; in fire cases 0.0038 ( $1.74 \times 10^{-33}$ , 0.015 95% HPDI), in immersion 0.024 ( $4.08 \times 10^{-16}$ , 0.079 95% HPDI), and in traffic cases 0.013 ( $2.65 \times 10^{-11}$ , 0.043 95% HPDI).

**Certainty of assessment:** Regardless of change in COD and MOD, the change in certainty in COD was highly variable. In fire cases, the probability of change was 0.074 ( $4.25 \times 10^{-7}$ , 0.25 95% HPDI), in immersion 0.74 ( $1.42 \times 10^{-7}$ , 0.26 95% HPDI), and in traffic cases 0.11 ( $1.69 \times 10^{-7}$ , 0.37 95% HPDI).

**Conclusions:** Based on the results, and when considering the economic, ethical, and legal aspects, it is concluded that routine histologic sampling is not mandatory in any of the three study group scenarios. Instead, histologic sampling should be left to the experienced forensic pathologist to decide on a case-by-case basis.

### H9 Fibroplasia Ossificans Progressiva (FOP): Could Autopsy Define Syndromic Features?

Vittorio Bolcato, MD, Department of Public Health, Pavia 27100, ITALY; Matteo Moretti, MD\*, University of Pavia, Pavia 27100, ITALY; Claudia Carelli, Cossato, ITALY; Davide Radaelli, Pavia 27100, ITALY; Paolo Musto, Portacomaro, Asti 14037, ITALY; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand this rare genetic disorder, characterized by ossification of soft tissues, and be aware of the most frequently associated causes of death: thoracic insufficiency syndrome, recurrent respiratory infections, and accidental trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with the understanding that postmortem investigations could discover additional features, unknown in the clinical setting, improving the knowledge about the pathophysiology of rare diseases. This could directly impact also on earlier diagnosis, prevention of complications, and rehabilitation of patients.

This study describes the autopsy findings in a 27-year-old woman affected by FOP who died after a fall from a stairway. Cardiopulmonary resuscitation was unsuccessfully performed by responders. While the death was suspected to be attributable to traumatic head injury and intracranial hemorrhage, an autopsy was requested due to the unclear circumstances of the fall.

FOP is a rare (1/2.000.000 inhabitants) autosomal dominant disorder resulting in progressive bone formation in soft tissues due to the mutation of the Activin Receptor 1 (ACVR1) gene, which encodes for Bone Morphogenetic Protein type-1 Receptor (BMPRI). The ossification of muscles, tendons, ligaments, and other mesenchymal tissues, in association with congenital skeletal malformations, leads to a severe reduction of joint mobility and therefore to severe disability.

At autopsy, rigor mortis was difficult to evaluate due to FOP-related firm rigidity as the upper and lower extremities were diffusely fixed in flexion. An ogival palate with tooth overcrowding was also seen. There was kyphoscoliosis of the spine and major deformity of the chest wall resembling pectus carinatum. Hallux valgus was also observed.

There was evident trauma of the head, including a laceration of the scalp in the vertex region and a diastatic median skull fracture originating from the vertex and involving the fused metopic suture, crossing the anterior cranial fossa and ending in the sella turcica. Associated diffuse subdural hemorrhage and subarachnoid hemorrhage, especially in the cerebellum and around the brainstem, was evident. There was also a right periorbital hematoma with bruising of the left forearm, the back side of the left hand, and the right leg. Microscopic sections of the brain demonstrated recent cerebral hemorrhage. The spine was intact, whereas ribs were fractured on both sides. Both lungs showed subpleural petechiae, edema, and congestion. Microscopic sections of the lungs showed acute emphysema and intra-alveolar hemorrhage, with areas of edema. The thyroid gland appeared grossly unremarkable, but histologically showed diffuse lymphocytic infiltration and some fields of fibrosis. In a histologic sample of muscular tissue (quadriceps femoris), small areas with necrosis of myocytes and hyperplasia of fibroblasts were seen, indicating an initial thin fibrosis. Also, the tendon of the left pectoralis major muscle was completely ossified.

The cause of death of this young woman was certified as being due to severe head and brain trauma. Joint stiffness could explain the walking disability and thus the fall. The investigation led to the manner of death being certified as accidental. The finding of thyroiditis—although clinically silent—appeared consistent with the other reports and probably correlated to the gene mutation. Even non-affected muscle areas already exhibited microscopic foci of inflammation and degeneration. Further study of these elements could better help define characteristics of FOP syndrome.

#### Fibroplasia Ossificans Progressiva, Thyroiditis, Fibrosis

## H10 A Questionable Cause of Death Alphabet Soup: Anaphylaxis, Bees, Cocaine, Diabetic Ketoacidosis (DKA), Emphysema, Fogger, Hypothermia, Insecticide, and Opiates

Thomas B. Duong, BS\*, Western Michigan University School of Medicine, Kalamazoo, MI 49007; John Winterholler, BS, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007; Prentiss Jones, Jr., PhD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will gain a better understanding of the proposed mechanism and etiologies of gastric Wischnewsky Lesions (WLs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a case in which a clear cause of death was confounded by various findings via history, forensic autopsy, toxicology, and other testing.

WLs are dark, discrete mucosal lesions 1mm to 4mm in diameter found scattered on the gastric mucosa. Since their discovery, they have been thought to be virtually pathognomonic for hypothermia-related death. More recently, they have been associated with pancreatitis, burns, and DKA.<sup>1-3</sup> Here is presented the case of a diabetic man who was found dead in his home in the wintertime with multiple potential causes of death, including DKA, hypothermia, anaphylaxis, drug overdose, and insecticide poisoning.

A 58-year-old man with a history of hypertension, diabetes, and bee sting allergy was found naked and deceased in his home in December. Found within the home were plastic bags containing a powdery white substance, a room with hundreds of dead yellowjacket wasps, empty cans of insecticide and foggers, and a used epinephrine pen. The home's furnace was working, and the temperature was 69°F. Forensic autopsy revealed multiple healing excoriations of the lower extremity, some of which contained dark, linear foreign bodies measuring 3–4mm in length. Early decomposition was also present, with softening of the internal organs and decomposition fluid within the pleural cavities. The lungs revealed pink-red crepitant parenchyma consistent with chronic asthmatic bronchitis. The stomach contained partially digested food/fluid, and the gastric mucosa contained numerous well-developed WLs. Toxicology testing on urine was positive for alprazolam, morphine, codeine, and benzoylecgonine, while heart blood testing revealed alprazolam (3.2ng/mL), morphine (28.4ng/mL), codeine (587ng/mL), acetone (0.038%), and isopropanol (0.025%). The absence of cocaine and the cocaine metabolite benzoylecgonine in the blood was not unexpected given that these compounds are extensively degraded in unpreserved blood. Serum trypsin was 15.9ng/mL and urine n-methylhistamine was 177mcg/g. Vitreous acetone was 0.062%, vitreous glucose was <2mg/dL, and hemoglobin A1c was 5.9%. Despite the multiple potential competing possibilities, the major contributing cause of death was considered diabetes mellitus with ketoacidosis.

WLs were once thought to be pathognomonic for hypothermia, with one study suggesting 88.3% specificity.<sup>4</sup> While the exact mechanism is unknown, current hypotheses involve gastric gland hemorrhage secondary to hypothermic stress, metabolic derangement, and coagulopathy.<sup>5</sup> In particular, coagulopathy is thought to be a potential link between hypothermia, DKA, and WLs, as hypothermia can have an anticoagulative effect that is enhanced by acidosis.<sup>6-7</sup> While the presence of WLs was suggestive of hypothermia and/or DKA in the present case, a definitive cause of death was precluded by multiple confounding findings. While the patient's naked state raised the possibility of "paradoxical undressing" often seen in hypothermia, the working furnace and temperature made this less likely. Similarly, while a history of diabetes and vitreous acetone of 0.062% suggested DKA, the vitreous glucose was <2mg/dL and hemoglobin A1c was only 5.9. The history of bee sting allergy, the presence of yellowjackets, and the used epinephrine pen further obscured the picture; however, serum trypsin and urine n-methylhistamine were within reference ranges. The presence of used insecticide cans and foggers raised the possibility of toxicity due to pyrethroids, synthetic insecticides whose popularity have recently climbed due to increasingly restricted use of organophosphates and use as a recreational drug.<sup>8</sup> Additionally, natural disease (hypertension, asthma) and/or drug use (cocaine, opiates) could not be totally excluded as being potentially contributory to death. Ultimately, the presence of acetone and isopropanol, as well as the florid gastric WLs, led to the conclusion that ketoacidosis probably played the most significant role in death. This case represents an excellent example of a situation in which multiple competing potential factors may have contributed to death. Forensic pathologists are well aware of the fact that, in many cases of this type, a definite answer is unable to be determined with certainty.

### H11 The Importance of Dashboard Camera Analysis in Fatal Vehicle-Pedestrian Crash Reconstruction

*Paolo Fais, PhD\**, Department of Medical and Surgical Sciences, Bologna 40126, ITALY; *Jennifer Pascali, PhD*, Piazzale L.A. Scuro 10, Verona 37134, ITALY; *Guido Pelletti, MD*, Department of Medical and Surgical Sciences, Bologna 40126, ITALY; *Alessio Giusti, Bologna 40125, ITALY*; *Susi Pelotti, MD*, University of Bologna, Bologna 40126, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the importance of a comprehensive investigation at the death scene, including the analysis of Digital Video Recorder (DVR) dashboard camera images for the reconstruction of car crashes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the risk and the benefits related to the use of a DVR. Indeed, as demonstrated from the reported case, a DVR may be of the utmost importance to protect the driver against the distortion of facts. On the other hand, DVR devices attract negative attitudes for privacy concerns and are not legal in many states.

A DVR is an onboard camera that continuously records the view through a vehicle's front windscreen and sometimes through the rear or other windows. Moreover, some dashboard cameras (i.e., "dashcams") include a camera to record the interior of the car and can automatically send pictures and video. Some more sophisticated DVRs may even allow for recording of other data, such as acceleration/deceleration (g-force), speed, steering angle, and Global Positioning System (GPS) information.

The case of a vehicle-pedestrian fatal crash illustrating the importance of DVR analysis is herein presented. A car rolled many times over the road. The driver was able to climb out of the car and walked toward the street, but was subsequently hit by a Russian articulated lorry (i.e., a tractor-trailer truck.) An autopsy was performed one day later and demonstrated multiple extensive traumatic injuries, including fractures and lacerations of the head with intracranial hemorrhage. There were also traumatic injuries of the thorax, abdomen, and multiple internal organs. Toxicologic analyses were performed on postmortem blood and urine with results positive for 11-Nor-9-Carboxy-Delta-9-Tetrahydrocannabinol (THC-COOH) in urine and negative for all other tested substances (namely, alcohol and common drugs of abuse.) Based on these results, the death was determined to be attributable to the massive cranio-encephalic trauma, and prior cannabis abuse was suspected. The manner of death was initially hypothesized to be an accident based on the absence of previous suicidal attempts/ideation, and scene investigative findings, including the lack of a sidewalk and the very narrow roadside available for pedestrians on the rural road where the collision occurred. Ultimately, however, the analysis of DVR images clearly identified a deliberate rush at the front of the Russian articulated lorry, leading to the certification of the manner of death as suicide.

While dashcams are gaining in popularity as a method of protection against the distortion of facts, they may also attract negative attitudes due to privacy concerns. Different countries have varying laws on the use of dashcams. As a result, in some nations (e.g., Russia) DVRs are very popular and are widely used as medicolegal evidence, while other countries ban or strongly limit their use due to concerns regarding privacy. As illustrated by the case reported herein, additional evidence derived from DVRs may be of the utmost importance in accurately determining the manner of death and preventing a miscarriage of justice.

#### Forensic Pathology, Dashboard Camera, Traffic Accident

### H12 Computed Tomography (CT) and X-Ray Angiography on a Case of Traumatic Carotid Artery Occlusion Following a Physical Altercation Resulting in Cerebral Infarction

Francesco Pontoriero, DO\*, State of Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223; Rochelle A. Simon, MD, State of Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223; Zabiullah Ali, MD, State of Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223; Nikki Mourtzinou, DO, State of Maryland Office of the Chief Medical Examiner, Baltimore, MD 21204; David R. Fowler, MD, State of Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to serve to heighten the awareness of the setting in which carotid artery lesions could potentially be missed on autopsy. Application of postmortem CT or X-ray angiography can aid in the identification and evaluation of these lesions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness regarding the appropriate process involved in the evaluation of carotid artery trauma and thrombosis due to blunt force injury.

There is a paucity published in the medical forensic literature on cases related to carotid arterial injury. Furthermore, there is a risk that such a finding may be overlooked during postmortem examination, especially in the presence of multiple blunt force injuries, with misinterpretation of findings leading to incorrect cause and manner of death certification. CT and X-ray angiography can aid in the identification of such an injury. This presentation describes such a case, which provoked a brief review of related available literature.

The decedent was a 33-year-old man with no significant medical history who was involved in a physical altercation with another individual and subsequently complained of feeling unwell. Three days later he was found unresponsive at his residence; emergency medical services responded and transported him to a local hospital where he was diagnosed with a large left-sided stroke. An ultrasound revealed carotid artery occlusion. Despite medical interventions, he was pronounced deceased after brain death was confirmed, and after the family elected to remove life support.

At autopsy, the external examination revealed a healing abrasion on the left posterolateral upper neck, and multiple healing abrasions on the chest, back, and extremities. CT and X-ray angiography of the head and neck were performed and showed occlusion of the left internal carotid artery. Internal examination revealed superficial hemorrhage of the left sternocleidomastoid muscle and patchy soft tissue hemorrhage posterior to the left internal carotid artery, the lumen of which showed an occluding thrombus just distal to the bifurcation of the left common carotid artery. There was no histologic evidence of medial dissection. The thrombus extended to involve the left middle cerebral artery with associated cerebral infarction involving the left cerebral hemisphere. The left cerebral hemisphere showed marked edema. Left cingulate herniation and left uncal herniation were apparent, as well as bilateral tonsillar herniation of the cerebellum. The remainder of the autopsy was essentially unremarkable. The toxicology screen was negative for drugs of abuse. The cause of death of this decedent was certified as acute cerebral infarction due to traumatic carotid artery occlusion following a physical altercation. The manner of death was certified as a homicide due to the temporal relationship between the physical altercation and the development of symptoms.

Singh and associates have reported occlusion involving the internal carotid artery and, in a separate case, occlusion involving the common carotid artery.<sup>1</sup> Both cases had presentations that could have led to misinterpretation of medical findings, leading to missed diagnoses of carotid artery injury and occlusion due to trauma. According to Liu et al., blunt carotid artery injury leading to thrombosis and neurologic impairment has an incidence rate of 1%.<sup>2</sup> Biomechanically, they reported such injuries can occur either via direct blunt force injury, hyperflexion of the cervical spine resulting in arterial compression involving the mandible and spine, oropharyngeal trauma, hyperextension of the cervical spine and rotation, and the fracture of the basal skull causing injury of the intracranial segment of the internal carotid artery. In the forensic literature, An reported that fatal thrombosis involving the internal and common carotid arteries can occur in the setting of little-to-no evidence of external or internal injury, as was seen in the presented case.<sup>3</sup>

### H13 IL-15, CD-15, and Tryptase as Markers of Wound Vitality in Compressed Neck Skin: When Conventional Macroscopic and Histological Findings Fail

Omar Bonato, MD\*, University of Ferrara, Ferrara 44121, ITALY; Sara Chierici, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Ferrara 44121, ITALY; Letizia Alfieri, MD, University of Ferrara, Ferrara 44121, ITALY; Enrica Calabrese, MD, University of Ferrara, Ferrara 44121, ITALY; Paolo Frisoni, MD, University of Ferrara, Ferrara 44121, ITALY; Matteo Fabbri, MS, University of Ferrara, Ferrara 44121, ITALY; Matteo Marti, PhD, University of Ferrara, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY

**Learning Overview:** The goal of this presentation is to expose two cases of hanging suicide in which autopsy and conventional histology were not conclusive in determining the vitality of the ligature mark by analyzing and drawing attention to the use of an immunohistochemical investigation, especially regarding IL-15, CD-15, and tryptase.

**Impact on the Forensic Science Community:** Though most hangings are suicide, homicide and subsequent hanging of the victim are described. This presentation will impact the forensic science community by presenting two cases in which autopsy and conventional histology were not conclusive in determining the vitality of the ligature marks, while immunohistochemistry techniques provided a substantial contribution to the ligature marks vitality estimation.

In forensic practice, it is necessary to distinguish between hanging and simulated hanging. To differentiate between these two occurrences, forensic pathologists have to distinguish antemortem from postmortem ligature marks. Conventional macroscopic and histologic findings may be unreliable; this particularly applies to soft ligature marks, where vital tissue reaction signs are often deficient or absent. Hemorrhagic infiltration is typically considered to be evidence of vital reaction, but Red Blood Cell (RBC) extravasation can also occur after circulatory arrest. The presence of inflammatory cells is the only solid standard histologic finding indicating antemortem origin, and immunohistochemistry is the method of choice to help assess for this in forensic pathology.

Two cases of hanging are presented herein in which the macroscopic findings and conventional histology were not sufficient to enable discrimination between antemortem versus postmortem ligature marks.

**Case 1:** A 29-year-old man was found hanging partially suspended by trousers tied to the bars of the armored door of his cell on the same night he was incarcerated. His cellmate declared that he had not noticed anything. Crime scene investigation was conducted with the presence of the forensic pathologist; there was a small skin abrasion of the left side of the neck (i.e., a barely defined ligature mark only on the left side of the neck). Simulated hanging was suspected. Autopsy external examination revealed conjunctival petechial hemorrhages. Two parched skin abrasions were observed in the frontal and lumbar regions; others skin abrasions were detected on the hands. Internal examination of the neck showed small hemorrhages of both thyrohyoid muscles and of the thyroid cartilage. No fractures were found. Histologic hematoxylin- and eosin-stained sections showed scant erythrocytes in the subcutaneous tissues of the left site of the neck; no others evidence of vital reaction was noted. In order to thoroughly evaluate the case, immunohistochemical investigation of neck skin samples was performed utilizing antibodies against IL-15, CD-15, and tryptase. A positive reaction was achieved for all the antibodies used. The results of the forensic examination, together with immunohistochemical investigation, confirmed the vitality of the skin wound reaction. The cause of death was certified as mechanical asphyxia due to suicidal hanging.

**Case 2:** A 61-year-old man was found hanging by two belts attached to a shower box. The ligature was removed by his brother, who called the police. The autopsy was performed the next day. Two ligature marks, horizontally oriented, were present above the level of thyroid cartilage. There were no petechial hemorrhages. Dissection of the neck showed only limited extravasation of blood in the suprahyoid muscles. The laryngo-hyoid apparatus was intact. Histologic examination of the skin of the ligature furrow did not show the presence of erythrocytes in the tissues, so immunohistochemical studies were performed utilizing antibodies against tryptase and IL-15. Positive staining was observed in the sample, confirming a vital tissue reaction within the ligature mark. The death was attributed to suicidal hanging.

Presented here are two cases in which autopsy and conventional histology were inconclusive in determining the vitality of ligature marks, but immunohistochemistry provided substantial contribution to wound vitality estimation. Tryptase, IL-15, and CD15 can prove to be useful and reliable forensic studies for determining vital tissue reaction in ligature marks.

#### Hanging, Vitality, Immunohistochemistry

### H14 Where is the Neoplasm? The Postmortem Diagnosis of Intravascular Large B-Cell Lymphoma (IVLBCL)

*Zoe Del Fante, MD\*, Rome, ITALY; Nicola Di Fazio, Università La Sapienza di Roma, Rome 00161, ITALY; Silvia Romano, Università La Sapienza, Rome 00161, ITALY; Alessandra De Matteis, MD, University Sapienza of Roma, Rome 00100, ITALY; Paola Santoro, MD, Rome, ITALY; Aniello Maiese, MD, Sapienza University of Rome, Rome 00185, ITALY*

**Learning Overview:** The goal of this presentation is to share the study results that demonstrate that the best instrument to make a diagnosis is represented by immunohistochemical staining of a tissue specimen (with a specific panel made of CD20 and CD45), while instrumental exams (Computed Tomography [CT], Magnetic Resonance Imaging [MRI], Positron Emission Tomography [PET], and biopsy) exhibit a high number of false negative results.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by how this results in a valid aid for the pathologist when approaching an extremely rare disease, such as IVLBCL.

IVLBCL is a rare non-Hodgkin extranodal B-cell lymphoma that occurs with a prevalence lower than 1%. It has an aggressive clinical behavior and it is characterized by the presence of malignant lymphoid cells within the blood vessels, more specifically capillaries. Making the diagnosis can be challenging because of the heterogeneous and non-specific presentation of the disease due to the generalized organ dysfunction secondary to vascular obstruction; neurological signs and symptoms are the most common presentation of the disease. Clinical diagnosis is based on imaging (CT scan, MRI), peripheral blood smear, cerebrospinal fluid cytology, biochemical examination, and bone marrow biopsy results. Nevertheless, diagnosis may be difficult and literature suggests that very often the disease is recognized only after autopsy examination.

The case presented herein is that of a 50 year-old man with a history of myeloradiculitis hospitalized for paraparesis. The CT showed no evidence of lesions or other altered findings. Lumbar-spine MRI showed conus medullaris swelling between D11 and L1 and vasogenic edema of anterior and posterior cords. Although PET imaging showed an increase uptake in the adrenal glands and a focal area within the mesenteric adipose tissue, both serologic exams and bone marrow biopsy were negative. Spinal cord biopsy showed necrotic nervous tissue with low CD68+ macrophage infiltrates, reactive gliosis, and negative staining for MAP2. After two months, the patient died of respiratory failure.

Gross autopsy examination was negative, apart from findings suggestive of pulmonary infection and reduced consistency of the spinal cord. Examination of histologic samples from the brain, heart, lung, and liver tissue showed collections of atypical cells with enlarged, pleomorphic, hyperchromatic nuclei within blood vessels and interstitium as well as lymphocyte infiltration. Immunohistochemical examination was performed evaluating for the following markers: cytokeratin, CD3, CD20, CD45, PDL-1, CK20, CK7, MCK, and TTF1. A strong intravascular positivity for CD45 and CD20 was found. In sum, these findings would support a B-cell lineage for the neoplastic cells and the postmortem diagnosis of intravascular large B-cell lymphoma.

This case report demonstrates that the most reliable means of making the postmortem diagnosis of IVLBCL is via immunohistochemical staining of tissue specimens (with a specific panel including CD20 and CD45). Other techniques such as radiologic studies (CT, MRI, PET) or bone marrow biopsy show a high number of false negative results.

#### **Intravascular Large B-Cell Lymphoma, Postmortem Diagnosis, Immunohistochemistry**

### H15 Numerical Postmortem Interval (PMI) Estimation Streamlined for Forensic Practice: Combining Photogrammetry, Thermal Imaging, and Computed Tomography (CT)

*Leah Wilk\*, Academic Medical Center, Amsterdam, Noord Holland 1105AZ, NETHERLANDS; Gerda Edelman, Netherlands Forensic Institute, The Hague, 2497 GB, NETHERLANDS; Maurice Aalders, Academic Medical Center, Amsterdam, North Holland 1105AZ, NETHERLANDS*

**Learning Overview:** After attending this presentation, attendees will have learned how computational algorithms and advanced imaging techniques can be combined to streamline numerical postmortem temperature-based PMI estimation for forensic practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting, for the first time, an easy-to-use, accurate, and flexible method for temperature-based PMI estimation, potentially replacing the frequently inaccurate current gold standard.

The PMI represents crucial information in forensic investigations and can aid in the reconstruction of the timeline of events. Currently, this information is either guessed at or provided by an empirical model (Henssge's nomogram) based on a set of rectal temperature measurements performed under standardized experimental conditions. In practice, many forensic cases strongly deviate from these standardized conditions, rendering the model's PMI predictions largely inaccurate. A more rigorous and versatile approach to temperature-based PMI estimation was previously developed combining a comprehensive numerical (finite-difference) thermodynamic model and exterior (skin) temperature measurements. In this approach, a discrete (cubic) spatial grid is used to generate a 3D, computational representation of the body and its surroundings, enabling calculation of the heat exchange between the two. Here, this heat exchange is modelled as a combination of heat conduction, convection, and radiation; the body is approximated as an assembly of cones, ellipsoids, and cylinders (composed of adipose and non-adipose tissue) the proportions of which are dictated by standardized anatomical measurements (e.g., length of the arms and legs, as well as the circumference of the head, torso, upper arms, and wrists). Consequently, body posture, body dimensions, and environmental variables, such as contact surface, (partial) submersion in water, and (partial) coverage by clothes, are all readily included in the model. Knowledge of the thermal properties of the involved materials and timely probing of the heat exchange process (prior to thermal equilibrium) then allows the estimation of the PMI. Indeed, cooling curves measured on deceased human bodies are in close agreement with the model predictions yielding estimated PMIs within, at most, 2.7h of true PMIs between 7h and 20h. As a result, this approach is not only more versatile and widely applicable than Henssge's nomogram, but also outperforms it in terms of accuracy of the predicted PMI.

Despite the predictive capabilities of this approach, its laborious anatomical measurement routine renders application in forensic practice challenging. To address this challenge and streamline this technique, this study introduced photogrammetry-based generation of the model body. Here, the 3D shape of the body is reconstructed from a set of 2D images. This 3D information then serves to simultaneously render the dimensions and the posture of the model body in a robust and rapid manner. Furthermore, photogrammetry allows highly accurate spatial co-registration of measured and simulated skin temperatures through the use of coded imaging targets. This not only increases the PMI estimation accuracy, but also enables the integration of thermal imaging by the same token. As a result, this integrated approach requires minimal user input and physical contact. Besides accurately modelling the geometry of the body and its surroundings, it is crucial that the model's material composition closely resembles reality to ensure accurate simulation of the temperature evolution. An important factor in this effort is the body fat percentage, which was previously estimated using the United States Navy circumference method. In order to model the body composition more accurately, this study utilized PM CT scans to derive the 3D adipose tissue distribution that then served in the thermal property assignment for the model body. Similarly, this tomographic information also allows the modelling of body cavities filled with air (or other materials). Here, this presentation demonstrates the successful integration of co-registered photogrammetry, thermal imaging, and CT scans within a previously developed and validated finite-difference framework for numerical PMI estimation. Together, the versatility, limited required user input, and sample contact constitute the streamlined nature of this integrated approach and, consequently, establish its potential for future use in forensic practice.

**PMI, Thermodynamic, Numerical**

### H16 When Hidden Elder Abuse Leads to Death: An Analysis of Casework

*Alberto Amadasi, MD\**, Università di Bologna, Bologna 40126, ITALY; *Federica Fersini, Bologna 40138, ITALY*; *Paolo Fais, PhD, Department of Medical and Surgical Sciences, Bologna 40126, ITALY*; *Guido Pelletti, MD, Department of Medical and Surgical Sciences, Bologna 40126, ITALY*; *Maria Carla Mazzotti, MD, Department of Medical and Surgical Sciences, Bologna 40126, ITALY*; *Susi Pelotti, MD, University of Bologna, Bologna 40126, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the fatal consequences of elder abuse and its different forms, the current situation of underestimation of the problem, and the need to develop effective prevention programs based on the understanding of risk factors.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an analysis of six forensic cases in which the diagnosis of elder abuse was only raised postmortem after an accurate investigation of the scene, of the circumstantial data, and of the autopsy evidences.

According to the World Health Organization (WHO), elder abuse is defined as “a single, or repeated act, or lack of appropriate action, occurring within any relationship where there is an expectation of trust, which causes harm or distress to an older person.” It is currently considered a major public health issue, even though underestimated and underreported, with identification remaining a challenge, especially in the health care context. Moreover, specific “gold standard” diagnostic criteria/markers are still lacking. Therefore, the identification of elder abuse may occur only after the death of the victim. In the present study, six forensic cases of death where elder abuse was suspected were analyzed. In these cases, elder abuse was not always directly related to death, but often contributed to the context in which death occurred. The determination of elder abuse was made based on the combination of all the findings available from the autopsy, the scene analysis, and the circumstantial data.

Case 1 was the homicide of an 85-year-old woman due to strangulation by her cohabiting mentally ill son; the cachectic corpse and the presence of untreated bedsores indicated long-lasting neglect that was unrecognized and unreported. Case 2 was a 65-year-old man who lived alone and died due to winter exposure in a home with broken windows and no heat; self-neglect contributed directly to death. Case 3 was an 81-year-old man sharing an apartment with his mentally ill son; although his death was attributed to natural causes, a context of neglect was evident as he showed postmortem signs of rat injuries to his legs. Case 4 was a 73-year-old completely isolated woman who died of natural causes at home, but was found with her face and neck disfigured by her dog; the modality of death was based on the isolated vulnerable status of the elderly woman. Case 5 was that of a cohabiting mentally ill son who kept the body of his 92-year-old mother at home for about two weeks after her natural death; elder abuse was determined due to lack of social and health services, despite the presence of risk factors. Case 6 was an 86-year-old man who suffered a femur fracture while trying to escape from a long-term care facility where residents were maltreated. The fracture led to hospitalization and death: mistreatment of residents by staff members in these facilities occurred with sufficient frequency to be of concern to health professionals.

In all the cases, the common denominator was the fact that the diagnosis of elder abuse or neglect was only made postmortem based on scene investigation, autopsy, and analysis of all the circumstantial data. The gathering of this information allowed for recognition of the presence of risk factors not previously assessed or reported by anyone. Currently, there are no specific markers of elder abuse, but history and background information together with the autopsy findings indicative of neglect and/or evidence of physical injuries may lead to diagnosis and show that the early recognition of risk factors could help in prevention and treatment approaches.

#### Elder Abuse, Autopsy, Risk Factors

### H17 A Corpse in a Suitcase: A Case of Strangulation

*Francesco Amico, MD\*, Medicina Legale, Catania 95123, ITALY; Marco Torrì, University of Catania, Catania 95123, ITALY; Dario Condorelli, University of Catania, Catania 95100, ITALY; Ilenia Russo, Catania 95123, ITALY; Martina Fichera, MD, University of Catania, Catania 95123, ITALY; Giuseppe Cocimano, MD, University of Catania, Catania, Italy; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY; Monica Salerno, MD, PhD, University of Catania, Forensic Medicine, Catania 95123, ITALY; Angelo Montana, MD\*, University of Catania, Catania 95123, ITALY; Fabrizio Vanaria, MD\*, Department of Italian State Police, Catania, ITALY*

**Learning Overview:** The goal of this presentation is to report the case of a 54-year-old woman strangled and hidden in a suitcase. A careful crime scene investigation, an external examination, and a complete autopsy with the histological study of skin specimens to determine the vitality of injuries are mandatory to establish the differential diagnosis between the different types of asphyxia deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the usefulness of a multidisciplinary forensic approach by the crime scene analysis, external examination, autopsy, and histological/immunohistochemical and toxicological investigation in cases of strangulation.

A 54-year-old woman was found lifeless inside a suitcase on a cliff near a mountain road in southern Italy. The prosecutor's officer alerted the forensic pathologist, and a detailed crime scene investigation was performed. The body was found curled in a left lateral position with the head flexed. The right upper limb was abducted anteriorly, flexed and intrarotated, and the left upper limb was abducted and flexed; the flexed left hand rested on the left knee, and the lower limbs were flexed to the maximum degree, with feet twisted and placed right on the left. The head was wrapped by a jacket. The cadaveric temperature was 19°C. Rigor mortis was present in all the examined anatomical regions and hypostasis was fixed.

At autopsy, external examination revealed widespread deepithelialized areas and purplish areas on the face and the right anterior neck. The fifth metacarpal bone of the right hand demonstrated a deepithelialized area with the shape of a dental arch. The victim had multiple petechiae and areas of hemorrhage in both sclera and conjunctivae. Many reddish, half-moon-shaped deepithelialized areas were founded on the anterior side of the neck. During internal examination, the tissues of the neck were dissected in layers, revealing diffuse hemorrhagic infarction of subcutaneous tissues. Autopsy also showed airway hemorrhagic infarction, especially in the thyroid cartilage region. Diffuse subarachnoid and intraventricular hemorrhages and pulmonary petechiae were found as well. The analysis of the other organs was unremarkable. Hematoxylin and Eosin (H&E) stained histologic sections revealed polyvisceral stasis, extensive cerebral subarachnoid and intraventricular hemorrhages, pulmonary edema, and acute emphysema. An immunohistochemical investigation of skin samples was performed utilizing antibodies anti-CD15, anti-tryptase, and anti-IL15, which appear to be reliable markers of vital tissue reaction. Immunohistochemistry showed a patchy dermal strong positivity of CD15, tryptase, and IL-15, confirming a vital reaction within injured tissue. Blood toxicologic examination was negative for alcohol or drugs.

Signs of asphyxial death (i.e., petechiae, areas of hemorrhage in both sclera and conjunctivae, pulmonary edema, and acute emphysema), half-moon-shaped deepithelialized areas on the anterior side of the neck, the airway hemorrhagic infarction, and the acute vital reaction within injured tissues together allowed for confirmation of the cause of death as homicide by strangulation.

### Strangulation, Homicide, Corpse Concealment

### H18 The Analysis of Head Injury in the Evaluation of Manner of Death: A Forensic Case Series and a Review of the Literature

Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Carmen Scalise, MD\*, University of Catanzaro, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Matteo A. Sacco, MD, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to describe the role of a head injury pattern.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how head injuries show typical patterns according to the mode of death.

Head injuries are very common in forensic pathology. Injuries are classified by mechanism, morphology, and severity. According to mechanism, the injuries are open or closed. According to morphology, there are concussions, hematomas, contusions, and cerebral hemorrhages. Severity is assessed through the symptoms. In forensic pathology, head injuries are important in determining the cause and manner of death. They may differ in cases of murder, accident, work-related, or natural deaths; the pattern shows typical features according to the manner. Further, in each case, the analysis of head injuries provides useful information. Described herein are the patterns of head injuries that occurred in four forensic cases.

A woman was found murdered. The autopsy showed 20 different open head injuries. Each injury had indented edges with rounded and convex features. The lesions were overlapped, with depressed skull fractures. The morphology of the edges suggested that the perpetrator hit the woman's head repeatedly using a circular metallic tube. This dynamic was confirmed by the murderer.

In the second case, a man of about 50 years of age fell from a height during work. There were multiple bruises on his head. The autopsy showed major head injury with cerebral hemorrhage, subarachnoid hemorrhage, and multiple right frontal-parietal-temporal region fracture lines. The man was not wearing either a helmet or body harness.

In the third case, a man died in a road traffic accident as a passenger. The man was found outside the car with a large head injury and exposure of the brain. Head trauma was characterized by a large parietal fracture and laceration of the skin. The car had a broken window (point of impact), and the encephalon residues were also found on the guardrail. The autopsy showed that the man was not wearing a seat belt.

In the last case, a man was found dead in the countryside. The man had a bruise on the left parietal region, with red lividity on the thorax and neck. The autopsy revealed no fractures nor brain injuries and proved that the man died from heart failure.

According to a literature review, 39% of deaths related to head injuries are accidents, 43% are homicides, and 17% are undetermined. In work-related deaths, head injuries are the most common finding. There are no data about natural deaths.

The review showed that multiple overlapping injuries with subdural hemorrhage and depressed skull fractures are a typical pattern seen in homicide by blunt trauma. Analysis of wound edges is crucial for determining the weapon, while the evidence of skull fractures and brain injury is useful for estimating the strength of the strokes inflicted. The dynamics can be reproduced using experimental models, then compared with the suspects' witnesses.<sup>1,2</sup>

In cases of accidents, it is common to find multiple, extended, comminuted cranial fractures involving the base of the skull, with Le Fort fractures of frontal facial bones. These findings must be compared with the data collected on judicial inspection and by analyzing the role of the victim (driver, passenger, pedestrian). Also in accidents, injuries are crucial for reconstructing the dynamics of the impact.

In work-related deaths, head injuries are, in most cases, a consequence of fatal falls from a height. Therefore, the severity depends on the height. Head injury pattern can prove the lack of adequate safety measures. In the case reported, the autopsy findings proved the worker did not wear a helmet or body harness. The head injury pattern was subsequently reviewed/utilized in court proceedings.

In literature, there are no data about natural deaths. In the case reported, only bruises related to a fall were found, with no signs of cranial fracture or brain injury. In cases of unilateral, single, and minor head injuries, investigating for typical signs of natural events, such as red hypostasis on the neck and thorax, is suggested. Autopsy can solve the doubtful cases and establish the cause of death.

This study underlines that head injuries are relevant forensic evidence. The pattern changes depending on the case, but it shows recurring features depending on the mode of death. Therefore, this study proposes always performing an accurate investigation of the pattern. The circumstantial data and autopsy are necessary for a precise reconstruction of the event.

### H19 The Anesthesiologist's Responsibility in Intracranial Placement of the Nasogastric Tube (NGT): A Case Series and Literature Review

*Alessandro Bonsignore, MD, PhD\*, University of Genova, Genova, Liguria 16132, ITALY; Gianluca Landi, Siena, ITALY; Federico Longhini, MD, Magna Graecia University, Catanzaro, Italia 88100, ITALY; Francesca Buffelli, PhD, MD, Istituto Giannina Gaslini, Genova 16147, ITALY*

**Learning Overview:** The goal of this presentation is to share the dangers of NGT misplacement and penetrating the cranial cavity as the consequence of a perforated ethmoid-sphenoid floor. Medical past history and patient records need to be analyzed before any clinical decision, even in an emergency setting, and correct positioning of the NGT ascertained with X-ray or a dedicated pH indicator paper.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees of the risks of an apparently simple and uneventful medical procedure, which nevertheless could cause serious, sometimes fatal, complications.

This presentation aims to share with forensic science community the risk and consequences of NGT misplacement, including perforation of the ethmoid-sphenoid floor with subsequent penetration of the cranial cavity. NGTs have a key role in the management of hospitalized patients, especially critically ill ones. Numerous cases of inadvertent penetration of the intracranial compartment by an NGT in the setting of skull-based trauma and/or surgery have been reported. Blind endonasal procedures are particularly at risk of being associated with severe complications. Inadvertent insertion of NGTs into the cranial cavity has also been reported in non-traumatic settings, especially when certain congenital or acquired anatomic anomalies are present. Marked nasal septal deviation, underdevelopment of nasal turbinates, and high-grade pneumatization of the paranasal sinuses are examples of anomalies that may predispose to incorrect positioning of a NGT.

The first illustrative case presented here is that of a psychiatric patient with a history significant for the occasional use of hashish and other drugs and an unknown lesion of the ethmoid sinus. One morning, he was found unconscious in the bathroom of the hospital. Due to suspicions of drug use and a positive response to opioid antagonist administration, an NGT was placed. The second case is that of a patient with intracranial bleeding following pituitary macroadenoma transphenoidal surgery. During emergent decompressive craniotomy, the anesthetist placed an NGT. Retrospective analysis of two such cases provides an important opportunity to assess the effect of a malpositioned NGT from a medicolegal point of view, educate regarding evidence-based methods for device insertion, and overall reduce risks.

Before any invasive procedure (even if emergent), it is advisable to take time to review patient history and medical records. Most importantly, the clinical situation should be carefully assessed for factors such as impaired consciousness, anatomical facial abnormality, and head-facial injury. The second evaluation that must always be carried out is to determine whether nasogastric feeding is appropriate for the patient, and the rationale for any decision must be recorded in the patient's medical notes. To prevent malpositioning of an NGT, a radiological control must be performed; if this is not available, pH indicator paper should be used to test for human gastric aspirates. If there is insufficient support to confirm NGT placement, placement should be delayed until that support is available (unless clinically urgent.) These procedures are useful in order to avoid subsequent damage to anatomic structures; however, they are futile if intracranial insertion of the tube has already caused brain injury.

In the first presented case, the patient survived the malpositioned NGT without neurological sequelae, while in the second case the patient died due to intracranial hypertension. From a medicolegal point of view, the anesthetist's decision to place an NGT in the first case was not deemed wrong due to the suspected drug use; the public prosecutor thus acquitted the anesthetist of criminal negligence. In the second case, however, the decision to insert an NGT was deemed incorrect due to the previous known surgical procedure; the public prosecutor thus convicted the anesthetist of incompetence and imprudence. In conclusion, though typically uneventful, NGT positioning can rarely be complicated by misplacement. Past medical history and patient records should be reviewed before making the clinical decision to insert an NGT—even in an emergent setting. Correct NGT positioning can be ascertained via X-ray or dedicated pH indicator paper.

## H20 Powder-Free DNA Extraction Protocol From Bones and Teeth

Heitor Correa\*, University of Brescia, Brescia 25123, ITALY; Gloria Brescia, University of Brescia, Brescia, ITALY; Venusia Cortellini, PhD, University of Brescia, Brescia, ITALY; Andrea Verzeletti, MD, University of Brescia, Brescia 25123, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of how to better choose a protocol to extract DNA from bones and teeth. Most importantly, attendees will be encouraged to conduct the same modifications to the pulverization protocols they currently use, which may improve DNA typing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping forensic practitioners in extracting DNA of enough quality and quantity from decomposed teeth and bones to obtain a full Short Tandem Repeat (STR) profile. In addition, the performance of the presented protocol was shown to be superior to a validated commercial protocol in an actual forensic case.

DNA analysis is considered the gold standard in the identification of human remains. In that context, the aim of genetic analysis is to obtain a DNA profile from a deceased person to compare to those of putative relatives or personal objects. However, DNA must first be extracted from a biological substrate in order to be analyzed. Often, hard substrates, such as bones and teeth, are sampled from decomposing corpses, especially in cases of long postmortem intervals. That is because hard tissues usually preserve DNA better than soft tissues. Nevertheless, there is no consensus in the forensic community regarding which method should be used for extracting DNA from skeletal samples. There is a widely adopted practice only regarding sample preparation, which involves pulverization of bone pieces or teeth.<sup>1</sup> As an example of this, the commercial kit QIAamp® DNA Investigator by QIAGEN® provides a validated protocol for use with bones and teeth that require sample pulverization. It must be noted, however, that powdering mineralized tissues has setbacks, which has led to some researchers advocating for less destructive and powder-free protocols.<sup>2,3</sup> For example, pulverizing bone and teeth precludes future morphological analysis, as well as destroys unique specimens. Furthermore, bone and tooth powder are affected by static from the contact with plasticware. That phenomenon may attract particles to the outside of microtubes, promoting sample loss and contamination. In fact, the commercial protocol mentioned above has been used in the laboratory and has failed to provide a DNA profile using bones and teeth collected from real cases. Considering those and other results published in the literature, it appears that sample powdering may negatively affect the integrity of DNA molecules.<sup>4</sup>

Therefore, the goal of this study was to assess the performance of a modified protocol for DNA extraction from bones and teeth that does not require sample powdering. Premolar teeth and femur diaphysis samples, collected from a human body buried in a cemetery for 46 years, were processed. Two femur samples and a tooth were processed using the standard protocol, while two femur samples and two teeth were processed using the modified one. For the standard protocol, the QIAamp® DNA Investigator kit protocol for bones and teeth was followed. For the modified protocol, whole teeth and femur pieces were individually demineralized in 20mL of EDTA solution (0.5M, pH 8) at room temperature. Teeth crowns were first covered in parafilm, after which the specimens were demineralized for approximately 18 hours. Femur pieces were demineralized for at least three days. After demineralization, up to 200mg of the demineralized portions of the samples were cut off with disposable scalpel blades and processed using the same commercial kit following the protocol designed for “soft” tissues. For teeth, the lower half of the roots were sampled, especially the tips.<sup>5</sup> Extracted DNA was quantified using an in-house quantitative Polymerase Chain Reaction (PCR) assay that targets two human-specific DNA regions, of 67 and 170–190 base pairs. The samples were submitted to amplification of 16 DNA markers using Thermofisher Scientific’s™ NGM™ Select, and detection of DNA fragments was conducted in a Thermofisher Scientific™ 3500 Genetic Analyzer.

The standard commercial protocol studied did not yield detectable quantities of DNA from the femur or tooth samples. On the other hand, the proposed modified protocol provided good enough quantity and integrity of DNA to produce full and concordant DNA profiles. These findings reinforce the need to fully demineralize bone and teeth samples prior to DNA extraction, which is not achieved by the standard commercial protocol used.<sup>6</sup> Moreover, a previously reported protocol that did not pulverize bone samples was also shown to be more efficient than when pulverization was performed.<sup>4</sup> In conclusion, the results of this study are in accordance with other studies, also suggesting that full demineralization of bones and teeth portions may be more efficient than extracting DNA from pulverized bones and teeth.<sup>4,5</sup>

### H21 A Complete Transection of the Aorta During Resuscitative Efforts

Amanda Ho\*, Southwestern Institute of Forensic Sciences, Dallas, TX 75207; Grant W. Herndon, DO, Southwestern Institute of Forensic Sciences, Dallas, TX 75207

**Learning Overview:** The goal of this presentation is to present an unusual injury sustained during resuscitative efforts and explain the rationale behind the classification of the injury.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating attendees about the characteristics of resuscitative injuries, which will allow scientists to classify injuries appropriately, even when atypical.

A variety of resuscitation injuries and their frequencies have been reported in the literature, including contusion and thermal injury of the chest, sternum and rib fractures, lacerations to underlying organs, and laryngeal and tracheal contusions.<sup>1-3</sup> They are accepted as a risk of potentially life-preserving measures of last resort. On occasion, though, these injuries may be so severe that they would likely prove fatal were the patient to regain a pulse. They also may cause confusion for investigators performing an examination after death.

This report presents a case of a complete transection of the aorta in a decedent who received in-hospital resuscitation, an occurrence that has not previously been reported as a consequence of vigorous resuscitation efforts. In this case, a 56-year-old woman was found unconscious but alive in a vehicle along a roadway with no signs of injury, according to the report by first responders. She was transported to a hospital, where she was admitted to intensive care for ten hours with a differential diagnosis of sepsis or hyperthermia with dehydration before she lost a pulse. Over the course of the next three hours, Cardiopulmonary Resuscitation (CPR) was performed five times before resuscitation efforts were halted and death was pronounced. At autopsy, she had a contusion over the midline of the chest, a sternal fracture, fractures of the first through eighth ribs bilaterally, lacerations of the epicardium and myocardium, and complete transversely oriented transection of the descending aorta posterior to the heart. The surrounding mediastinal soft tissue contained a mild to moderate amount of hemorrhage without dissection planes and without hemothoraces.

Such an injury would not be compatible with life were she to have survived with return of spontaneous circulation, raising questions about the futility of resuscitative efforts for the medical community. For medical examiners, this or similar injury may be incorrectly attributed to forceful deceleration in a different circumstance, especially since the decedent was found in a vehicle. However, the decedent would not have survived 13 hours in the hospital (in addition to the unknown amount of time at the scene) if the injury had occurred around the time that she was found. Additionally, the mild to moderate amount of hemorrhage present in the mediastinum without significant blood in the pleural cavities indicates the injury occurred shortly prior to death, before development of significant bleeding under arterial pressure. Correlation of the autopsy findings with hospital records also provides a way to attribute the injury to resuscitative efforts. While CPR may vary greatly in efficacy and force among those performing it, the reports of prolonged, repeated resuscitation performed by trained health care providers in this case offers a plausible mechanism of injury.

### H22 A Proposal of a Score to Evaluate Discrepancies Between the Results of External Body Examination and Forensic Autopsy

Sara Gioia, MD\*, via Tristano di Joannuccio SNC, Terni 05100, ITALY; Valentina Rosati, MD\*, Via del Giochetto, Perugia 06126, ITALY; Massimo Lancia, MD\*, via Del Giochetto, SNC, Perugia 05100, ITALY; Fabio Suadoni, MD, via Tristano di Joannuccio SNC, Terni 05100, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware that there is a great discrepancy between the results of external body examination and a full forensic autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a mathematical calculation method in order to standardize the analysis of discrepancies existing between the external body examination and a complete forensic autopsy.

In many countries, such as Italy, there has been a gradual decline of forensic autopsies, mostly due to economic considerations aimed at containing justice departmental spending. This reduction of the forensic autopsy has been replaced by external body examinations without subsequent autopsy. The goal of this study was to evaluate the consequences of this trend by establishing the rate of discrepancies between the results of external-only body examination and full forensic autopsy. Similar studies have been previously performed.<sup>1-3</sup> However, there has been no standardization of the analysis method. Therefore a calculation score is proposed in order to standardize methodology and results.

A retrospective study was carried out on 312 autopsy cases of traumatic deaths performed in the Department of Forensic Medicine and Pathology of the University of Perugia and Terni. The results obtained in this study, based on the scoring system proposed, showed a high discrepancy between the results of the external-only body examination versus the full autopsy. The discrepancy was absent in a very small number of cases, for which the external examination alone was exhaustive; it was high, however, in the majority of cases, in which the autopsy was shown to be fundamental in establishing the correct diagnosis of death. Overall, these study results did not support replacing the forensic autopsy with external-only body examinations; rather, they reinforced the fundamental role of autopsy as a gold standard to accurately assess cause and manner of traumatic deaths. Moreover, autopsy, as it identifies a greater number of traumatic injuries, provides much critical data useful for reconstructing scene event dynamics.

The present study conclusions are in agreement with forensic recommendations in the general literature that advise against carrying out an external cadaveric examination alone. External-only examination without autopsy has been shown insufficient in the majority of cases to determine cause of death or obtain other critical information necessary for the purposes of justice. The systematic introduction of a standardized scoring algorithm for trauma in postmortem examinations will further strengthen the leading role of autopsy, helping to create a common language for all aspects of fatal trauma research.

### H23 Immunohistochemical Detection of Fibronectin, P-Selectin, FVIII, HSP-70, and MRP-8 in the Skin of Ligature Marks of Suicidal Hangings

Fiorella Caputo, MD\*, Department of Legal and Forensic Medicine, Genova 16132, ITALY; Rosario Barranco\*, University of Genova, Department of Legal Medicine, Genova 16132, ITALY; Francesco Ventura, MD\*, University of Genova, Department of Legal Medicine, Genova 16132, ITALY; Tony Fracasso, MD, PhD, University Center of Forensic Medicine, Geneva 1211, SWITZERLAND

**Learning Overview:** After attending this presentation, attendees will understand that the determination of the vitality of skin injuries is one of the most central research areas in forensic pathology because it is often necessary to discriminate antemortem wounds from postmortem damage. Typical is the case of hanging in which real hanging has to be distinguished from postmortem suspension of a body. Despite the fact that researchers have intensively investigated this topic in the past, reliable ancillary testing methods are still lacking.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of the identification of early markers of tissue vital reaction in cases of hanging.

**Materials and Methods:** Fifteen human skin samples from ligature marks and 15 uninjured skin samples from deaths by suicidal hanging were analyzed (11 males and 4 females, mean age of 43.46 years). Fifteen skin samples from ecchymoses in victims of homicide with a short survival interval (9 males and 6 females, mean age of 43.26 years) were studied as control group. Sections were stained with hematoxylin and eosin and were also processed for immunohistochemistry to detect the expression of fibronectin, p-selectin, Factor VIII (FVIII), Heat Shock Protein-70 (HSP-70), and Myeloid-Related Protein 8 (MRP8.) Immunohistochemical reactions were classified semiquantitatively. For statistical analysis, Student's *t*-test was performed and a level of  $P < 0.05$  was considered as statistically significant.

**Results:** Fibronectin—In ligature marks, fibronectin was significantly less expressed compared to ecchymoses. Its expression was similar in hanging marks and uninjured skin. P-selectin—In both ligature marks and ecchymoses, the expression was significantly increased in the endothelial cells and in the perivascular spaces compared to uninjured skin. FVIII:—In both ligature marks and ecchymosis, expression of FVIII was significantly decreased in the epidermis compared to uninjured skin. In the epidermis of ligature marks, FVIII was significantly less expressed compared to ecchymoses. HSP-70—In the epidermis of both ligature marks and ecchymoses, the expression was decreased compared to uninjured negative controls. In the epidermis of ligature marks, the expression was significantly lower compared to ecchymoses. MRP8—In both ligature marks and ecchymoses, the expression of this factor was significantly increased in blood vessels of dermis and hypodermis and also in the hemorrhagic areas compared to uninjured skin.

**Discussion and conclusions:** In uninjured skin, fibronectin is physiologically expressed in the epidermal basement membrane, around skin appendages, and in blood vessels. In the ligature marks, it is just a little more expressed in the hemorrhagic areas, so its detection is not useful in the determination of vitality. P-selectin plays a role in the early binding of leukocytes to endothelium during inflammation and in the recruitment of platelets at areas of vascular injury. In ligature marks, it is extensively more expressed compared to uninjured controls so it could be useful in the determination of vitality. FVIII is a blood coagulation factor that mediates the adhesion of thrombocytes to subendothelial connective tissue. In uninjured skin, it is expressed in the epidermis and in the blood vessels. The decreased expression of FVIII in epidermis of ligature marks could be due to the compression of the skin that reduces the diffusion of the factor in the epidermis; the marker is instead more expressed in the areas of dermal hemorrhage, and it could be useful in the determination of vitality. HSP-70 play an important role in cell responses to stress, and its expression is very high in epidermis of uninjured skin. Mechanical injury due to hanging can reduce the expression of this marker in the epidermis, so it is valuable in the study of vitality of ligature marks. Finally, MRP8 is an early marker of inflammation and because of its increased expression, it could be useful in the study of vitality of ligature marks.

In conclusion, the results of this study show that immunohistochemical study of early inflammatory and coagulation factors could be valuable to determine the vitality of ligature marks. In particular, the combined analysis of p-selectin, FVIII, HSP-70, and MRP-8 can be considered for this purpose while fibronectin seems not to be useful.

#### Suicidal Hanging, Vital Wounds, Immunohistochemistry

### H24 A Metabolomic Profile of Aqueous Humor in a 24-Hour Period After Death: An Animal Model for Postmortem Interval (PMI) Estimation

*Emanuela Locci, PhD, Cagliari, ITALY; Matteo Stocchero, PhD, Padova, ITALY; Alberto Chighine, MD\*, Cagliari, ITALY; Fabio De Giorgio, MD, Catholic University of the Sacred Heart, Rome 00168, ITALY; Matteo Nioi, MD, Cagliari, ITALY; Ernesto d'Aloja, MD, PhD, Rome, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the potential role of metabolomics in estimating PMI through the study of aqueous humor.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing one more tool in the investigation of PMI.

The estimation of the time since death or PMI remains a major challenge in forensic pathology. Several forensic laboratories are involved in ongoing efforts to characterize and validate an objective analytical method for this purpose. Besides traditional methods based on macroscopic corpse modification, different analytical procedures have been recently proposed for this aim. These include the evaluation of messenger RNA (mRNA) or DNA degradation in postmortem tissues, human tissue transcriptomes, and gene expression patterns, muscle protein degradation based on protein or peptide signatures, the estimation of the hypoxic inducible levels of vascular endothelial growth factor, and assessing postmortem biochemical changes in body fluids (e.g., blood, synovial, pericardial, and cerebrospinal fluids.) Ocular tissues and fluids—especially vitreous humor— have been frequently chosen as reference biological samples due to being more anatomically isolated. Recently, metabolomics have shown to be a potential tool to investigate the time-related postmortem metabolite modifications in animal models. While traditional techniques for PMI estimation are quite subjective in nature, and other proposed methodologies are based on the estimation over time of a single to a few parameters that are potentially prone to the influence of intrinsic/extrinsic factors, the analysis of metabolomic modifications, relying on multiple metabolites/biomarkers quali-quantitative changes, shows a greater predictive power. Here is proposed, for the first time, the use of a  $^1\text{H}$  NMR metabolomic approach for the estimation of PMI from Aqueous Humor (AH) in an ovine model.

A total of 59 AH samples were collected at different PMI (spanning from 118 up to 1,429 minutes, at a 60-minute pace). Thirty-eight (38/59) were used for the training set, while the remaining 21 were employed as test set.  $^1\text{H}$  NMR experiments were performed, and the spectral data was analyzed by multivariate statistical tools. Exploratory data analysis was performed by Principal Component Analysis (PCA) to discover outliers and specific trends in the data. Thus, supervised data analysis based on Projection to Latent Structure regression (PLS2) was applied to evaluate the effects of PMI on the metabolomic profiles of the collected samples. A multivariate calibration model was built to estimate PMI on the basis of the metabolite content of the samples. The model was validated with an independent test set, obtaining a prediction error of 59 minutes for PMI less than 500 minutes, 104 minutes for PMI from 500 to 1,000 minutes, and 118 minutes for PMI greater than 1,000 minutes. During the first 1,000 minutes, lactate was accumulated and strongly influenced the sample distribution along PC1. Early PMI samples were characterized by high levels of leucine and isoleucine, arginine, and lysine, while late PMI samples (>1,000 minutes) showed high levels of taurine, succinate, and choline. Moreover, the metabolomic approach suggested a picture of the mechanisms underlying the postmortem biological modifications, highlighting the role played by taurine, choline, and succinate. The time-related modifications of the  $^1\text{H}$  NMR AH metabolomic profile in the first 24 hours after death seem to be encouraging in addressing the issue of a reproducible and robust model to be employed for the estimation of PMI.

### H25 Muscle Protein Degradation in Postmortem Interval (PMI) Estimation: Recent Accomplishments and Current Challenges

Stefan Pittner, PhD\*, Salzburg University, Salzburg, AUSTRIA; Bianca Ehrenfellner, MS, University of Salzburg, Salzburg 5020, AUSTRIA; Katharina Weitgasser, MS, University of Salzburg, Salzburg, AUSTRIA; Angela Zissler, PhD, University of Salzburg, Salzburg 5020, AUSTRIA; Peter Steinbacher, PhD, University of Salzburg, Salzburg, AUSTRIA; Fabio Carlo Monticelli, Interfaculty Department Forensic Pathology, Salzburg 5020, AUSTRIA

**Learning Overview:** After attending this presentation, attendees will better understand the current state of the art and a specific international collaboration project on postmortem protein degradation for use in PMI estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that time-since-death estimation is a crucial topic in forensic routine, yet currently applied methods are often insufficient or produce unsatisfactory outcomes. New approaches, such as the one presented, are required to contribute to the methodical spectrum.

**Background:** Estimation of the PMI is one of the most challenging aspects of routine forensic work. Current available methods are often limited to a certain timeframe or may be insensitive due to specific case preconditions or the circumstances surrounding the death. The search for additional methods and respective postmortem biomarkers is, thus, a central topic in forensic science and has become of increasing interest since the rise of sophisticated molecular biology approaches over the past decades. This study proposes a novel approach based on muscle protein degradation that has shown great promise by a first successful application in a forensic case. However, respective impacts of individual and environmental influencing factors reveal an important task that necessarily has to be addressed to achieve significant practical relevance in PMI estimation. Also, the applicability to a large heterogeneity of cases requires an appropriate evaluation of the sufficiency and the limitations of a method.

**Methods:** This study investigated possible metabolic influences, such as injury/regeneration or atrophy, in a rodent model and humans. Variances of protein degradation kinetics in different muscle groups (thigh, calf, and abdominal muscle) in rats and humans were examined. A field and crime scene sampling protocol was implemented. The possible influence of changing weather conditions and insect activity on a pig model were investigated.

**Results:** Analysis of muscle protein degradation represents a promising new tool for PMI estimation and is based on a catabolic process that is well-preserved in different mammalian species. Thus, animal models—when thoughtfully employed—represent valid approaches to analyzing various possible influencing factors. This study successfully implemented field and crime scene protocols and demonstrated that postmortem protein patterns can clearly be distinguished from *in vivo* metabolism.

**Conclusion:** This study reinforces the importance of analyzing factors that may influence biomedical postmortem alterations used to estimate the PMI. It also highlights the advantages and utility of muscle protein degradation analysis as a tool for forensic investigations. Overall, it offers insight into the general requirements of novel approaches for time-since-death estimation and the specific challenges of incorporating muscle protein degradation analysis into routine forensic work.

#### Protein, Degradation, PMI Estimation

### H26 The Importance of Being Earnest: The Role of Autopsy in Preventing Litigation Related to the Management of Liver and Digestive Disorders

*Stefano D'Errico, PhD, Department of Legal Medicine, Lucca, Italy 55100, ITALY; Benedetta Baldari, MD, Rome 00161, ITALY; Alessandro Santurro, MD, Sapienza University of Rome, Rome 00161, ITALY; Mariarosaria Aromataro, MD, PhD, Rome 00161; Matteo Scopetti, MD\*, Sapienza University of Rome, Rome 00161, ITALY*

**Learning Overview:** After attending this presentation, attendees will better appreciate the role of clinical autopsy in cases of unexpected death after gastrointestinal surgery or endoscopic diagnostic procedures for the management of liver and digestive diseases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting the clinical autopsy as a transparency enhancer able to identify procedural pitfalls and prevent medical malpractice claims.

In recent years, the assertion that autopsies are unnecessary has been strengthened as a result of advanced antemortem diagnostic testing options that have been deemed sufficient to identify clinically significant pathological conditions and causes of death in most cases. Similarly, there is a certain reluctance on the part of non-pathology physicians to request clinical/medical autopsies due to the fear that diagnostic or therapeutic errors may be detected. Only a few studies have investigated the role of autopsy in litigation prevention and clinical risk management. Similarly, the phenomenon of litigation related to the performance of invasive or surgical procedures in the context of digestive and liver diseases is poorly studied despite the hypothesis of a greater risk for the physicians involved.

The case series presented consists of 17 cases of patients who died unexpectedly following endoscopic or surgical procedures for the diagnosis and/or treatment of digestive and hepatic diseases. In all the cases, a preliminary analysis of the medical records and a consultation with the health professionals involved in the management of the patient was carried out. A complete postmortem examination was subsequently performed in the presence of physicians representing the ward and relatives of the deceased. The autopsy technique was tailored to the clinical characteristics of the patients and the suspected diagnosis. Histologic studies were ordered to complete the autopsy investigations and confirm the diagnosis of death. At the end of the investigations, the results obtained were jointly presented and discussed in the interests of transparency.

Overall, this adopted postmortem investigative protocol resulted in confirmation of the initial clinical diagnosis in only two cases (12%). In eight cases (47%), the autopsy provided formulation of a diagnosis different from the clinical one, while in the remaining seven cases (41%), the postmortem examination was decisive since the clinical diagnosis was previously unknown. In 15 cases (88%), the clinical autopsy made it possible to establish the cause of death and—through the sharing of the findings—was fundamental in the prevention of litigation. In the other two cases (12%), the evidence gathered during the postmortem examination did not prevent litigation but did have a decisive impact in the court trial.

In conclusion, the present case series demonstrates the critical role of the clinical/medical autopsy in the management of deaths of patients admitted to the hospital for liver and digestive disorders. In particular, the added value of postmortem diagnostics lies in the possibility of obtaining a definitive diagnosis (which may or may not be consistent with the suspected antemortem diagnosis) and of generating useful evidence for the prevention of litigation or for the better management of a subsequent court trial.

#### Clinical Autopsy, Digestive and Liver Disease, Claims Prevention

### H27 A Preliminary Assessment of the Persistence of Prostate Specific Antigen (PSA) Transfers Under Various Conditions

Keryne Skead\*, University of New Haven, West Haven, CT 06516; David San Pietro, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to provide attendees with a better understanding of the persistence of PSA detection in semen stains under various conditions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of the persistence of PSA resulting from different manipulated environmental and transfer conditions.

PSA, also known as p30, is a protein used as an effective marker for the identification of seminal fluid lacking spermatozoa cells. The ABACard® p30 test is extremely sensitive and can be used to detect the presence of the PSA protein at levels as low as 4ng/mL.<sup>1</sup> Most current research surrounding the stability of PSA over time looks at it within the female reproductive tract; however, very little research examines the detection of PSA outside of the human body where other environmental factors can influence its detection.<sup>2</sup>

The conditions examined in this study were dry versus wet transfer-receiving substrates, pH, drying time, and differing semen dilution concentrations. For all variables manipulated, the ABACard® p30 test was used for detection. The reaction environment for PSA was manipulated with differing pH levels, starting from a pH of 7, with detection of the protein still possible, up to a pH of 12. The length of time each sample was allowed to dry prior to testing for PSA did not appear to affect detection; however, the rate of appearance of the test band on the ABACard® was found to be directly dependent on the sample's dilution concentration. Fifteen microliters of semen were allowed to dry on a nitrile glove for varying time periods before being transferred to a cotton swatch with the use of constant pressure upon application. It was found that the transfer stains were typically non-detectable by the ABACard® p30 test, under the dry receiving substrate conditions. When the cotton receiving swatch was treated with a personal jelly lubricant, chosen for its water-based formula, the test was positive regardless of the length of time waited prior to transfer. For the wet and dry receiving substrate conditions, as well as the dilution series, Adobe® Photoshop® was utilized to examine test band intensity on the ABACard® p30 cards from photographs taken under controlled conditions. Wet conditions utilized personal jelly lubricant in an attempt to replicate possible moist environments the protein could be transferred to. It was found that the wet conditions yielded more color intense test bands than the dry conditions. Additionally, the wet conditions seemed to stabilize the detection of PSA at differing dilution concentrations, causing the test to behave more consistently. The differences observed between the wet and dry conditions of test band intensity were found to be statistically significant through *t*-testing ( $p < 0.0054$ ). For the dilution series, it was found that lower concentrations yielded fainter test bands on the ABACard® p30 tests. Based on results obtained, PSA is detectable as well as durable under these different environmental conditions. Further research examining longer time periods under certain conditions, as well as increasing the overall number of replicates, would help to more accurately assess any possible statistically significant differences in the findings.

## H28 Recovery of DNA From Washed Bloodstains

Isil T. Erdogan, MS\*, Üsküdar University, Istanbul 34662, TURKEY; Tugba Ünsal, PhD\*, Üsküdar University, Istanbul 34662, TURKEY; Aysun Gungor, MS, Üsküdar University, Istanbul 34662, TURKEY; Kaan Yilancioglu, PhD, Üsküdar University, Istanbul 34662, TURKEY; Sevil Atasoy, PhD, Üsküdar University, Istanbul 34662, TURKEY

**Learning Overview:** After attending this presentation, attendees will be aware that in the forensic sciences body fluids, such as blood and bloodstains, are frequently encountered in homicides. Such evidence, which is biologically obtained at various crime scenes, plays a strong role with forensic identification in determining whether a suspect or victim has an association with the crime. For this reason, DNA analysis is performed routinely in forensic laboratories from biological materials, such as blood, saliva, semen, and hair, that are collected from crime scenes in order to connect the crime scene with suspects and victims.<sup>1,2</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relating the importance of obtaining DNA from washed clothes for the purpose of revealing powerful physical evidence after the event. In general, bloodstains are the most common evidence at the crime scene and generally can be detected with the naked eye. For this reason, blood and bloodstains that potentially relate to the crime are usually cleared or washed for the purpose of liberation from evidence related to the incident. As a result of different cleaning methods after the crime, body fluids such as bloodstains exposed to cleaning chemicals cannot be seen by the naked eye. Primarily, researchers suggest that washed bloodstains may not have a sufficient quality of DNA for DNA profiling analysis. However, some studies have shown that bloodstains can be used for DNA analysis even after harsh washing protocols.<sup>2-4</sup>

The goal of this study was to determine the rate of DNA recovery after washing bloodstains on different types fabric at different levels. In this study, a representative crime scene was created and bloodstains were made on cotton and nylon fabrics. After washing with laundry detergent at 40°C, 60°C, and 90°C, visualization and identification of bloodstains was conducted. There have been previous attempts to determine whether the amount of DNA required for forensic genetic identification can be recovered from washed laundry. In parallel with the literature on the subject, the current study determined that DNA recovery is directly related to the fabric type; DNA was lost more from non-absorbent nylon fabric types due to easy exposure to external factors. It was demonstrated that greater recovery of DNA can be obtained from cotton-type fabrics, which are more absorbent. The rates of obtaining DNA from bloodstains on different types of fabric that are washed at different temperatures were also evaluated in this study.

In conclusion, when considering the triangle of the crime scene, the perpetrator, and the victim, obtaining necessary biologic evidence to ensure that justice is served is critical. Even in cases in which bloodstained clothing has been washed, it may still be possible to recover a sufficient quantity of DNA for purposes of DNA profiling analysis, as demonstrated by this study.

### H29 Changes in Receptor Expression of $\sigma$ -1R in the Pineal Gland Related to Different Causes of Death

*Elvira Ventura Spagnolo, MD\**, University of Palermo, Palermo 90127, ITALY; *Cristina Mondello, MD\**, University of Messina, Messina 98123, ITALY; *Gennaro Baldino, MD\**, Palermo 90100, ITALY; *Antonio Guajana, MD*, Palermo 90149, ITALY; *Letteria Minutoli, MD*, University of Messina, Messina 98125, ITALY; *Domenico Puzzolo, MD*, University of Messina, Messina 98125, ITALY; *Vincenzo Macaione, MD*, University of Messina, Messina 98125, ITALY; *Luigi Cardia, MD*, University of Messina, Messina 98125, ITALY; *Antonina Argo, PhD*, University of Palermo, Palermo 90100, ITALY; *Stefania Zerbo, MD*, Palermo 90100, ITALY; *Alessio Asmundo, University of Messina, Messina 98125, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand the importance of improving knowledge regarding pineal gland involvement in response to stress related to the death process and their possible changes related to the different causes of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting: (1) whether the pineal gland undergoes structural changes in relation to different causes of death; (2) if these changes have significant differences; and (3) if it is possible to better demonstrate molecular changes in the gland.

N,N-Dimethyltryptamine (DMT) is a potent psychedelic substance produced in the human body, especially in the pineal gland. It has been proposed that DMT is secreted by the pineal gland in large quantities under extreme stress, such as during dying or for a certain period after death.<sup>1</sup> The  $\sigma$ -1 Receptor ( $\sigma$ -1R), is particularly well-expressed in the pineal gland, is located in the endoplasmic reticulum, and plays an important role in regulating the mechanisms of calcium release through the receptor for Inositol Triphosphate (IP3). DMT is the only endogenous agonist ligand capable of activating this receptor: once activated, DMT binds to the receptor and regulates cellular ionic channels, in particular K<sup>+</sup> channels.<sup>2</sup> The goal of the present study was to demonstrate the impact of different causes of death on the expression of  $\sigma$ -1R with immunohistochemical techniques.

The pineal glands from 48 forensic autopsies were included. The specimens from the following causes of death were examined: hanging, stabbing, fire fatality, sudden cardiac death, hemorrhagic shock, and drowning. All autopsies were performed within 24 to 48 hours after death. Pineal glands obtained from the autopsies were fixed in 4% paraformaldehyde in 0.2M Phosphate Buffer Saline (PBS), dehydrated in graded ethanol, cleared in xylene, and embedded in paraffin. Histological sections (5 $\mu$ m) were processed for  $\sigma$ 1-R immunohistochemistry according to the manufacturer's instruction; sections were deparaffinized in xylene and rehydrated in ethanol. Antigen retrieval was performed with pH 6.0 buffer citrate and endogenous peroxidase blocked with 0.3% Hydrogen Peroxide (H<sub>2</sub>O<sub>2</sub>) in PBS. Primary antibody (1/100 dilution) was incubated overnight at 4°C in a moisturized chamber. The day after, peroxidase-conjugated secondary antibody (1/50 dilution; Pierce anti-rabbit, anti-goat, and anti-mouse) was added and the reaction was visualized with 3,3'-Diaminobenzidine (DAB). Counterstaining was performed in Mayer's hematoxylin. Negative control slices were tested using PBS instead of the primary antibody. Overall, results of this study revealed a different expression of  $\sigma$ 1-R immunopositivity in relation to the cause of death, being particularly evident in hanging, fire fatality, and sudden cardiac death. The results were then analyzed in relation to factors such as sex, age, and timing of the death process.

#### Receptor Expression of $\sigma$ -1R, Pineal Gland, Different Causes of Death

### H30 Early Myocardial Ischemia: An Immunohistochemical Analysis of Dystrophin and Matrix Metalloproteinase 9 (MMP-9)

*Cristina Mondello, MD\**, University of Messina, Messina 98123, ITALY; *Elvira Ventura Spagnolo, MD*, University of Palermo, Palermo 90127, ITALY; *Salvatore Rocuzzo, MD*, University of Palermo-Messina, Messina 98124, ITALY; *Luigi Cardia, MD*, University of Messina, Messina 98123, ITALY; *Alessio Asmundo, University of Messina, Messina 98123, ITALY*

**Learning Overview:** After attending this presentation, attendees will understand that the forensic diagnosis of early myocardial ischemia is based on the knowledge of the immuno-inflammatory pathophysiology and cellular phenomena accompanying cardiac alterations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the usefulness of immunohistochemistry to detect early myocardial ischemic damage through the analysis and comparison of C5b-9, fibronectin, dystrophin, and MMP-9 expression.

Sudden Cardiac Death (SCD) is an unexpected natural death due to cardiac causes that occurs within a short time period in a person without any prior condition that appears to be fatal. Coronary Artery Disease (CAD) and ischemic cardiac damage are the main causes of SCD. In cases of cardiac death arising due to ischemia in which the death occurs within six hours from the onset of ischemic damage, the histologic myocardial changes are not specific and cannot provide clear evidence for the postmortem diagnosis.

Immunohistochemical analysis has been suggested as a technique to help bridge the gap in the histologic diagnosis of early myocardial ischemia and several markers have been analyzed.<sup>1</sup> Thus, knowledge about the chronology of the inflammatory reaction and myocardial tissue response after the ischemic insult become very useful in determining immunohistochemical markers relevant to forensic research.

This study evaluates the expression of dystrophin and MMP-9 in cases of SCD due to coronary atherosclerotic disease both with and without definitive microscopic evidence of myocardial ischemia. These proteins have different roles in cardiac tissue: dystrophin is normally expressed in cardiomyocytes contributing in stabilizing the sarcolemma during cardiac contraction and in the transmission of myofibers contraction force, while MMP-9 is a protease generally associated with degradation and regulation of the extracellular matrix and recently related to regulatory mechanism for precise cellular control of biological processes. Their expression was also compared to C5b-9 complex and fibronectin expression to analyze if markers provided the same or no findings.

Results of this study revealed that dystrophin and MMP-9 show different post-ischemic time-dependent expression as, respectively, depletion of sarcolemmal staining and increasing of interstitial and leukocytes immunopositivity occurs. Dystrophin and MMP-9 seem to be useful immunohistochemical markers for the detection of early ischemic damage. These proteins (and especially dystrophin) show early modification of expression as well as of C5b-9 complex.

### H31 A Case of Suicide by Hemlock Intoxication

Stephanie Diu, BA\*, Kew Gardens Hills, NY 11367; Erica Maney\*, Duquesne University, Pittsburgh, PA 15282; Pamela L. Marshall, PhD, Duquesne University, Pittsburgh, PA 15282; Jennifer L. Hammers, DO, Cyril H. Wecht & Pathology Associates, Pittsburgh, PA 15219

**Learning Overview:** The goal of this presentation is to highlight the death of a 52-year-old Caucasian male due to hemlock intoxication, a rare method of suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the deadly effects of hemlock intoxication on adults and educating attendees on how to identify possible hemlock poisoning through scene investigation and autopsy and also how to confirm the presence of hemlock in various samples through forensic laboratory testing.

**Introduction:** Poison hemlock (*Conium maculatum*), the infamous plant responsible for the death of Socrates, is toxic to humans and animals. Ingestion has been recorded in the literature, mostly in cases of accidental ingestion due to its similar appearance to other plants. In cases where hemlock led to death, the cause of death is usually associated with respiratory arrest, muscle paralysis, or complications of acute renal failure.<sup>1</sup> While the entire plant is toxic, the most dangerous part is the seeds, which contain the highest alkaloid concentration.<sup>2</sup> It contains eight piperidine alkaloids, with the most potent one being coniine. Coniine is a neurotoxin that disrupts the function of the peripheral nervous system, causing respiratory paralysis. Initial symptoms include nausea, vomiting, abdominal pain, hypertension, tachycardia, tremor, and temperature increase.<sup>1,3</sup> Symptoms progress toward central nervous system depression, coma, muscular weakness and/or paralysis, with respiratory distress.<sup>2</sup> In some cases of hemlock ingestion, renal failure and renal tubule damage have been reported.<sup>3</sup> The concentration of alkaloids found in each plant varies depending on age of plant, season, and precipitation.<sup>4</sup> No antidote exists for hemlock specifically.<sup>2</sup>

**Materials and Methods:** This case involved a well-developed (5 feet, 10 inches; 176 pounds) 52-year-old Caucasian male who committed suicide by ingesting hemlock. The decedent had a history of suicidal ideations, as evidenced most recently by suicidal text messages found on his phone. His text messages revealed symptoms of muscle weakness, difficulty walking, and decreasing consciousness. His text messages revealed that he had recently attempted suicide by hemlock ingestion but had been unsuccessful. He also had a history of tobacco use, anxiety, depression, and attention deficit disorder. Various samples were tested using liquid extraction and solid phase extraction and Gas Chromatography/Mass Spectrometry (GC/MS).

**Results:** Aside from slight atherosclerosis and left and right ventricular hypertrophy, postmortem examination revealed no evidence of any significant natural disease process, physical violence, or trauma. The stomach contained 275cc of green leafy material with a small amount of dark red to brown admixed liquid. The proximal duodenum contained a small amount of similar green leafy material. No pills or capsules were identified in the stomach. Confirmatory testing is pending at this time, but circumstantial evidence indicates that the decedent died from intentional hemlock ingestion, and the death certificate has been finalized.

**Discussion:** Ingestion of hemlock is a rare method of suicide. Botany examination of the leafy material recovered from the decedent's stomach contents confirmed that the material was consistent with *Conium maculatum*, also known as poison hemlock. This case emphasizes the need for further investigation regarding hemlock intoxication, as diagnosis of hemlock poisoning is challenging and there is a lack of scholarship on its biological half-life, levels at which hemlock is fatal, and human metabolism of hemlock alkaloids.

#### Hemlock, Intoxication, Suicide

### H32 A Fatality by Caustic Soda: Accidental or Suicidal?

*Manoj Bhusaheb Parchake, MD\*, Seth GS Medical College & KEM Hospital, Mumbai, Maharashtra 400012, INDIA*

---

**Learning Overview:** After attending this presentation, attendees will understand the pattern of injuries caused by Caustic Soda (NaOH) on the skin surface, the mucosa of the mouth, and internally. Attendees will understand the classification of esophageal and gastric caustic in addition to postmortem findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving to identify and ascertain cause and manner of death in a fatality by NaOH ingestion. This presentation will also be helpful in providing education regarding current guidelines in the management of esophageal caustic injury.

NaOH is a strong base with a very high corrosive potential. In Indian households, NaOH is used for making soap by an empirical method in many poorer regions. Caustic ingestion represents a public health problem worldwide, despite efforts and educational campaigns to reduce its occurrence. Ingestion is the most frequent route of exposure. Accidental ingestion most typically occurs in infants and children less than six years of age, especially between the ages of 1–4 years. Otherwise, ingestion in adolescents and adults may be related to suicidal behaviors. In the United States, an incidence of 5,000 to 15,000 cases per year are estimated to occur. The type of corrosive agents varies from country to country. Reports from Denmark, Israel, the United Kingdom, Spain, and Australia showed that although alkaline agents are most commonly used in developing countries, the majority of caustic ingestion is due to acids. Caustic ingestion induces a local toxicity leading to upper gastrointestinal system damage that can range from mild to extensive injuries.

The current case is that of a 76-year-old woman who presented with a medical history significant for a cataract in one eye and suspected consumption of NaOH. Corrosive injury was present over the lips and tongue. Esophageal endoscopic examination revealed grade IIb injury. Circumferential lesions with ulceration focally extending into the muscle layers was apparent. The stomach revealed grade IIIb injury; the gastric mucosa appeared dusky, very black, with deep ulcerations (transmural tissue involvement was suspected). The patient died and an autopsy was requested. On postmortem examination corrosive injury was confirmed to extend over lips and tongue and appeared brownish in color. On internal examination, brown-colored corrosive injury extended over the esophagus with resultant narrowing of the lumen. The stomach demonstrated corrosive injury involving the pylorus that likewise appeared brown in color. Further detailed history and crime scene investigation revealed that a bottle of NaOH was found near the woman. The investigating officer queried the manner of death. Further case history will be reviewed as part of this presentation.

---

**Caustic Soda, Accidental, Suicidal**

### H33 The Evolution of Safety Systems in Traumatic Deaths Due to Road Traffic Accidents: A Case Report and Review of the Literature

Luigi De Aloe, MD\*, Institute of Legal Medicine, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Orazio Malfa, MD, University "Magna Graecia" of Catanzaro, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will be more aware of safety systems in traumatic deaths due to road traffic accidents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by underlining the role of new safety devices in the reduction of fatal events in impacts between motor vehicles.

In 2016, there were 175,791 road traffic accidents in Italy resulting in 3,283 deaths (i.e., dead within 30 days of the accident) and 249,175 injured victims.<sup>1</sup> According to the Italian National Institute of Statistics (ISTAT) data, the number of road traffic accidents overall has decreased. This decrease is likely attributable to new legislation on the reduction of the driving license score (i.e., a law introduced on July 1, 2003, in Italy), as well as the increased active and passive safety systems newer vehicles are equipped with. The role of seat belts has also been established, though more focus in scientific studies has recently been given to other security systems, such as airbags. The causes of road accidents are many, but major factors appear to be distraction, imprudence, and high speed. In a significant percentage of cases—particularly those involving young people—driving while under the influence of alcohol plays a major role.<sup>2,3</sup> The injuries and consequences that occur as a result of road traffic accidents are diverse and depend on many variables. These may include bruises, fractures of the limbs, brain injuries, visceral ruptures, pulpification, cervical spinal injury (more frequently seen in motorcycle accidents), or other serious consequences leading to immediate death. The introduction of the new technology in road vehicle safety systems has allowed for a reduction in adverse outcomes secondary to road accidents, although some studies have noted that the use of seat belts can actually result in neck ecchymoses, carotid thrombosis, fracture of the aortic arch, clavicular or costal fractures, pneumothorax, and abdominopelvic lesions due to strong traction during an impact.

This presentation reports the case of an elderly man found dead inside an Ape Classic<sup>®</sup> vehicle due to a frontal motor vehicle collision. Scene investigation revealed that the other vehicle involved in the collision was a common modern car. Injuries to the elderly man, including an abdomen extensively lacerated by the mechanical components of the handlebar of the Ape Classic<sup>®</sup> that precluded easy removal of the body. The kinematic engineering consultancy showed that the Ape Classic<sup>®</sup> vehicle was traveling at a low speed. An autopsy was performed. External examination showed an abdominal wound about 18–20cm deep with jagged margins and an internal foreign body belonging to the handlebar of the Ape Classic<sup>®</sup>. In the lower limbs, there was a contused laceration of the knee with tibial and femoral fracture. On internal examination, there was a splenic laceration, massive traumatic hemoperitoneum, rupture of the rectum and inferior mesenteric intestinal loops with right-sided pelvic/sacral traumatic fractures due to the foreign body. Toxicological analysis was negative for alcohol and drugs in both the victim as well as the driver of the other car. A histopathologic assessment was performed. All collected data was reviewed in order to better understand the causes and the dynamics of the accident. Overall, it appeared the decisive element in the different evolution of the outcomes of the described incident was the intrinsic characteristics of the vehicles involved. The Ape Classic<sup>®</sup> was totally devoid of the common active and passive safety systems that were present in the other vehicle involved in the collision. As a result, the elderly man was mortally wounded by the impact; whereas, the driver of the other vehicle lived.

The frontal motor vehicle collision reported in this case confirms that the presence of airbags or the evolution of vehicle safety systems would have almost certainly prevented the deep abdominal wound caused by the impact on the steering wheel and the windshield, and ultimately the victim's death. In conclusion, the role safety belts play in the reduction of fatal events in the impacts between motor vehicles is emphasized. It is also noted that although most newer vehicles have safety systems, many of those that are often involved in road accidents are older and thus may have limited-to-no safety devices. An evolution of road regulations is needed in order to reduce fatal events due to the lack of vehicle safety systems.

### H34 Is the Survey of Forensic Botany Useful? The Application and Limits of Forensic Case Analysis

*Isabella Aquila, MD, PhD\**, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; *Luigi De Aloe, MD*, Institute of Legal Medicine, Catanzaro 88100, ITALY; *Francesco Sicilia, MD*, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; *Matteo A. Sacco, MD\**, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; *Carmen Scalise, MD*, University of Catanzaro, Catanzaro, ITALY; *Fabrizio Cordasco, MD*, Università Magna Graecia CZ, Catanzaro, ITALY; *Roberto Raffaele, BE\**, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; *Vincenzo Rania, MD*, Institute of Legal Medicine, Catanzaro, ITALY; *Paola Frati, PhD*, University of Roma "La Sapienza," Roma 00161, ITALY; *Vittorio Fineschi, MD, PhD*, University of Foggia, Foggia I-71100, ITALY; *Santo Gratteri, MD*, Catanzaro 88100, ITALY; *Pietrantonio Ricci, PhD*, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of forensic botany in crime scene investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the influence of forensic botany in the evaluation of manner of death, in analyzing the dynamics of death, and in clarifying the primary crime scene.

In recent years, botany has become an extremely important tool for forensic analysis. The study of plants and their alterations as a result of the dynamics of criminal events is able to provide critical interpretative information during the judicial inspection of the crime scene and may inform the determination of manner of death. In this study, each reported case involved a detailed scene analysis performed at least twice. In each judicial inspection, all the botanical elements were analyzed and cataloged. In addition, botanical analyses were carried out on the clothing and/or on the victims' bodies. In cases in which multiple botanical elements were found, a method of taxonomic comparison was applied between the environmental elements with the vegetative elements found on the corpse. Each element was analyzed macroscopically and compared with photographic surveys. This presentation reports six forensic cases in which forensic botany analysis was employed. The purpose of this study is to better understand and characterize the nature of the forensic cases in which botanic studies prove most useful.

In the first case, the suspected suicide of a girl was analyzed, due to a fall from a height. The dynamics of the fall were not initially clear. On the girl's hair and clothing, investigators found botanical elements that were compared to plant elements of a garden hedge. This analysis allowed for the reconstruction of the impact point and the subsequent projection during the fall, thus clarifying the mode of death.

The second case involved a man's sharp force slash murder. During the inspection and at the autopsy, botanical elements were found on the neck in the region of the sharp force injuries, together with other elements on the back that were completely crushed and mixed with soil residues overlying a large lumbosacral ecchymosis. These botanical data, together with the autopsy evidence, suggested that the victim was dragged after the murder and clarified the position of the body at a different point from the site of the murder.

The third case concerns a boy found dead due to a suspected pedestrian versus motor vehicle collision, albeit at a considerable distance from the accident site. Neither the dynamics of the collision nor the driver's statements regarding the impact were clear. The presence of botanical elements on the corpse suggested the actual point of impact of the corpse following the projection due to the impact with the car.

The fourth case concerns a demented elderly woman who was found dead following a mid-height fall. At the autopsy, there were small botanical elements that suggested the path taken by the woman before the fall, also clarifying the mode of death.

The fifth case concerns a boy's fall from a height. The discovery of specific botanical elements overlying the soles of the shoes and on clothing suggested the boy's fall from an area made up of bushes at a height of about 20 meters.

The sixth case concerns the death of a man with electrical and other traumatic injuries who was found in an apartment. The analysis of botanical elements in the hair directed the investigators to search for another crime scene, clarifying the dynamics of death that occurred accidentally during the theft of copper from high voltage pylons.

In total, these cases show that forensic botany can be an important aid in investigations for: (1) clarifying the method of death; (2) analyzing the points of loss of balance and impact in falls; (3) clarifying the dynamics of suicides or accidental traumatic events, such as pedestrian versus motor vehicle accidents; (4) identifying the primary crime scene with respect to a secondary one; (5) unveiling false crime scenes; and (6) revealing the dynamics of concealment of the corpse in cases of homicide or displacement of the body.

Certainly, this investigation is limited by the wide geographical areas, by the state of integrity of the analyzed elements, and by the timing with which the investigations are carried out. To date, the standard analytical method is the macroscopic and microscopic comparison of the elements in their taxonomic characteristics.

---

#### Forensic Sciences, Forensic Botany, Autopsy

### H35 The Immunohistochemical Analysis in the Diagnosis of Freshwater Versus Saltwater Drowning: A Case Report and a Review of the Literature

Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; Orazio Malfa, MD, University "Magna Graecia" of Catanzaro, Catanzaro, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD, Università Magna Graecia CZ, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to describe which investigations are most useful in cases of death due to drowning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of immunohistochemical analysis and the need for the research of a pathognomonic parameter for the differential diagnosis between freshwater and saltwater drowning.

Drowning is one of the most frequent causes of death. According to recent epidemiologic research, the incidence is about 400,000 deaths per year in the world, of which 30,000 occur in Europe.<sup>1</sup> In most cases, these are accidental deaths or suicides.<sup>2</sup> Drowning is a form of asphyxia. The liquid filling the airways replaces air contents resulting in pulmonary edema and anoxic-ischemic encephalopathy. The pathophysiology of drowning depends on the characteristics of the inhaled liquid. If it is hypertonic (i.e., saltwater), the consequences will be hemoconcentration with hypovolemia, sodium, calcium, and magnesium increase, impaired cardiac function (without ventricular fibrillation), and massive pulmonary edema. Death occurs in 8–9 minutes. If the liquid is hypotonic (i.e., freshwater), it will inactivate the surfactant and is rapidly absorbed into the bloodstream, inducing hypervolemia, dilution anemia, and hemolysis with the release of intracellular potassium and lethal ventricular fibrillation. Death occurs in 3–5 minutes. Foaming at the mouth, cyanosis, bright red color hypostasis, and goosebumps are some indicative external signs. Histologic examination plays an essential role. It can establish the presence of irregular areas of dilatation and rupture of alveolar trabeculae, hemorrhage, and edema. The purpose of this work is to compare forensic investigation results in freshwater versus saltwater drowning.

Two forensic cases are presented. The first case is that of a man who fell from a boat into the Ionian Sea. The second case is that of a man who fell into the water of a lake. Autopsy, cartometric testing, and histopathologic and toxicologic examination were performed in both cases. In both cases, external examination showed signs indicative of drowning. In the first case, the lungs were emphysematous and crackling with evidence of petechiae and pulmonary edema at autopsy. Cartometric testing showed greater hemodilution of blood within the right ventricle as compared to the left. In the second case, the lungs appeared congested and edematous. Cartometric testing showed greater hemodilution of the blood within the left ventricle as compared to the right. The renal and cerebral immunohistochemical analyses showed a different expression of aquaporins in the two presented cases. The results obtained from these investigations were compared with those found in a non-systematic review of the literature conducted via the PubMed NCBI search engine.

The diagnosis of drowning remains a challenge for the forensic pathologist. There is no single pathognomonic autopsy finding, especially with regard to distinguishing between freshwater and saltwater drowning. As presented in these cases, the cartometric test and, above all, the immunohistochemical analysis are fundamental in the forensic investigation. The cartometric test entails dropping blood taken from the ventricles onto a sheet of bibula paper and subsequently observing the size and color tone of the marks. In cases of hemodilution, the blood from the left ventricle will leave a larger and lighter red-colored mark than the right (e.g., as in the second presented case). The opposite occurs in cases of drowning in saltwater (e.g., as in the first presented case). Immunohistochemical investigations already play an important role in distinguishing between drowning and other types of asphyxia.<sup>3,4</sup> In differentiating between freshwater and saltwater drowning, it is important to evaluate the expression of aquaporins, a protein-channel family responsible for transmembrane passage of liquids. Their expression at tissue level varies according to changes in plasma osmolarity. In particular, in cases of freshwater drowning, aquaporin-2—which is normally found on the renal collecting ducts—is hypo-expressed, while the aquaporin-4—normally found in astrocytes—is hyper-expressed.<sup>5,6</sup> The opposite pattern is seen in cases of saltwater drowning. The two cases presented here confirm these expression patterns. Literature highlights how the study of aquaporin-5—normally expressed in type I pneumocytes—is more useful to distinguish between drowning in fresh water and postmortem immersion.<sup>7</sup> At present, the investigations described herein are the most reliable and accurate means of distinguishing fresh versus saltwater drowning, as there is not yet a single pathognomonic histopathologic marker.

#### Forensic Sciences, Drowning, Immunohistochemical Analysis

### H36 Death From Pheochromocytoma Initially Presenting as a Suspected Homicide

Apoorva R. Dharmadhikari\*, Western Michigan University, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be aware of the importance of performing autopsies in all cases of suspected homicide. Also, this case will provide an additional example to the forensic literature of a natural death that initially presented as a suspected homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that a natural death, in this case, one related to a pheochromocytoma in conjunction with postmortem animal activity and suspicious scene findings, can mimic homicidal violence.

**Introduction:** One of the most important aspects of medicolegal death investigations involves the examination and documentation of homicidal deaths. Appropriate evaluation of such cases, including evidence collection, may have far-reaching implications for subsequent adjudication. In this report, the case of a suspicious death which, after complete investigation and autopsy, was determined to be caused by a pheochromocytoma is presented.

**Case Report:** A 66-year-old man was found unresponsive by Emergency Medical Services (EMS) at his residence in an isolated pole barn. After confirming the man was deceased, the on-scene police officers immediately labeled the death suspicious, as initial signs indicated violence had occurred, with evidence of a significant injury on the decedent's head and multiple guns and power saws at the scene. Additionally, skin and flesh were noted to be missing from the decedent's left ring finger and middle finger. Mice were noted to be present within the barn. Medical history, provided by the decedent's friend who called 911, revealed that the patient had complained of flu-like symptoms in the week prior to his death. Upon further investigation, most of the head injuries appeared to be consistent with postmortem rodent feeding, with no lethal injuries identified. Autopsy revealed a 7cm, mostly solid mass in the right adrenal medulla, as well as a markedly enlarged heart (750g), with coronary artery atherosclerosis, and kidney findings consistent with hypertension. Adrenal tumor cells stained positive for chromogranin A, synaptophysin, and neuron-specific enolase, confirming the diagnosis of pheochromocytoma. The cause of death was hypertensive and atherosclerotic cardiovascular disease, with a contributing factor of an underlying pheochromocytoma. The manner of death was natural.

**Discussion:** The full investigation and autopsy in this case highlight the importance of considering rare diseases as potential causes of death. While adrenal pheochromocytoma may be classified as a rare disease, nearly 50% of pheochromocytomas are first diagnosed at the time of autopsy.<sup>1</sup> The other half tend to be discovered incidentally. Pheochromocytomas are tumors that arise from the chromaffin cells of the adrenal medulla. While they are usually benign, these tumors can often secrete excess levels of catecholamines, such as epinephrine and dopamine, causing a wide range of adverse effects. Diagnosis is complicated by the wide range of non-specific, sometimes hidden, clinical symptoms. One of the hallmark symptoms of a pheochromocytoma is hypertension. The clinical triad widely used to suspect these tumors consists of headache, palpitation, and diaphoresis. Pheochromocytomas may also present with anxiety, chest pain, dyspnea, nausea, and vomiting. Such symptoms are common in a wide range of diseases and tend to broaden the differential. From a forensic perspective, this case represents an example of a natural death that initially presented as a homicide. While both accidental traumatic and natural deaths initially presenting as homicides have been reported in the forensic literature, such cases are uncommon and often puzzling. Only via cooperative efforts between law enforcement and death investigators, along with a detailed postmortem examination, can homicide be conclusively ruled out and the true nature of the death be recognized.

**Conclusion:** This case initially presented as a suspected homicide due to traumatic postmortem animal activity; however, the true cause of death was related to an underlying pheochromocytoma. This case serves to educate forensic professionals and law enforcement officials that natural deaths can occasionally be mistaken as homicides. This case also serves to raise awareness in the medical community of the variable clinical presentation of pheochromocytomas as well as the disease's sometimes silent nature.

#### Pheochromocytoma, Sudden Death, Suspected Homicide

### H37 A Spontaneous Aortic Rupture: A Report of Two Cases

Shashank Tyagi, MD\*, Seth GS Medical College and KEM Hospital, Mumbai, INDIA

**Learning Overview:** After attending this presentation, attendees will understand the concept of spontaneous aortic rupture. Through a detailed pathological analysis in addition to a ten-year review of the literature, this study sought to clarify the clinico-pathologic features of this uncommon entity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a postmortem diagnosis in the sudden cardiac death and treatment of a spontaneous aortic rupture.

**Background:** Acute aortic syndromes comprise a heterogeneous group of life-threatening disorders and are characterized by acute-onset chest or back pain with or without cardiovascular collapse.<sup>1</sup> The major syndrome entities include acute aortic dissection, penetrating atherosclerotic ulcer, and intramural hematoma.<sup>2</sup> Spontaneous rupture of the ascending aorta in the absence of trauma and without antecedent aneurysm or dissection is one of the rare causes of sudden cardiac death.<sup>3</sup>

**Case Reports:** Two female decedents are presented with similar aortic pathologic findings. One was 68 years old and had been admitted to a private health care facility with uremic encephalopathy arising in a background of chronic kidney disease and hypertension. This was followed by sudden onset of breathlessness and altered sensorium. The second woman was 70 years old with hypertension. She presented with retrosternal chest pain and breathlessness, followed by unconsciousness.

**Material and Methods:** Complete autopsies were performed in both cases.

**Results:** Both hearts showed hemopericardium that developed as a result of a circumferential through-and-through tear of the proximal ascending aortic wall (unlike acute aortic dissection) with adventitial rupture. A circumferential tear, seen in relation to uncomplicated atherosclerotic plaques, was present 4.2cm above the sinu-tubular junction and 0.5cm proximal to the origin of the right brachio-cephalic artery, respectively. Hemopericardium and resultant cardiac tamponade occurred in the two elderly hypertensive women due to almost identical pathology. In each case, there was a tear, through and through, involving both the intima and the media with no or limited dissection of the ascending aorta. Spontaneous Aortic Rupture (SAR) is defined, in its broadest sense, as a non-traumatic simultaneous rupture of the intima and media of a non-aneurysmal aorta, when other acute aortic syndrome pathologies have been ruled out by appropriate imaging modalities and/or histopathological studies of the surgically excised segments or at autopsy.<sup>4</sup> Thus, both cases were designated as SARs.

**Conclusion:** When acute intrapericardial bleeding develops with no evidence of aortic aneurysm or dissection, spontaneous aortic rupture should be suspected. It is important to keep SAR in the differential diagnosis of patients presenting with chest pain and cardiovascular collapse so that timely and emergency intervention can be deployed to ensure better chances of survival. But forensic pathologists should be aware that rapid onset, misdiagnosis, and unpredictability may result in rapid disease progression and death; thus, diagnosis may not be made until the time of postmortem examination. Since the diagnosis may elude even the most experienced and knowledgeable of clinicians, missing the diagnosis does not necessarily represent negligent medical care. At the same time, the clinical findings, differential diagnosis, investigations, treatment plan, and follow-up instructions should be documented scrupulously.

#### Spontaneous Aortic Rupture, Acute Aortic Syndrome, Sudden Cardiac Death

### H38 HIV Post-Sudden Cardiac Death (SCD): Rates of Autopsy-Defined Sudden Arrhythmic Death (SAD) Are 80% Higher in Persons With HIV

Ellen Moffatt, MD\*, City & County of San Francisco San Francisco, CA 94124; Eric Vittinghoff, PhD, University of California, San Francisco, San Francisco, CA 94158; Annie Bedigian, BS, University of California, San Francisco, Electrophysiology Department, San Francisco, CA 94122; Joseph K. Wong, MD, University of California, San Francisco, San Francisco, CA 94122; Philip Ursell, MD, Medical Sciences, San Francisco, CA 94143; Andrew Connolly, MD, PhD, University of California, San Francisco, San Francisco, CA 94143; Jeffrey Olgin, MD, Moffitt Hospital, San Francisco, CA 94143; Priscilla Hsue, MD, San Francisco General Hospital, San Francisco, CA 94110; Amy P. Hart, MD, San Francisco Office of the Chief Medical Examiner, San Francisco, CA 94124; Zian Tseng, MD, Electrophysiology & Arrhythmia Service, San Francisco, CA 94143

**Learning Overview:** This presentation will show that autopsy material informs the living. After attending this presentation, attendees will know that certain chronic HIV infection increases the risk of sudden death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that HIV-infected persons are more likely to die suddenly of an arrhythmic death, and they may benefit from the implantation of a defibrillator.

**Background:** Persons living with HIV have higher rates of Cardiovascular Disease (CVD), including acute myocardial infarct and heart failure. High rates of out-of-hospital presumed SCDs were first reported using World Health Organization (WHO) criteria.<sup>1</sup> However, the precise incidence of actual SADs in HIV remains unknown.

**Methods:** Between 2011 to 2016, this study prospectively identified all incident deaths attributable to out-of-hospital cardiac arrest among individuals with and without HIV aged 18–90 years in San Francisco County for medical records review and comprehensive autopsy, toxicology, and histology via medical examiner surveillance of consecutive out-of-hospital deaths. Autopsy-defined SAD had no extracardiac cause of death or acute heart failure. Final cause was adjudicated by a committee of pathologists, cardiologists, HIV clinicians, and electrophysiologists.

**Results:** One hundred twenty-six out-of-hospital HIV-infected deaths were identified, and 47 of these met WHO SCD criteria. The mean age was 65.6 years, 94% were male, 57% were White. Compared to uninfected WHO-defined (presumed) SCDs ( $N=505$ ), SCDs with HIV were more likely to have a history of myocardial infarct, psychiatric disorder, cigarette smoking, and substance abuse. About half (22 of 47, 47%) of WHO-defined SCDs were autopsy-defined SADs; the remainder were non-cardiac and included 16 due to occult overdose. Presumed SCDs with HIV were more likely to be due to occult overdose (13% vs. 34%,  $p<0.0001$ ) and renal failure (1% vs. 6%,  $p=0.0031$ ) as compared to uninfected presumed SCDs. Adjusted incidence ratios for WHO (presumed) SCDs and autopsy defined SADs were both significantly higher in HIV (IRR 1.82, 95%CI 1.4–2.4,  $p<0.0005$  and IRR 1.83, 95%CI 1.2–2.8,  $P=0.006$ , respectively). After adjustment for age, gender, heart disease, and Coronary Artery Disease (CAD), SCDs with HIV had 60% higher interstitial fibrosis by myocardial trichrome staining compared to uninfected SCDs.

**Conclusions:** In this countywide postmortem study, one-third of apparent SCDs in HIV over a five-year period were due to occult overdose. However, adjusted rates of both presumed SCDs and autopsy-defined SADs were 82% and 83% higher, respectively, in HIV compared to the uninfected population. Higher levels of cardiac fibrosis in HIV, a known substrate for SAD in the general population, may underlie the mechanism by which HIV increases risk for SAD. Development of criteria and evaluation for implantable defibrillators in HIV should be carefully considered in the future as a means to prevent SAD in this high risk population. The underlying cause of increased cardiac fibrosis in HIV-infected persons is under investigation by this study group and will be the subject of a future publication.

### H39 A Fatal Case of Histoplasmosis With Colonic Perforation in a Patient With Acquired Immune Deficiency Syndrome (AIDS)

Danielle Harrell, DO\*, West Tennessee Regional Forensic Center, Memphis, TN 38105; Marco Ross, MD, West Tennessee Regional Forensic Center, Memphis, TN 38105

**Learning Overview:** The goal of this presentation is to introduce a case of extrapulmonary histoplasmosis in a patient with a postmortem diagnosis of AIDS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing an interesting presentation of an AIDS-defining illness postmortem. This presentation will also address the utility of obtaining serum at autopsy for postmortem testing.

*Histoplasma capsulatum* is a fungal organism most prevalent in the Ohio and Mississippi River Valleys. Humans are exposed to *Histoplasma* through the environment, especially soil contaminated with bird or bat droppings. Typical infections are pulmonary and self-limited, although immunocompromised patients are at risk for severe and potentially fatal infections. Histoplasmosis, extrapulmonary or disseminated, is an AIDS-defining illness.

The goal of this case presentation is to introduce a fatal case of disseminated histoplasmosis in a patient with undiagnosed AIDS. A 41-year-old male inmate with a past medical history of diabetes mellitus and hypertension was found unresponsive in his cell. Death was pronounced soon after discovery, and an autopsy was ordered. There was no evidence of foul play at the scene and the decedent had no significant mental health history. The autopsy was performed at the West Tennessee Regional Forensic Center in Memphis, TN.

External examination was unremarkable with no evidence of trauma. Internal examination revealed a fibrinous peritonitis associated with 350 milliliters of turbid ascites fluid. A colonic perforation was identified, distal to the splenic flexure, with extensive induration of the adjacent mesentery and retroperitoneal tissue. Additional findings at autopsy consisted of cardiomegaly and coronary artery atherosclerosis. Histologic examination of the colonic perforation site showed granulomatous inflammation with granulation tissue. Histologic examination of the liver revealed small periportal and intralobular granulomas with periportal-based mononuclear cell infiltrates. A Gomori Methamine Silver (GMS) stain was ordered and highlighted intracellular and extracellular organisms morphologically consistent with *Histoplasma* within the colon and liver sections.

The West Tennessee Regional Forensic Center in Memphis, N, attempts to collect blood from all decedents in a serum separator tube in the event postmortem serum testing is warranted. Blood may also be collected in Ethylenediaminetetraacetic Acid (EDTA) -containing tubes in select cases in the event molecular testing is indicated. Due to the extrapulmonary and disseminated nature of the decedent's infection combined with the lack of known predisposing risk factors, Human Immunodeficiency Virus (HIV) combined antibody and antigen testing on postmortem serum was ordered. The result of the combined testing was positive and identified to be HIV-1 by confirmatory antibody testing. The cause of death in this case was determined to be peritonitis secondary to colonic histoplasmosis with perforation. Given the positive postmortem HIV testing and that extrapulmonary histoplasmosis is an AIDS-defining illness, the underlying cause of death was certified as AIDS.

This case exhibits the importance of obtaining postmortem serum in the event additional laboratory testing is warranted secondary to findings at autopsy. The presence of extrapulmonary disease prompted postmortem testing to determine the HIV status in this case, also highlighting the importance of knowledge regarding AIDS-defining illnesses in postmortem evaluations.

#### **Histoplasmosis, Human Immunodeficiency Virus, Colonic Perforation**

### H40 The Implementation of a Forensic Pathology Rotation for Medical Students

*Mario Rascon, MD\*, El Paso County Office of the Medical Examiner, El Paso, TX 79905*

---

**Learning Overview:** After attending this presentation, attendees will be exposed to the inception, implementation, execution, and management of the El Paso County Office of the Medical Examiner (EPOME) elective forensic pathology rotation for medical students from the Texas Tech Paul L. Foster School of Medicine (PLFSOM). This experience provides an early introduction to forensic pathology to medical students through an educational curriculum that has performance objectives carefully aligned with the Accreditation Council for Graduate Medical Education (ACGME) core competencies for Graduate Medical Education (GME).

**Impact on the Forensic Science Community:** The forensic science community will be impacted by this presentation in that it provides an effective blueprint to managing, implementing, and evaluating the project of a student rotation in a forensic field. Promoting early visibility of forensic sciences through high-quality, meaningful exposure has been mentioned as one of the key strategies that can contribute to individuals choosing forensic specialization fields. The rotation outlined in this presentation has accomplished that by: (1) allowing students to acquire basic knowledge of forensic pathology; (2) teaching students advanced forensic autopsy techniques; (3) allowing students to become familiar with the daily duties of a forensic pathologist, such as daily interactions (with family, attorneys, other medical professionals), courtroom testimony, administrative issues; (4) providing students with literature and resources to broaden their fund of knowledge; (5) mentoring students on academic projects; and (6) supporting the students' applications to pathology residency positions.

Prior to this rotation, the autopsy pathology exposure the medical students from the PLFSOM experienced was limited to a 4-week Laboratory Medicine rotation, which included time spent in both the anatomic and clinical pathology labs with limited, if any, hospital autopsy exposure. Following implementation of an elective forensic pathology rotation, the students have had the opportunity to view daily autopsy cases in a medical examiner setting, participate in morning conferences where cases are presented, attend lectures provided by the faculty, join slide review sessions, and have graduated responsibilities in the autopsy suite, up to taking ownership of forensic autopsy cases, including formulating opinions on ancillary testing (histology, toxicology) and learning how to produce formal, written autopsy reports.

This presentation is intended to outline key project management steps, including: defining the project, setting goals and milestones, putting together a team, monitoring tasks, keeping stakeholders informed and increasing their buy-in, and bringing the project to completion. Also described are monitoring strategies to ensure continued quality improvement as well as ongoing strategies to optimize the didactic value of the student experience (e.g., student customization of the rotation, bidirectional feedback, and aligning the academic sessions with the students' ongoing curriculum).

---

#### Medical Education, Student Rotation, Forensic Pathology

### H41 A Molecular Diagnostic Determination of Human vs. Bovine Origin of Viral-Associated Aggressive Natural Killer (NK) Cell Leukemia

Natalie E. Taylor, MD, MS\*, University of Wisconsin Hospitals and Clinics, Madison, WI 53792; Erik A. Ranheim, MD, PhD, Madison, WI 53792; William M. Rehrauer, PhD, Madison, WI 53792; Erin G. Brooks, MD, University of Wisconsin Hospital and Clinics, Madison, WI 53705

**Learning Overview:** After attending this presentation, attendees will have: (1) gained familiarity with diagnostic features of aggressive NK cell leukemia, a fulminant malignancy that may remain undetected until the time of postmortem examination; (2) developed an understanding of the critical role viruses can play in the development of such malignancies; and (3) appreciation for the utility of molecular diagnostic testing in elucidating the nature/source of viral infections.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of collaborating with pathology specialties, such as molecular and hematopathology, in order to more effectively investigate and accurately certify deaths in cases of suspected viral-associated hematologic malignancies.

A 51-year-old Hispanic male with no known medical history who worked on a dairy farm presented with acute hepatic failure of unknown origin three days prior to his death. Laboratory testing in process at the time of death ultimately revealed quantitative Epstein-Barr Virus (EBV; *human gammaherpesvirus 4*) DNA copies at >1,000,000IU/mL. At autopsy, external and internal examination was notable for diffuse jaundice, anasarca, and evidence of disseminated intravascular coagulation. The liver revealed a background of micronodular cirrhosis with superimposed acute necrosis. There was marked splenomegaly (1,290g) with extensive geographic necrosis. Hepatosplenic histologic sections showed atypical lymphocytes that were positive for EBV-encoded RNA (EBER) and CD56, consistent with EBV-infected NK cells. Circulating EBV-infected NK cells were also seen in sections of vessels. Overall these findings—in conjunction with the patient's fulminant clinical presentation—appeared consistent with EBV-associated aggressive NK cell leukemia.

The state Occupational Safety and Health Administration (OSHA) was subsequently contacted due to a third parties' concern that this represented a work place-acquired viral infection and death. While there is a *bovine gammaherpesvirus 4* (BHV-4) linked to respiratory and reproductive clinical manifestations in dairy cattle, it is not known to commonly infect and/or cause disease in humans. Due to presumed genetic similarity between the human (EBV) and bovine (BHV-4) herpesviruses, there was concern that the Polymerase Chain Reaction (PCR) primer used for the antemortem EBV test could have amplified BHV-4, and thus been erroneously reported as an EBV DNA PCR copy number. To address this concern, real-time PCR (rtPCR) was repeated on a patient blood sample obtained at the time of autopsy, and the amplicon generated from rtPCR was Sanger sequenced. Sequence comparison of the amplification product to various nucleotide sequence databases using Basic Local Alignment Search Tool confirmed the viral infection to be EBV (human origin) rather than BHV-4 (bovine origin).

EBV is one of the most common human viruses in the world. Antibodies to EBV have been demonstrated in all population groups with a worldwide distribution; approximately 90%–95% of adults are EBV-seropositive. EBV infection has been associated with the development of an array of hematologic malignancies, including NK cell leukemia. Aggressive NK cell leukemia is a rare hematologic malignancy that is most commonly seen in Asia, Central America, and South America. The disease has a highly aggressive course with a median survival of <2 months. High levels of circulating plasma EBV at the time of diagnosis (as were found in the current case) have been suggested to portend a worse prognosis. Hepatosplenomegaly and acute hepatic failure have been reported in conjunction with aggressive NK cell leukemia. In conclusion, the cause of death in this case was fulminant acute hepatic failure due to EBV-associated aggressive NK cell leukemia. This case serves to illustrate the utility of molecular diagnostic testing in distinguishing human vs. bovine viral origin in cases in which there is concern for occupational exposure to the infectious agent.

#### Molecular Diagnostics, EBV, Aggressive NK Cell Leukemia

### H42 Neurodegeneration in the Forensic Setting: General Principals and Diagnostic Applications

*William T. Harrison, MD\**, Wake Forest Baptist Medical Center, Winston-Salem, NC ; *Patrick E. Lantz, MD*, Wake Forest School of Medicine, Winston-Salem, NC 27157-1072; *Jerri McLemore, MD*, Wake Forest School of Medicine, Winston-Salem, NC 27157

**Learning Overview:** After attending this presentation, attendees will learn how to diagnose Alzheimer Disease (AD), Lewy Body Disease (LBD), and Frontotemporal Degeneration (FTD) by performing a cost-effective dementia workup on decedents who were reported to be cognitively impaired before death and will see several examples of these practical workups.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demystifying the diagnostic criteria for the most common neurodegenerative diseases and by providing a way to reasonably diagnose these conditions with minimal tissue sampling and immunohistochemical workup.

The incidence of neurodegenerative conditions is continuing to increase as the population ages. The most common of these disorders is AD, followed by LBD and FTD. The prevalence of these conditions is projected to exponentially increase over the next several decades and, without effective treatments, the costs to society will be catastrophic. Neurodegenerative disorders frequently contribute to non-natural deaths in the elderly by increasing the likelihood of devastating falls, choking, and wandering activity, which can lead to lethal environmental exposures and other injuries. As such, an ever-increasing number of elderly deaths are falling under medical examiner/coroner jurisdiction. These degenerative disorders can only be definitely diagnosed at autopsy and many forensic pathologists find these assessments difficult. Additionally, the postmortem workup of these disorders can be expensive, and many offices cannot afford to routinely perform the comprehensive assessment recommended by the National Institute of Aging-Alzheimer's Association (NIA-AA) guidelines.

To help combat this problem and empower forensic pathologists to more confidently perform their own assessments, this study proposes a condensed workup that includes sampling the hippocampus, frontal lobe, occipital lobe, basal ganglia, and midbrain that can be performed using 2–3 tissue cassettes. Immunohistochemical staining of these blocks with  $\beta$ -amyloid, tau, and  $\alpha$ -synuclein should be sufficient to accurately diagnose most causes of neurodegeneration in the cognitively impaired elderly. Even without these immunostains, a great deal of information can still be obtained by looking for neuritic plaques, neurofibrillary tangles, and Lewy bodies with routine hematoxylin and eosin staining. Herein, several autopsy cases of individuals with cognitive impairment are reviewed utilizing this postmortem protocol with final diagnoses, including AD, LBD, and FTD. The accurate pathologic diagnosis of dementing disorders can have a significant impact on a decedent's family and help resolve certain medicolegal issues surrounding the death. Additionally, more accurate data about the prevalence of these diseases is required to understand their contribution to deaths, especially in the forensic setting.

#### Neurodegeneration, Dementia, Alzheimer Disease

### H43 Hypothermia-Related Deaths: A Ten-Year Retrospective Study of Two Major Metropolitan Cities in the United States

Gregory M. Dickinson, MD\*, Montefiore Medical Center, Bronx, NY 10467; Gene X. Maya, MD, Washington, DC 20011-5965; Hannah C. Jarvis, MRCS\*, Harris County Institute of Forensic Sciences, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will understand the epidemiology, risk factors, autopsy, and toxicological findings associated with hypothermia-related deaths during the past ten years in New York City, NY, and Houston, TX.

**Impact on the Forensic Science Community:** This presentation will impact the forensic and public health communities by identifying the risk factors for these fatalities in large metropolitan areas and will assist in reducing these deaths in susceptible populations.

Deaths due to hypothermia are preventable and affect vulnerable populations, including the homeless, elderly, and people with substance abuse and mental illness. Hypothermia is defined as a core body temperature of less than 95°F.<sup>1</sup> There are approximately 1,300 deaths due to hypothermia in the United States every year, most of which occur in the Midwest or West; however, Southern states may exhibit rapid temperature drops at night, in stark contrast to the daytime heat, leaving people unprepared.<sup>2-4</sup> The postmortem diagnosis of hypothermia can be challenging, as there are no pathognomonic signs.<sup>5</sup> This study reviewed the medical examiner case files on all deaths due to hypothermia over a ten-year period in two large populous cities in distinct geographic regions of the United States (New York City and Houston) to study the autopsy findings, toxicologic results, and the epidemiologic patterns of these fatalities.

The New York City Office of Chief Medical Examiner and Harris County Institute of Forensic Sciences electronic databases were searched for all fatalities where the cause of death included hypothermia, between January 2009 and July 2019. There were a total of 189 fatalities (139 in New York City, and 50 in Houston). The following data was collected: age, sex, ethnicity, survival interval, manner of death, place of death, place found, initial body temperature, outdoor temperature (high and low), precipitation, residence, autopsy findings, and toxicological results.

Of the 189 fatalities, there were 143 males and 46 females, and the average age was 60.1 years in New York and 64 years in Houston; age ranged from a neonate to 97 years old. The ethnicities were Black ( $n=76$ ), White ( $n=61$ ), Hispanic ( $n=39$ ), and Asian ( $n=13$ ). The known number of homeless fatalities ( $n=84$ ) versus those with a fixed residence ( $n=93$ ) was similar. A survival interval occurred in 91 cases, ranging from the time required to complete the rewarming protocol (hours) up to 33 days, of whom, the coldest recorded body temperature was 68.3°F, and the highest was 92°F. The average daytime high temperature in New York was 41.7°F and in Houston was 54.4°F; the average nighttime low in New York was 27.2°F and in Houston was 36.1°F. Precipitation (rain and snow) was noted in the weather report for 56 cases. The most cases by year for both cities was 2018, with a total of 23 in New York and 11 in Houston.

All causes of death were due to hypothermia and the manner of death was divided among accident ( $n=181$ ), undetermined ( $n=5$ ) and suicide ( $n=3$ ). The most common autopsy findings were Wischnewski spots in the stomach ( $n=107$ ) and pancreatic hemorrhage ( $n=29$ ). Toxicologic analysis detected ethanol ( $n=69$ ) with an average blood concentration of 0.20gm% in New York, and 0.27gm% in Houston; cocaine ( $n=9$ ); and others, including opioids, benzodiazepines, stimulants, and antipsychotics were more rarely detected. Other postmortem findings included cardiovascular disease ( $n=81$ ) and chronic obstructive pulmonary disease ( $n=16$ ). Pre-existing diagnoses of dementia ( $n=8$ ) or a mental illness, such as schizophrenia or bipolar disorder, ( $n=14$ ) were also noted.

Hypothermia is an important cause of preventable weather-related deaths in major metropolitan cities in the United States. Despite the different geographic locations and climates of New York City and Houston, many similarities were noted between the patient populations, including male sex, advancing age, and the number of deaths occurring equally between homeless people and those with a fixed residence, suggesting that even people who have access to shelter are at risk. Local agencies can use this data to target these higher-risk populations and offer appropriate intervention to try to prevent these deaths. The lack of pathognomonic autopsy findings emphasizes the importance of a thorough scene investigation; otherwise, these deaths may be underreported. The role of the medical examiner is crucial in the accurate classification of these deaths, to assist in improving public education, targeted interventions, and emergency response planning.

### H44 Leaving the Familiar: Suicidal Tourism in Cook County, Chicago, Illinois

Katrina M Thompson, MD\*, Cook County Medical Examiner's Office, Chicago, IL 60612; Michael D. Eckhardt, MD, Cook County Medical Examiner's Office, Chicago, IL 60612; Adrienne Segovia, MD, Cook County Medical Examiner's Office, Chicago, IL 60612

**Learning Overview:** After attending this presentation, attendees will have gained knowledge in suicidal tourism within Cook County, IL.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data of a relatively rare phenomenon of suicidal tourism and the challenges this provides to death investigation, suicide prevention, and public health.

For many, suicide is a very personal and individualized act. Whether it is spontaneous or meticulously planned out, the action of taking one's life usually revolves around the familiar. It occurs at home, at work, or in a location the decedent is most comfortable with. In rare occasions, however, a person chooses to leave their immediate surroundings to commit suicide, in an act referred to as suicidal tourism.<sup>1</sup> Many who choose to travel head to larger cities and national landmarks. Places like the Golden Gate Bridge in San Francisco, CA, and the Grand Canyon National Park in Arizona are hotspots for those seeking to commit suicide away from home.<sup>2,3</sup> As a destination for suicidal tourism, Chicago and Cook County are different, as they lack well-known national landmarks, large national parks, or famous high bridges. What attracts people to Chicago to commit suicide is currently unknown. The goal of this investigation is to answer that question and look for epidemiologic and locational patterns to better support the public health mission of suicide prevention.

A retrospective search of the Cook County Medical Examiner's Office (CCMEO) electronic database, LABLynx ELab (LabLynx, Inc.), was undertaken. All cases where the manner was classified as suicide between 2014 and 2018 were collected and reviewed.

A total of 2,045 suicides were examined at the CCMEO over a five-year period (2014 through 2018). Of those, 4.6% (94/2,045) were committed by persons whose home address lay outside of Cook County. Persons with out-of-state addresses made up 1.9% (39/2,045) of total suicides. The leading five causes of death in descending order of frequency included jumping from height, self-inflicted gunshot wounds, hanging, train deaths, and drug overdose. Over half of the individuals travelled to Cook County from other parts of Illinois (59%; 55/94). Fewer travelled from out of state (41%; 39/94). No cases of international travelers were identified. Ages ranged between 17 and 75 years old, with an average age of 39. Most were identified as Caucasian (85%; 80/94), and the male-to-female ratio was 3.27. Common types of suicidal locations included hotel rooms, parking garages, train stations, and forest preserves.

For forensic pathologists, suicides present a unique challenge. Though the cause and manner of death may be relatively straightforward, the prevention of such deaths is not. The uniqueness of each suicide makes recommendations for prevention difficult to formulate. Studies such as the current one are crucial to provide data to help families, law enforcement, and medical professionals recognize individuals at risk of suicidal tourism and the common locations within Chicago that they frequent, in an attempt to prevent further loss of life.

### H45 Shallow-Water Blackout: A Rare Case of Death During Pool Free Diving

*Aldo Liberto, MD\**, University of Catania, Catania 95123, ITALY; *Martina Fichera, MD*, University of Catania, Catania 95123, ITALY; *Pasquale Malandrino, MD*, University of Catania, Catania 95123, ITALY; *Dario Condorelli*, University of Catania, Catania 95100, ITALY; *Giuseppe Cocimano, MD*, University of Catania, Catania, Italy; *Orazio Cascio, MD*, University of Catania, Catania, ITALY; *Edmondo Scoto*, University of Catania, CATANIA 95123, ITALY; *Monica Salerno, MD, PhD*, University of Catania, Forensic Medicine, Catania 95123, ITALY; *Angelo Montana, MD*, University of Catania, Catania 95123, ITALY; *Giulio Di Mizio, MD, PhD*, Magna Graecia University, Catanzaro 88100, ITALY

**Learning Overview:** The goal of this presentation is to present a rare case of prolonged laryngospasm in a fit diver who was found submerged and lifeless on the bottom of a public swimming pool while he was training in free diving.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the usefulness of a multidisciplinary forensic approach by autopsy, histological/immunohistochemical, and toxicological investigation in cases of sudden and unexpected death in the water, particularly in all cases in which common signs of drowning are not found on the body.

The sudden and unexpected death of a young, fit diver in a public swimming pool represents a challenge to the forensic pathologist. The lack of internal and external drowning signs requires the consideration of a differential diagnosis that includes at least four syndromes (i.e., preexistent cardiac disease, abnormalities in electrical conduction, epilepsy, and hypoxic blackout). Hypoxic blackout can occur at any dive depth, including at constant depth, on ascent from depth, or at the surface following ascent from depth. “Shallow water blackout” is a term referring to the loss of consciousness that occurs when hypoxia is expedited by hypocapnia caused by voluntary hyperventilation before the dive, and where alternative causes of unconsciousness have been excluded.

During free diving, divers can rely only on the oxygen found in their lungs, blood, and tissues. Oxygen (O<sub>2</sub>) tends to decrease, while carbon dioxide (CO<sub>2</sub>) increases in the blood level, stimulating the brain centers associated with breathing. These impulses will induce an urgency to surface and to inspire, while powerful diaphragmatic contractions begin. This moment has been designated the “inspiration break point.” During voluntary diving, if a diver engages in prolonged presubmersion hyperventilation, the pre-dive CO<sub>2</sub> levels will fall and the subsequent CO<sub>2</sub> rise during submersion may not be sufficient to provoke the stimulus to surface before the O<sub>2</sub> blood levels fall and the individual loses consciousness. At this point, the inspiration break point occurs and the unconscious submerged victim is at high risk of drowning.

Presented here is a case report of a Caucasian, 32-year-old man, 171cm in length, found submerged and lifeless on the bottom of a swimming pool where he usually went to train. He had no family history of cardiovascular disease. He was retrieved after a few minutes, but cardiopulmonary resuscitation attempts were ineffective. A multidisciplinary forensic approach, including autopsy, histologic, and toxicologic investigation, was performed. The autopsy external examination showed no injuries. Internal examination, however, revealed subarachnoid hemorrhage and diffuse petechiae overlying the pleural surfaces of the congested and edematous lungs. Once sectioned and compressed, much serousanguinous fluid was extruded. The larger bronchial branches revealed foamy liquid contents. There were no gastric contents. Hematoxylin and Eosin (H&E) -stained histologic sections revealed polyvisceral stasis, thin cerebral hemorrhagic suffusion, and massive pulmonary edema. The toxicologic examination did not reveal drugs or alcohol in the serum. No diatoms were observed in either the water samples or the marrow.

In sum, these anatomic and pathologic findings would support a death attributable to a hypoxemic-hypercapnic condition induced by prolonged laryngospasm due to the apnea during immersion. The autopsy showed very little volume of liquid in the airways, but histologic evidence of acute pulmonary edema. The lack of ingested liquid would be compatible with a laryngeal spasm and cardiac arrest, the consequence of a voluntary respiratory arrest in prolonged apnea conditions.

#### Apnea, Sudden Death, Hypoxic Blackout

### H46 The Elphinstone Tragedy: Understanding the Chaos of a Human Stampede on the Staircase of a Railway Station Footbridge

*Manoj Bhausahab Parchake, MD\*, Seth GS Medical College & KEM Hospital, Mumbai, Maharashtra 400012, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand the Elphinstone Tragedy, a human stampede and its classification, the clinical aspects of a stampede, the cause of death, and injury patterns in a stampede.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping to find the cause of death, understanding the mechanics of a stampede, and the reason behind it. This presentation will also be helpful to emergency medicine to clinically diagnose and treat survivors in a stampede. Additionally, this presentation will be impactful by analyzing the reasons behind such tragedy and the multidisciplinary approach to implement preventative measures.

Human stampedes are a major cause of mortality in mass gatherings, but they have received limited scientific attention. At approximately 10:30 a.m. local time on September 29, 2017, a stampede broke out at the Dussehra festival in Mumbai, India. The stampede arose on the staircase of a narrow footbridge of the Elphinstone railway station. Elphinstone railway station is located on the western railway lines and connects two of the major suburban lines in Mumbai. Ultimately, a total of 23 people were killed and 39 were injured. By approximately 11.30 a.m., 22 casualties had been transported to the King Edward Memorial (KEM) Hospital and 40 injured patients were admitted to the ward. Among those injured, one patient had sustained serious injuries and survived for 26 hours before expiring. The remaining victims sustained more minor injuries and were subsequently discharged. Of the total 23 casualties, 15 were men and 8 were women. On external examination, the most commonly injured body region was chest (19 cases), followed by lower limbs (15 cases), upper limbs (11 cases), head (8 cases), neck (3 cases), abdomen (2 cases), and spine (1 case). In 8 cases, there were associated rib fractures. The age group most commonly affected was 31–40 years old (7 cases), followed by 41–50 years old (5 cases), and 21–30 years old (4 cases.) In the Elphinstone Tragedy, mechanisms of death varied, including traumatic asphyxia (7 cases), crush injuries of the chest (7 cases), shock and hemorrhage due to vital organ injury (3 cases), head injury (3 cases), head injury associated with lung injury (1 case), blunt trauma of chest and abdomen (1 case), and positional asphyxia (1 case.)

Further investigation revealed that the incident occurred during the morning rush hour of the Dussehra festival at Elphinstone station when four trains arrived simultaneously at the station. It was raining at the time, and there were already numerous people crowded onto the staircase of a narrow bridge. It was postulated that someone may have slipped and fell when passengers resumed their travel after the rain, leading to the stampede; additionally, a rumor that the pedestrian bridge was collapsing may have caused the passengers to surge the staircase in order to flee.

A multidisciplinary approach to identifying crowded places and implementing appropriate preventive measures is needed. Prevention measures are related to planning for crowd management and venue design, with review of their effectiveness. Drills are recommended in the preparedness phase to improve coordination and communication. Delays in decisions, poor triage, and/or loss of medical records are common problems in the response phase and may lead to worsened outcome. Broad footbridges and deployment of security guards to the platforms of crowded places are a few recommended measures to prevent this type of tragedy from occurring in other developing countries in the future.

## H47 A Unique Pattern of Tusk Injuries by Wild Boar: A Ten-Year Autopsy Analysis

Nilesh Keshav Tumram, MD\*, Department of Forensic Medicine and Toxicology, Nagpur, Maharashtra 440013, INDIA

**Learning Overview:** After attending this presentation, attendees will be able to identify the uniqueness of injuries caused by the tusk of wild boar, which may be of a distinct type.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating awareness of another unique form of injury that may be of medicolegal significance if such a case is found in deserted places with no witness to the incident. This presentation highlights these type of injuries, which are rarely mentioned in the available literature.

Wild boar is a common name for various species of the pig of the genus *Sus*, part of the biological family *Suidae*. It is one of the most common and widespread large mammals in the world.<sup>1</sup> The body of the wild boar is compact, with a large head and relatively short legs. The fur consists of stiff bristles and usually additional finer fur.<sup>2</sup> The average weight and length of a wild boar are 50 to 90kg and 120 to 180cm, respectively. After two years of age, male wild boars grow tusks from both the upper and lower canines that curve upward. The lower tusks are extremely sharp and usually measure 6cm in length. These tusks serve as weapons during fighting. Wild boars are primarily nocturnal animals and are naturally timid; therefore, confrontations between wild boars and humans are typically very rare.<sup>3</sup>

Recently, however, extinction of natural wild boar enemies (e.g., tigers, wolves, bears, louboutins, leopards, and lynxes) coupled with their high reproduction rates and their ability to adapt to a variety of environments have led to an increase in the wild boar population.<sup>4</sup> They are potentially dangerous animals due to their razor-sharp tusks and may cause serious injuries if confrontations do occur. Wild boars are known to be more aggressive during the mating season and when cornered.<sup>5</sup> It is suspected that wild boar attacks are underreported, and forensic pathologists may be unfamiliar with the pattern of the wild boar tusk injuries as the features are rarely described in the literature.<sup>5-8</sup>

The present study characterizes the mechanism of injuries caused by wild boar attacks. This presentation also describes the specific pattern of injuries over the body which seem to be unique to wild boar attacks. The size and shape of injuries caused by wild boar are very specific and identifiable, even in the absence of a witness, making it important in medicolegal autopsy cases with limited or inadequate history. This presentation will also review the importance of having such knowledge in order to accurately certify such deaths in medicolegal cases.

### Wild Boar, Tusk Injuries, Injury Pattern

### H48 Hypothermia Deaths and Altered Mental Status

Jasmine Saeedian\*, Western Michigan University Homer Stryker MD, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will understand classic patterns that occur among hypothermia deaths related to altered mental status, as well as be able to consider future methods to reduce mortality from hypothermia in these populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting some of the inherent risks of hypothermia deaths related to altered mental status. Understanding these risks will set the stage so that preventive strategies may be further developed and implemented with the goal of reducing mortality within specific vulnerable populations.

Much of the United States experiences sub-freezing winters. While most people who have access to shelter would find themselves apt to seek shelter and safety indoors, those who are cognitively impaired have difficulty eliciting or acting on this reflexive behavior.<sup>1</sup>

Hypothermia is a state in which core body temperature is approximately 33°C or below. Hypothermia from environmental exposure to the cold is termed “primary hypothermia,” and it can result in either focal or systemic injury. The risk of death from hypothermia is noteworthy and particularly high during prolonged exposures to sub-freezing temperatures, though it may also occur in higher temperatures or even indoors.<sup>2</sup>

This presentation provides a review of multiple cases of lethal hypothermia where the deaths were related to some form of altered mental status. Various causes of impaired judgment found include, but are not limited to, dementia, physiologic hormone or electrolyte imbalance, and drug use or abuse.<sup>1</sup> The context of each case differed from the others, but several classic morphologic stigmata of hypothermia were commonly seen, including gastric Wischnewski spots and “frost erythema.” Paradoxical undressing was another relatively common finding.

Among others, altered mental status is a well-known risk factor for hypothermia. Common causes of altered mental status include substance use as well as degenerative neurologic disorders, including various forms of dementia.<sup>1</sup> Though each examined death in this study was related to hypothermia, many of the decedents’ comorbidities often had coexisting physical manifestations; these may have played a contributing role in these deaths.

Hypothermia appears to be responsible for the deaths of seemingly healthy people who are unable to obtain help after being accidentally exposed to cold temperatures, especially in the winter in the Midwestern United States. While acute circumstances of altered mental status may appear to be the triggering event for the examined cases, it is critical to understand the decedents’ preexisting diseases. Considering comorbidities, such as atherosclerosis, respiratory disease, alcohol misuse, or metabolic disturbances, can provide insight to the inappropriate thought process and inability to seek shelter in cold conditions, which ultimately can lead to loss of consciousness and death.<sup>2</sup>

**Hypothermia, Freezing, Impaired**

### H49 An Evaluation of Sudden Deaths Due to Myocarditis: A Study of Autopsy Cases

*Xiang Zhang, MD\**, Office of the Chief Medical Examiner, Baltimore, MD 21223; *Puping Lei, MD\**, Kunming Medical University, Kunming, Yunnan 650500, CHINA; *Rong Li\**, Nanjing Medical University, Nanjing, Jiangsu 211166, CHINA; *Mary G. Ripple, MD*, Baltimore, MD 21223; *David R. Fowler, MD*, Office of the Chief Medical Examiner, Baltimore, MD 21223; *Ling Li, MD\**, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** After attending this presentation, attendees will better understand the characteristic features of acute myocarditis as a cause of death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of forensic autopsy examination with thorough histological study on all sudden unexpected deaths and by understanding the challenges to forensic pathologists when diagnosing acute myocarditis.

Causes of sudden cardiac deaths have been widely reported with limited data focused specifically on myocarditis. Myocarditis is an inflammatory disease of the heart that can cause sudden and unexpected deaths in otherwise healthy individuals. Cases were selected for this study with the following criteria: (1) sudden and unexpected deaths; (2) autopsied cases with complete records, including death scene investigation report and available medical records, autopsy report, toxicology report, and (3) myocarditis was the primary cause of death. The following information was extracted for each case: (1) demographic data, including age, race, and gender; (2) investigation report, including the circumstances of death and known medical history prior to death; (3) autopsy findings; and (4) toxicology report.

This retrospective review of cases from a statewide Office of the Chief Medical Examiner (OCME), MD, yielded a total of 103 sudden unexpected deaths due to myocarditis (1.7% of all natural deaths) in the past ten years. Of the 103 cases, 58 were male and 45 were female (male:female=1.3:1); 37 were African American and 51 were Caucasian. The mean age at death was 31±17 years, with a median age of 30 years. Of the 103 cases, 45 (43.7%) patients were witnessed collapsed. Conditions surrounding death were recorded in 66 cases, with 34 deaths occurring during sleeping or resting. Twenty-six deaths occurred during normal daily activity, such as walking, working, or watching television. Four deaths occurred during exertion, such as exercising at the gym or heavy physical work, and 2 deaths were associated with emotional stress. Eight-six (83.5%) individuals reported chest pain, nausea, or palpitations during a time period less than one day to more than two weeks prior to their deaths. None of the patients sought medical attention. Common cardiac macroscopic findings included ventricular dilatation (39.8%), mild coronary stenosis (17.5%), mottled myocardial appearance (15.5%), and myocardial fibrosis (10.7%). The histological classification of myocarditis was based on the predominant type of inflammatory cell infiltration. In this study group, lymphocytic myocarditis was most common, accounting for 56 cases (54.4%), followed by neutrophilic (32 cases, 31.7%), eosinophilic (13 cases, 12.6%), and giant cell type (2 cases, 1.9%). Microscopic examination revealed myocyte necrosis in 69 cases (67.0%) and interstitial or perivascular fibrosis in 48 cases (46.6%). The percentage of myocyte necrosis was 75.0% (42/58 cases) in lymphocytic, 65.6% (21/31 cases) in neutrophilic, 30.8% (4/13 cases) in eosinophilic, and 100% (2/2 cases) in giant cell myocarditis.

Determination of myocarditis as the cause of death continues to present a major challenge to forensic pathologists because histopathologic findings can be subtle and the diagnosis of myocarditis remains difficult. In cases of sudden unexpected death, especially sudden death in young people, forensic pathologists should consider myocarditis as possible cause. Representative sections from the anterior, lateral, and posterior wall of the atria and ventricles and sections from the ventricular septum should be submitted for microscopic examination.

#### Acute Myocarditis, Sudden Death, Forensic Autopsy

### H50 A Case of Pulmonary Artery Dissection in a Woman With Chronic Pulmonary Hypertension

Robyn Parks\*, Los Angeles, CA 90033; Lawrence Nguyen, MD, Thousand Oaks, CA 91362

**Learning Overview:** After attending this presentation, attendees will better understand pulmonary artery dissection as a fatal complication of chronic pulmonary hypertension and its autopsy findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of sudden death in adults with long-standing pulmonary hypertension.

A 57-year-old woman with a history of pulmonary hypertension and a remote history of polysubstance abuse (1998) was found unresponsive in her locked residence by a neighbor after reportedly feeling unwell for a couple days.

At autopsy, external examination noted digital clubbing. Opening the chest cavity revealed a tense, discolored pericardial sac containing 650mL of liquid and clotted blood. Hemorrhage was identified at the root of the pulmonary artery, and careful examination revealed a 2mm full thickness tear, located 5mm distal to the pulmonic valve. The dissection extended 6.0cm distally to the left main pulmonary artery, terminating 5mm proximal to the take-off of the apicoposterior and anterior segment branches. The pulmonary trunk was dilated, measuring 3.8cm in diameter at the pulmonary root, 3.8cm at the left main pulmonary artery, and 3.2cm at the right main pulmonary artery. There was diffuse atherosclerosis extending into the distal branches of the pulmonary artery. The heart weighed 530 grams and displayed right ventricular hypertrophy with a wall thickness of 8mm, as well as dilated tricuspid, pulmonic, and mitral valves (12.5cm, 9.3cm, and 11.0 cm, respectively).<sup>1</sup> Multiple cavernous hemangiomas of the liver ranging in size from 5mm to 35mm were incidentally identified.

Histologically, the pulmonary artery showed extensive medial degeneration with a large defect extending from the tunica media into the adventitia with associated hemorrhage. The small and large pulmonary vessels showed medial hypertrophy, highlighted with elastin stain. Scattered plexiform lesions were identified. Elastin stain further highlighted fragmentation and loss of elastic fibers with increased intralamellar and translamellar extracellular mucoid material noted on Alcian blue stain. The aorta showed intact elastic fibers with no increase in extracellular mucoid material.

While right ventricular failure is the main cause of death in patients with pulmonary hypertension, autopsy is rarely performed in these cases of sudden death in otherwise stable patients. It has been reported that 28% of pulmonary artery hypertension patients die unexpectedly within three years of diagnosis. Dilatation of the pulmonary artery has been independently associated with unexpected death in these patients with two possible mechanisms: pulmonary artery rupture/dissection and potentially arrhythmogenic pulmonary artery compression of the left main coronary artery. In one study, 2 of 26 unexpectedly deceased pulmonary hypertension patients underwent autopsies, and both showed cardiac tamponade due to pulmonary artery dilatation and dissection.<sup>2</sup>

Pulmonary artery dissection is a rare, but fatal, complication of chronic pulmonary hypertension. Some of the underlying etiologies include: congenital cardiac diseases, pulmonary artery obstruction due to emboli (thrombotic, tumor or foreign material), fibrosing pulmonary diseases, emphysema and left-sided cardiac conditions. If there is no underlying etiology discovered, a diagnosis of primary or idiopathic pulmonary hypertension is made. Histologic findings are often most pronounced in small pulmonary arteries and include medial thickening due to smooth muscle hyperplasia and hypertrophy, intimal thickening due to intimal smooth muscle cells or fibrosis, plexiform lesions, and dilation lesions.<sup>1</sup>

Overall, pulmonary artery dissection as a result of chronic pulmonary hypertension is a rare but fatal entity that may be seen in the forensic pathology community.

### H51 Mal D’Afrique: The Mysteries of Endomyocardial Fibrosis in Western Countries

*Claudia Perrone, MD\*, Legal Medicine, Department of Public Health Sciences, Bari 70124, ITALY; Alessio Ostuni, MD, Sections of Legal Medicine and Criminology, Bari 70124, ITALY; Silvia Trotta, Institute of Legal Medicine, Bari 70124, ITALY; Andrea Andrea Marzullo, MD, Bari 70124, ITALY; Biagio Solarino, PhD, Università degli Studi di Bari, Bari 70125, ITALY*

**Learning Overview:** After attending this presentation, attendees will be aware of a very uncommon cause of death in Western countries: endomyocardial fibrosis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the features of an uncommon cardiac disease that is rather endemic in African men under the age of 30 years old.

Endomyocardial fibrosis is caused by fibrous thickening of the endocardium, involving one or both ventricles and the atrioventricular valves. Its first description dates back to 1948 in Uganda. Epidemiologic studies report endemic prevalence in Sub-Saharan Africa and other tropical areas. For Western countries, such as Italy, however, endomyocardial fibrosis is rare and somewhat mysterious in terms of clinical manifestations, etiology/pathophysiology, diagnosis, and therapeutic management.

This report presents the case of a 21-year-old man (height 166cm, weight 50kg) from the Republic of Gambia in West Africa who suddenly collapsed at a center for asylum seekers located in Apulia, in Southeastern Italy. One week earlier, he had presented to a local physician with high fever, chest pain, and asthenia; he was prescribed antibiotic therapy for a presumed influenza infection. The man was unable to be resuscitated and was pronounced dead. A judicial autopsy was requested. External examination was notable for Janeway spots, cachexia, and the absence of traumatic injuries. The heart weighed 350g and showed a slightly increased shape and volume. Coronary arterial sectioning revealed subcritical stenosis of the left coronary artery that was complicated by a small thrombus. The right coronary artery was patent. The right ventricular wall was partially substituted by fibrosis; the left ventricle likewise revealed fibrotic remodeling. Additionally, the left ventricular apex was completely occluded by endoluminal vegetation. Histologic examination confirmed that the left cardiac ventricular wall was replaced by diffuse endomyocardial fibrosis associated with an inflammatory infiltrate consisting of lymphocytes, plasma cells, and a rich eosinophilic component that was surmounted by a large vegetative fibrinous thrombus in the initial phases of organization. No histologic evidence of acute ischemia was detected. In accordance with these medicolegal investigative results, the cause of death was attributed to endomyocardial fibrosis leading to sudden cardiac death.

In Western countries, endomyocardial fibrosis was previously considered an “obscure” or “obsolete” pathology, scarcely investigated and without specific therapies. The clinical signs are not easy to evaluate, and this makes it difficult to determine the correct diagnosis clinically and, consequently, to administer appropriate therapy. The recent increase of this disease in Western countries is closely linked to migratory flows. According to the United Nations High Commissioner for Refugees (UNHCR) data, 119,247 refugees arrived in Italy between January 1–December 31 in 2017. For this reason, in industrialized countries like Italy, endomyocardial fibrosis—along with other previously obscure cardiovascular diseases such as Chagas disease—now represent novel and emerging diseases.

Currently, there is an epidemiologic transition occurring in which cardiac diseases previously deemed obscure at certain latitudes are now on the rise due to increasing numbers of immigrant citizens. Health care professionals—including forensic pathologists—are thus advised to develop familiarity with the features of these emerging cardiomyopathies. Creating a registry of rarer cardiac entities aimed at increasing knowledge of the diseases as well as diagnostic and therapeutic strategies is suggested.

#### **Endomyocardial Fibrosis, Cardiovascular Diseases, Restrictive Cardiomyopathy**

## H52 Emphysematous Gastritis: A Rare Disease With a Fulminant Course

Melissa E. Toeller-DeSimone, BS\*, University of Wisconsin Madison School of Medicine, Madison, WI 53074

**Learning Overview:** After attending this presentation, attendees will understand features and clinical history distinguishing emphysematous gastritis from common mimics at autopsy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the risk factors, casual organisms, and mortality associated with emphysematous gastritis. This presentation will assist the community overall by increasing awareness of and aiding in the diagnosis of this infectious condition at autopsy.

**Background:** Emphysematous gastritis is a gastric wall infection with intramural pneumatosis suspected to arise due to microbial gas production. It has a fulminant course and significant mortality. Due to the relative rarity, limited published literature exists. Additionally, the disease may be underreported as it can be mistaken for other entities, such as gastric emphysema (i.e., gastric pneumatosis without underlying infection) or postmortem decompositional change.

**Methods:** Autopsy reports from the University of Wisconsin Madison School of Medicine's electronic database between 2003 and 2018 were searched utilizing the term "emphysematous gastritis." All retrieved cases were reviewed. A systematic PubMed® literature search utilizing the same search terms with limits "English language" and "human subjects" between 2000 and 2018 was also conducted. Data on patient demographics, causal pathogens, and outcomes were abstracted.

**Results:** A single case of emphysematous gastritis was diagnosed via postmortem examination at the University of Wisconsin Madison School of Medicine over the preceding 15 years (i.e., a 60-year-old woman undergoing chemotherapy for metastatic mucinous adenocarcinoma suspected to be of gastrointestinal origin). Three days prior to death, she presented with intractable nausea and vomiting that quickly progressed to diffuse abdominal pain. X-ray revealed marked gastric distension with probable gastric pneumatosis but no definitive pneumoperitoneum. She became hemodynamically unstable and expired. Autopsy was performed the day after death and revealed a primary gallbladder carcinoma. The gastric mucosa appeared markedly dusky and hemorrhagic with a palpable crepitation of the wall. No discrete gastrointestinal tear or perforation was evident. Microscopic sections revealed vacuoles consistent with gas bubbles extensively involving the gastric wall as well as admixed bacterial organisms that were predominantly gram-negative rods by gram staining.

Fifty-nine additional cases of emphysematous gastritis were identified in the literature via PubMed® search. Analysis showed a mean age at diagnosis of 50.5 years (range: 2–94 years). There was a slight male predominance (1.3:1). Greater than half of patients were immunocompromised (34/60; 56.7%). Other risk factors included peptic ulcer disease (11/60; 18.3%), history of abdominal surgery (11/60; 18.3%), caustic ingestion (9/60; 15%), and malignancy (7/60; 11.7%). Multiple risk factors were present in nearly half of the cases (28/60; 46.7%), with lesser numbers having a single risk factor (24/60; 40%) or no known risk factors (8/60; 13.3%). Causal pathogens were identified in 45% of cases. Most commonly, these were bacterial only (14/60; 23.3%) or polymicrobial (9/60; 15%); however, a few were fungal only (4/60; 6.7%). In more than half of the cases, infectious disease testing was either not reported (23/60; 38.3%) or else was reportedly negative (10/60; 16.7%). The overall mortality of emphysematous gastritis was 33.3% (20/60). Malignancy ( $n=7$ ) portended a worse prognosis, with a mortality of 42.9%. No cases of emphysematous gastritis associated with gallbladder carcinoma were reported.

**Conclusions:** This presentation reports the first case of emphysematous gastritis arising in association with gallbladder adenocarcinoma. As in this case, the clinical presentation with emphysematous gastritis is typically fulminant with symptoms such as nausea/vomiting, abdominal pain, and hematemesis. Gastric emphysema, conversely, is typically asymptomatic, arises due to disruption in gastric mucosal integrity leading to air entry, and resolves spontaneously. Given its high mortality, pathologists should become familiar with the epidemiologic and histopathologic features of emphysematous gastritis, as well as how to distinguish it from common mimics. Autopsy should be encouraged in all suspected cases to improve understanding of the disease pathogenesis.

### Forensic Autopsy, Emphysematous, Gastritis

## H53 Cardiac Amyloidosis—Two Cases

Stephen Peltier, BS\*, Kalamazoo, MI 49004; Juliana Molosky\*, Kalamazoo, MI 49004; Theodore T. Brown, MD, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will better understand the genetic and pathologic differences between various forms of cardiac amyloidosis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting two cases of cardiac amyloidosis that were diagnosed at autopsy.

Reported here are two cases of death caused by amyloidosis with cardiac involvement. One case involved a 71-year-old Vietnamese woman. Autopsy revealed severe cardiac interstitial fibrosis/amyloidosis, with associated cardiomegaly (470 grams), as well as focal, microscopic amyloidosis within the stomach, liver, and kidney. Mass spectrometry of cardiac tissue was consistent with transthyretin-type amyloid deposition. Transthyretin sequencing expressed a mutation (Ala97Ser) indicative of hereditary transthyretin amyloidosis.

The second case involved a 77-year-old male with a past medical history most significant for congestive heart failure and clinical work-up concerning amyloidosis. Autopsy revealed diffuse cardiac amyloidosis, with associated cardiomegaly (830 grams), dilated heart, and biventricular hypertrophy, as well as microscopic amyloidosis within the liver and kidneys.

Heart disease is the most common cause of death in the United States, with the majority of cases attributable to ischemic and hypertensive heart disease. More rare are the infiltrative cardiomyopathies, which includes amyloidosis.<sup>1</sup> Cardiac amyloidosis may be cardiac-limited or have associated extracardiac involvement, and is nearly always caused by one of two proteins: immunoglobulin light-chain or transthyretin.<sup>2</sup>

Amyloid Light-chain (AL) amyloidosis is the most common type of pathologic cardiac amyloidosis and usually occurs in the setting of plasma cell dyscrasias.<sup>3</sup> Amyloid Transthyretin (ATTR) amyloidosis can be due to wild-type or mutated (hereditary) transthyretin. Wild-type ATTR (previously senile) amyloidosis is the second most common cause of cardiac amyloidosis and occurs mostly in elderly men. Hereditary ATTR amyloidosis is less common, presents at a younger age, and has various geographic distributions.<sup>4</sup> Mortality from cardiac amyloidosis is often due to heart failure or fatal arrhythmias.<sup>5</sup>

The cases serve to highlight cardiac amyloidosis in the forensic autopsy setting. Forensic pathologists need to be aware of the various forms of cardiac amyloidosis and the types of postmortem testing available to better characterize the diagnosis. Depending on the type of amyloidosis, notification of surviving family members may be appropriate, as some cases have a familial tendency.

### Cardiac Amyloidosis, Infiltrative Cardiomyopathy, Transthyretin

### H54 An Anomalous Origin of Right Coronary Artery as a Possible Cause of Sudden Cardiac Death in an Athlete: A Case Report

*Pauline Saint-Martin, MD, PhD\*, Service de Medecine Legale, Tours 37000, FRANCE; Camille Rerolle, MD, Service de Medecine Legale, Tours 37000, FRANCE; Nemo Grasset, MD, Institut Medico Legal, Tours 37044, FRANCE; Melanie Seignier, MD, Institut De Medecine Legale, Tours 37044, FRANCE; Justine Canales, MD, Institut Medico Legal, Tours 37044, FRANCE*

**Learning Overview:** After attending this presentation, attendees will better understand an anomalous origin of right coronary artery, a rare condition that can be asymptomatic, but can also lead to sudden cardiac death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a cause of cardiac sudden death in athletes and the potential legal repercussions for the physicians that were responsible for the medical follow-up.

Sudden cardiac death of athletes is a source of confusion for the relatives as well as the general public, not only because it affects young individuals, but also because practicing sports is generally considered to be associated with an improved quality of life.

**Case Report:** An 18-year-old male was found dead in his bed by his roommates. He was a young professional soccer player and had been an intern in a soccer training center for two years. He had no significant medical history. At external examination, no signs of trauma were found. The body weighted 70kg with a length of 181cm. At autopsy, the organs were congested. The heart weighted 383g and showed an anomalous origin of the right coronary artery. The right coronary artery arose 1.5cm above the right coronary sinus. There was a small bridge of tissue that recovered the origin of the artery. The right coronary then made an angulation before assuming the expected path in the coronary sulcus. The rest of the autopsy was unremarkable. Histology confirmed the right coronary arterial anomaly. As a result of this anomaly, it was suspected that the death could have been due to a temporary interruption of blood flow leading to myocardial ischemia. Toxicologic analysis was negative. After the autopsy, the medical charts of the deceased were analyzed. An electrocardiogram and echocardiography had been performed upon the arrival of the male at the training center, as well as a cardiac stress test. He had another complete examination one year later. These repeated evaluations met the criteria that are required by French law for professional athletes and were strictly normal.

**Discussion:** The prevalence of anomalous origin of the right coronary artery is estimated at 0.25% in the literature. It is an infrequent congenital anomaly. The right coronary artery originates either from the left coronary sinus or from the aortic wall above the coronary sinus, as in this case. The patient may be asymptomatic, but this condition may also lead to myocardial infarction, angina pectoris, or sudden death. In this case, it was important to establish that this type of anomaly cannot be detected by standard echocardiography, so that the medical center that evaluated the health of the athletes was not legally responsible.

**Forensic Science, Sudden Cardiac Death, Anomalous Origin of Coronary Artery**

## H55 A Tell-Tale Heart: A Case of Takotsubo Cardiomyopathy at Autopsy

Meredith A. Reynolds, MD\*, University of Chicago Medical Center, Chicago, IL 60637; Kyle G. Parker, MD, University of Chicago Medical Center, Chicago, IL 60637; Kelly A. Pokrywiecki, BA, BS, University of Chicago Medical Center, Chicago, IL 60637; Jeffrey J. Schulte, MD, University of Chicago Medical Center, Chicago, IL 60637; Kammi J. Henriksen, MD, University of Chicago Medical Center, Chicago, IL 60637; Aliya N. Husain, MBBS, University of Chicago Medical Center, Chicago, IL 60637

**Learning Overview:** After attending this presentation, attendees will recognize the clinical history of Takotsubo Cardiomyopathy (TCM) and be familiar with its pathological findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing attention to a rare cardiomyopathy that, while pertinent to a medicolegal investigation, may go unrecognized outside of a hospital setting.

**Background:** TCM, also known as stress cardiomyopathy, is an acute and transient left ventricular wall-motion abnormality involving the apex and mid portions of the ventricle while sparing the base, which can simulate acute coronary syndrome in the absence of significant coronary artery stenosis.<sup>1,2</sup> It is often preceded by emotional or physical stress.<sup>1,3</sup> Although the precise mechanism behind this contractile dysfunction remains elusive, it is thought to be due to a catecholamine excess resulting in microcirculatory dysfunction and direct myocardial toxicity.<sup>1,4</sup>

**Case Report:** A 51-year-old female with Type 2 diabetes mellitus, end-stage renal disease on hemodialysis, and severe peripheral arterial disease was admitted with a gangrenous wound of the hand and concern for osteomyelitis, as well as altered mental status and septic shock. Despite amputation of the hand and broad-spectrum antimicrobial treatment, she became increasingly hypotensive, with rising lactate. High-sensitivity Troponin T was 173ng/L on hospital day three, eventually peaking at 328ng/L on hospital day four before trending downward over the course of hospital day five (reference range: <14ng/L). Serial electrocardiograms demonstrated ST abnormality and inverted T waves, concerning for ischemia. An echocardiogram on hospital day four demonstrated a significant large apical wall motion abnormality of the left ventricle, extending to mid segments, with hyperkinesis of the basal segments. These findings differed dramatically from the previous day's echocardiogram, and were suspicious for TCM. The patient's condition worsened, and she developed unstable ventricular arrhythmias, which progressed into Pulseless Electrical Activity (PEA) arrest. Per her code status, no aggressive resuscitation was initiated, and she expired on hospital day five.

**Pathological Findings:** At autopsy, the heart weighed 269g, with a moderate amount of epicardial fat. The coronary arteries demonstrated minimal to mild atherosclerosis, with up to 40% stenosis in the left anterior descending artery. There was no hemorrhage, fibrosis, or other evidence of infarct. The mitral valve was modestly dilated at 11.5cm (average: 8–10.5cm). Histologically, the myocardium demonstrated striking myocyte hypertrophy with "boxcar nuclei," present throughout the bilateral atrial and ventricular free walls and interventricular septum. Interstitial fibrosis was also present, with scattered mononuclear cell infiltrates and contraction bands. Immunohistochemical staining demonstrated these mononuclear cells to be largely CD68 positive macrophages, with scattered single CD3 or CD20 positive lymphocytes. Staining with C4d demonstrated scattered foci of myocyte necrosis. The left ventricular free wall demonstrated fibrinous pericarditis with a CD3 positive lymphocytic infiltrate. Geographically, the left ventricle was the most severely affected, with the base more involved than the apex. The right atrium was more involved than the left atrium.

**Discussion:** In this case, TCM was preceded by significant physiologic stress (infection, septic shock, amputation). The patient's Electrocardiogram (ECG) findings were non-specific, as is usual in 85% of TCM cases.<sup>2</sup> Troponin T was markedly elevated, which, while not typical for TCM, has been reported.<sup>3-5</sup> The clinical and radiological features of TCM are well-documented, but the pathological findings are less so, as TCM is largely a clinical diagnosis.<sup>1,2</sup> Described microscopic findings include myocyte hypertrophy, C4d positive myocyte necrosis, interstitial fibrosis, mononuclear cell infiltrate, and contraction bands with or without necrosis, the likes of which are present in the current case.<sup>1,2,4,5</sup> Despite the generally good prognosis, complications of TCM include heart failure, thromboembolism, ventricular arrhythmia, and ventricular free wall rupture.<sup>2</sup>

**Conclusion:** TCM is a left ventricular wall-motion abnormality often precipitated by emotional or physical stress, and thought to be due to an excess of catecholamines resulting in myocyte toxicity and microcirculatory dysfunction. In spite of an overall good prognosis, TCM is not a harmless entity. Recognition of the clinical presentation, complications, and pathologic findings is important for death investigation.

### H56 Autopsy Findings of Individuals Displaying Symptoms of Pica

*Heather M. McLendon\**, Mississippi State Medical Examiner's Office, Pearl, MS 39208; *Katie C. Donohue\**, Mississippi State Medical Examiner's Office, Pearl, MS 39208

---

**Learning Overview:** After attending this presentation, attendees will be able to visually understand the physical complications of an individual who suffers from a mental disorder known as pica. Pica is an eating disorder that involves the individual craving and eating items that are not generally thought of as food and contain no nutritional value. Some of these items may include carpet fibers, hair, dirt, and other common household items. Pica is considered a dangerous and often deadly illness if not monitored due to the likelihood of intestinal blockages or perforations from the toxicity of the items that are sometimes consumed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by displaying three cases of patients that displayed pica symptoms at the Mississippi State Medical Examiner's Office for autopsy and by exhibiting the pathological findings of each case.

**Case 1:** A 2-year-old, White male was found unresponsive in his playpen. His mother stated that he had been pulling at his ears and throat for some time before he was found. He had no known medical history and, other than not feeling well the past few days, was considered a healthy child. However, the victim's mother also stated that she had recently reached out for medical attention regarding her son missing milestones, such as walking and talking. At autopsy, the child's abdomen was severely distended, and he showed multiple lacerations to his face and mouth. Internal examination of the stomach revealed that the child had developed a bezoar due to his ingestion of foreign materials. These materials seemed to primarily include items such as carpet fibers, jean fibers, and hair.

**Case 2:** A 31-year-old, White male was transported to the hospital from prison after complaining of abdominal pain. The patient had no known significant medical history but had been anecdotally reported to eat the toothpaste tubes from the prisoner hygiene kits. At autopsy, examination of the gastric contents revealed multiple non-edible items including paper towels, toothpaste tubes, and apple juice cartons. The victim's ultimate cause of death was peritonitis from a bowel obstruction.

**Case 3:** A 19-year-old, African-American male was a patient at the state mental hospital and had previously been diagnosed with pica. During a transportation to facilities, the victim vomited what was thought to be fecal matter along with a latex glove. It was believed that the glove had become lodged in his airway for too long, and he later died from the incident. Upon internal examination at autopsy, it was found the victim's gastrointestinal tract contained items such as pens, plastic bags, latex gloves, and coins.

---

#### Pica, Mental Disability, Foreign Material

### H57 Unexpected and Sudden Cardiac Death Due to Eosinophilic Myocarditis (EM): Still a Difficult Task for Forensic Pathologists

Rosario Barranco\*, University of Genova, Department of Legal Medicine, Genova 16132, ITALY; Davide Bedocchi, MD, Istituto Di Medicina Legale E Delle Assicurazioni, Genova 16132, ITALY; Alessandro Bonsignore, MD, PhD\*, University of Genova, Genova, Liguria 16132, ITALY; Francesco Ventura, MD\*, University of Genova, Department of Legal Medicine, Genova 16132, ITALY

**Learning Overview:** The goal of this presentation is to highlight that that antemortem diagnosis of EM is difficult due to ambiguous and non-specific symptoms. Although predisposing factors exist, EM may occur in healthy persons with no history of hypersensitivity. Death due to EM could be avoided through a prompt diagnosis and the administration of appropriate therapy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of exhaustive and detailed cardio-pathological analysis in cases of sudden and unexpected death. The anamnestic analysis (when possible) is also fundamental to track down any prodrome or predisposing factors. Although infrequent, EM must always be considered in cases of sudden death, even in young subjects and in the absence of specific symptoms.

In this presentation, a rare case of unexpected death caused by an undiagnosed and undetected EM is described. This topic is still controversial, even though myocarditis represents one of the main causes of sudden cardiac death. The criteria for the diagnosis of EM are debated in the forensic science community, and no standard protocol has been agreed upon.

**Case Report:** A 52-year-old man, in apparent good health, suddenly died while he was working as an accountant. According to the medical history, he suffered a mild temperature and diarrhea about ten days before death; however, the symptoms had disappeared after two to three days. He had no previous history of chronic or autoimmune pathologies, allergies, drug abuse, parasitic infections, or recent vaccinations.

**Autopsy Findings:** The external examination was unremarkable. The macroscopic heart examination showed no significant signs of hypertrophy. The coronary arteries were patent and free of moderate/severe atherosclerosis. The myocardium appeared flaccid, dilated, and pale. The lungs were edematous and congested. There were no other macroscopic pathological findings.

**Microscopic Examination:** Hematoxylin and eosin-stained histologic sections showed inflammatory myocardial damage of the subepicardial and mid-mural region of the right ventricle and the anterior and posterior wall of the left ventricle. The inflammatory myocardial infiltrate consisted of many eosinophils (partially degranulated), macrophages, and a few neutrophils and T lymphocytes. Immunohistochemical analysis showed largely CD15+ and CD68+ cells. Toxicologic investigations did not reveal the presence of drugs or substances of abuse.

**Discussion and Conclusion:** In this case, a complete forensic approach led to the conclusion that death was caused by a fatal arrhythmia related to the extensive myocardial inflammatory damage (EM). The World Health Organization (WHO) defines myocarditis as “an inflammatory disease of the heart muscle, diagnosed by established histological, immunological and immunohistochemical criteria.” EM is an uncommon but potentially lethal type of myocarditis. The clinical as well as postmortem diagnosis of EM is difficult and often underrated. A comprehensive cardio-pathologic investigation is mandatory for a postmortem diagnosis of EM. Extensive myocardial sampling circumferentially, including the left and right ventricles in transverse section (as advised by the Association for European Cardiovascular Pathology guidelines), is always required.<sup>1</sup>

The histology of EM changes significantly depending on the extent and composition of inflammation, as well as associated myocardial damage. Necrosis of myocardial cells can be absent, focal, multifocal, or rarely extensive. Eosinophils can be preponderant or be a portion of mixed inflammatory cells with macrophages, plasma cells, lymphocytes, and even neutrophils. The role of the forensic pathologist is particularly important in correctly identifying EM at autopsy, particularly in cases that have remained undiagnosed antemortem. Because symptoms are non-specific and underestimated, the diagnosis is often not made until the time of autopsy. On completing this presentation, attendees will have gained knowledge of EM, including how a complete forensic investigation is essential to ascertain the cause of death.

## H58 An Unusual In-Custody Death

Baiyang Xu, MD\*, Allegheny County Medical Examiner's Office, Pittsburgh, PA 15222

**Learning Overview:** After attending this presentation, attendees will have learned of an unusual death in jail and more considerations for the investigation of the “in-custody” death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a complicated case with the decedent’s psychological behaviors and secondary adrenal insufficiency that could have been the cause or result of one another.

In-custody deaths are invariably complex and high-profile cases. They require thorough investigation of the scene, including acquisition of any videos of the scene, the decedents’ behaviors prior to the death, eyewitness’ statements, and the circumstances surrounding the event. It is also important to get the decedents’ medical histories and perform complete autopsies with toxicologic studies.

The case of a 27-year-old White male found unresponsive in his jail cell is presented. His medical history was significant for bipolar disorder and borderline personality disorder. He also suffered from panhypopituitarism due to resection of his pituitary for a craniopharyngioma while still a child. He was being treated with desmopressin but had recently indicated that he was on a hunger strike, which included refusing water, food, and medications. Following transport to the hospital he was diagnosed with hypoglycemia, electrolyte insufficiencies, dehydration, and shock. He ultimately expired and an autopsy was requested. Autopsy findings included replacement of the pituitary gland by a 1.5cm greenish fluid-filled cyst. However, residual pituitary tissue was identified microscopically. The right adrenal gland was not identified, and the left adrenal gland was markedly atrophic (4.4 grams), as was the thyroid gland (10 grams). Other significant findings included bilateral pleural effusions (500ml on each side) and ascites (500ml).

Secondary adrenal insufficiency occurs when the pituitary gland fails to produce enough Adrenocorticotropic (ACTH), a hormone that stimulates the adrenal glands to produce the hormone cortisol.<sup>1</sup> If ACTH output is too low, cortisol production drops. Eventually, the adrenal glands can shrink due to a lack of ACTH stimulation. The etiology of secondary adrenal insufficiency may include stoppage of corticosteroid medication and surgical removal of pituitary tumors; other less common causes include tumors or infections of the pituitary gland, loss of blood flow to the pituitary gland, exposure of the pituitary gland to radiation, or the surgical removal of parts of the hypothalamus.<sup>2</sup> The slowly progressing symptoms of adrenal insufficiency can rapidly evolve into an adrenal crisis with any additional stresses.<sup>3</sup> The symptoms of adrenal crisis include dehydration, low blood pressure, loss of consciousness, and death. In the current presented case, it is suspected that adrenal crisis likely contributed to and/or was exacerbated by the grave consequences of the decedent’s hunger strike with resultant hypoglycemia, electrolyte insufficiencies, and dehydration.

### H59 A Case of Fulminant Spontaneous Necrotizing Soft Tissues Infections (NSTI) of the Chest Wall in a Man With No Risk Factors

Sara Gioia, MD\*, via Tristano di Joannuccio SNC, Terni 05100, ITALY; Valentina Rosati, MD\*, via del Giochetto, Perugia 06126, ITALY; Lisa Franceschetto, MD, University of Perugia, Perugia, ITALY; Fabio Suadoni, MD, via Tristano di Joannuccio SNC, Terni 05100, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the case of a patient with no risk factors who developed a mono-microbial spontaneous NSTI of the chest wall that was rapidly lethal.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting that NSTI of the chest wall, usually described in patients with pleural empyema or with a chest tube, can also occur spontaneously, in the absence of risk factors. Moreover, this presentation will impact the forensic science community by highlighting that a fulminant mono-microbial NSTI can occur in an immunocompetent patient.

NSTI refers to infection of any layer within the soft tissue compartment with associated necrotic changes.<sup>1,2</sup> It can be caused by different types of bacteria, including *Bacteroides*, *Streptococcus*, *E. coli*, and *Clostridium*—among many others.<sup>3</sup> The infections are usually polymicrobial, but may be monomicrobial in immunosuppressed patients. NSTI are most commonly described as occurring in the extremities, perineum (i.e., Fournier gangrene), abdomen, and head/neck.<sup>4-6</sup> Thoracic NSTI are extremely rare; the few cases reported in the international literature describe patients who have undergone thoracic surgery or had pleural empyemas.<sup>7</sup>

The case of a 67-year-old man who developed spontaneous NSTI of the chest wall following minimal muscle strain and in the absence of other risk factors is reported. He was admitted to the Emergency Room (ER) for moderate back pain radiating from the 3<sup>rd</sup>-4<sup>th</sup> right ribs. Clinical examination described a hematoma. He was discharged with prescribed painkillers but returned a few hours later for therapy-resistant pain. Clinical examination revealed edema of the right chest and right abdominal wall. A High-Resolution Computed Tomography (HRCT) scan showed right axillary lymphadenopathy with imbibition of the soft tissue compartment of the right chest wall. Laboratory investigation revealed increased myocytolysis indicators. While the patient was initially afebrile with normal vital signs, his clinical condition deteriorated while being evaluated with worsening Glasgow coma scale (12), decreasing blood pressure (90/50mmHg), tachypnea (22bpm), and metabolic acidosis. Blood tests showed normal levels of white blood cells, acute kidney injury, and an increase of the non-specific inflammation indices. Septic shock was suspected. Broad spectrum antibiotic therapy was started with a concomitant norepinephrine infusion due to his fluid resuscitation-resistant hypovolemia. In a few hours, the clinical condition of the patient deteriorated significantly and he died (22 hours after first ER admittance) of refractory septic shock and multiorgan failure.

The prosecutor ordered a forensic autopsy that was performed 48 hours later. The main external findings were multiple large reddish areas on the right hemithorax that spread down the right side and to the right gluteus with de-epithelialized areas. Histologic examination of the organs revealed widespread necrosis of the soft tissues and muscle fibers of the right hemithorax, buttocks, right flank, and pectoral region. The cause of death was certified as septic shock. Postmortem Matrix-Assisted Laser Desorption/Ionization-Time-of-Flight (MALDI/TOF) mass spectrometry identified *Streptococcus pyogenes* as the cause of the NSTI. This finding was interesting because *Streptococcus pyogenes* is a typical cutaneous bacteria that rarely causes mono-microbial NSTI in the absence of a cutaneous lesion or in immunocompetent patients with no risk factors.

#### NSTI, Spontaneous Infection, Streptococcus Pyogenes

### H60 Acute Colonic Pseudo-Obstruction (ACPO) (Ogilvie Syndrome) Leading to Respiratory Compromise and Death

*John Dewey, BS\*, Western Michigan University, Kalamazoo, MI 49007; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007*

**Learning Overview:** The goal of this presentation is to educate attendees about a condition known as ACPO, or Ogilvie Syndrome, and how to differentiate it both clinically and at autopsy from true obstruction.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating an unusual case in which ACPO, or Ogilvie Syndrome, resulted in sudden death related to respiratory compromise.

In this case, a 19-year-old severely disabled man with Cerebral Palsy (CP) and autism experienced shortness of breath in association with a markedly distended abdomen and subsequently had an unwitnessed cardiac arrest. Records at his care facility reported the patient had experienced shortness of breath and diarrhea earlier in the evening prior to the arrest. He was transported to an Emergency Department (ED), but resuscitative efforts failed to revive him. A significantly distended abdomen that was notably hard on palpation was noted.

At autopsy, external examination revealed developmental deformities consistent with CP, a markedly distended abdomen, and rectal prolapse. A postmortem radiograph revealed massively distended bowels; this finding was confirmed on internal examination where the small and large intestines were distended to such an extent that the diaphragm was displaced significantly upward bilaterally, with associated compression of the lungs. Further analysis of the gastrointestinal tract failed to identify any signs of perforation or obstruction.

Sectioning of the compressed lungs revealed dark red-blue, moderately congested, compressed parenchyma. Microscopically, the lungs showed considerable compression with areas of collapsed parenchyma and areas of pulmonary edema. There were also focal areas of hyperexpanded alveoli and extravasated blood. Microscopic examination of the Gastrointestinal (GI) tract was unremarkable. Subsequent record review revealed that the patient had experienced similar episodes in the past (relieved via decompression in the ED), but as he was a relatively new resident at the care facility, staff were apparently unaware of this history. In addition, the patient had been receiving multiple medications with constipation as a known side effect, and his laxative medications had been withheld for several days, which potentially aggravated the problem. The cause of death was determined to be respiratory compromise secondary to diaphragmatic compression as a result of ACPO, with contributing underlying factors of CP and autism, including possible medication mismanagement.

The present case highlights the fact that severe intestinal obstruction can lead to significant diaphragmatic elevation with accompanying respiratory compromise and death. When evaluating a decedent for a potential intestinal obstruction at autopsy, it is important to consider a number of potential etiologies, including physical/structural obstruction from tumor, compression, adhesions, volvulus, or intussusception. When careful evaluation fails to reveal a physical/structural obstruction, consideration must be given to other conditions, including toxic megacolon, postoperative ileus, drug-induced obstruction, and ACPO.

#### ACPO, Intestinal Obstruction, Death

## H61 Intramyocardial Lipoma of the Right Atrium: Two Cases Diagnosed at Forensic Autopsy

Sydney C. Pawsey, BS\*, Eastern Virginia Medical School, Norfolk, VA 23510; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will be aware of the possible effects an intramyocardial lipoma may have on a patient and the associated risks.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing suspicion of the role of a lipomatous tumor in accelerating death in correlation to external factors.

Lipomatous tumors of the heart are rare, usually asymptomatic entities that typically present as incidental findings at autopsy. A few case reports describe presenting symptoms such as dizziness and shortness of breath; it is estimated that approximately 17% of all patients with cardiac tumors exhibit neurological symptoms.<sup>1</sup> Intramyocardial lipomas are most commonly found in the right atrium and the left ventricle.<sup>2</sup> Both atrial and ventricular lipomatous tumors are typically incidental findings on echocardiogram; Magnetic Resonance Imaging (MRI) can be used to better characterize the fat stranding, density, size, and location, while biopsies can be performed to rule out malignancy. Two unrelated decedents with right atrial intramyocardial lipomatous tumors were first identified at forensic autopsy.

A 70-year-old moderately obese man with a history of peripheral vascular disease, emphysema, and essential hypertension was pronounced dead in the emergency room following an altercation in his home. He had recently developed symptoms of irregular heartbeat and sweating episodes; thyroid function testing was planned. He had also developed forgetfulness and disordered thought processes. Autopsy corroborated the medical history, showed evidence of dementia, and documented an intramyocardial lipoma in the right atrium measuring 3.2 x 2.4 x 2.0cm. The lipoma was located in the upper margin of the fossa ovalis between the inferior vena cava and the superior vena cava, and displaced atrial muscle; it did not reach the crista terminalis. Death was attributed to external factors.

A 55-year-old ill-appearing woman, found dead in her bed, with a history of hypertension, was suspected to have died of a drug overdose; although no drug paraphernalia was found at the scene, she had an antecubital ecchymosis and a possible dermal puncture in each antecubital fossa. Her heart demonstrated significant concentric left ventricular hypertrophy, with four-chamber dilatation, and a 3 x 5cm right atrial intramyocardial encapsulated lipomatous tumor. The tumor extended from the area adjacent to the superior vena cava down to the auricle and into the anterior and right anterolateral atrial wall, sparing the septum.

**Discussion:** Primary cardiac tumors are rare, with an autopsy incidence of 0.001% to 0.03%; only 25% of them are found in the myocardium.<sup>2</sup> Intramyocardial lipomas may cause hemodynamic and electrical conduction changes, resulting in arrhythmias that may cause sudden death; approximately 0.0025% of sudden cardiac deaths are estimated to occur from primary cardiac tumors.<sup>3</sup> A few reports describe intramyocardial lipomas that were identified during life, after patients presented with shortness of breath, dizziness, and/or hypertension, which warranted an echocardiogram. All were successfully surgically resected; patients had a speedy recovery (approximately eight days in the hospital) and were asymptomatic/lipoma free for follow-ups recorded from one to four years post operation. Prompt diagnosis of primary cardiac tumors and surgical resection has often led to complete cures; surgery with a minimally invasive approach offers a low-risk procedure with an excellent long-term prognosis approaching 100%.<sup>2</sup>

In the current study, one decedent's symptoms of irregular heartbeat and sweating episodes were attributed to probable thyroid disease. Emphysema may have masked dyspnea, and dementia may have interfered with diagnosis of neurological symptoms. In the second case, a lipoma might have accelerated hemodynamic compromise under conditions of drug-related hypoxia. In both cases, it was unclear whether the lipoma played a contributing role in death through vulnerability to arrhythmia. Both of these cases support the literature favoring surgical excision of intracavitary or intramyocardial lipomatous tumors to decrease the risk for antiarrhythmic firing or sudden death; if such a tumor is encountered at forensic autopsy, consideration should be given to its possible role in the mechanism of death.

### H62 A Fatal Case of Chemical Peritonitis Caused by a Spontaneous Rupture of the Pancreatic Pseudocyst: A Forensic Approach

Massimiliano Esposito, MD\*, University of Catania, Catania 95123, ITALY; Giuseppe Cocimano, MD\*, University of Catania, Catania, Italy; Giuseppe D. Albano, MD, University of Catania, Forensic Pathology, Foggia 95123, ITALY; Aldo Liberto, MD, University of Catania, Catania 95123, ITALY; Diego Geraci, PhD, Catania 95100, ITALY; Martina Fichera, MD, University of Catania, Catania 95123, ITALY; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY; Pasquale Malandrino, MD, University of Catania, Catania 95123, ITALY; Fabrizio Vanaria, MD, Department of Italian State Police, Catania, ITALY; Monica Salerno, MD, PhD, University of Catania, Forensic Medicine, Catania 95123, ITALY

**Learning Overview:** The goal of this presentation is to examine the clinical and histopathological aspects of a fatal case of chemical peritonitis due to spontaneous rupture of the pancreatic pseudocyst in a patient with pancreatic adenocarcinoma.

**Impact on the Forensic Science Community:** This presentation describes a patient with pancreatic adenocarcinoma presented with spontaneous rupture of the pancreatic pseudocyst. This coexisting condition is difficult to diagnose, and prognosis remains poor despite the advances in technology. This presentation will impact the forensic science community by describing the necessity for an accurate autopsy to preserve the surgical field and assess the cause of death in a malpractice claim.

A pancreatic pseudocyst is a localized fluid collection that is rich in pancreatic enzymes, such as amylase, and is enclosed by a wall of fibrous tissue that is not lined by epithelium. The lack of epithelial lining distinguishes pseudocysts from other cystic pancreatic lesions. Pseudocysts are linked with the pancreatic duct system, either via direct communication or indirectly via the pancreatic parenchyma.<sup>1</sup> Regardless of the etiology of the pseudocyst, the incidence is low, ranging from 1.6%–4.5% in adults.<sup>2</sup> Pseudocysts are most commonly detected after pancreatitis or trauma and are associated with alcoholism and gallbladder disease. Spontaneous perforation and fistulization of pancreatic pseudocysts occur in fewer than 3% of cases.<sup>2,3</sup> Spontaneous rupture of pancreatic pseudocysts and/or fistulization has been reported in the stomach, duodenum, biliary tract, renal collecting system, colon, bronchial tree, and peritoneal surface.<sup>3</sup> Chemical peritonitis is another possible pseudocyst complication that can arise due to inflammation of the peritoneum caused by rupture of an abdominal organ. Symptoms may include severe pain, swelling of the abdomen, fever, or weight loss. Complications may include shock and acute respiratory distress syndrome. Many potential causes exist, and the peritonitis may be classified as primary or secondary, local or diffuse, acute or chronic, or according to the causative agent.<sup>4</sup>

**Case Report:** A 37-year-old alcoholic male smoker was admitted to the hospital with a two-day history of fever, diarrhea, and recurrent vomiting. Laboratory tests showed an increase in pancreatic enzymes, anemia, thrombocytopenia, and hyperglycemia. He was admitted to the intensive care unit due to the worsening condition that same day, but ultimately died after two days. Due to relatives' claims of malpractice, the prosecutor's office ordered an autopsy. A complete autopsy was performed within four days. On internal examination, 400cc of brownish liquid was observed in the abdominal cavity. After the dissection of the peritoneal surface, a nodular pancreatic tail mass measuring 30mm in maximal dimension was appreciated. The cervical and thoracic organs were dissected via Gohn's technique (i.e., en bloc), and a Rokitansky modified technique was utilized for the gastrointestinal tract. After fixation, the 30mm pancreatic mass was further assessed and found to be connected with the pancreatic duct system. The peritoneal surface was sampled. Hematoxylin-Eosin (H&E) -stained sections of pancreatic parenchyma revealed a haphazard arrangement of glands, nuclear pleomorphism, incomplete glandular lumina, luminal necrosis, glands adjacent to muscular vessels, perineural invasion, lymphovascular invasion, and severe cytologic atypia (i.e., cytologic enlargement, hyperchromasia, loss of polarity, prominent nucleoli). Sections of the pancreatic mass showed a 1cm thick and calcified cyst wall, with a lack of epithelial lining. H&E-stained sections of the peritoneal surface showed an inflammatory reaction with associated neutrophils. Overall, the medical record data, complete autopsy, and macroscopic and microscopic pancreatic findings confirmed that the cause of death in this case was chemical peritonitis from spontaneous rupture of a pancreatic pseudocyst.

#### Pancreatic Pseudocyst, Spontaneous Rupture, Pancreatic Adenocarcinoma

### H63 Idiopathic Liver Rupture: An Italian Case Report

Gianni De Giorgio\*, Section of Legal Medicine, Bari 70124, ITALY; Fiorenza Zotti, PhD, Bari 70124, ITALY; Eloisa Maselli, MD, Bari 70122, ITALY; Davide Ferorelli, Bari, ITALY; Francesca Donno, MD, University of Bari, Bari 70121, ITALY; Valeria Bruno, MD, DIM, Bari, Puglia 70124, ITALY; Giulia Gubinelli, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand that spontaneous bleeding due to a non-traumatic liver rupture is a rare but possible occurrence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that in cases of hemoperitoneum, spontaneous liver rupture should be considered, not only in patients with known predisposing factors.

Non-traumatic liver rupture is not uncommon in pregnant women with Hemolysis, Elevated Liver enzymes, and Low Platelet count (HELLP) syndrome and in association with some liver diseases, but very rarely occurs among healthy individuals.<sup>1</sup> It is usually diagnosed by imaging studies such as ultrasonogram or Computerized Tomogram (CT) or may be detected as an incidental finding in an emergency laparotomy. Very few cases of idiopathic liver rupture have been reported in literature. Reported here is the case of a patient with three visits to emergency health care services over a four-day span. Ultimately—although managed surgically—he died of a liver rupture without history of antecedent abdominal trauma or other clear etiology.

A 72-year-old man presented to the emergency department with abdominal pain. Physical examination elicited pain in the left hypochondrium and a positive Murphy sign. Laboratory tests revealed only a slight rise in white blood cells with neutrophilia, while abdominal ultrasonogram showed a “slightly thickened gallbladder wall.” He was discharged with instructions to return the following morning for a surgical evaluation. The following morning, he returned to the same hospital where the surgeon diagnosed him with acalculous cholecystitis. Two days later, he returned to the emergency room with fever (39°C) and abdominal pain. Laboratory studies showed the following: hemoglobin 12.3gm/dl, white cell count 10.600/cmm, platelet count 97.000/cmm. Liver function tests showed elevated bilirubin and enzymes.

The patient was admitted to the general surgery department where abdominal ultrasonogram raised the suspicion of a perihepatic fluid effusion. That night, the patient developed diarrhea. Early the following morning, he was found to be in shock with a blood pressure of 80/60mmHg. Laboratory studies showed a significant increase in liver function indices, severe anemia, and low hemoglobin (Hb 9g/dl at 4:15 a.m. → 5.90g/dl at 8:06 a.m.). CT revealed a large intraparenchymal and subcapsular hematoma with hemoperitoneum. At emergency laparotomy, there was blood in the peritoneal cavity while the right hepatic lobe showed a deep laceration between the 7<sup>th</sup> and 8<sup>th</sup> segments. Other solid viscera and bowel were unremarkable. Peritoneal washing and perihepatic packing and hemostasis were performed. Despite these measures, the patient died the next day. An autopsy was requested. On internal examination, the liver grossly demonstrated a rupture on the posterior hepatic surface (segments 7–8) and multiple hemorrhagic infiltrates (more marked in the right lobe sections.) Histologic sections showed extensive hepatic necrosis and hemorrhage, including large areas of coagulative necrosis of hepatocyte trabeculae with a central-midlobular extension.

In conclusion, this case provides many topics for thought. First, spontaneous intrahepatic hemorrhage and liver rupture usually occur in patients with predisposing factors, such as hepatocellular carcinoma or adenoma, HELLP syndrome, Ehlers Danlos disease, and graft-vs-host disease.<sup>2</sup> Second, spontaneous liver rupture should be considered in cases of atraumatic hemoperitoneum. Third, a high index of suspicion is required for early diagnosis and intervention to reduce morbidity and mortality in cases of liver rupture. In this case, spontaneous liver rupture and hemoperitoneum occurred in a patient without known risk factors, a very rare occurrence, making early diagnosis and treatment even more challenging.

### H64 A Determination of the Efficacy of Two Processing Methods for Molar Teeth as a Source of DNA in Missing Persons and Unidentified Human Remains (UHR) Investigations

*Lily Josephs, BS\*, University of New Haven, West Haven, CT 06516; Ira R. Titunik, DDS, New York, NY 10021; Timothy M. Palmbach, JD, University of New Haven, West Haven, CT 06516; Angie Ambers, PhD, University of New Haven, Forensic Science Department, West Haven, CT 06516*

**Learning Overview:** The goal of this presentation is to provide attendees with an empirical evaluation of two different processing methods for molar teeth as a source of DNA in missing persons and UHR casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the specific approach used to prepare a molar tooth for DNA extraction can impact DNA recovery and downstream Short Tandem Repeat (STR) typing results.

Bones and teeth are a valuable source of DNA in forensic, anthropological, and archaeological investigations. There are many scenarios in which bones/teeth may be the only viable sample type for DNA testing, including fires, explosions/bombings, natural disasters, war conflicts, airline crashes, homicides, and mass graves. Typically, compact weight-bearing long bones (such as the femur or tibia) and molar teeth are the preferred sample types for forensic genetic testing of skeletonized or highly decomposed remains. There currently is not a standardized protocol for processing molar teeth for DNA extraction. Some forensic laboratories pulverize the entire tooth, while others horizontally transect the tooth and drill into the inner cavity of the crown and roots to collect tooth powder. Pulverization of the entire tooth is a less time- and labor-intensive approach, and it requires less manual manipulation of the sample (an important consideration in contamination prevention). However, pulverization is a destructive process that completely consumes the sample, eliminating the possibility of re-testing and/or additional analyses that may be informative (e.g., amino acid racemization, isotopic analysis). In contrast, horizontal sectioning preserves the structural integrity of the tooth (which may be important for museum or other precious specimens), although it generates less powder for DNA extraction. In highly degraded remains, the latter approach may be prohibitive to recovery of sufficient DNA to make an identification or association.

Understanding the structural, molecular, and biochemical composition of teeth is an important consideration for forensic genetic testing. A molar tooth can be divided into two physical regions: the crown (the portion that visibly extends above the gumline) and roots (which are embedded within the alveolar bone of the maxilla and mandible). Additionally, teeth consist of four molecularly differentiated layers: enamel, cementum, dentin, and pulp. Enamel (the hardest substance in the human body) and its adjacent layer (cementum) provide a strong physical barrier that protects endogenous DNA from environmental insult. However, fractures or caries in enamel expose the inner layers of the tooth (and endogenous DNA) to damage, as well as to exogenous contamination. Dentin, which lines the inner pulp cavity, is targeted for DNA testing because it is rich in hydroxyapatite. Hydroxyapatite directly interacts (binds) with the backbone of the DNA molecule, purportedly protecting DNA from degradation. Often the pulp (soft tissue) within the crown of the tooth has decomposed by the time skeletal remains are recovered, leaving the rigid microstructure of the tooth as the only potential source of DNA. A principal rationale for using targeted drilling to process molar teeth lies in the protection afforded to the DNA molecule via direct interaction and binding to hydroxyapatite in the dentin layer.

This research specifically focused on comparing the effectiveness of two common mechanical processing strategies—complete pulverization vs. targeted drilling—for: (1) burned molar teeth, and (2) teeth that have been subjected to burial in acidic soil. These conditions reflect two of the most common forensic casework situations in which skeletonized remains are recovered. Effectiveness of each tooth-processing method was determined via comparison of total DNA recovery (ng), average signal per locus (peak heights, in Relative Fluorescence Units [RFUs]), and total number of alleles detected (i.e., completeness of Short Tandem Repeat [STR] profiles). Additionally, special considerations for targeted drilling techniques (and potential associated complications) will be discussed.

#### Unidentified Human Remains (UHR), Molar Teeth, DNA

### H65 The Vitality of Skin Lesions in Decomposed Corpses: A Morphological and Immunohistochemical Study

Matteo Moretti, MD, University of Pavia, Pavia 27100, ITALY; Fiorella Lanzillotta, MD\*, Aosta, ITALY; Elena Mercuri, Pavia 27100, ITALY; Giada Pansardi, Pavia, ITALY; Luisa Andrello, MD, Bellinzona, Canton Ticino 6500, SWITZERLAND; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY

**Learning Overview:** After attending this presentation, attendees will be better informed about a new combination of morphological and immunohistochemical methods useful in the evaluation of skin lesion vitality in decomposed corpses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by experimentally validating a comprehensive protocol applicable, even in a judicial context, in cases of decomposed corpses when traumatic death is suspected.

The present research investigates three different aspects of the issue of skin lesion vitality, including the correlation between morphologic and immunohistochemical data, the differentiation between hypostasis and vital blood infiltration, and the identification of a suitable immunohistochemical panel of red blood cells markers (i.e., hemoglobin, glycophorin A and  $\beta$ -spectrin). The evaluation of wound vitality has always been one of the most debated topics in forensic practice. Especially in decomposed bodies, determining if a skin's hemorrhagic infiltrate should be considered a vital tissue reaction or just a postmortem phenomenon is still a challenge for forensic pathologists. As is well described in literature, morphological and immunohistochemical methods have proven to be useful in the assessment of skin lesion vitality.

In this study, ten cases of traumatic immediate death with a postmortem interval of <72 hours were selected. To delete confounding factors, corpses with poor hypostasis or cutaneous putrefactive changes were not included. At forensic autopsies, two skin samples were taken from each case (i.e., one from a recent lesion and one from a hypostatic region). Each sample was experimentally kept in incubator at a temperature of 20°C to allow for experimental decomposition. Histologic specimens were obtained at defined time intervals (i.e., 0, 7, 15, and 30 days) from each sample. Each specimen was formalin-fixed, paraffin-embedded, then stained with Hematoxylin-Eosin (H&E) and Masson's trichromic, as well as with Immunohistochemical (IHC) stains for hemoglobin and glycophorin A and  $\beta$ -spectrin. As a negative control, undamaged and non-hypostatic skin was utilized and treated as described above. Finally, the samples were examined with an optical microscope by two independent observers.

Study results showed good correlation between morphologic and immunohistochemical data in the early period of putrefaction. After longer postmortem intervals, IHC proved to be more effective than H&E and Masson's trichromic for the detection of bleeding and for differentiating bleeding from hypostasis. The usage of more than one IHC marker as opposed to a singular marker improved the evaluation. Overall, such results suggest the usefulness of performing complete skin dissection during putrefied bodies' autopsy, and collecting—for histologic analysis—all lesions suspected to be vital. These samples should be microscopically analyzed using both classic histologic methods as well as multiple IHC markers.

#### Wound Vitality, Decomposition, Immunohistochemistry

### H66 Mendelian Simulation of Short Tandem Repeat (STR) Genotypes From Existing Sample Data to Create Standard Truth Pedigrees for Benchmarking New Familial Inference Methods

*Stephen Turner\**, Signature Science, Charlottesville, VA 22911; *Chris Hulme-Lowe, PhD*, Signature Science LLC, Austin, TX 78759; *Chris Simpson*, Charlottesville, VA 22911; *Carlos Acevedo, MS*, Signature Science, Charlottesville, VA 22911

**Learning Overview:** The goal of this presentation is to provide an overview of how to create simulated truth STR genotype data for benchmarking new pedigree inference methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information regarding creating simulated truth STR genotype data for benchmarking new pedigree inference methods. This work describes methods and software needed for simulating STR genotype benchmarking data that can assist in development, testing, and evaluation of a new familial searching methodology.

Current methods used in forensic DNA analysis evaluate the likelihood of a match based on STR length. Recently, there has been interest in extending the use of DNA databases beyond exact matching toward identifying potential familial relationships between individuals in a DNA database and/or with an unidentified person of interest whose DNA is found at a crime scene. When developing algorithms for identifying relationships, inferring pedigrees, and quantifying uncertainty, it is critical to have known ground truth data against which novel algorithms can be benchmarked. This data should include STR genotype profiles together with complete pedigree information against which inferences can be compared.

This study describes computational procedures developed for sampling individuals from an existing database and simulating offspring having STR genotypes following Mendelian rules of inheritance. In the absence of an existing database, publicly available allele frequency information can be used to simulate a founder population from which simulated offspring can be generated. By adjusting parameters, such as population size, Poisson rate of gravidity, endogamy, etc., population dynamics can be tailored to mimic those of an actual population of interest. The resulting simulated population will contain multigenerational pedigrees having individuals with STR genotypes where all individuals' relationships are known (e.g., parent-offspring, full sibling, half-sibling, and more distant second- and third-degree relationships). This methodology can be used to simulate pedigrees with STR data from any population at any number of loci where existing data are available, not just those where STR population allele frequencies are publicly available. The entire process is implemented in the R programming language, consisting of two modules. Module 1 includes procedures needed for ingesting, cleaning, and extracting STR genotypes from unrelated individuals in an STR genotype database. This module can be omitted or may need adapting, depending on the structure and quality of the input data. The second module comprises a method for simulating offspring and tracking relationships among initial founders and simulated offspring. Female individuals can be created from an all-male database by removing Y-chromosomal STR (Y-STR) genotypes. Mating events are created by randomly sampling two individuals from a pool of founders to create one or more children. Rates of half-sibling mating is also an adjustable parameter. The resulting simulated data can be used as a standard to assist development and conduct rigorous benchmarking of new methods for familial DNA searching, relationship inference, and quantifying uncertainty.

#### Bioinformatics, DNA, Simulation

### H67 An Investigation on Circular RNA (circRNA) Expression in Diabetic Cardiomyopathy (DCM) to Improve Understanding of Sudden Cardiac Death (SCD)

Shengzhong Dong\*, Fudan University, Xuhui District, Shanghai, CHINA; Yiwen Shen\*, Shanghai, CHINA; Chunyan Tu\*, Fudan University, Shanghai, CHINA

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the underlying relationship between DCM and SCD, as well as the present unveiled functions of circRNA in forensic applications and its possible role in DCM.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing the potential role of circRNA in DCM when associated with SCD, thus laying the foundation for further study of the pathogenesis in DCM and promoting understanding of SCD.

SCD is a devastating outcome of a number of cardiovascular disorders, and determining SCD etiology/pathophysiology continues to be a ongoing challenge for forensic scientists. DCM, an severe cardiovascular complication of diabetes, has been proven to be strongly associated with SCD. Nevertheless, the pathogenesis of DCM remain to be fully elucidated. In recent years, a novel type of non-coding RNA known as circRNA was found to play a significant role in various diseases and showed great promise in forensic applications. Characterized by stability and tissue-specificity, circRNAs could not only serve as an ideal biomarker, but could also be of help in elucidating the mechanisms underlying various diseases.

In this study, the hearts of db/db mice were harvested and the circRNA expression of these hearts was analyzed using high-throughput RNA sequencing technology. Reverse Transcription-quantitative Polymerase Chain Reaction (RT-qPCR) analyses were used to validate the expression levels of circRNAs. Co-expression networks of circRNA-microRNA (miRNA) were constructed based on the correlation analysis between the selected circRNAs and their target miRNAs, and a further Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses for these circRNAs interacted miRNAs and their target genes were investigated. To excavate the key circRNAs in DCM, significant miRNAs that have been confirmed to be related to myocardial alterations were searched and the potential competing endogenous RNA (ceRNA) regulatory network was predicted. Finally, Internal Ribosome Entry Sites (IRES) of circRNA were predicted to detect the protein-coding potential of these circRNAs.

A total of 58 significant differentially expressed circRNAs were captured in the db/db sample. Six upregulated circRNAs and seven downregulated circRNAs were detected by RT-qPCR and analyzed through the GO and KEGG method. Ultimately, five key circRNAs (mmu\_circ\_0000652, mmu\_circ\_0000547, mmu\_circ\_0001058, mmu\_circ\_0000680, and mmu\_circ\_0001160) and a newly identified circRNA (novel\_circ\_0004285) were predicted to have potential binding sites with respective miRNAs that were firmly involved in myocardial injury. IRES predictions indicate that mmu\_circ\_0001160 and novel\_circ\_0004285 may have the potential to be translated into proteins.

Taken together, this analysis unveiled potential biomarkers and molecular mechanisms in DCM, which could promote the understanding of the pathogenesis of DCM. Moreover, further studies on the promising circRNA related to myocardial injury could be of help in exploring the underlying mechanisms of SCD.

#### CircRNA, Diabetic Cardiomyopathy, Sudden Cardiac Death

### H68 The Effects of Heat and Explosions on Forensic DNA Analyses

Marwan Khoury\*, University of Leicester, Leicester, Leicestershire LE1 7RH, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will see the results of a four-year-long project that was completed in July 2019. This presentation includes specific temperature treatments that are required to produce partial DNA profiles from biological stains, the different effects on DNA that are caused by different types of explosions, and how the strength of such evidence (partial profiles) is affected. Attendees will also see how such challenging samples were analyzed through both the conventional capillary electrophoresis technique and massively parallel sequencing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing what may occur to biological evidence in cases that involve fire, explosions, or other sources of high heat. The samples were chosen to reflect realistic situations in which the identification of both victims or suspects is required. The community will also assess the uses and limitations of applying capillary electrophoresis-based methods or massively parallel sequencing to such a challenging type of casework.

This project explores the effects of high temperatures and explosions on DNA samples of forensic value. This project aims to determine the conditions under which biomaterials may degrade in accidental disasters, bombings, and/or crimes involving fire, and how degradation affects interpretation. The experiments were designed to reflect situations requiring victim and suspect identification, and thus involved testing various human samples, including blood and saliva stains. Some samples were heated under laboratory conditions, while others were attached to pipe bombs and detonated outdoors with the assistance of United States police bomb enforcement officers. A sensitive mitochondrial DNA multiplex system was devised and successfully used to detect DNA degradation prior to more costly analyses. Capillary electrophoresis-based Short Tandem Repeat (STR) typing and massively parallel sequencing were compared in terms of their performance on degraded DNA. Treatment at 180°C for 30 minutes was required to induce the first signs of DNA degradation in dried blood and saliva stains, reflected by reduced post-Polymerase Chain Reaction (PCR) DNA detection or drop-out of longer amplicons. There were no interpretable DNA products when heat treatment increased to 200°C. Similar degraded DNA effects were observed in 27% of stains placed on and within smokeless powder-charged pipe bombs, but no sign of degradation was observed with the more energetic C4 explosive, probably because of the shorter duration of heat exposure.

DNA degradation poses challenges to the interpretation of retrieved genetic data. These challenges were investigated both in real profiles from heat-treated samples and in simulated data. In addition, a real case of an unidentified male victim (the Blazing Car Murder, 1931) was analyzed. The combination of real and simulated data provided realistic scenarios, but also allowed control of parameters that affect evidential strength, such as population size and diversity, through lowering of the likelihood ratio and increasing the number of random matches in a database.

#### DNA Degradation, Partial Profiles, Extreme Conditions

## H69 Creating a Real Time-Quantitative Polymerase Chain Reaction (RT-qPCR) -Based Method for Studying Temporal DNA Degradation in Waterlogged Bone

Isis Thornton\*, Virginia Commonwealth University, Richmond, VA 23220; D'Arcy P. Mays III, Virginia Commonwealth University, Richmond, VA 23284-3083; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Claire M. Cartozzo, MS, Richmond, VA 23220; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will better understand the influences of time and temperature, type of bone, extraction method, and source of freshwater on DNA retrieval, variation in quantity, and variation of degradation in waterlogged porcine skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information concerning the ideal time interval in which DNA can be successfully obtained and amplified from submerged bone samples. Additionally, attendees will understand how extraction methods and skeletal element selection impact DNA extraction and amplification. Ultimately, laboratories will be able to evaluate whether submerged bone samples will provide viable DNA, thus saving time, labor, and money.

Human activities are often centered around the presence of water; thus, it is not surprising that there are many water-related human deaths, including those from mass disasters, murder, and/or clandestine body disposal. Scavenger activity, Accumulated Degree Days (ADD), and other aquatic variables may affect DNA retrieval from waterlogged bone. Organic and inorganic material in bone have an increased vulnerability, as water causes bone dissolution. This process can destroy the DNA contained in the osteocytes.<sup>1</sup> Calcium and collagen in bone can inhibit the PCR necessary to produce a Short Tandem Repeat (STR) profile; the current solution is a time-consuming organic extraction, reported to produce a 99% recovery rate.<sup>2</sup> While there are examples of research on DNA degradation in terrestrial bone over time, there has been little work done on submerged bone samples.<sup>3</sup> Although case studies are not controlled experiments, they are informative for research on human samples. One case report concerns skeletal and soft tissue remains of a murdered child who had been submerged in water for up to three years. DNA retained in the bone was still extractable DNA in this case.<sup>4</sup>

This research project was based on a long-term, controlled experiment that offers potential answers to the problem of DNA retrieval in waterlogged bone. The research also provides a shorter solid-phase protocol and a way to estimate over what length of time/temperature (in ADD) DNA may be extracted from skeletal remains, thus allowing a crime lab to determine if effort should be applied.

Fresh rib and scapulae from pigs (*Sus scrofa*) were submerged at Henleys Lake (November 2016–November 2017) and in the James River (November 2017–November 2018), with water temperature and quality measured every 500 ADD, using a 0°C as a base temperature for ADD calculation. The total sample size began with 200 ribs and 200 scapulae, though 46 samples were lost over time due to varying factors. In the lab, they were cut into pieces, placed into a mortar with liquid nitrogen, and ground into powder. Some of the bone powder was used in the ChargeSwitch® gDNA Plant Kit, following the Invitrogen™ CST Protocol for Extracting gDNA from Bone Samples (2009). The final elution volume was 100ul. The phenol-chloroform organic DNA extraction method followed Iyavoo et al., with a final elution volume of 150ul.<sup>5</sup> All samples were stored at -20°C until further analysis. These samples were amplified using PCR, and then subject to gel electrophoresis to determine the DNA quality. Those that failed to amplify (21.18% Chargeswitch, 22.32% organic) were all successfully cleaned up using the DNeasy® PowerClean Pro Clean Up kit. The cleaned samples were run through PCR and another gel was run to confirm quality. A TaqMan® qPCR approach was utilized to determine quality and quantity of extracted DNA. Two primer pair sets were chosen to amplify a short (62bp) and a large (147bp) fragment of porcine DNA extracted from submerged bone samples. For RT-qPCR, plates were run using the ABI® 7500 Real Time PCR Machine with analysis using SDS v1.x software. The statistics were run using fixed modeling on RStudio.

An Analysis of Variance (ANOVA) of the preliminary data indicates that extraction method ( $p=1.954e-05$ ) and bone type ( $p=.04104$ ) have a statistically significant ( $\alpha=.05$ ) effect on DNA quantity, while the location of the freshwater body did not. The overall results suggest that: (1) the simpler, time-saving ChargeSwitch® method is more effective than the current protocol of organic extraction; and (2) that one bone is better for extraction than another. Results for the DNA degradation index over the submersion interval are forthcoming.

### H70 Forensic DNA Phenotyping (FDP): A Prediction of Human Externally Visible Traits in Missing Person Identification

Matteo Fabbri, MS\*, University of Ferrara, Ferrara 44121, ITALY; Letizia Alfieri, MD, University of Ferrara, Ferrara 44121, ITALY; Omar Bonato, MD, University of Ferrara, Ferrara 44121, ITALY; Mauro Coppone, MD, University of Ferrara, Ferrara 44121, ITALY; Paolo Frisoni, MD, University of Ferrara, Ferrara 44121, ITALY; Rosa Maria Gaudio, University of Ferrara, Ferrara 44121, ITALY; Elena Lucenti, MD, University of Ferrara, Ferrara 44121, ITALY; Chiara Marini, MD, University of Ferrara, Department of Legal Medicine, Ferrara 44121, ITALY; Matteo Marti, PhD, University of Ferrara, Ferrara 44121, ITALY; Margherita Neri, MD, PhD, University of Ferrara, Ferrara 44100, ITALY

**Learning Overview:** The goal of this presentation is to inform attendees of a new “DNA intelligence” tool that is approaching forensic biology, due to its ability to predict Externally Visible Characteristics (EVCs) from biological material, such as that found at crime scenes, in disaster victim identification, or in cases of missing person identification. EVC prediction from forensic samples, or from body parts, is expected to help concentrate police investigations toward finding unknown individuals at times when conventional DNA profiling fails to provide informative leads.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by attempting to prove and underline the utility of FDP in missing person identification cases. Due to the lack of data in literature, this work involved the application of the HIRISplex system for eye, hair, and skin color prediction to 20 Italian missing person identification cases previously studied. In order to evaluate the accuracy of the multiplex tested, 20 cases for which victim pictures or portraits were available were chosen.

Predicting EVCs using informative DNA molecular markers has started to become a rapidly developing area in FDP. The most relevant forensic cases for DNA-based EVCs prediction would be those in which the evidence DNA is useful for describing a person’s physical appearance from skeletal remains. This study evaluates the HIRISplex DNA test multiplex for the simultaneous prediction of eye, hair, and skin color in 20 Italian skeletal remains from 20 different missing person identification cases in which identification was previously performed using the conventional Short Tandem Repeat (STR) -based method. In all 20 cases, victim pictures or portraits were utilized as a reference in order to test the reliability and accuracy of the DNA-based EVCs prediction.

The DNA-based system used consists of a SnapShot® multiplex assay targeting a total of 41 Single Nucleotide Polymorphisms (SNPs) involved in skin, eye, and hair color prediction<sup>1</sup>. A total of 20 different bone samples (14 femurs and 6 tibias) were evaluated and processed. Bone samples were cleaned chemically, using diluted bleach, and irradiated with Ultraviolet (UV) light for 30 minutes prior to grinding into a fine powder. Genomic DNA was obtained from 0.5g of bone powder using the QIAamp® DNA Investigator Kit. The DNA extracts were quantified using the Investigator QuantiPlex™ HYres Kit. The reactions were carried out in a Rotor-Gene® 5-plex System according to the manufacturer’s instructions. Polymerase Chain Reaction (PCR) amplification of all 17 SNPs was performed in a single multiplex PCR assay, in a final volume of 10µl, as described by Chaitanya et al.<sup>1</sup> The amplified PCR products were purified with Thermo Scientific® ExoI and incubated at 37°C for 45min and 80°C for 15min. Single Base Extension (SBE) was carried out for all PCR products simultaneously in a single multiplex reaction using 2µl of the purified PCR products. Finally, the purified SBE products were analyzed on the ABI® 310 HID Genetic Analyzer. Gene Mapper® ID-X v1.0 software program was used for the allele calling and analysis of the results. Prediction of eye, hair, and skin color was performed using a web interface at <https://hirisplex.erasmusmc.nl/> allowing the retrieval of individual prediction probabilities for three eye color, four hair color, and now five skin color categories from HIRISplex genotype input data of 41 SNPs. Each victim picture’s iris, hair, and skin color were subjectively and objectively determined for all 20 skeletal remains analyzed. For the subjective determination, examiners classified victims’ pictures in the same color category (i.e., iris, hair, and skin color) for 84% of the documents examined.

Study results showed overall prediction accuracies of 91.6%, 90.4%, and 91.2%, respectively, for iris, hair, and skin color at the 0.7 threshold. The sample set had only two inconclusive results as compared to the IrisPlex database. This is likely due to the fact that these samples showed an intermediate eye and hair color. In conclusion, these results demonstrate the robustness and reliability of the HIRISplex genotyping system. Utilization should be encouraged for the prediction of eye, hair, and skin traits from DNA in missing person cases and in outside anthropological applications to determine eye, hair, and skin color of deceased persons via analyzing skeletal remains or body parts.

#### Forensic DNA Phenotyping, Predictive DNA Analysis, IrisPlex

## H71 The Detection of Rat Decomposition Products in a Plywood Platform Following Specimen Removal

Gabrielle E. DiEmma, BS\*, Arcadia University, Glenside, PA 19038; Heather L. Harris, JD, Glenside, PA 19038; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038

**Learning Overview:** After attending this presentation, attendees will have a better understanding of cadaveric Volatile Organic Compounds (VOCs) and changing decomposition odor profiles across animal models as well as novel methods and techniques for sampling decomposition products in plywood matrices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the Decompositional Odor Analysis Database for a previously unstudied model organism, specifically the Sprague-Dawley rat in the advanced stages of decomposition.<sup>1</sup>

Twelve rats were placed in cages on separate plywood platforms and left to decompose outdoors for 222 days through the summer and winter months in Pennsylvania. Following the removal of the advanced-stage decomposition rats from a plywood platform, a modified arson Gas Chromatography/Mass Spectrometry (GC/MS) method was used to test for the presence of decomposition products (VOCs and Volatile Fatty Acids [VFAs]) in the wood of the cage. The goal of this study was to investigate the unique odor profiles of rats and potentially contribute to the growing database of decomposition odor profiles important for entomofaunal succession and cadaver dog training.<sup>2,3</sup>

Expanding upon research that looks to the soil of the Cadaver Decomposition Island (CDI) and the indoor surfaces upon which human decomposition products (microbial macromolecule degradation and the leaching of waste products from the body cavity) may be deposited, this project acted as a pilot study to look at how rat decomposition products were absorbed and retained by a wood platform in an outdoor environment.<sup>4</sup> Arson cans, activated charcoal extraction, and GC/MS were used to determine the presence or absence of cadaveric VOCs, VFAs, and amino acid metabolic products commonly cited in the literature in the wood platform.<sup>3,5</sup>

Numerous studies in multiple countries have been conducted to work toward a comprehensive understanding of the VOCs evolved from decaying human and animal remains as a function of time and environmental conditions, leading to the development of the Decompositional Odor Analysis Database.<sup>1</sup> This database can assist forensic investigators in determining which compounds to look for in cases where there is suspicion that a body has been moved postmortem or when authorities are looking for clandestine graves. However, while there seems to be great interest in this area, many researchers using a variety of different methods and animal models have found it difficult to obtain reproducible decomposition odor profiles that are of any use in postmortem interval estimations or standardized Human Remains Detection (HRD) canine training procedures.<sup>6</sup> While there is extensive research pertaining to VOCs in the soil and air around different animal models for decomposition, it does not appear that these volatile decomposition products have been studied extensively in rat models or from a wood matrix. Therefore, this research sought to determine if decomposition products could be detected from a plywood matrix using a modified arson method, and to use this method to identify the compounds present in the field samples qualitatively following rat removal.

The rats were in the advanced stages of decomposition at the time of removal from the plywood platform, so it was hypothesized that only the higher molecular weight compounds would be detected in the field samples. Few well-known decomposition products were recovered, such as 2-ethyl-1-hexanol, while most of the recovered compounds were indicative of the local entomofaunal activity and the presence of several plant species near the experimental set-up.<sup>7</sup> The modified arson method used shows potential for recovering a variety of compounds, such as cyclic amines and sesquiterpenes, from field samples, but future work is needed to optimize and validate this method.

### H72 Aquatic Decomposition of Vertebrate Remains: An Experimental Test for a Cold Case Investigation

Joseph P. Receveur, BS\*, Michigan State University, East Lansing, MI 48823; Sierra Kaszubinski, BS, Integrative Biology, East Lansing, MI 48824; Breanna R. Wydra, BA, East Lansing, MI 48823-3850; Brianna Timmons, BS, Michigan State University, East Lansing, MI 48824; Katelyn A. Smiles, East Lansing, MI 48423; Nicholas Babcock, MS, Michigan State University Extension, East Lansing, MI 48824; Courtney Weatherbee, MS, Michigan State University, East Lansing, MI 48824; M. Eric Benbow, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** The goal of this presentation is to provide attendees with the ability to better understand how conditions in aquatic environments impact the decomposition of vertebrate remains and how such information can be informative to death investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on how insects and microbes colonize and change on remains in aquatic environments and how decomposition progresses under environmental conditions in a way that informed a cold case death investigation.

Decomposition of remains in aquatic environments remains an understudied area of forensics, especially under conditions with direct relevance to death investigations. The objectives of this study were to determine how terrestrial and aquatic invertebrates and bacteria colonize and change on vertebrate remains over the course of decomposition and compare those findings to a cold case in a similar habitat that occurred in 2005 (referred to as the Aquatic Case [AC]).

At a similar time of year to the AC (July-August), swine carcasses ( $N=5$ , approx. 45kg) were euthanized and transported to the study location before being dressed in clothing to resemble the apparel found on the AC. The carcasses were introduced to the pond and evaluated for invertebrate activity at three-day intervals. In addition to evaluating the carcass for invertebrate activity and visual changes, cotton swabs were used to collect DNA samples from several different regions on the carcasses. DNA present on these swabs was extracted using a commercially available kit and quantified fluorometrically. Targeted amplicon sequencing was performed to amplify the 16S ribosomal RNA (rRNA) region (V4) using an Illumina<sup>®</sup> MiSeq<sup>®</sup> platform (2 x 250 base pair, paired ends). Resulting sequences were filtered and taxonomically assigned using QIIME<sup>™</sup> 2 and the SILVA database before open source statistical tools, including machine learning algorithms, were used to identify bacterial indicators of decomposition stage.

During the experiment, there was not a significant difference in air temperatures at the experimental pond compared to those recorded during the 21 days when the decedent of the AC was missing in 2005. Within three days of carcass placement, there was considerable bloating and large numbers of larval and adult blow flies (Diptera: Calliphoridae) present on all experimental carcasses as well as multiple taxa of aquatic invertebrates. When comparing the experimental results to the lack of any insect evidence reported in the AC autopsy and death investigation reports, the findings suggested that the AC body had a low probability of being at or near the surface for several days; these findings matched autopsy photos and medical examiner notes indicating only moderate decomposition. While the experimental results suggested extensive colonization of a carcass at the surface by both terrestrial and aquatic invertebrates would occur quickly, the potential remains that the AC body could have sunk and remained neutrally buoyant for 20 days at a depth where decomposition was slowed. Significant changes in the bacterial communities were found across decomposition with distinct bacterial communities present at different decomposition stages. Several diversity metrics including Faith's Phylogenetic Diversity (PD) and observed richness significantly differed among decomposition stage, with freshly submerged carcasses showing the highest bacterial diversity. Several bacterial genera, predominately from *Proteobacteria* and *Firmicutes*, were identified by as indicator taxa for decomposition stage by machine learning models. Future aquatic death investigations could take advantage of taking bacterial swabs that could be used as a "microbial clock" of decomposition in the aquatic habitat using the methods tested in this experiment.

In conclusion, this research highlights that the decomposition of vertebrate remains in aquatic environments is a complex process mediated by both biotic and abiotic factors and that both microbes and invertebrates change over the course of decomposition and have the potential to be used as forensic indicators.

#### Aquatic Decomposition, Microbiome, Cold Case

## H73 The Alterations of HMGB and Troponin in Postmortem Interval (PMI): The First Experimental Study on Humans and a Review of Literature

Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD, Università Magna Graecia CZ, Catanzaro, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Natalia Malara, PhD, Viale Europa, Germaneto, Catanzaro 88100, ITALY; Ivan Presta, PhD, University of Catanzaro, Catanzaro, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of High-Mobility Group Box-1 (HMGB) and troponin in PMI estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the quantitative alterations of these proteins in the PMI on humans.

Time of death represents a challenge in forensic research. Multiple extrinsic factors may make it challenging to estimate PMI. Several authors have suggested employing new scientific approaches, such as proteomics, to help improve estimation accuracy. In the forensic literature, numerous studies have emerged describing the changes proteins within tissues or biological fluids undergo with advancing PMI. However, most of these studies were carried out on animals or on corpses found after several hours, without knowing the exact hour of death. In fact, before the collection of the samples, the corpse has already been exposed to the action of extrinsic factors that are often unknown. This presentation proposes the results of an Enzyme-Linked Immuno-Sorbent Assay (ELISA) analysis carried out on human plasma taken at the exact time of death. The markers examined were HMGB and Troponin T (TnT). This is the first experimental study on human samples performed at “zero time.”

The experimental model was created at the Institute of Legal Medicine of the University Magna Graecia of Catanzaro. The model is based on taking peripheral blood samples from patients who died at the intensive care unit. The study was approved by the Ethics Committee. The informed consent was signed by family members before the death of the patient. The corpses were exposed to constant room temperature. The samples were taken at seven predefined time intervals, starting from the exact moment of death up to the next two hours. The samples were immediately centrifuged and stored at -80°C. Subsequently, the samples were analyzed by ELISA 96-wells in order to examine the quantitative changes of the HMGB and TnT markers. The kits used were MyBioSource® with human target. The following procedure was conducted: (1) add 100µL standard or sample to each well. Incubate for 90min–2hrs at 37°C; (2) remove the liquid. Add 100µL Biotinylated Detection Ab. Incubate for one hour at 37°C; (3) aspirate and wash three times; (4) add 100µL Horseradish Peroxidase (HRP) conjugate. Incubate for 30min at 37°C; (5) aspirate and wash five times; (6) add 90µL substrate reagent. Incubate for 15–30min at 37°C; (7) add 50µL stop solution. Read at 450nm immediately; and (8) the results were compared with the data published in literature.

Twenty-four cases were collected and divided into two main groups by age (cut-off 69.6 years), sex, and cause of death. Of these, ten cases were selected in proportional numbers from each group in order to guarantee the homogeneity of the sample and reduce the role of intrinsic potential variables. The patients were both male and female, aged between 56 and 86 years, and died from cardiogenic shock (seven cases), respiratory failure (two cases), and septic shock (one case).

This study showed a variability of HMGB-1 over time, with increasing levels of the marker at 2h compared to “zero time” (seven cases/ten) regardless of the cause of death. In the other three cases, an oscillation of the marker was observed with substantial stability. These results appear in agreement with the published literature regarding the potential increase in HMGB-1 expression levels as a function of PMI.<sup>1,2</sup> TnT revealed levels of variable expression within a wider range. Troponin levels were higher at 2h in seven cases out of ten. The increase was progressive and linear in cases of myocardial ischemia. A reduction in expression at 2h was observed in three cases of cardiogenic shock with systemic failure, pulmonary fibrosis, and septic shock. These results, also in agreement with the literature data, suggest that the marker levels strongly depend on the cause of death.<sup>3,4</sup> Being a marker of muscle damage, its expression would therefore be expected to be greater in cases of cardiac death. Although the analyzed sample is small, the proposed model is the first to perform proteomic investigations on human biological samples from the exact moment of death without exposing the corpse to temperature variations or other extrinsic factors.

In summary, this operating model is intended to identify the possible role of peripheral blood protein biomarkers procured at the precise time of death in the estimation of PMI, verify and evaluate the variation of the proteomic profile of markers already published in the literature, and improve analysis of the so-called “early PMI” for forensic purposes.

### H74 Fetoneonatal Deaths—The Role of Forensic Investigations and Differential Diagnosis for Solving Complicated Forensic Cases: A Rare Case of Infanticide

Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Francesco Sicilia, MD\*, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; Carmen Scalise, MD\*, University of Catanzaro, Catanzaro, ITALY; Orazio Malfa, MD, University “Magna Graecia” of Catanzaro, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will be able to describe the role of differential diagnosis in cases of infanticide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of a standard forensic protocol for this diagnosis.

The term “stillbirth” refers to a fetus born dead and with a gestational age of at least 28 weeks.<sup>1</sup> In Western countries, fetal-neonatal mortality is 3 deaths per 1,000 births, while in underdeveloped countries it is ten times higher. The causes of death include perinatal asphyxia, infections during pregnancy, maternal disorders, congenital anomalies, or abnormal fetal growth.<sup>2,3</sup> Death is not always the result of pre-natal/perinatal complications but also of crimes, such as infanticide. Infanticide is the murder of an unwanted newborn or a baby within the first year of life. Established parental risk factors for infanticide include a history of child abuse, domestic violence, psychiatric disorders, and economic hardship.<sup>4,5</sup> In such cases, the role of the forensic pathologist is to establish whether the fetus was born alive and determine the cause of death. There are no published standardized forensic procedures for differentiating between infanticide and fetal-neonatal death from other diseases. A forensic protocol for cases of suspected infanticide is proposed and explored via presentation of an educational case example.

A woman presented to the hospital with hemorrhage and showing signs of a recent parturition. The physicians asked about the birth and health of the neonate. She confessed that she had given birth to a dead fetus. In her house, the fetus was found dead. An autopsy was performed. External examination showed a term fetus with no congenital anomalies. There was cyanosis of the nail beds, cutaneous pallor, subconjunctival hemorrhage, and traces of meconium. The umbilical cord, measuring 68cm, was around the neck. It was ischemic and appeared to have been cut. The placenta showed no anomalies. Internal examination showed some lung petechiae; a hydrostatic lung test was positive. Histologic sections showed the alveoli were expanded and functioning when he was born, with signs of acute pulmonary emphysema and rupture of the alveolar septae. A forensic mother’s examination was performed excluding uterine or vaginal diseases. The investigations showed that the birth had occurred regularly. Death was due to bleeding because the umbilical cord was not clamped, with asphyxia also.

Infanticide is a worldwide issue.<sup>6</sup> In literature, infanticide is related to maternal psychiatric disorders. Infanticide sometimes occurs in the absence of support for the mother.<sup>4</sup> The case reported is emblematic. The mother gave birth alone at home and cut the umbilical cord, without any health or family care. Asphyxia is the most common cause of death. In such cases, establishing whether the fetus suffered from perinatal complications (e.g., an umbilical cord looped around the neck) is critical. Features supportive of asphyxia include a cord that is very long and fetal petechiae. The forensic examinations in the reported case showed that the fetus had breathed and the cord was not clamped. Death was due to both hemorrhage and asphyxia and—had routine medical care been provided—it is suspected the newborn would have lived. This case shows that the diagnosis of infanticide is challenging, and there can be various modes of death. A standardized forensic protocol can assist in detecting infanticide cases and prevent them from remaining unsolved. A recommended investigative protocol includes the following: (1) evaluate anthropometric data and signs of fetal maturity; (2) perform full fetal autopsy, including histopathology with microscopic analysis of the lungs; (3) measure the length of the umbilical cord and evaluate for placental abnormalities; (4) perform a physical examination of the mother to exclude illegal abortion; (5) compare the data with the mother’s witness reports; and (6) assess the mother’s psychiatric comorbidities for imputability.<sup>7</sup>

### H75 Bleach Decontamination in the Forensic Laboratory and at the Crime Scene: Investigating the Efficacy of DNA Damage in Native Versus Naked Templates

Alyssa N. Tuccinardi\*, Stamford, CT 06902; Angie Ambers, PhD, University of New Haven, Forensic Science Department, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to educate attendees about differences in the efficacy of bleach in generating damage to native and naked DNA templates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that amplifiable DNA can often still be recovered from human blood that has been exposed to bleach, especially if the DNA is still encompassed in its native tissue upon initial exposure.

In forensic casework, there are three major factors that significantly impact successful recovery of a DNA profile from evidence, including low-quality (degraded) DNA, low-quantity DNA, and the presence of endogenous or environmental inhibitors. The latter two factors have largely been mitigated by recent advances in instrumentation, “increased sensitivity” methods, and improvements in DNA extraction techniques. However, DNA damage/degradation is inherent in an evidentiary sample when it arrives in the laboratory. The degree and spectrum of DNA damage present depends on the environment to which it was exposed and the length of exposure time. In the natural environment, ultraviolet light, acidity, heat, and humidity all contribute to various forms of damage in the molecular structure of DNA. In addition to environmental insult, chemicals can be used to damage DNA. Bleach is used intentionally by criminals to clean up crime scenes and destroy DNA evidence.

Bleach (sodium hypochlorite [NaOCl]) degrades DNA through oxidative damage and production of chlorinated base products. Knowledge of this damaging effect of bleach on DNA is the basis for its use in forensic laboratories to clean workbenches and prevent cross-contamination of samples between cases. Although decontamination procedures in a forensic laboratory setting are carried out with dilute (10%) bleach, criminals are likely to use much higher concentrations (100%) in attempts to destroy DNA evidence. A previous study demonstrated that bleach has a decreased effect on native DNA that is still encompassed within a body fluid (compared to naked DNA that has already been extracted).<sup>1</sup> Completion of the clotting mechanism appeared to interfere with bleach’s ability to cause substantial DNA damage. This decreased effect of bleach on native templates may be explained in part by understanding the physical packaging of DNA, as it exists within human cells or body fluids. Nuclear DNA is not a “naked” molecule. In its native conformation, DNA is a supercoiled structure that is highly packaged into chromatin and is associated with a variety of other molecules, such as histone proteins, residual proteins, phosphoproteins, RNA species, and lipids. Hence, the manner or degree in which damage occurs to DNA in its native complexed form is likely quite different than in its “naked” counterpart. Native DNA may be afforded some protection from damage because it is surrounded by a cellular milieu of proteins, lipids, carbohydrates, and other nucleic acids (RNA).

This research expanded on a previous study, with an increased sample size and expanded data set. Whole human blood (native DNA) and extracted (naked) DNA were immersed in 10% and 100% bleach solutions for one hour. Ten times the volume of bleach was used for the damaging experiments on whole blood or naked DNA, respectively (10:1 bleach: blood/DNA). DNA extractions were performed with the QIAamp® DNA Investigator Kit; recovered DNA was quantified using the Quantifier™ Human DNA quantification kit and a 7500 Real-time Polymerase Chain Reaction (PCR) system. Results were consistent with the previous study. Sufficient DNA was recovered for Short Tandem Repeat (STR) typing, for both native and naked DNA templates and after exposure to both 10% and 100% bleach solutions (with higher DNA recovery from native templates and the lower percentage bleach concentration). These findings have value because they indicate that current decontamination methods using bleach in the laboratory may not be as effective as perceived (at least for DNA complexed with other materials). Decontamination of laboratory workbenches may actually partially be due to physical removal of DNA from a surface (“wiping away”) as opposed to solely chemical destruction. Additionally, it is often assumed that if a criminal has cleaned a crime scene with bleach, any underlying DNA evidence has been destroyed (which may prevent investigators from swabbing the area and submitting samples to laboratories for DNA analysis). This study demonstrates that evidentiary items presumably exposed to bleach still should be collected and submitted for DNA testing.

### H76 Vertebrate Scavenging Behavior and the Decay Rate of Buried Carcasses

*Luigi Mastrogiuseppe, Servizio Veterinario, Campobasso, ITALY; Valentina Bugelli, MD\*, Department of Medicine and Health Sciences, Campobasso 86100, ITALY; Carlo P. Campobasso, MD, PhD\*, University of Campania, Napoli 80138, ITALY; Francesco Porcelli, PhD, via G Amendola, 165/a, Bari 70126, ITALY*

**Learning Overview:** After attending this presentation, attendees will better understand the role of animal scavenging during decomposition and its implications for forensic investigation and determination of postmortem interval.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an understanding of the impact of wildlife on carcasses in protected (burial) and unprotected (surface) outdoor environments and the timing of decay.

A 46-year-old woman was last seen alive in May of 2011. Eight months after her disappearance, her remains were found partially buried in a forested area in the inner middle region of Italy. The right femur, still attached to the body, was found above the ground surface. The remainder of the right lower limb was disarticulated and missing, while the remainder of the body was buried in a shallow grave a few centimeters deep. No other relevant disarticulation was observed. The head and the limbs were skeletonized while the rest of the body was well preserved and mummified. Insects on the body were identified as larvae of Syrphidae and Stratiomyidae. No Diptera of the first wave of colonization were recovered. According to these findings, the time of death was undetermined but consistent with a Postmortem Interval (PMI) of several months of burial. At autopsy, the cause of death was determined to be asphyxia due to strangulation. The victim's boyfriend was indicted for the crime. He provided an alibi for the time of death and claimed to be innocent. He recruited an expert who determined the PMI to be only a couple of months; the basis for this assertion was that a body buried in a forest area for longer would presumably have been scavenged by carnivores (e.g., boars, wolves, vultures), and thus the well-preserved state of the body would not be consistent with a longer PMI, such as eight months.

Can animal scavenging assist in estimation of the PMI? This is one of the most common questions asked of forensic experts since previous published studies have revealed a correspondence between stages of disarticulation and the PMI. A multidisciplinary team with forensic veterinary expertise was requested to provide a reliable answer. A field experiment using animal models was set up and performed in winter in a forested area. The goal was to determine the habits of scavengers when decomposing tissues are available in shallow graves or when exposed on the surface. Five carcasses were buried (two boars, one fox, one rabbit, and one hare). One fox carcass was exposed on the ground surface. Motion-sensitive cameras were placed in close proximity to the burial sites in order to check daily animal activity. Site visits were conducted every three days. The results showed that only the rabbit and the hare were scavenged: the first one a few hours after burial and the second one within seven days. The other four carcasses, including the fox on the surface, were not scavenged by wildlife. According to videotape recording, boars and wolves visited the experimental sites just around the carcasses, but without scavenging the remains.

These results confirm that: (1) burial can slow decomposition and influence the time required for insects to reach the remains; and (2) the scavenging of remains is not an event that necessarily occurs, even when there are decaying tissues exposed on the surface. Scavenging can be affected by several factors depending on hunger of the scavenger itself, intra- and inter-species competition, availability of other and more favorite food supplies, and the repellent effect of decompositional odors or invertebrate activity. Carnivores are unlikely to scavenge a corpse if there is a high concentration of insects until arthropod activity is over or decreased significantly. Vertebrate scavenging behavior is more common on fresh bodies, within the first hours after death, or in skeletonized corpses. The reasons for the low interest in putrefied carcasses can depend on: (1) access to the body; (2) the effort required by the scavenging; (3) freshness of soft tissue; and (4) the scavenger's food habits and diffidence toward new or different resources.

Finally, the absence of insect activity was the most important factor delaying decomposition, with only a very few signs of animal scavenging at the disarticulated lower limb. Overall, this field experiment highlights the importance of having knowledge of the type and behavior of local fauna as shallow graves can sometimes prevent not only insect activity but also scavenging by wildlife, thus explaining a slower rate of decomposition.

#### Forensic Taphonomy, Animal Scavenging, Buried Bodies

## H77 A Postmortem Interval (PMI) Estimation Based on Eukaryotic Community Associated With Soil Under Decomposing Porcine Remains

Amanda M. Haase, BS\*, Virginia Commonwealth University, Richmond, VA 23284; Shane Woolf, MS, Richmond, VA 23220; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how eukaryotic community associated with soil under carrion can be utilized for PMI estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping to increase the accuracy and reliability of current statistical models for PMI estimation and by stressing future research on alternate techniques for PMI estimation with necrobiome sequencing.

Recently, there has been an increased interest in the necrobiome in soils associated with decomposing carcasses. Recent studies have shown bacteria associated with soils under a carcass change significantly both temporally and spatially.<sup>1</sup> However, limited information exists on temporal and spatial changes in eukaryotic community structure associated with soil under decomposing remains. To pursue this technique accurately, more replication in field conditions are needed, as well as a long-term study using a model organism similar to humans. This study was designed to fill in these gaps and expand on previous studies to improve PMI estimation techniques. The main aim of this study was to determine the eukaryotic community structure associated with soil under relatively well-replicated porcine remains for PMI estimation and determination of cadaver decomposition sites. To accomplish this goal, soil samples were collected at 0m (beneath the corpse) and 3m away from porcine remains ( $N=6$ ). The sample collections started at T0 (Day 0, before porcine remains were placed) and continued daily until Day 3. Samples were then collected on Day 5, then collected weekly until Day 60 (two months, or 1,703 Accumulated Degree Days [ADD]). DNA was extracted from soil samples using DNeasy® PowerSoil Kit following the manufacturer's protocol. The variable region V9 of 18S recombinant DNA (rDNA) was amplified on an Applied Biosystems® Veriti® 96-well thermal cycler utilizing the primers and protocol referred to by the Earth Microbiome Project.<sup>2</sup> The 96-well Polymerase Chain Reaction (PCR) plate included a negative (nuclease free water, Promega® Corporation) control sample. Following amplification, all PCR products were visualized on a 1.8% agarose gel to ensure successful PCR amplification and that the PCR products are of expected size. All PCR products were cleaned using Agencourt® AMPure® XP kit using the manufacturer's protocol. Purified amplicons from each sample were pooled in equimolar concentrations for 18S rDNA dual-index MiSeq® sequencing as described by Kozich et al. on MiSeq® FGx sequencing platform.<sup>3</sup> Sequence data will be analyzed using mothur v1.39.5.<sup>4</sup>

PCR amplification of 18S rDNA yielded two products (one with the expected size and the other with a much smaller size) for many soil samples. The band that had the expected size was gel extracted, cleaned, and used for sequencing purpose. This eukaryotic succession data, or the combination of the eukaryotic and bacterial succession data, will help in reducing errors associated with current statistical models for PMI estimation.

In conclusion, attendees will become aware of the current and emerging techniques used for PMI estimation. The results from this research can be applied to forensic investigations and offer additional detail at crime scenes. Ultimately, this study will aid in expanding the amount of information that can be utilized from evidence in a forensic setting based on necrobiome sequencing.

### Postmortem Interval, Necrobiome, 18S rDNA

### H78 Atrioesophageal Fistulas (AEF) Caused by Percutaneous and Surgical Radiofrequency Ablation for Atrial Fibrillation (AF)

*Emiliano G. Maresi, MD\*, University of Palermo, Palermo 90100, ITALY; Stefania Zerbo, MD, Palermo 90100, ITALY; Elvira Ventura Spagnolo, MD, University of Palermo, Palermo 90127, ITALY; Pierangela Fleres, MD, Palermo, Sicily 90100; Antonio Guajana, MD, Palermo 90149, ITALY; Gennaro Baldino, MD, Palermo 90100, ITALY; Antonina Argo, PhD, University of Palermo, Palermo 90100, ITALY*

**Learning Overview:** The goal of this presentation is to show the development of atrioesophageal after percutaneous and surgical radiofrequency ablation for chronic AF.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting that in patients with neurological clinical signs with a positive history of radiofrequency ablation (percutaneous or surgical) of AF, it is always desirable to consider the risk of an Atriobronchial Fistula (ABF) or AEF.

Atriobronchial Fistulas (ABF) and AEF are rare but potentially lethal complications that may arise following percutaneous or surgical radiofrequency ablation for (AF). The anatomic relationship between the left bronchus, the esophagus, and the posterior wall of the left atrium is changeable: the bronchus and esophagus are more susceptible to injury near the endocardial ablation areas. Bronchial and esophageal ulcers due to high temperature achieved by radiofrequency technology typically seem to precede fistula development. A high index of suspicion is recommended in patients who develop chest pain, fever, neurological deficit, and/or sudden hematemesis within days or weeks of AF ablation. Early detection by Computed Tomographic (CT) scanning is safe and feasible. Survival depends on rapid diagnosis and intervention; when untreated, the outcome is often fatal. In this study, two cases of ABF and AEF formation, respectively, arising after percutaneous and surgical radiofrequency ablation for chronic Rapid Atrial Fibrillation (RAF) are reported.

**Case 1:** A 35-year-old Caucasian man with a history of paroxysmal AF presented to the emergency room in Cefalù, Italy, due to repeated loss of consciousness, asthenia and pain, and tingling hyposthenia in the right upper limb 12 days after undergoing percutaneous radiofrequency ablation for AF. Brain CT and brain Magnetic Resonance Imaging (MRI) were normal. Laboratory studies were inconsistent with inflammation or sepsis; the patient demonstrated positive meningeal signs (i.e., neck stiffness and Brudzinski's sign.) The neurologist suspected viral encephalitis. Twelve hours later, the patient became comatose before subsequently dying due to serious heart rhythm disorders. Autopsy found a fistula between the left atrium, esophagus, and left bronchus with many septic emboli in the brain, heart, and kidney. The fistula walls showed coagulative necrosis with sites of acute suppurative inflammation and bacterial colonies.

**Case 2:** A 50-year-old Caucasian man with a history of paroxysmal AF presented to the emergency room in Cagliari, Italy, due to neurological deficit with tonic-clonic seizures and high fever arising one month after surgical radiofrequency ablation for AF. Laboratory studies revealed a slight leukocytosis, but the blood culture was negative. About two hours later, the patient died due to ventricular fibrillation. Autopsy found a fistula between the left atrium and esophagus and septic emboli in the brain and kidney. The fistula walls showed coagulative necrosis with sites of acute suppurative inflammation and bacterial colonies.

**Conclusions:** This study shows that adults presenting to emergency care with suspected meningitis, stroke, tonic-clonic seizures, disorders of consciousness and fever, and a recent history of radiofrequency ablation for AF (percutaneous or surgical) should be investigated. In these cases, the occurrence of AEF and/or ABF should be strongly considered. The diagnosis must be immediately confirmed by chest radiography or CT with contrast in order to promptly begin surgical therapy. In these two reported cases, the possibility of fistula formation wasn't considered despite the known history of radiofrequency ablation.

#### Radiofrequency Ablation, Fistula, Chronic Atrial Fibrillation

### H79 The Suitability of Cerebral Matter for the Forensic Identification of Highly Decomposed Bodies

*Katharina Helm, PhD, University of Salzburg, Salzburg 5081, AUSTRIA; Bettina Dunkelmann, PhD, University of Salzburg, Salzburg 5081, AUSTRIA; Stefan Pittner, PhD\*, Salzburg University, Salzburg 5081, AUSTRIA; Christian Staufer, PhD, University of Salzburg, Salzburg 5081, AUSTRIA; Gabriele Kreindl, ING, University of Salzburg, Salzburg 5081, AUSTRIA; Tamara Kastinger, BS, University of Salzburg, Salzburg 5081, AUSTRIA; Eva Müller, BS, University of Salzburg, Salzburg 5081, AUSTRIA; Waltraud Zahrer, BS, University of Salzburg, Salzburg 5081, AUSTRIA; Ines Griefßner, MSc, University of Salzburg, Salzburg 5081, AUSTRIA; Jan Cemper-Kiesslich, PhD, University of Salzburg, Salzburg 5081, AUSTRIA; Fabio Carlo Monticelli, Interfaculty Department Forensic Pathology, Salzburg 5020, AUSTRIA; Franz Neuhuber, PhD, University of Salzburg, Salzburg 5081, AUSTRIA*

**Learning Overview:** After attending this presentation, attendees will have learned about methods and materials that are suitable and effective for the identification of highly decomposed bodies in forensic case work.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying how the identification of highly decomposed bodies in forensic case work is still a time- and resource-consuming topic. Therefore, further progress and research in this field is very important. The future goal is to develop a method for a fast and reliable method for DNA profiling of bodies where decomposition processes did reach advanced stages.

**Context:** When bodies are highly decomposed and identification based on morphologic features is no longer possible, Short Tandem Repeat (STR) genotyping has been proven to be a convenient and reliable alternative. But at very advanced decompositional stages, postmortem tissue putrefaction processes can have an effect on microsatellite instability; therefore, not every type of postmortem tissue is still suitable for STR genotyping and subsequent forensic identification. In many cases, bone or dental material is used, but such materials require elaborate reprocessing. Thus, multiple studies have focused on the eligibility of soft tissues and organs where DNA extraction is a lot easier and faster.

**Goals:** By evaluating different cases ( $n > 10$ ) in which successful forensic identification was only possible with DNA material extracted from specific tissues, effectively compare the differential suitability of soft tissues for DNA analysis in highly decomposed bodies.

**Material and Methods:** A systematic classification of decomposed bodies and analyzed organs was performed to evaluate the qualification of various soft tissues for DNA profiling in respect to the degree of decomposition. Swab samples were procured from the aorta, urinary bladder, brain, muscle tissue, liver, and oral cavity from bodies in a decomposition state with a Total Body Score (TBS) per Megyesi et al. ranging from 6 to 35 based on morphologic features.<sup>1</sup> Subsequent to DNA extraction, DNA concentrations and the DNA degradation status of the samples was evaluated. Finally, STR-marker profiles of each tissue sample were generated and compared.

**Conclusion:** Differences were detected in the suitability of various soft tissues for DNA-based identification. Cerebral matter turned out to be one of the most useful samples in highly decomposed bodies. Even in highly decomposed cases with a high TBS score, it is still possible to obtain a full STR-marker profile from brain tissue. Samples from the urinary bladder and the liver do not seem to be as stable for DNA profiling.

#### Identification, Decomposition, DNA

### **H80 Acute Gastric Dilatation After Binge Eating: Overlapping Complications Determining a Race Against Death**

*Vittorio Gatto, MD, Sapienza University of Rome, Rome 00161, ITALY; Federico Manetti, MD\*, Rome, ITALY; Alessandro Santurro, MD, Sapienza University of Rome, Rome 00161, ITALY; Matteo Scopetti, MD, Sapienza University of Rome, Rome 00161, ITALY; Cemyigit Deveci, MD, Akdeniz University, Antalya 07070, TURKEY; Martina Padovano, MD, Sapienza University of Rome, Rome, ITALY; Mariantonia Di Sanzo, MD, Rome 00161, ITALY; Antonio Grande, MD, PhD, Forensic Science Police Service, Rome 00173, ITALY*

**Learning Overview:** After attending this presentation, attendees will have meaningful insights on sudden death due to acute gastric dilatation, a condition frequently associated with eating disorders and often difficult to prevent.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the report of fatal complications related to acute massive gastric dilatation subsequent to a binge-eating episode.

Acute gastric dilatation is a rare condition usually related to mechanical obstruction, neurological syndromes, or binge eating episodes. Although the stomach is known for being densely vascularized and resistant to ischemia, in rare cases the massive distension can cause a remarkable increase in intraluminal pressure and a significant vascular compression leading to circulatory insufficiency. Such a condition is usually followed by two main life-threatening complications: gastric wall necrosis and perforation.

This report presents the case of a 30-year-old woman with a clinical history of eating disorder who was transported to the emergency department with severe acute abdominal pain. Radiologic investigations documented subcutaneous emphysema, gastric dilatation, and a minimal layer of free air along the smaller gastric curvature. In light of these findings, emergent surgical intervention was requested. Despite the prompt diagnosis, the patient developed bradycardia and went into cardiac arrest refractory to resuscitation efforts just before reaching the operating room.

At autopsy, opening of the thoracoabdominal cavities revealed significant distension of the stomach, which occupied almost the entire left side of abdomen, displacing the small intestine. Prior to evisceration, 1,000cc of semi-liquid material that appeared consistent with gastric contents was recovered from the thoracoabdominal cavities. The stomach contained more than 3,000cc of partially digested material and was found to have a perforation along the smaller curvature. As a collateral finding, a prolapsed rectum extending about 15cm in length beyond the anus was found.

In this case, the huge food intake during a binge eating episode led to the development of acute massive dilatation of the stomach complicated by perforation. The peculiarity of the described case consists in the concomitance of multiple overlapping pathological conditions, which caused the death of the subject. Specifically, in addition to stomach perforation, abnormal gastric dilatation caused severe bradycardia—probably attributable to vagal stimulation—that resulted in irreversible cardiac arrest.

In conclusion, the rapid evolution of an infrequent disease and the superimposition of different pathological mechanisms precluded antemortem therapeutic interventions, thus requiring autopsy investigation to make a definitive diagnosis.

### H81 Stent Thrombosis After Percutaneous Coronary Intervention (PCI) in Spontaneous Coronary Artery Dissection (SCAD)

*Federico Manetti, MD\*, Rome, ITALY; Cemyigit Deveci, MD, Akdeniz University, Antalya 07070, TURKEY; Matteo Scopetti, MD, Sapienza University of Rome, Rome 00161, ITALY; Vittorio Gatto, MD, Sapienza University of Rome, Rome 00161, ITALY; Alessandro Santurro, MD, Sapienza University of Rome, Rome 00161, ITALY; Mariantonia Di Sanzo, MD, Rome 00161, ITALY; Antonio Grande, MD, PhD, Forensic Science Police Service, Rome 00173, ITALY*

**Learning Overview:** After attending this presentation, attendees will better appreciate the issues related to no-reflow in revascularization treatment by percutaneous intervention in spontaneous coronary dissection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reporting the major complications related to PCIs and their management in forensic pathology.

SCAD is a rare non-atherosclerotic cause of Acute Coronary Syndrome (ACS), accounting for 0.1% to 0.4% of all cases. SCAD occurs mostly in young women  $\leq 50$  years of age, and its causes are poorly understood and thought to be multifactorial with genetic, hormonal, and environmental influences. SCAD usually affect distal parts of coronary arteries and is caused by sudden disruption of the coronary arterial wall, resulting in separation of the intimal lining from the outer vessel wall and intramural hematoma formation. Pressure-driven expansion of the hematoma causes propagation of the dissection plane with formation of a false lumen containing thrombus. SCAD with active ischemia requires revascularization, preferably via stent implantation by PCI. PCI in SCAD has a success rate of  $< 50\%$ ; the major causes of morbidity and mortality after PCI are typically ischemic complications due to coronary dissection/hematoma propagation and stent thrombosis with abrupt vessel closure.

The presented report highlights the case of a 35-year-old woman admitted to the hospital emergency department with constrictive retrosternal pain radiating to the jugular area. Electrocardiogram (ECG) revealed pathologic waves in V1-V4, and laboratory tests showed an increase in myocardial enzyme levels (myoglobin 192.90U/L, total CK 1,053U/L, CK-MB 118U/L, LDH 639U/L). Coronary angiography revealed a spiral-shaped dissection in the Left Anterior Descending (LAD) coronary artery extending from the middle to the apex with a Thrombolysis-In-Myocardial-Infarction (TIMI) grade 2 flow. The following day, an ST-elevation (1mm) in V2-V5 was observed in the ECG (i.e., ST-Elevation Myocardial Infarction [STEMI]) and coronary angioplasty was performed with a subsequent decrease in myocardial enzyme levels and a remission of symptoms. After ten days, the patient again developed chest pain with an ST-elevation in the ECG (i.e., STEMI). Emergent PCI with implantation of a zotarolimus-eluting stent (3.5 x 16mm) was performed, but within 12 hours the condition of the patient rapidly declined and she expired.

An autopsy was performed to determine the cause of death. Gross examination of the heart revealed coronary vessels characterized by tortuous course and a bluish color. A palpable endovascular device was evident in the medial portion of the LAD coronary artery. Coronary arterial sectioning revealed an intimal dissection with a false lumen occupied by thrombotic material extending from 1cm after the origin of the LAD to the cardiac apex. Approximately 2cm after the origin of the LAD, a stent was found; the stent lumen, however, was completely occluded by thrombus. The thrombus originated from the stent and extended to the distal lumen of the LAD. Myocardial sectioning revealed an extended hemorrhagic infarction within the anterior wall of the Left Ventricle (LV) and the anterior interventricular septum.

In the presented case, stent thrombosis complicated PCI intervention; the presence of thrombotic endoluminal material in correspondence to the stent developed suddenly with resulting occlusion of the LAD coronary artery, resulting in an extensive myocardial infarction. The rapid evolution a relatively infrequent disease and possibility of different complications make any therapeutic intervention challenging—especially considering that current SCAD therapy is based upon opinion rather than randomized clinical trials. On the other hand, PCI results have also proven suboptimal in this challenging group of patients.

#### Coronary Artery Dissection, Percutaneous Coronary Intervention, Autopsy Investigation

## H82 The Relationship Between Wischnewski Spots and Stress Hormones During Hypothermia

*Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN*

**Learning Overview:** After attending this presentation, attendees will know the main risk factors of hypothermia in Japan, and the hypothermia animal model could be expected to help clarify the mechanisms underlying Wischnewski spots in hypothermia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying additional morphological and pathological findings in regard to hypothermia.

Numerous classical morphologic findings are commonly associated with the diagnosis of hypothermia, including Wischnewski spots (gastric erosions), color differences between left and right heart blood, frost erythema, and urinary retention. In general, risk factors for hypothermia include being a child or elderly, cold environmental conditions, wet clothing, being under the influence of alcohol or drugs, head trauma, decreased production of body heat, and malnutrition. There are many methods for creating a hypothermia animal model. For example, in the water bath model, a young animal is placed in a refrigerator at  $-20^{\circ}\text{C}$  until the core body temperature drops below  $35^{\circ}\text{C}$ . Then, the animal is placed in a Styrofoam™ box packed with ice. However, with such methods, morphologic features such as Wischnewski spots do not develop. The present study developed a hypothermia animal model based on risk factors and characteristic morphologic findings (including adrenal glands.)

Risk factor analysis was performed based on the records of autopsies performed between 2008 and 2018. Eighty-three deaths related to either hypothermia or secondary cold exposure were investigated. Sex, age, Body Mass Index (BMI), medical history, clothing, prescription medicine, urinary bladder and stomach contents, Wischnewski spots, blood alcohol level, detected drugs, and autopsy findings were reviewed. Out of 83 autopsies, 52 deaths were attributed to hypothermia and 31 involved secondary cold exposure. The decedents ranged in age from the high 60s to the 80s, with 26% more males than females. Regarding the BMI, 47% were underweight, and 43% were normal weight. Medical records showed that the most common condition in decedents was a history of high blood pressure ( $n=23$ ), followed by dementia ( $n=13$ ). Most cases showed evidence of paradoxical undressing ( $n=58$ ). Overall, no stomach contents were found in 76% of the cases, and Wischnewski spots were present in 92%. In addition, 45 cases in which Wischnewski spots were present showed evidence of being under the influence of alcohol. Postmortem toxicologic analysis showed evidence of opioids and barbitals ( $n=5$ ), benzodiazepines ( $n=4$ ), and tricyclic antidepressants ( $n=3$ ).

For the corresponding hypothermia animal model, Sprague Dawley rats were used and cold exposure conditions were created based on the human risk factors. Computed Tomography (CT) was used for postmortem imaging after cold exposure. The adrenal glands, stomach, and intestines were fixed in 4% paraformaldehyde embedded in paraffin. Each section was stained with the stress hormone corticosterone, hematoxylin, and eosin. With this animal model, Wischnewski spots were observed under the following conditions: an environmental temperature below  $5^{\circ}\text{C}$ , being under the influence of alcohol (2%), and if the animal model was hairless and the age group was 15~30 weeks. Fasting and water deprivation for three days resulted in the expression of Wischnewski spots involving more than 90% of the stomach; however, emphysema was not seen on Computed Tomography (CT). Regarding the immunohistologic findings, in the adrenal glands, corticosterone was mainly localized in the cytoplasm for the alcohol-induced, fasting, and dehydrated hypothermia model. Positive staining was seen in 60~80% of the zona fasciculata cells. Therefore, an animal model of hypothermia was established based on risk factors and morphological findings. Most of the classical morphological findings, including color differences between the left and right heart blood, retained urine contents, and the presence of Wischnewski spots, were visible in this animal model.

### Hypothermia, Animal Model, Risk Factors

### H83 New Biomarkers of Myocardial Necrosis Identification in Decomposed Bodies

Pasquale Malandrino, MD\*, University of Catania, Catania 95123, ITALY; Francesco Amico, MD, Medicina Legale, Catania 95123, ITALY; Federico Patanè, MD, University of Catania, Catania 95123, ITALY; Angelo Montana, MD\*, University of Catania, Catania 95123, ITALY; Dario Condorelli, University of Catania, Catania 95100, ITALY; Massimiliano Esposito, MD, University of Catania, Catania 95123, ITALY; Edmondo Scoto, University of Catania, CATANIA 95123, ITALY; Giulio Di Mizio, MD, PhD, Magna Graecia University, Catanzaro 88100, ITALY; Monica Salerno, MD, PhD, University of Catania - Forensic Medicine, Catania 95123, ITALY; Cristoforo Pomara, MD, PhD, Catania, Foggia, ITALY

**Learning Overview:** In cases of prolonged postmortem interval, the forensic histopathological diagnosis is limited due to autolysis and putrefaction processes and detecting early Myocardial Infarctions (MIs) can be challenging. After attending this presentation, attendees will know two potential new biomarkers of myocardial necrosis identification in decomposed bodies: CD 68 and Myeloperoxidase (MPO).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that the autopsy has always had a critical importance as well as the histologic findings in MI diagnosis in medical malpractice cases. Using antibodies to human CD68 and MPO and their application in forensic fields may be a sensitive diagnostic tool to enhance accuracy of postmortem diagnosis of MI in putrefied bodies.

MI is one of the main sequelae of coronary heart disease and one of the most common causes of death worldwide.<sup>1</sup> Many medical malpractice claims are attributable to misdiagnosis, however.<sup>2</sup> Traditionally, the postmortem diagnosis of MI is made via histopathology using a combination of Hematoxylin-Eosin (H&E) staining and immunostaining on preserved heart tissue. In the case of decomposed myocardial tissue, immunohistochemistry plays a particularly important role in reaching the diagnosis of MI. In fact, although biological structures are predisposed to autolysis in the postmortem period, leukocytes and the nuclei of granulocytes are very resistant to autolysis and putrefaction.<sup>3</sup>

While there are many studies published in the scientific literature regarding postmortem MI diagnosis and timing of early ischemic injury, only a few studies have been performed on putrefied bodies. In these few studies, some immunohistochemical markers were found to improve diagnostic accuracy, including C5b-9 and NP57.<sup>4</sup> The current study examines two new biomarkers to determine whether they might potentially further improve diagnostic accuracy in cases of putrefied bodies.

Human CD68 is a transmembrane glycoprotein expressed in monocyte lineages and some other leucocytes. MPO is a heme-containing peroxidase stored in azurophilic granules of polymorphonuclear neutrophils and macrophages and released into extracellular fluid during inflammatory processes. These white blood cells are recruited immediately after an ischemic cardiac event. An immunohistochemical study was performed to evaluate morphologic changes in heart samples procured from eight autopsies performed on decomposed bodies after variable postmortem intervals ranging from 3 to 11 months. All were cases of presumptive medical malpractice due to the misdiagnosis of MI.

Control hearts from traumatic death cases did not show any immunoreactivity to MPO or CD68 markers. Immunohistochemical investigations of CD68 and MPO were able to confirm an MI diagnosis in all eight decomposed cases. Overall, these results suggest that autopsy plays a critical role in detecting histologic findings diagnostic of MI in potential medical malpractice cases. Using antibodies to human CD68 and MPO may increase postmortem diagnostic sensitivity in cases of suspected MI in putrefied bodies.

### H84 Viral Load: Handling an (Unexpectedly) High-Profile Case

*Kirstin E. Howell, MD\*, Cook County Medical Examiner's Office, Chicago, IL 60612; Kristin C. Escobar Alvarenga, MD, Chicago, IL 77388-3955*

---

**Learning Overview:** After attending this presentation, attendees will be aware of what can happen when a case goes unexpectedly viral and how to approach an unexpectedly high-profile case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of coroners, medical examiners, and forensic investigators of how a seemingly routine case can capture the public's attention, how that interest can affect the office and personnel involved, and how medical examiners' and coroners' offices can be prepared to respond to the increased public scrutiny.

Sometimes it is easy to anticipate when a case is going to be high profile. Police-involved shootings, deaths in custody, deaths of celebrities, and deaths in public places frequently get discussed and dissected in the news and on social media. In such instances, there is often an increased awareness among the death investigation team at the time of notification of death and at autopsy to make certain that any reasonably foreseeable questions regarding the circumstances, and cause and manner of death, are addressed. Measures can be taken beginning at the time of autopsy to anticipate and respond to the expected public scrutiny so that everyone is prepared for the intense interest. But what happens when a case unexpectedly captures the fascination of the public?

Such a case was investigated by the Cook County Medical Examiner's Office. A scene investigation was performed according to office protocol and the autopsy was completed within hours of discovery of the deceased. By that evening, there were already posts on social media and in the news about the death. As the death investigation progressed, so did public involvement as various individuals evaluated the information provided by the media and by online information, videos, and photographs posted by friends and acquaintances of the deceased.

There were protests, social media rants, and YouTube® videos analyzing the investigation and those involved. Attempts at transparency were met largely with suspicion, more demands for answers, increased lay interpretation of evidence, and efforts to become involved in the investigation.

After a discussion with the family, the Medical Examiner's Office expedited closure of the case and issued a formal press release. But closing the case neither stopped the demands for answers nor diminished allegations of cover-ups, which accused police and medical examiner personal of complicity in foul play. Demands for justice came from around the world through letters, emails, telephone calls, Facebook® messages, Tweets, and visits to the office.

Who knows why a case goes viral? In this age of the "CSI effect," social media, armchair detectives, and lay sleuths, this case provides an example of how forensic pathologists and offices can best deal with the unexpected media and popular scrutiny, and what their responsibility is to respond to those requests.

### High Profile, Social Media, Autopsy

### H85 Increasing Transparency: The Utility of Layered Images in Postmortem Identification

Farnaz Khalafi, MD\*, University of Alabama Birmingham, Birmingham, AL 35233; Brandi C. McCleskey, MD, Jefferson County Coroner/Medical Examiner's Office, Birmingham, AL 35233

**Learning Overview:** After attending this presentation, attendees will be able to utilize a simple method of comparing radiographic images to identify remains. The goal of this presentation is also to present rationale for medical examiner access to electronic health records.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the usefulness and reproducibility of radiographic comparison for identification.

Accurate identification of decedents is of paramount importance in medicolegal death investigation. There are multiple well-recognized methods of identification with the most utilized being direct visual identification by family members or close friends, which is often quick and accurate. In some circumstances (fire-related deaths, decomposition, no known next of kin, etc.), visual identification cannot be accomplished. Fingerprint identification is generally as rapid as the availability of the agency that performs the comparison, but lack of antemortem or postmortem prints may prevent such identification. DNA comparison introduces significant delays, and dental records can be challenging to acquire.

Electronic access to antemortem radiographs may prove useful, timely, and accurate as a comparison tool for postmortem radiographs. In cases of unidentified remains at the Jefferson County Coroner/Medical Examiner's Office, seven decedents were identified using a novel and simple technique of superimposing images captured from both the postmortem radiograph and antemortem records. The superimposition (or layering) was performed using an easy method in Microsoft® Word. The transparency of the overlaid image was adjusted to ensure skeletal features were consistent (if not identical) in both radiographs. Often the medical examiner had access to medical records on the day that the decedent was examined, which drastically improved the time to identification (usually one to three days) and release of remains to family members.

Traditional methods of acquiring physical Computer Discs (CDs) containing digital images usually involves facsimile requests to local hospitals, delivery by mail or in person, and review of image files with appropriate software. This process resulted in significant delays for establishing identification (5 to 41 days in this cohort). In either scenario (electronic access vs digital image from CD), many skeletal landmarks, including frontal sinus morphology, vertebral shapes, and pelvic and femoral shape, were used.<sup>1-4</sup> Of course, this radiologic comparison was used in conjunction with other circumstances from the case to conclusively identify the decedent. The resultant Microsoft® Word document can become a physical visual aid that is a permanent record within the case file and could provide a useful tool in courtrooms and meetings with individuals not accustomed to comparing side-by-side radiographic images.<sup>5</sup> The practice of capturing images for comparison is limited by the paucity of plain radiographs available in the modern medical record. Computed Tomography (CT) scans are the mainstay of clinical imaging and are difficult to compare to postmortem radiographs, unless evidence of surgery or bony trauma is obvious. However, offices with CT scanning capability may be able to use this same layering technique with antemortem CT images to aid in identification of remains.

This case series presents a novel strategy for timely and accurate identification, as well as highlighting the importance of a medical examiner's office having access to the electronic health records of local hospitals.

#### Identification, Radiology, Forensic Pathology

### H86 An Interdisciplinary Approach to Data Collection of Unidentified Juvenile Remains at the Georgia Bureau of Investigation (GBI)

*Jonathan Eisenstat, MD\**, Georgia Bureau of Investigation, Decatur, GA 30034-3830; *Alice F. Gooding, PhD*, Kennesaw State University, Kennesaw, GA 30102

**Learning Overview:** After attending this presentation, attendees will understand some of the challenges facing the identification of juvenile skeletal remains and learn about the effectiveness of a multi-step protocol for the collection of biometric and biological data from juvenile remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showcasing how an interdisciplinary approach in the medical examiner's setting is vital to aiding in the identification of a large collection of unidentified individuals.

The GBI houses the skeletal remains of unidentified individuals ( $N=272$ ) dating back to the 1960s. Legislation was passed in 2016 to allow for the burial of these individuals. Prior to internment, it was decided that a thorough examination of every case was necessary to create a robust case file in the event that a lead on identification should arise. Of these cold cases, anthropological analyses were used to determine that approximately ten percent ( $n=26$ ) were juvenile (e.g., skeletally immature). Long bone length, the appearance and union of epiphyses, and the development and eruption of the dentition were used to approximate the age at death of each individual, ranging from 20 weeks *in utero* to 25 years of age.

The identification of juvenile remains is particularly difficult because many of the other standard components of an anthropological analysis, such as biological sex and ancestry estimation, are less reliable before skeletal maturity. Further, the condition of these remains varies. While some cases are largely complete skeletons, others are comprised only of bone fragments or else the present bone is in extremely poor condition due to weathering or burial. As a result, a uniform approach to analyses would be ineffective. In response, this study developed a diverse, multi-step, interdisciplinary protocol to collect a large range of biometric data and biological specimens from each individual before internment. Each set of remains was photographed, inventoried, and analyzed using gross morphological techniques. Metric measurements of all present elements were also collected. In addition to traditional DNA comparison, bone samples were extracted for stable isotope analysis. Unique isotopic signatures (carbon, nitrogen, oxygen, and strontium) in bone may be distinguished based on regional differences in drinking water supply. For individuals in which the cranium was fully formed, crania were scanned at 0.5mm intervals with a peripheral Quantitative Computed Tomography (pQCT) scanner at Kennesaw State University. The completed Digital Imaging and Communications in Medicine (DICOM) stacks will subsequently be used to print 3D models for forensic artistic reconstruction. While all cases in the GBI's unidentified collection will receive a thorough examination, this study argues that this multi-step data collection protocol using new technological developments is key to the potential identification of juvenile individuals.

#### Unidentified, Juveniles, Anthropology

### H87 Lost and Found: Forensic Anthropology and the Recovery of a 21-Year-Old Plane Crash

*Kerianne Armelli, MS\*, Department of Biomedical Science, Kent, OH 44240; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI 48824; Jane Wankmiller, PhD, Northern Michigan University, Marquette, MI 49855; Rachel E. Smith, BS, Marquette, MI 49855*

**Learning Overview:** After attending this presentation, attendees will understand how forensic anthropologists can assist medical examiners and forensic pathologists in complex scene recoveries involving skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the expertise forensic anthropologists provide in recoveries of highly fragmented skeletal remains that may be found in medicolegal death investigations.

This presentation will review the case of a 21-year-old plane crash in which the Medical Examiner of Mackinac County, MI, consulted with forensic anthropologists for the recovery of highly fragmented human skeletal remains. The remains were presumed to be Mark and Janet Davies, a married couple who disappeared on September 14, 1997, when their personal plane left Drummond Island, MI, with the intention of traveling to the Livingston County Airport, MI. The forensic anthropology teams from Northern Michigan University and Western Michigan University Homer Stryker M.D. School of Medicine assembled in St. Ignace, MI, on August 7, 2018, at 8:00 a.m. to partake in a planning meeting with teams representing the United States Forest Service, Mackinac County Medical Examiner's Office, Mackinac County Sheriff's Office, Federal Aviation Administration, National Transportation Safety Board, and Piper Aviation. The scene, discovered by United States Forest Service interns conducting a tree survey, was located within the Hiawatha National Forest, approximately half a mile from the nearest trail.

The plane was dismantled in sections from the top working down and the various teams of investigators cooperated to ensure that everyone had the opportunity to meticulously collect evidence relevant to their respective disciplines. Skeletal elements were recovered from the control panel and footwell of the cockpit, as well as from the soil just outside the fuselage. The anthropology team, accompanied by deputies from the Mackinac County Sheriff's Office, returned on August 8 to continue the recovery and excavated additional skeletal material from the surrounding soil. The remains were transported to Western Michigan University Homer Stryker M.D. School of Medicine's Forensic Anthropology Laboratory, where skeletal analyses were performed. Evidence of blunt force trauma consistent with a plane crash was present, including a compression fracture of the first cervical vertebra, spiral fractures, and butterfly fractures of various skeletal elements. A minimum number of two individuals was established based on repeated elements. Commingling was resolved by separating repeated elements and comparing sexually dimorphic size differences in the elements recovered. Taphonomic analysis revealed animal scavenging activities and weathering. Comparative dental radiography confirmed the decedents to be Mark and Janet Davies. After the completion of the skeletal analyses, the remains were returned to Mark's and Janet's next-of-kin. Remains that could not be reliably associated with either Mark or Janet Davies due to extreme fragmentation were slated for cremation together, an arrangement that was agreed upon by both families.

This unique case highlights the need for interdisciplinary teams within the forensic sciences. As forensic anthropologists are experts in the recovery and analysis of human skeletal remains, they can be valuable in difficult cases where fragmentary skeletal remains need to be located and recovered. In this case, the forensic anthropologists provided expertise in the search and recovery of highly fragmented skeletal remains, the analysis of skeletal trauma, the resolution of commingling, and the positive identification of the victims.

### H89 The Complicated Recovery of a House Fire Victim in Northern Michigan

*Jane (Wankmiller) Harris, PhD\*, Northern Michigan University, Marquette, MI 49855; Rachel E. Smith, BS, Marquette, MI 49855; Carl W. Hawkins, MD, Office of the Medical Examiner, St. Ignace, MI 49781*

**Learning Overview:** After attending this presentation, attendees will understand how forensic anthropologists can assist medical examiners and forensic pathologists in scene recoveries involving fragmentary, thermally altered skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the value of involving forensic anthropologists when recovering highly fragmentary skeletal remains as part of a medicolegal death investigation.

This presentation will review the recent recovery of fragmentary human skeletal remains from the scene of an intense, unwitnessed house fire in northern Michigan. Michigan's Upper Peninsula (UP) is known for its extensive Great Lakes shoreline, extreme winter weather, and a low population density that allows residents and visitors to disconnect from the bustle of life in larger cities and enjoy relative isolation. The overall population density changes seasonally, with far fewer people residing in the UP in winter than in summer. In February of 2019, a single-family residence caught fire. Because the nearest residences were unoccupied at the time and the nearest neighbor was over one-half mile away, the fire went unwitnessed and unreported until it had essentially burned itself out. The residence was known to have been a single-story ranch-style house with a full basement, owned and occupied by a single homeowner. Extremely fragmentary, calcined human skeletal remains were located in an area of the lower level, indicating the victim had been on the main floor but had fallen into the basement when the floor collapsed during the fire. No foul play was suspected by investigators.

Extreme winter weather conditions and unsafe temperatures following the fire complicated the investigation. Overseen by the Mackinac County Medical Examiner, the recovery of human skeletal remains from the basement was primarily conducted by law enforcement and fire personnel. The investigators did their best at the time, but the onset of heavy snow during this initial recovery obscured visibility of both the remains and any potentially hazardous conditions in the home. By the next day, approximately two feet of snow covered the scene (and snow continued to accumulate for the next several weeks). Further recovery was halted, and the medical examiner transferred custody of the remains to the Forensic Anthropology Research Laboratory at Northern Michigan University (NMU) for analysis. Anthropologists were asked to determine the minimum number of individuals, analyze the skeletal trauma, provide a biological profile, and identify the victim. Identification at that time was complicated due to the fragmentary and incomplete nature of the remains, as only approximately 50% of the body was represented, resulting in the absence of comparable features for comparative radiography.

Approximately three months later, when the snow finally melted and the scene was once again visible, the medical examiner and local law enforcement initiated a second excavation to complete the recovery of the victim. The medical examiner, recognizing the need to work with skeletal specialists on a case involving such fragmentary, extensively burned remains, called upon the NMU anthropologists to assist with this phase of recovery. The NMU anthropologists methodically excavated the area of the basement where the victim was known to have been located, resulting in the location of skeletal elements representing all regions of the body that were missing following the first recovery, many of which had not been recognized as bone during the initial recovery effort due to extreme thermal alteration and difficult visibility. As a result of the additional excavation, a positive identification was made using comparative dental radiography and the medical examiner was able to issue a death certificate.

This case highlights the complicated nature of forensic recovery of human remains from scenes that involve adverse conditions, such as fire damage and extreme winter weather, as well as the need for collaborative, interdisciplinary teams. The forensic anthropologists in this case provided much-needed expertise in skeletal identification and excavation. The medical examiner considered this service vital for both victim identification and to be certain no remains were left behind in the ruins.

## H90 Selfie-Related Injuries and Deaths in Italy

Sara Gioia, MD\*, via Tristano di Joannuccio SNC, Terni 05100, ITALY; Fabio Suadoni, MD, via Tristano di Joannuccio SNC, Terni 05100, ITALY; Dora Mirtella, MD, University of Macerata, Macerata, ITALY; Mariano Cingolani, MD, University of Macerata, Macerata 62100, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware that the incidence of taking extreme selfies to be shared on social media is increasing, also leading to selfie-related trauma and death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting that the incidence of selfie-related injuries and deaths is not negligible worldwide and is a problem that also cannot be ignored in Italy.

According to the Oxford dictionary, a selfie is defined as “A photograph that one has taken of oneself, typically one taken with a smartphone or webcam and shared via social media”. Clicking selfies and sharing them on social media has become a common means of self-expression. However, individuals sometimes portray themselves in dangerous settings so as to gain attention on social media sites. In some cases, this may have fatal consequences. A “Killfie” is actually a term used in the common language to define an extreme selfie which is potentially life-threatening for the photographer. Cases of selfie-related death or mortality are defined as accidental deaths precipitated by the process of self-photography; these may occur just before, during, or just after the process, which is typically documented via cell phone. This worldwide phenomenon also occurs in Italy, though incidence has not been well established, and scientific medical journal articles on the subject are lacking.

In order to better define the exact incidence of selfie-related injuries and deaths in Italy, a media-based search from 2014 to 2019 was performed; medium age, geographical locations, and manner of occurrence were analyzed and compared with other media-based searches in the literature from other countries.<sup>1,2</sup>

Study results suggest that information and awareness campaigns are necessary, especially among the youngest: in India, for instance, “no selfie zones” have been created, while in Russia, a campaign urging people to take safer selfies has been launched. It is probable that there is an underestimation of the real number of selfie-related injuries and deaths in the studies conducted worldwide; in fact, other studies, by considering only English language media articles, do not take into consideration the local press written in other languages. Researchers worldwide should therefore conduct similar studies in order to describe this phenomenon in a thorough manner in all nations, to obtain an actual count of selfie-related injuries and deaths.

With regard to selfie-related deaths, the forensic pathologist’s role entails shedding light on the dynamics of the events; although the cause of death is rarely in doubt, the manner of death is often unclear. Consequently, the inquiry needs to be thorough to establish if the death was indeed accidental rather than suicidal or homicidal in nature.

### H91 The Introduction of a Mobile Application to Assist in the Evaluation and Investigation of Death Scenes in Forensic Medical Practice

*Gert Saayman, FCPATH\*, Department of Forensic Medicine, University of Pretoria, Pretoria, Gauteng 0007, SOUTH AFRICA; Cornelia van Graan, MS, ARCADIA, Pretoria 0002, SOUTH AFRICA*

---

**Learning Overview:** The goal of this presentation is to discuss the development of a mobile app designed to function on smart phones and tablets, to assist Medical Examiners (MEs) and death investigators in the systematic evaluation and contemporaneous recording of appropriate findings at a death scene. Other ME offices and those officials involved in medicolegal investigation of death may benefit from this overview.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing/proposing the use of a relatively simple but functional mobile app to ensure contemporaneous and standardized collection and recording of information at the death scene, which can then be relatively easily shared with other parties at distant locations.

The introduction of mobile application technology may substantially assist in ensuring that relevant and standardized information is systematically and contemporaneously captured, stored, and made available for assessment by trained professionals, thereby assisting in eventual criminal and civil justice administration. This tool may have potential for significantly improving the quality of medicolegal death investigation, not only in South Africa, but internationally.

Thorough medicolegal death/crime scene investigation—and the recording of relevant findings—plays a critical role in the overall understanding and elucidation of non-natural deaths. Information gathered at the scene of death assists in planning the subsequent death investigation (including, in particular, the autopsy and related special investigations, such as toxicology) and thus ultimately may play an important role in establishing and validating the cause and manner of death.

By applying commonly available smart phone/tablet technology in the form of an application (“app”) to the death scene, a simple yet effective aid to death investigation has been developed at the Department of Forensic Medicine of the University of Pretoria for routine use by death investigators and pathologists. This application allows for structured, rapid, and real-time capture and storage of relevant information in electronic format (including photographs), which can in turn be immediately made available by means of wireless transmission technology to off-site parties, including consultant pathologists, police officers, etc. Security of information is ensured by appropriate data encryption technology.

A multiplicity of relevant facts or information fields may be easily and accurately incorporated into the on-site data capture, including elements such as crime/death scene Global Positioning System (GPS) coordinates, ambient temperature, scene photographs, etc. The information can then be transmitted and stored in electronic format and/or linked to existing (or subsequent) data archives. This application is specifically geared toward supplementing or enhancing the information fields/sets that forensic pathologists may require or find to be of value in order to prioritize scene attendance, plan and conduct their postmortem examinations or viewing procedures, or to interpret subsequent autopsy findings. The tool may particularly benefit countries or communities where there is a lack of adequately skilled or trained death scene investigators—which may indeed compromise the quality of the initial investigation (and even lead to grave miscarriages of justice).

---

#### Mobile Application, Death Scene Investigation, Forensic Pathology

### H92 An Evaluation of Selected Hematopoietic Immunohistochemical Stains in Decedents in Varying States of Decomposition

Catherine R. Miller, MD\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; Juan P. Olano, MD, The University of Texas Medical Branch, Galveston, TX 77555-0001; Judith Aronson, MD, The University of Texas Medical Branch, Galveston, TX 77555; You-Wen Qian, MD, The University of Texas Medical Branch, Galveston, TX 77555

**Learning Overview:** The goal of this presentation is to present data on the utility of postmortem Immunohistochemistry (IHC) in decedents in varying states of decomposition. IHC is often utilized in the surgical and cytopathology realms but is less commonly used in autopsy pathology. This study sought to discover if the quality of immunohistochemical stains decreases with increased decomposition. This will allow institutions to make decisions regarding the benefit of performing the selected stains evaluated in this project on decedents with prolonged death intervals and/or significantly autolyzed tissues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing utility data to practitioners considering performing postmortem hematopoietic immunohistochemical stains.

**Hypothesis:** The quality of immunohistochemical staining decreases with increased autolysis.

**Methods:** Mediastinal lymph nodes were collected prospectively from ten autopsy cases at The University of Texas Medical Branch. The postmortem interval ranged from one to five days. The lymph nodes were fixed in 10% formalin and submitted for routine histologic processing. Each lymph node was stained with Hematoxylin-Eosin (H&E), CD45, CD5, CD20, CD79a, and CD2. Lymph nodes and the IHC markers were chosen for several reasons: (1) approximately 12 cases of lymphoma are diagnosed at UTMB postmortem (no pre-mortem diagnosis available) making lymph nodes a very important postmortem source for hematopoietic markers; (2) mediastinal lymph nodes are more centrally located than peripheral tissue and are thus less susceptible to rapid heating and cooling from transport and storage of bodies; (3) mediastinal lymph nodes are easy to identify at autopsy; and (4) membranous stains were chosen to minimize the number of variables encountered by the reading pathologists.

The signal intensity and quality of the IHC stains were scored by three board-certified pathologists (i.e., observers) including: two autopsy pathologists and one hematopathologist. Average scores for each stain in each case were calculated. These scores were plotted to compare degree of autolysis (represented by H&E average scoring) against quality of IHC staining (represented by the average score of each IHC stain in each case). Inter-Observer Variability (IOV) was assessed using the weighted kappa statistic.

**Results:** The postmortem interval did not correlate with the degree of autolysis observed in the histologic sections, but observers rated the degree of autolysis seen in each H&E stained section (scale: 1=normal histology with no sinus histiocytosis; 5=severe autolysis) before reading each associated immunohistochemical IHC stain. For the degree of autolysis seen in each H&E section, IOV kappa score was moderate to substantial ( $k=0.444-0.653$ ). A line plot of average scores for both H&E and IHC showed that as the degree of autolysis increased, the quality (signal intensity and completeness) decreased. A line plot of average scores for H&E compared to average weighted kappa values for each case showed no appreciable change in IOV regardless of H&E scores. That is, the degree of autolysis did not appear to affect the observer agreement scores ( $m=-0.1159$ ). IOV kappa score for IHC was highest for CD79a ( $k=0.6$ ), followed closely by CD20 ( $k=0.595$ ). The lowest IOV kappa score was for CD45 ( $k=0.312$ ).

**Conclusion:** Though IHC is not commonly used in forensic pathology, it is generally available to the forensic pathologist who needs it. IHC is more frequently used in the hospital autopsy setting than in the forensic setting, but its utility for tissues with varying degrees of autolysis has been only rarely studied. This study confirms the prevailing belief among pathologists that usefulness of IHC in the autopsy setting decreases with increased tissue autolysis.

#### Autopsy, Immunohistochemistry, Lymphoma

## H93 “Forens-OMICS”: The Application of Omics Sciences to Forensic Investigations

Noemi Procopio, PhD\*, Northumbria University, Newcastle upon Tyne NE1 8ST, UNITED KINGDOM; Natalie R. Langley, PhD, Mayo Clinic School of Medicine, Scottsdale, AZ 85259; Beatrix Dudzik, PhD, Lincoln Memorial University, Harrogate, TN 37752; Paul Wood, PhD, Lincoln Memorial University, Harrogate, TN 37752

**Learning Overview:** After attending this presentation, attendees will understand the potential of “omics” methodologies to estimate Postmortem Interval (PMI). Attendees will be introduced to “Forens-OMICS” as the first global application of several “omics” technologies to forensics and will discuss current state and preliminary findings from omics data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing an innovative approach to PMI estimation. Combining molecular methods with visual observations may provide more precise and unbiased estimates and help overcome current methodological limitations.

Estimates of time-dependent biological processes (e.g., PMI and age at death) are based primarily on visual observations and require considerable experience and expertise. Moreover, most methods rely on the completeness of remains or presence of certain skeletal elements. This limits the possibility to obtain precise estimates from incomplete remains, a common situation in mass disasters, conflicts, terrorist attacks, and routine casework.

Biomolecules, such as proteins and lipids, are abundant in bone tissue and persist long after death. Consequently, these biomolecules may retain and reveal information about time-dependent biological processes significant to forensic investigations. Proteomics provides information about age at death and PMI, and lipidomic analyses of skeletal muscle and bone marrow are useful for PMI estimation.<sup>1-5</sup> This presentation demonstrates an integrative approach using various sources of omics data to reveal quantitative biomarkers for estimating PMI and age at death from remains in advanced states of decomposition, including skeletonization.

Omics data were obtained from four sources: pig bones, mice bones, human bones, and human skeletal muscle tissue. Liquid Chromatography with Tandem Mass Spectrometry (LC/MS/MS) was used to identify biomarkers on pig ( $n=4$ ) and mice carcasses ( $n=96$ ) of prolonged PMIs (up to six months). Proteomic studies identified biomarkers suitable for PMI, as well as age-at-death estimation (e.g., fetuin and biglycan). Lipidomics analyses of human muscle tissue from 16 human bodies at the University of Tennessee Anthropological Research Facility ( $n=262$  samples, Accumulated Degree Days [ADD] 0–2,000) were analyzed via MS/MS. Cell membrane glycerophospholipids, specifically phosphatidylglycerol and phosphatidylethanolamine, showed the highest predictive power of PMI (R-square=0.85). Lipidomic analyses of human trabecular bone from three skeletal sites (calcaneus, proximal tibia, vertebral body) were conducted on 135 individuals. The sample consists of a cross-sectional and longitudinal component: (1) 115 skeletons from the William M. Bass Donated Skeletal Collection (PMI=1–30 years); and (2) 20 individuals placed at the University of Tennessee Anthropological Research Facility in 2018, which are being sampled every six months for two years. Analyses with a high-resolution electrospray ionization lipidomics analytical platform have identified 76 potential N-acyl amino acids; two have been validated via generation of the MS2 product ion for serine (palmitoyl and oleoyl serine).

These preliminary results show that omics data have great potential for transforming current approaches for estimating time-dependent biological processes of forensic import (e.g., PMI and age at death). Further lipid and protein class candidates are being validated with MS/MS, and machine learning algorithms will be used to analyze the combined omics data in addition to other omics results (e.g., DNA methylation data from bones) with the goal of improving predictive power and identifying the most accurate methodology to assess time-dependent forensic parameters.

Weber, BS*, Signature Science, Austin, TX 78759

**Learning Overview:** After attending this presentation, attendees will understand that it is possible to isolate both DNA and protein from human touch samples, providing a second meaningful source of genetic information on which forensic analysis can be based, in addition to traditional DNA analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by aligning with the competencies of attendees who process trace forensic samples. Proteomic analysis is rapidly maturing, providing value to attendees focused on performance who are looking to implement these methods to derive additional value from these challenging sample types. These results demonstrate that this approach permits traditional DNA analysis and parallel protein analysis, highlighting the relevance to both the core competencies and performance requirements of typical attendees.

Human touch samples represent an increasing fraction of forensic casework analysis each year. Unfortunately, these samples are also among the most difficult to analyze effectively, especially with respect to traditional DNA analysis. Trace DNA in touch samples commonly leads to marker drop-out and other artifacts and can complicate analysis of DNA mixtures. Certain evidence types, such as brass shell casings, may further contribute to DNA degradation or inhibition. Proteins represent a separate, often overlooked, class of biomolecules in touch deposits that are both highly abundant and environmentally robust. The use of mass spectrometric-based proteomic analysis to identify Genetically Variable Peptides (GVPs) has been recently demonstrated to provide forensically relevant match probabilities to suspected individuals.

This study describes the application of a novel complete casework-oriented proteogenomic analysis method that encompasses sample preparation, DNA profiling, proteomic analysis, and a GVP-specific Random Match Probability (RMP) calculator specifically designed to use proteogenomic data sets. Using both human fingerprint samples as well as artificial fingerprints to standardize DNA and protein inputs, the study demonstrates that this approach maximizes DNA and protein yield across multiple surface types, including glass, plastic, laminate, and brass. Critically, the sample collection and extraction procedure stratifies and differentially extracts DNA and protein fractions, enabling parallel DNA and GVP analysis without significant loss of either fraction. This capability promotes future casework laboratory implementation by positioning GVP analysis as a complimentary tool and enhancement to standard DNA analysis (as opposed to promoting GVP analysis as a replacement of the current gold standard). Using this novel method, the current study demonstrates improved DNA yield in comparison to standard extraction methods. By extracting and analyzing protein markers from the same sample, these results further show that humans can be identified from touch samples with RMP values ranging from  $10^{-5}$  to  $10^{-16}$  regardless of DNA content. Taken together, this novel sample preparation strategy and custom analysis method provides a transformative capability for the analysis of touch samples.

## H95 Developing Biological Models for the Probabilistic Genotyping of Next Generation Sequencing (NGS) Data

Kevin Cheng\*, *Institute of Environmental Science and Research, Sandringham, Auckland 1025, NEW ZEALAND*; Meng-Han Lin, PhD, *Institute of Environmental Science and Research, Auckland 1025, NEW ZEALAND*; Jo-Anne Bright, PhD, *Institute of Environmental Science and Research, Auckland, NEW ZEALAND*; James M. Curran, PhD, *University of Auckland, Auckland 1142, NEW ZEALAND*; John S. Buckleton, PhD, *Auckland, NEW ZEALAND*

**Learning Overview:** The goal of this presentation is to explain the need for models that describe the behaviors of NGS DNA profiles and the methods for developing said models for probabilistic genotyping software.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing current efforts in the modeling of NGS profiles.

Conventional Polymerase Chain Reaction (PCR) -based amplification of Short Tandem Repeats (STRs) at different discriminatory loci, and subsequent fragment characterization using Capillary Electrophoresis (CE), is currently the predominant DNA profiling approach used in forensic laboratories. Early methods for the interpretation of the resulting electropherogram (epg) profiles were very limited, utilizing a binary approach. This binary interpretation was largely threshold-based and did not account for the probability of drop-in and drop-out of alleles in a DNA profile.<sup>1</sup>

As technology developed, DNA profiles increased in complexity with more sensitive DNA profiling methods, resulting in more mixed DNA profiles. This resulted in the need for probabilistic genotyping methods. This is where additional information, such as peak heights and stutter peaks, present in an epg is also considered in the interpretation of a profile.

The analysis of forensic DNA methods using STR and CE methods have been used within forensic DNA laboratories internationally for more than 20 years.<sup>1</sup> More recently, laboratories have started investigating NGS methods for analysis of forensic samples. There are known limitations with a CE-based approach that NGS methods may be able to resolve.<sup>2</sup>

An example of the benefits of an NGS approach is its capability of resolving iso-alleles. These are alleles with the same number of STRs, but with different DNA sequences.<sup>3</sup> Using the sequence information within these iso-alleles, different repeat patterns of the same repeat motif(s) can be observed, allowing for increased discrimination of profiles and possibly improved resolution of contributors.<sup>4</sup>

Analogous to how interpretation methods were limited during the early implementation of CE-based technology, the current methods for the interpretation of DNA profiles obtained through an NGS approach are limited. There have been examples in which existing probabilistic genotyping software, which is developed for the interpretation of CE DNA profiles, is modified to interpret NGS DNA profiles.<sup>5</sup> The assumption is that the models that exist within these probabilistic genotyping software are suited for the interpretation of NGS. There is an increasing need for the development of more sophisticated biological models for use within probabilistic genotyping software for NGS DNA profiles.

In order to develop biological models for the interpretation of NGS DNA profiles, it is first necessary to understand how these profiles behave. This presentation explores the behavior of NGS DNA profiles, including aspects such as stutter, peak height variability, and locus-specific PCR efficiency. The goal is to identify the similarities and differences between CE and NGS DNA profiles. Experiments designed to determine these models and findings are presented.

### H96 Decomposition Odor Production in a Tropical Savannah

Lena M. Dubois, MSc, University of Liège, Liège 4000, BELGIUM; Carlos A. Gutierrez, MS, Chaminade University of Honolulu, Honolulu, HI 96816; David O. Carter, PhD, Chaminade University of Honolulu, Honolulu, HI 96816; Jean-François M. Focant, PhD, University of Liège, Liège 4000, BELGIUM; Katelynn A. Perrault, PhD\*, Chaminade University of Honolulu, Honolulu, HI 96816

**Learning Overview:** After attending this presentation, attendees will understand the relation of the Volatile Organic Compound (VOC) profile emitted from decomposing remains in a tropical climate to those in other climate regions.

**Impact on the Forensic Science Community:** This presentation will benefit the forensic science community by providing information about the reproducibility of decomposition odor for a new and common climate region. This is crucial to the courtroom defense of applications that rely on the detection of decomposition odor for search and recovery.

Cadaver detection canines perform an important role in the search and recovery of human remains in missing persons cases, homicides, and mass disasters. In recent years, significant advances have been made in the analytical tools used to profile the VOCs constituting the target odors for cadaver detection canines. It is well known that these canines are highly efficacious, especially in scenarios that involve a large search area or challenging terrain. They are also capable of locating human remains in a variety of weather conditions and climates across the world. However, decomposition odor research has only been performed in select locations in the past, and, therefore, more detailed information is required to understand what is consistent to odor evolution regardless of the local environment. The purpose of this study was to perform the first decomposition odor study in a Tropical region, specifically the Tropical savannah climate experienced in Honolulu, HI. Honolulu is a contrasting location to areas that have been previously studied due to relatively consistent and warm temperatures year-round, as well as minimal temperature differences throughout the day. Tropical savannah is also the world's second most common climate type (following Hot desert), and these regions experience many climate events, such as tropical storms, that may contribute to a need for forensic search and recovery. Therefore, it is very important to improve our understanding of decomposition odor in these regions. The hypothesis was that a major portion of the VOC profile would be comparable to previous studies performed in other environments.

Three pig (*Sus scrofa domestica*) carcasses were placed on an exposed soil surface and decomposed for two weeks. Every second day, the pig carcasses were sampled for VOCs by covering them with a stainless steel hood and pumping air from above the carcasses onto a sorbent tube. Additional VOC samples were also collected from larval masses at each carcass during the period that they appeared. Sorbent tubes were thermally desorbed and analyzed using comprehensive Two-Dimensional Gas Chromatography/Quadrupole Mass Spectrometry/Flame Ionization Detection (GC×GC/qMS/FID). Approximately 30 compounds were tentatively identified from the decomposing remains, the majority of which have been reported in previous literature. This demonstrates consistency in the decomposition VOC profile in a new geographical region. Temporal trends were tracked for several compounds prominent in literature, such as alcohols, aldehydes, ester, ketones, and sulfur-containing compounds, and longitudinal trends were confirmed to present similarly to past studies. In addition, larval mass samples were found to contain rich VOC profiles, with high abundance of compounds known to be present in the decomposition VOC profile (e.g., 2-butanone, dimethyl disulfide, and 1-butanol). Larval mass data may assist in understanding the metabolic contribution of larval masses to the overall decomposition odor profile.

This research is significant because it is the first study to establish the decomposition odor profile in a Tropical savannah. This supports the development of a core VOC profile that will help provide a chemical foundation for the highly efficacious use of scent detection canines. Such information is essential to the courtroom defensibility of biological detectors, such as canines, as well as the development of chemical sensors that may help in the future to assist in large-scale search and recovery efforts where resources may be limited.

#### Forensic Taphonomy, Scent Detection Canines, Volatile Organic Compounds

### H97 Comparing Resolution of Mixtures by DNA Sequencing Using the Illumina® MiSeq® FGx System

Michael Moretto, MS\*, Wolverine Lake, MI 48390; Robin W. Cotton, PhD, Boston University School of Medicine, Boston, MA 02118

**Learning Overview:** The goal of this presentation is to show that the MiSeq® FGx system is concordant with current Capillary Electrophoresis (CE)-based analysis and provides additional sequencing data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing a possible alternative to CE-based Short Tandem Repeat (STR) analysis that can provide additional sequencing information to mixture samples.

The use of STRs for genotyping forensic case samples has long been an effective tool for human identification. However, deconvolution of forensic STR mixture samples can be difficult and being able to obtain additional information to aid in this process will be important. Allele overlap and stutter during PCR can cause drop-out of the minor contributor's alleles and result in incorrect allele calling. The GlobalFiler® Polymerase Chain Reaction (PCR) Amplification kit targets 21 autosomal STRs, amelogenin, and 2 Y-indels. In comparison, the ForenSeq™ Signature Prep Kit on the MiSeq® FGx targets an additional 6 autosomal STRs, 24 Y-chromosomal Short Tandem Repeats (Y-STRs), 7 X-chromosomal Short Tandem Repeats (X-STRs), and 94 Single Nucleotide Polymorphisms (SNPs), and it also provides the DNA sequence of those targets. The additional loci as well as separation of alleles by sequence should provide much more information for resolving mixture samples. The contributor ratio accuracy and MiSeq® FGx performance is analyzed here and compared to current CE-based methods. The DNA sequencing process used here requires three PCR amplification steps overall. Additionally, there are many wash steps and transfer steps involved in the purification and normalization of the libraries prior to sequencing. Together, the number of steps may increase profile variability.

A side-by-side assessment of the ForenSeq™ Signature Prep Kit with the MiSeq® FGx system and the GlobalFiler® PCR Amplification Kit using equivalent samples containing two-person DNA mixtures at three different mixture ratios is presented. The ratio of two contributors was calculated at three mixture ratios (1:1, 1:4, and 1:9) to use as a means of comparison. Each mixture was analyzed in quadruplicate twice on two separate amplifications. The mean contributor ratios calculated on the MiSeq® FGx were 1.799, 7.595, and 13.524 for the 1:1, 1:4, and 1:9 mixtures, respectively. This was not significantly different from the CE mean contributor ratios of 1.818, 7.722, and 14.827, respectively. There was a total of 68 minor contributor alleles (9.09% of the total possible alleles) that were lost on the MiSeq® FGx™ and only 20 on the CE (3.38% of the total possible alleles). Most of those alleles lost on the MiSeq® FGx (61 or 8.15%) and CE (18 or 3.03%) were from the 1:9 mixtures. This difference may seem large, but there were an additional five minor contributor alleles, per replicate, that could be identified by sequence. A high preferential amplification of the D22S1045 was seen, which resulted in the loss of that locus for contributor ratio calculations.

The SNP loci were also analyzed here to determine if they present a more accurate representation of mixture ratio at lower concentrations, as they are shorter in length and more readily amplified. The contributor ratios for the SNP loci were calculated to be 1.787, 8.726, and 21.077 for 1:1, 1:4, and 1:9, respectively. Only three SNP alleles dropped out, one at 1:4 and two at 1:9; however, the contributor ratio values were significantly higher than STRs calculated on either the CE or sequencing platform. Overall, the data showed that the MiSeq® FGx was concordant with the CE, which should facilitate the introduction of sequence data as an additional tool for use in forensic DNA testing.

#### Next Generation Sequencing, Mixture Interpretation, Contributor Ratio

### H98 Seasonal Differences in Soil Chemistry and Biology Impacted by Long-Term Human Decomposition

Lois S. Taylor, MS\*, University of Tennessee, Knoxville, TN 37996; Allison R. Mason, BS, University of Tennessee, Knoxville, TN, TN 37996-1937; Ernest C. Bernard, PhD, University of Tennessee, Knoxville, TN 37996-4560; Mary C. Davis, MSc, University of Tennessee, Knoxville, TN 37996; Dawnie W. Steadman, PhD, University of Tennessee, Department of Anthropology, Knoxville, TN 37996; Jennifer M. DeBruyn, PhD, University of Tennessee, Knoxville, TN 37996

**Learning Overview:** After attending this presentation, attendees will gain an understanding of patterns in soil chemistry as well as soil microbial and microfaunal community succession resulting from two-year-long human decomposition studies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving understanding of environmental changes that occur during human decomposition in terrestrial environments and how these changes vary seasonally, introducing new indicator organisms, and discussing implications for time-since-death predictions.

Human decomposition creates dynamic biogeochemical hotspots in the soil, resulting in rapid and persistent changes in soil chemistry and biology.<sup>1</sup> Existing studies have largely focused on the period associated with rapid soft tissue loss (i.e., active decay) rather than later time periods; thus, it is not well known to what extent these chemical and biological changes persist. Additionally, little attention has been focused on the impacts on microfaunal members of the soil food web; nematodes in particular are sensitive to environmental disturbances, and they have been proposed as environmental indicators.

The purpose of this study was to perform a long-term, high temporal resolution assessment of changes in soil chemistry in conjunction with microbial and nematode succession beneath decomposing human bodies in order to identify patterns associated with decomposition progression. Six donated human subjects were decomposed on soil at the University of Tennessee Anthropology Research Facility, three in the spring, and three in the winter. Soil sampling consisted of 1cm interfaces and 0–15cm cores from beneath donors. Soil temperature, pH, Electrical Conductivity (EC), Dissolved Oxygen (DO), respiration (CO<sub>2</sub>), NH<sub>4</sub><sup>+</sup>-N, NO<sub>3</sub><sup>-</sup>-N, and extracellular enzymes were measured. Nematodes were counted and identified to family and genus level by microscopy.

In both seasonal studies, the introduction of decomposition fluids into the soil was immediately accompanied by lowered pH and elevated NH<sub>4</sub><sup>+</sup>-N and CO<sub>2</sub>. Interface (0–1cm) samples exhibited the greatest changes, the timing and magnitude of which varied by season. The spring study was marked by the onset of active decay (day 8), accompanied by an immediate increase in EC (mean 969µS cm<sup>-1</sup>). DO decreased 61% by day 12 during late active decay, concomitant with a peak in NH<sub>4</sub><sup>+</sup>-N (mean 6,905µg gdw<sup>-1</sup>). Respiration peaked on day 27 during early advanced decay (mean 10,134ppm CO<sub>2</sub> day<sup>-1</sup>). Unexpectedly, nematode abundances remained suppressed until day 58, after which a bloom of bacterial-feeding nematodes was observed (Rhabditidae). Nematode abundances peaked on day 86 at 29,708 nematodes per 100gdw soil. By the end of the one-year study, the disturbance was still evident: no metrics except DO had returned to control values, and nematode community composition remained shifted toward a predominance of bacterial-feeding taxa.

In contrast, donors in the winter study were marked by a lack of bloating and insect activity due to cooler temperatures. By day 55, EC, CO<sub>2</sub>, and NH<sub>4</sub><sup>+</sup> peaked at mean values of 926.8µS cm<sup>-1</sup>, 9,263ppm day<sup>-1</sup>, and 2,811µg gdw<sup>-1</sup>, respectively. DO decreased by only 29% by day 75, concomitant with a peak in nematode abundance of 116,248 nematodes per 100gdw soil. Nematode abundances began to increase immediately upon deposition of decomposition products into the soil, and communities were shifted toward both opportunistic bacterial and fungal feeders (Rhabditidae, *Aphelenchoides*).

Taken together, these results show that soils continued to be impacted by decomposition products after a year, and that soil microfauna provide valuable supporting information about the decomposition environment.

*Funding for this project was provided by the National Institute of Justice Graduate Research Fellowship in Science, Technology, Engineering and Mathematics (GRF-STEM) to Law School Transparency (LST) (2017-R2-CX-0008).*

### H99 Jay Dix Memorial Bonus Day

*Joseph A. Prahlow, MD\**, Western Michigan University School of Medicine, Kalamazoo, MI 49007; *James R. Gill, MD\**, Office of the Chief Medical Examiner, Farmington, CT 06032; *Andrew M. Baker, MD\**, Hennepin County Medical Examiner's Office, Minneapolis, MN 55415; *Michael A. Graham, MD\**, Saint Louis University School of Medicine, Saint Louis, MO 63104

**Learning Overview:** After attending this presentation, attendees can expect to understand how and why deaths related to the topics specified below occur. Attendees will learn a systematic approach to the evaluation of such deaths that can easily be implemented in their daily practices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a comprehensive review of what causes and contributes to deaths related to the topics specified below. Attendees will be able to systematically evaluate deaths they encounter in their daily practices in which the topics specified below may have played a role.

A proper medicolegal death investigation is a multidisciplinary process that often involves non-medical personnel as well as medical professionals. This annual lecture series provides non-forensic pathologist forensic scientists a basic review of selected topics in forensic pathology in order to increase familiarity and understanding and enhance inter-discipline communication.

This year's lecturers will discuss the medicolegal investigation of deaths related to environmental conditions, deaths due to asphyxia, deaths due to firearm injuries, deaths involving blunt and sharp force trauma, and deaths temporally associated with law enforcement custody.

Electricity is a ubiquitous entity in our lives. Some of it is intentionally generated to provide power, and some of it originates as a force of nature (lightning). Interaction between humans and electricity is common and typically has no untoward effects. However, under some conditions this interaction may result in morbidity and/or mortality. Multiple causes, mechanisms, and contributory factors play a role in injury and deaths involving electricity. Understanding and evaluating injuries and deaths in which electricity may have played a role requires basic knowledge of electricity and how it affects various biological vital functions. Recognition of injuries and deaths caused by electricity is particularly important because of implications regarding the safety of others. This lecture will provide a comprehensive review of these issues.

Blunt and sharp force injuries encompass the major categories of mechanical injury. Blunt force injuries are among the most common injuries sustained by persons. These injuries include abrasions (scrapes), contusions (bruises), and lacerations (tears). Blunt force is also a substantial component of chop wounds, injuries caused by relatively heavy-edged objects, such as a machete or axe. Sharp force injuries result from the mechanical division of tissues by edged or pointed objects. Sharp force injuries include stab wounds, cuts (incised wounds), and chop wounds. Multiple factors and mechanisms are involved in injuries and deaths involving blunt and sharp forces. Understanding and evaluating injuries and deaths in which these forces may have played a role requires basic knowledge of these injuries and how to distinguish them from other types of trauma, recognition of patterned injuries, and recognition of injury patterns. This lecture will provide a comprehensive review of these issues.

Human life requires the uptake and utilization of oxygen along with the release of metabolic waste. Failure of these processes leads to asphyxia. Proper evaluation of asphyxial deaths requires knowledge of the entities that cause asphyxia, pathophysiologic mechanisms, asphyxia death scenarios, and factors that contribute to death. This lecture provides comprehensive discussion of the investigation of deaths that may involve asphyxia.

Firearm fatalities are a major cause of non-accidental morbidity and mortality in the United States. Multiple factors and mechanisms are involved in producing firearm injuries. Understanding and evaluating firearm injuries requires a basic understanding of how these injuries are produced and how to distinguish them from other types of trauma. This lecture will provide a comprehensive review of these issues.

There are multiple causes, mechanisms, and contributory factors that can play a role in deaths that are temporally related to law enforcement apprehension and custody. The apprehension and custody process can be divided into several stages—pre-apprehension, apprehension, and incarceration. Particular diseases and injuries tend to occur and/or become manifest during each of these stages. This lecture will systematically review what diseases and injuries cause/contribute to death in the apprehension and custody process, how they affect physiology and anatomy, when they are typically operative and how they are manifested. This lecture will review the conceptual and practical aspects of understanding and investigating deaths temporally related to apprehension and custody.

### Medicolegal, Death Investigation, Forensic Pathology

### H100 Volatile Substances Concentrations in Costal Cartilage in Relation to Blood and Urine

*Marcin Tomsia, Olkusz, woj.malopolskie 32-300, POLAND; Joanna Nowicka, Katowice, Silesia 40-752, POLAND; Elzbieta Chelmecka, Slaski Uniwersytet Medyczny w Katowicach, Sosnowiec, POLAND; Joanna Wójcik, Czestochowa, Slaskie 42-200, POLAND; Magdalena Was, Kielce, Swietokrzyskie 25-601, POLAND; Kornelia M. Drozdziok, Katowice, Silesia, POLAND; Rafal Skowronek, Department of Forensic Medicine in Katowice, Katowice, Upper Silesia 40-752, POLAND; Gulnaz T. Javan, PhD\*, Alabama State University, Montgomery, AL 36104*

**Learning Overview:** After attending this presentation, attendees will have learned to use costal cartilage to detect volatile substances, such as ethyl alcohol, isopropyl alcohol, and acetone, when soft tissue is not available for analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a method to detect volatile substances with non-soft tissues.

In Poland, there are rare cases of poisoning with non-consumable alcohol. In the material collected during autopsies in cases of poisoning with non-consumable alcohols (i.e., other than ethanol), isopropanol and acetone can be detected. In some forensic autopsies, blood is not available; hence, other matrices are sampled for toxicologic analysis. The goals of the present study were to: (1) examine whether volatile substances, such as ethyl alcohol, isopropyl alcohol, and acetone, can be detected in costal cartilage; and (2) investigate whether analyses of different forms of costal cartilage can give useful information about volatile substance concentrations in the peripheral blood. Presented here are the results of a comparative study of volatile substances concentration in postmortem Costal Cartilage (CC), blood, and urine samples collected during medicolegal autopsies. Examination of this type of material may be useful in cases: (1) when soft tissues are not available or in a state of advanced cadaver decomposition (i.e., as an alternative material); and (2) when the remains are almost completely skeletonized (as the main material).

Ethanol concentrations were determined in samples of Unground Costal Cartilage (UCC), Ground Costal Cartilage (GCC), Femoral Venous Blood (FVB), and Urine (U). UCC was obtained by scalpel fragmentation, whereas GCC was obtained by grinding in 3min preincubation, one grinding cycle for 2min, 12 Cycles Per Second (CPS). The studied group included CCs taken from cadavers in which the presence of ethyl alcohol in blood and urine was demonstrated. The control group consisted of CCs taken from cadavers with no ethyl alcohol detected. The samples were analyzed in duplicate by Gas Chromatography (GC) with a Flame Ionization Detector (FID) using the headspace analysis. The chromatographic separation was performed with a column. T-butyl alcohol was used as an internal standard. Results were obtained for 12 samples.

Distribution of variables was evaluated by the Shapiro-Wilk tests and quantile-quantile plot. The interval data was expressed as a mean value  $\pm$  standard deviation in the case of normal distribution or as a median (lower–upper quartiles; Me (Q1;Q3)) in the case of skewed or non-normal data distribution. Statistical significance was set at a p value below 0.05, and all tests were two tailed. Statistical analysis was performed using a statistics program.

There was a relationship between the method analyzing the amount of ethanol in the urine and the UCC and the GCC methods and the concentration of alcohol in the blood. In all cases, there was a strong positive correlation between the analyzed method and the concentration of ethyl alcohol in the blood (U:  $r=0.899$ ,  $p<0.001$ ; UCC:  $r=0.809$ ,  $p<0.01$ , and GCC:  $r=0.749$ ,  $p<0.01$ , respectively) In addition, there was a relationship between the method analyzing the amount of isopropanol in the urine and the UCC and the GCC methods and the concentration of alcohol in the blood. In all cases, there was a strong positive correlation between analyzed methods and the concentration of alcohol in the blood (U:  $r=0.979$ ,  $p<0.001$ ; UCC:  $r=0.866$ ,  $p<0.001$ ; GCC:  $r=0.942$ ,  $p<0.001$ ). Regarding a relationship between the analyzing acetone concentration methods, the statistical significance was observed only in the case of urine concentration ( $r=0.960$ ,  $p<0.001$ )

Overall, this study showed that higher volatile substance concentrations were determined in ground samples. This study is believed to be novel and the first to demonstrate the possibility of volatile substances detection in the postmortem costal cartilage.

#### Costal Cartilage, Volatile Substances, Gas Chromatography

### H101 The Relationship of Chronic Psychostimulant Use and Cardiovascular Disease

*Elly Riser, MD, University of Vermont, Burlington, VT 05401; Chamil Ariyaratne, MD, MBBS, Base Hospital, Balangoda, SRI LANKA; Irfan Chaudhry, MD\*, King County Medical Examiner's Office, Seattle, WA 98104; Caleb Banta-Green, PhD, University of Washington, Seattle, WA 98105; Richard C. Harruff, MD, PhD, King County Medical Examiner's Office, Seattle, WA 98104*

---

**Learning Overview:** The goal of this presentation is to assess the relationship between chronic psychostimulant abuse and the development of cardiovascular pathology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by using a retrospective and prospective study to compare cardiovascular disease development in psychostimulant abusers. Cardiac parameters, histological changes, and user demographics are discussed.

There is considerable literature on the contribution of chronic stimulant abuse in causing or contributing to the development of cardiovascular disease. While it seems clear that cocaine and methamphetamine adversely affect the heart and blood vessels, the explanation of how chronic use contributes to cardiovascular disease remains elusive. The challenge in defining their role is because the same diseases are common natural diseases, and it is difficult to assess whether stimulants directly contribute to the development of cardiovascular disease, accelerate it, or are merely coincidental. The present study addresses these questions.

**Methods and Materials:** Using autopsy material from the King County Medical Examiner's Office (KCMEO) in Seattle, WA, this presentation uses two different approaches to assess the role of stimulant abuse in developing cardiovascular disease. The first is a retrospective review of specific cardiac parameters: heart weight and coronary atherosclerosis in decedents of drug overdose involving cocaine, methamphetamine, or heroin. These parameters were compared between two groups: those dying of overdoses including stimulants, with or without heroin, and those dying of overdoses including heroin, without stimulants.

The second approach is a prospective study examining additional cardiac parameters: heart weight, left ventricular wall thickness, coronary atherosclerosis, and cardiac fiber diameter measured histomorphometrically. These parameters were compared between two groups: decedents between the ages of 19 and 39 years dying of causes other than drug overdose who were positive for either cocaine or methamphetamine and decedents in the same age range dying of causes other than overdose who were negative for cocaine or methamphetamine.

**Results:** In the retrospective study, there were 249 decedents positive for methamphetamine or cocaine, with or without heroin. In the stimulant-negative comparison group, there were 193 decedents positive for heroin but negative for cocaine or methamphetamine. The average age was 44 years in the former group and 39 years in the latter group. In the stimulant-positive group, mean heart weight was 554 grams, compared with 425 grams in the stimulant-negative group. Coronary atherosclerosis was present in 37% of the stimulant positive group compared with 26% in the stimulant-negative group.

In the prospective study, there were 28 decedents positive for stimulants and 32 decedents negative for stimulants. The stimulant-positive group had no differences in heart weight and left ventricular thickness, compared to the stimulant-negative group. In the stimulant-positive group, cardiac fiber diameter was statistically greater than that of the stimulant-negative group. In the stimulant-positive group, 32% had coronary atherosclerosis, compared to 6% in the stimulant-negative group.

**Discussion:** The present study uses two novel approaches to further understand the contribution of stimulant abuse toward developing cardiovascular disease. One approach uses a comparison group of overdoses involving heroin, in which stimulants are absent, and the second uses histomorphometry to assess early or subtle changes in cardiac morphometry. Despite obvious limitations in using postmortem data to assess natural disease progression, the results of the two approaches, taken together, provide evidence that stimulant abuse may accelerate the progression of natural disease, starting in early adulthood, and may represent an independent risk factor acting additively or synergistically with other recognized risk factors in promoting the development of premature cardiovascular disease. Furthermore, cardiovascular disease likely represents an important condition predisposing to death due to acute intoxication involving stimulants.

### H102 Suicide by Acute Substance Intoxication: A Retrospective Analysis of Cases in Cook County, Illinois

*Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Ponni Arunkumar, MD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

**Learning Overview:** After attending this presentation, attendees will have a better knowledge regarding suicides due to drug toxicity and the features that can help discern them from accidental suicides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting relevant information related to suicides by drug toxicity in a large metropolitan area to avoid misclassifying the manner of death.

Acute drug toxicity is one of the leading causes of death in the United States. According to the Centers for Disease Control and Prevention, since 2008, suicide has ranked as the tenth leading cause of death for all ages in the United States. Suicide is a cause of preventable mortality, but its prevention requires complex coordination and cooperation among health care providers, individuals and family members, and treatment services and the community. Medical examiners and coroners contribute to suicide prevention by assessing the manner of death. Accurate classification of the manner of death (natural, accident, suicide, homicide, or undetermined) is critical to public health. Information regarding the manner of death is directly reported into a mortality surveillance system that drives prevention, research, policy, monitoring and evaluation, and allocation of resources.

Fatal drug intoxications are thought to be among the most challenging cases for which to determine the manner of death. The intent of an overdose death can be hard to ascertain because of the lack of specific clues or the presence of potentially equivocal evidence regarding intent to die. These deaths are often classified as accidental or undetermined, leading to a potential underestimation of suicides. As a result of this, there is an inaccurate transmission of data to the public health databases. Possible misclassifications adversely impact suicide mortality surveillance, etiologic understanding, prevention, and hence, clinical/public health policy formation and practice.

In the present study, case files from the electronic database of the Cook County Medical Examiner's Office in Chicago, IL, were retrospectively reviewed over a five-year period from August 2014 to August 2019 for suicides in which the primary cause of death was acute drug and/or alcohol intoxication. The following keywords were searched in the "primary cause of death" field: "alcohol," "combined," "drug," "intoxication," and "toxicity." No limits regarding age, race, and sex were imposed. Only cases in which investigative and toxicologic reports were available were included in the study.

A total of 277 cases of suicides meeting the study criteria were found in the office database. The ages ranged from 15 to 91 years (mean: 46 years). There were 130 males, and 147 females. 235 subjects were Caucasian, 30 were African American, 9 were Asian, and 3 were Others. A full postmortem examination was performed in 236 cases.

There is an increasing trend of deaths related to substance overdose in the United States. A careful evaluation of these deaths is mandatory to identify potential suicides, providing a positive impact on public health surveillance and prevention efforts. This study adds valuable information that can be used to help determine the correct manner of death in cases of fatal drug/alcohol intoxication. The results of this study, including demographic comparisons, investigative evidence and toxicological data, will be presented to the attendees.

---

#### Suicide, Acute Toxicity, Drugs

### H103 Active Duty United States Military Deaths Due to 1,1-Difluoroethane Intoxication

*Sherry Jilinski, MD\**, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; *Alice Briones, DO\**, Principal Deputy Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; *Eric T. Shimomura, PhD*, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; *George F. Jackson, PhD*, Armed Forces Medical Examiner Services, Dover Air Force Base, DE 19902

**Learning Overview:** After attending this presentation, attendees will understand the prevalence of active duty military deaths due to intentional inhalation of difluoroethane and discuss possible preventative measures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing that all forensic autopsies performed should have routine testing for difluoroethane, especially in circumstances suggestive of its use, such as the presence of numerous cans of compressed air on scene.

Huffing, sniffing, or bagging of compressed air is a common method to “get high,” especially in teenagers and young adults, due to ease of access and difficulty in detecting its abuse. Compressed air contains 1,1-difluoroethane, a halogenated hydrocarbon gas; intentional inhalation can result in central nervous depression and cardiotoxicity, including sudden death, which is believed to be due to cardiac arrhythmias. Routine workforce drug screening, including the Department of Defense (DoD) Drug Testing Program, does not currently screen for volatiles such as difluoroethane; thus, abuse can go undetected (although some military services do require a breathalyzer test at the time of urinalysis to detect the presence of ethanol).

A retrospective review of all autopsies performed by the Armed Forces Medical Examiner System (AFMES) from 2010 until 2018 revealed 20 active duty service member deaths that were directly attributed to 1,1-difluoroethane intoxication. Four deaths of civilians (either military dependents or federal employees) due to difluoroethane were also noted but are not discussed further in this abstract. Scene investigation typically revealed numerous cans of compressed air. Autopsy findings were non-specific, and the most common finding was pulmonary edema. Although frostbite on the hands and face has been reported in the literature, this finding was not documented in any case. Histology was performed in about one-third of cases and again showed non-specific findings, with pulmonary edema the most common histology finding. Specimens submitted for toxicology testing (if able to be obtained) included peripheral blood (submitted in gray, purple, and red top blood tests), urine, vitreous fluid, gastric contents, bile, brain, heart, lung, liver, spleen, kidney, and adipose tissue. No special handling or unusual specimens, such as tracheal aspirates, were required for testing. Full postmortem toxicological testing was performed in all cases to include analysis via headspace gas chromatography with a flame ionization detector for volatiles. All positive findings were confirmed on at least two different bodily fluids and/or tissues using headspace gas chromatography/mass spectrometry.

A query of AFMES’ mortality data revealed an additional 12 deaths certified as difluoroethane intoxication by civilian jurisdictions over the same time period. Autopsy findings, other than cause and manner of death, and toxicology testing results were not available for the 12 cases performed by civilian jurisdictions. Demographics of all 32 decedents included predominantly men (91%), with an age range of 20 to 44 year (average age: 30 years). The decedents served in all branches of the United States Armed Forces and were predominantly in the enlisted ranks, although two officer deaths were noted.

Several years ago when difluoroethane deaths became more recognized in the United States, bitterants were added to the cans of compressed air, with the goal of reducing abuse. This office recommended that all cans of compressed air available at military shopping facilities have the bitterant. However, this data shows that deaths due to difluoroethane continue to be detected. Clearly, inhalant abuse is significantly underrecognized in the public and in active duty service members. This study identified 32 deaths of active duty service members over the past ten years that possibly could have been prevented if antemortem abuse was detected.

#### **Huffing, Difluoroethane, Military**

### H104 Why the “Kontroversy”? Is Kratom a Killer? The Emergence of Mitragynine in Drug-Associated Deaths in West Tennessee

Maxwell O. Rollins, MD\*, West Tennessee Regional Forensic Center, Memphis, TN 38105; Erica Curry, MD, Collierville, TN 38017

**Learning Overview:** After attending this presentation, attendees will have: (1) become familiar with the mechanism of action, adverse effects, and the legal status of kratom; (2) examined the epidemiology of kratom users; and (3) studied the relationship between mitragynine and other drugs on death certificates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness that kratom, the herbal medicinal plant native to Southeast Asia, with the major alkaloid mitragynine, continues to be increasingly implicated in drug toxicity-related deaths, either in multidrug toxicity and, rarely, as a sole cause of toxicity. Understanding the patterns of kratom use and associated drugs may be of use for the formation of public policy regarding this drug on the state and federal levels.

*Mitragyna speciosa* is a tropical evergreen tree that is a member of the coffee family, and is native to Southeast Asia, including Thailand, Malaysia, and Indonesia. The plant is commonly called “kratom” in Thailand. The leaves of the plant have been used in traditional herbal medicine for decades by being chewed, smoked, or brewed into a tea. The leaves contain over 25 various natural alkaloids, including the main indole alkaloid mitragynine, which reportedly accounts for approximately 66% of the alkaloid content. Mitragynine is an agonist of the  $\mu$ -,  $\kappa$ -, and  $\delta$ -opioid receptors; however, it is unique in that it has stimulatory effects at low doses and behaves as a sedative at higher concentrations. The controversial kratom has been shown to have addictive properties, and withdrawal symptoms have been reported anecdotally and in literature. The Drug Enforcement Administration (DEA) briefly added kratom to its list of Schedule I drugs in August 2016, but reversed its decision in October 2016 due to a large public outcry and currently the DEA classifies kratom as a “Drug and Chemical of Concern.”

All autopsy records and toxicology records (from the National Medical Services [NMS] laboratory) occurring in the jurisdiction of the West Tennessee Regional Forensic Center from 2015–2019 were reviewed for mitragynine. Mitragynine began to emerge at the West Tennessee Regional Forensic Center in 2016, with three positive cases. No cases were detected in 2017, and seven cases were detected in 2018. Three cases have occurred in 2019 thus far.

Of the 13 deaths that had mitragynine detected on postmortem toxicology, 11/13 (85%) were male, 13/13 (100%) were White, and the median age at the time of death was 32 years (range 22–54). In 12/13 (92%) of these deaths, mitragynine was listed on the death certificate in combination with other drugs. One death could not determine the degree mitragynine contributed, and was therefore not listed on the death certificate. In one death, mitragynine was listed as the sole cause of death in part 1, along with coronary artery disease and chronic alcoholism as contributing conditions.

A quantifiable mitragynine level was available in 10/13 (77%) of cases (NMS laboratory did not quantify mitragynine until 2017; thus, in the remaining three cases, the level was qualitative only). Of quantified levels, the median mitragynine level was 73.5ng/mL (range 25–680ng/mL). When multidrug toxicity was involved, drugs on the death certificate included fentanyl (6/12, 50%), alprazolam (6/12, 50%), ethanol (4/12, 33%), morphine (4/12, 33%), heroin (3/12, 25%), and 7-amino clonazepam (3/12, 25%).

This study demonstrates that mitragynine emerged in West Tennessee around 2016 and has continued to increasingly appear in deaths in West Tennessee, which is in concordance with NMS laboratory data. Interestingly, 2017 had no deaths with positive postmortem results for mitragynine. 2018 had the majority of the mitragynine-associated deaths, and already three deaths have been seen in association with it in 2019 (as of July 2019). A majority of the affected decedents were White males with a median age of 32 years. When mitragynine was seen in conjunction with multidrug toxicity, other opioids and central nervous system depressants were the most commonly seen, including fentanyl and alprazolam. Based on the high numbers of mitragynine in conjunction with fentanyl, perhaps the mitragynine powder is used as a bulking agent for fentanyl. Rarely, mitragynine is seen as a sole cause of death. Mitragynine continues to be detected on postmortem toxicology across the nation, and this study is presented to help further educate and help form future policy regarding kratom and to also prevent further deaths.

#### Kratom, *Mitragyna speciosa*, Toxicology

## H105 Pediatric Poisonings: An Epidemiological Study

Mete K. Gulmen, PhD, MD\*, Çukurova University, Adana 01330, TURKEY; Kenan Kaya, Çukurova University, Adana, Sarıcam 01330, TURKEY; Ozgenur K. Tok, MD, Çukurova University School of Medicine, Balçalı 01330, TURKEY

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the importance of childhood poisonings and of designing a detailed report to alert and inform the authorities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the clinical forensic medicine applications, examinations, and reporting of poisonings in a standard base so all medical doctors may improve their services with better understanding.

Poisoning is one of the most common medical emergencies in childhood. Poisoning is defined as cells being injured or destroyed by inhalation, ingestion, injection, or absorption of a toxic substance.<sup>1</sup> The prevalence and type of poisoning varies worldwide depending on the particular topography/environment, type of agricultural activities, amount of industrial development, cultural practices, and local beliefs/customs. The case fatality rate is largely determined by the degree of access to quality health care treatment.<sup>2</sup> Although pediatric poisonings are considered emergencies, more than 85% of cases need no medical intervention because the ingested material is typically not toxic or the amount swallowed is not clinically significant<sup>1</sup>.

Each year in the United States, more than one million poison exposures among children younger than six years of age are reported to the American Association of Poison Control Centers (AAPCC).<sup>1,3</sup> According to the World Health Organization (WHO), in 2004, acute poisoning caused more than 45,000 deaths in children and teenagers.<sup>3</sup> The most common agents implicated in childhood poisonings in developed nations were over-the-counter preparations (e.g., paracetamol, cough/cold remedies, vitamins and iron tablets, antihistamines, and anti-inflammatory drugs); prescription medications (e.g., antidepressants, narcotics, analgesics); recreational drugs; household products (e.g., bleach, disinfectants, detergents); pesticides (e.g., insecticides, rodenticides, herbicides); poisonous plants, and animal or insect bites.<sup>1</sup>

This is a retrospective study. Included in this study are all poisoned children admitted to the Forensic Medicine Council of Adana/Turkey in 2018. Data were collected from the medical records of children  $\leq 18$  years of age. In sum, acute poisoning was reported in 108 children. Of the total acute poisoning cases, 46.2% were males and 53.7% were females. Of the 108 cases, the youngest age was eight months and the average age was 78.4 months. Pharmaceutical agents were identified in 57.4% of cases. Analgesics were the most frequently ingested drugs (23.1%). Therapeutic drugs were most common cause at all ages. The manner of death in most of the drug intoxication cases in Turkey is suicide in adults; however, it is mostly accidental in childhood cases.<sup>4</sup> In the current study, accidental drug poisonings comprised 64.8% of total poisoning cases, while suicides accounted for 35.1%. Non-pharmaceutical agents were identified in 46 patients (42.5%), 20.3% of which were food poisoning. Other intoxications (24 cases; 22.2%) ordered by frequency were with mushrooms (9.2%), organophosphates (5.5%), carbon monoxide (4.6%), and others (2.7%).

Acute poisoning is considered as one of the most common medical emergencies in children.<sup>1,3</sup> Accidental poisonings are still highly common in most countries, despite the improvement of preventive measures, which consist of proper packaging of medicines and household products, doubled by raising awareness of the toxic items that should be kept out of children's reach.<sup>5</sup> Parental education about the prevention of childhood poisoning at home remains a major issue, especially with regard to keeping everyday medications and household products out of the children's reach. The use of child-resistant containers for medications or household products and the use of locked cabinets would help in prevention efforts.<sup>6</sup>

This study provides significant demographic data that can assist in alerting clinical colleagues to take further precautions. Therapeutic drug intoxications are one of the major serious childhood causes of admission to emergency services; patients typically recover much better with an appropriate treatment and follow-up. Forensic clinical examinations are important in daily practice as they can provide detailed reports informing clinicians—as well as emergency service personnel and Intensive Care Unit (ICU) caretakers—about childhood poisoning epidemiologic factors and risks.

### H106 An Opioid Analysis in “Natural” Manner Scene Inspection Cases

Mary G. Ripple, MD\*, Baltimore, MD 21223; David R. Fowler, MD, Office of the Chief Medical Examiner, Baltimore, MD 21223; Dawn Zulauf, Office of the Chief Medical Examiner, Baltimore, MD 21201; Rebecca Phipps, PhD, State of Maryland, Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to report a study investigating the increase in drug intoxication deaths in the older population and the results of performing drug analysis on natural manner scene inspection-only cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the need for thorough scene inspections in supposed natural manner cases.

At the State of Maryland Office of the Chief Medical Examiner (OCME), the majority of cases that fall under Medical Examiner (ME) jurisdiction are autopsied, but there can be a scene inspection by investigators with the ME completing the Death Certificate (DC). Typical scene inspections are cases  $\geq 55$  years of age with significant medical history. On non-natural scene inspections, two tubes of blood are drawn at the scene and sent to the OCME for toxicologic analysis. The analysis is primarily for ethanol but can be for other drugs as needed. Blood is not drawn on a natural manner scene inspection case. Since 2010 in the State of Maryland, there has been a five-fold increase in drug intoxication deaths for people over the age of 55 years. In 30%–33% of cases where heroin and fentanyl were positive, the decedents were 50 to 70 years old. Since many individuals  $\geq 55$  years of age fall under scene inspection criteria and since the age of these autopsied opioid deaths was increasing, this study investigated whether there were missing opioid deaths in this age group.

During a five-month period (163 days) from 4/8/2018 to 1/18/2019, the OCME performed a study looking for opioids/fentanyl in natural manner scene inspections in two of their highest volume counties, Baltimore County (BC) and Prince Georges County (PGC). Investigators drew blood and blood specimens that were screened for volatiles, morphine, and fentanyl. Volatiles screening for ethanol, methanol, acetone, and isopropanol was performed by headspace gas chromatography. Morphine screening was performed by Enzyme-Linked Immuno-Sorbent Assay (ELISA) with a cutoff concentration of 10ng/mL. Positive morphine ELISA results were confirmed by gas chromatography/mass spectrometry with a 10ng/mL reporting limit. Fentanyl screening was performed by gas chromatography/mass spectrometry with a 1.0ng/mL reporting limit.

During the study period, there were 400 total scene inspection cases in the state. There were 39 total scene inspections for BC and 87 for PGC. Of those, there were 13 non-natural cases in BC and 8 non-natural cases in PGC. All were suicides. This left 26 total “natural” scene inspections in BC and 79 in PGC. In 47 (45%) of these 105 cases, no toxicology sample was obtained for various reasons.

A total of 58 cases had toxicology drawn and only one (1.7%) tested positive for opioids. The age range was 40 to 93 years, mean age 68.67 years; 31% were female and 69% were male; 57% were African American, 31% were Caucasian, 8% were Hispanic, 2% were Asian, and 2% were Other. The positive case was a 59-year-old African American male from PGC with no Maryland physician, a medical history of hypertension, heart disease status/post (s/p) Coronary Artery Bypass Graft (CABG) and aortic valve replacement, Cerebrovascular Accident (CVA), and Gastroesophageal Reflux Disease (GERD) found unresponsive at home. There was no history of drug use reported and no illegal drugs or drug paraphernalia were present at the residence. Toxicologic analysis of heart blood showed fentanyl (0.010mg/L), free morphine (56ng/mL), and unquantified despropionyl fentanyl. His Death Certificate (DC) had been signed as Heart Disease with Aortic Valve Replacement, Natural. The DC was amended, adding the drug use and changing the manner to Undetermined.

In conclusion, a thorough scene inspection is necessary to make the appropriate decision to bring a case in for autopsy. Only one case in this study was positive for opioids. In a five-month period in these two high-volume counties, one opioid overdose case that would normally have been left out as a scene inspection and signed out as natural would have been missed. The study group is too small to be statistically relevant; however, it appears that if thorough scene investigation protocols are followed, the chance of missing an opioid death in an older individual with health history is small. The investigators are only as good as the information provided to them and their personal evaluation of the scene. In the future, the only way to catch this type of case would be to change the scene inspection protocol to include drug testing on all suspected natural deaths or to bring these cases in for autopsy. The physical and financial burden placed on investigators, toxicology staff, and medical examiners appears to outweigh the benefit of catching such a small percentage of cases.

#### Fentanyl, Opioid, Inspection

## H107 Fatal Excipient Lung Disease: An Autopsy Case Series

*Daniel Shapiro, MD, Mineola, NY 11501; Amy V. Rapkiewicz, MD\*, New York University Langone Health, Mineola, NY 11501; Mark J. Shuman, MD, Miami-Dade County, Miami, FL 33136*

**Learning Overview:** The goal of this presentation is to delineate the spectrum of clinical presentations and autopsy findings encountered in patients with fatal excipient lung disease and the need for careful scrutiny of deaths in patients receiving prescribed opioids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a non-specific spectrum of gross, histologic, and circumstantial findings that are associated with excipient lung disease, further decreasing the misclassification and underreporting of this entity.

**Introduction:** Excipients are described as filler or binder materials found in oral tablets or pharmaceutical substances. These materials are inactive, inert, insoluble, and added to pharmaceutical compounds to enhance the lubrication effect, form, absorption, solubility, and/or shape of the tablet. Some excipients found in oral tablets include talc (magnesium silicate), magnesium stearate, fumed silica, microcrystalline cellulose, crospovidone (a form of Polyvinylpyrrolidone [PVP]), and starch. Excipients and adulterants similar to those listed may be found in illicit drugs, such as heroin formulations representing typical contaminants or dilutants.

When pharmaceutical-grade tablets are crushed and injected intravenously, the excipient may induce a foreign body angio-granulomatous reaction within the lung, known as “excipient lung disease.” This foreign body granulomatous reaction is typically histopathologically similar to the described reactions in illicit intravenous drug user injection. Clinically, the patient can present with a toxidrome, as well as acute, subacute, or chronic signs and symptoms, such as sudden or unexpected death, pain, dyspnea, fever, pulmonary fibrosis, acute lung injury, thromboembolism, pulmonary hypertension, and/or non-specific centrilobular nodularity on imaging. As this medication may be prescribed to the patient for a legitimate medical reason or diagnosis, in the setting of positive detection by toxicologic studies, the pulmonary findings can be overlooked or attributed to another disease process and, therefore, left unchecked, resulting in respiratory failure. Identification of this pathologic process at autopsy is usually not difficult; however, attributing the disease to excipients and the correlation with the toxicology and circumstances can make the cause of death determination challenging. Furthermore, lack of recognition by clinicians and radiologists will leave many cases of excipient lung disease underreported and, therefore, misclassified as frequently the injection of the crushed tablets is clandestine. Reported herein is the autopsy findings in three cases of excipient lung disease in patients with complex medical histories and a range of clinical presentations.

**Methods:** Three cases from the Miami-Dade Medical Examiner and Las Vegas Clark County Coroner were identified during the period of 2015–2018. Autopsy reports and case files were reviewed, and pertinent gross and histologic findings were tabulated.

**Results:** All toxicology levels were either within therapeutic range and/or not considered fatal.

	Age; Sex	Medical Conditions	Known Intravenous Drug Use	Clinical Diagnostic Suspicion	Polarizable Foreign Material in Lungs	Postmortem Toxicology	Cause of Death
1	22; F	Sickle Cell Anemia, Depression, Opioid Dependence	No	None	Large Quantity	Oxycodone	Excipient Lung Disease
2	28 F	Asthma, Substance Abuse, Endocarditis, Arm Deep Vein Thrombosis	Yes	Mycobacterial Infection	Large quantity With Granulomas	Oxycodone, Quetiapine, and Venlafaxine	Excipient Lung Disease
3	44; F	Bipolar Disorder, Asthma, Obesity, Crohn’s and History of Hodgkin Lymphoma	No	Atypical Mycobacterial Infection	Large Quantity With Granulomas And Fibrosis	Fentanyl, Codeine, and Promethazine	Excipient Lung Disease

**Conclusion:** Excipient lung disease can be a difficult clinical and radiologic diagnosis due to the non-specific diagnostic findings and the range of clinical presentations along with potentially complex competing diagnoses. All three patients were prescribed opiates for underlying medical conditions. Both typical and atypical mycobacterial infection were considered in two of the three cases as the probable cause of the underlying lung disease. The cases described herein further delineate the potential spectrum of clinical presentations and autopsy findings encountered in patients with fatal excipient lung disease and the need for careful scrutiny of deaths in patients receiving prescribed opioids.

### H108 Loperamide Abuse: A Rising Public Health Concern?

Ian J. Puffenberger, MD\*, Denver, CO 80238; Meredith A. Frank, MD, Office of the Medical Examiner, Denver, CO 80204-4916; James Louis Caruso, MD, Office of the Medical Examiner, Denver, CO 80204

**Learning Overview:** After attending this presentation, attendees will better understand the pharmacology and toxicology of loperamide and its rising popularity as an opioid drug of abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a case report of a young woman who died of loperamide toxicity and by allowing for increased recognition of this potential drug of abuse that is readily available over the counter.

**Introduction:** Loperamide is a well-known, cheap, anti-diarrheal medication with  $\mu$ -opioid agonist activity that has been available over the counter in the United States since 1988.<sup>1</sup> Loperamide achieves an anti-diarrheal effect through binding opioid receptors in the wall of the bowel and inhibiting the release of chemical mediators, such as prostaglandins and acetylcholine, which leads to a reduction in peristalsis activity.<sup>2</sup> In addition, loperamide is thought to block calcium channels, which also contributes to a decrease in gastrointestinal motility.<sup>2</sup> This medication was originally thought to have little misuse potential for several reasons. These reasons include poor oral bioavailability, rapid hepatic first pass metabolism by the cytochrome P450 complex, and p-glycoprotein mediated efflux out of the central nervous system.<sup>3</sup> However, an opioid toxidrome, including euphoria, has been reported when taking large doses of up to 50–100 2mg pills.<sup>3</sup>

**Materials and Methods:** The decedent was a 27-year-old woman with chronic pain due to severe interstitial cystitis that was being treated with a sacral neurostimulator. She was found by her live-in boyfriend after complaining of nausea and vomiting throughout the day. Based on prescribed medication at the scene and medical records, the decedent may have had an opiate abuse or dependence problem.

**Results:** At autopsy, there was no evidence of significant trauma. Toxicology results revealed the decedent was positive for loperamide at levels of 630ng/ml and diphenhydramine at 2,000ng/ml. A single standard 2mg dose of loperamide gives an average peak plasma loperamide level of 0.24ng/ml at approximately six hours.<sup>5</sup> The toxicology results indicated the decedent took a dose of loperamide at orders of magnitude higher than the recommended dose. The amount of diphenhydramine was also unusually high. It is unknown if this drug played any role in potentiating the effect of the loperamide. The cause of death was determined to be due to the combined toxic effects of loperamide, diphenhydramine, and dextromethorphan.

**Conclusion:** This case report illustrates the potential toxic effects of loperamide when ingested in quantities that are far above the recommended dosing levels. Documented adverse effects from loperamide overdose include fatal cardiac arrhythmia, loss of consciousness, Electrocardiogram (ECG) alterations, and hypokalemia.<sup>4</sup> The opioid crisis occurring in the United States is undeniable. As greater restrictions are put on traditional opiate medications, addicts will likely increasingly turn to more available alternatives and over-the-counter medications such as loperamide. This has already begun to occur. Internet posts about illicit loperamide use have increased from 50 posts a quarter in 2005 to more than 275 posts per quarter in 2011, with an associated increase in published case reports of ten-fold by 2014.<sup>2,4</sup> Recognition and greater awareness of using these widely available alternative medications for obtaining a high is crucial for the public health.

## H109 Body Packing of Narcotics Leading to Gastric Perforation and Death: A Case Report and Review of the Literature

Daniel A. Kirsch, BA\*, Boston University School of Medicine, Boston, MA 02118; Irini A. Scordi-Bello, MD, PhD, Boston, MA

**Learning Overview:** The goal of this presentation is to address/highlight: (1) forensic investigation into body packing; (2) an unusual presentation of narcotic smuggling causing death; (3) the medical risks posed by body packing; and (4) differential diagnosis of body packing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of autopsies and forensic death investigations by showing an unusual presentation of body packing and by reminding investigators to keep a broad differential. This presentation will also serve to increase the body of knowledge around this activity, as it is most likely currently underreported. Attendees will come away with a greater understanding of narcotic body packing, which will hopefully improve performance in examination of this entity.

Gastric perforation leading to peritonitis can be due to an ulcer, malignancy (e.g., adenocarcinoma, lymphoma, or gastrointestinal stromal tumor), or penetrating trauma (e.g., gunshot or stab wound.) Presented here is a highly unusual and forensically relevant case of gastric perforation leading to organizing peritonitis due to the ingestion of a large number of packets (pellets) containing narcotics. The decedent was a 69-year-old man from Ghana, who prior to his death had only been in the United States for a single day and was found unresponsive in the bathroom of his friend's residence. The decision to perform an autopsy was primarily based on his recent long-distance travel and lack of any other medical history.

On external exam, the decedent was an overweight Black man with a Body mass Index (BMI) of 26.5 and a protuberant abdomen. Postmortem examination revealed organizing peritonitis with tan exudates covering the peritoneal lining serosal surfaces and a perforation in the pre-pyloric region of the stomach. Inside the stomach, there were 28 oblong, tightly wrapped latex packets, each measuring approximately 1½ x ½ inches and containing a white powder. The packages were distending and stretching the stomach; friction had most likely caused the wall of the stomach to rupture. All packages were intact. In addition to the 28 found in the stomach, 2 other packages were found that had progressed to the large bowel. The drugs were photographically documented and submitted as evidence to law enforcement agents.

Femoral blood toxicology was positive for delta-9-tetrahydrocannabinol. No cocaine, heroin, or fentanyl were detected in the decedent's blood. Other significant findings included hypertensive cardiovascular disease and pulmonary emphysema. There was no evidence of a pulmonary embolus. Cause of death was determined to be gastric perforation due to foreign bodies, and the manner was determined to be an accident.

Body packers, also known as "mules," are individuals who swallow or insert into a body cavity packets filled with illegal drugs for the purpose of evading customs. Body packers from poverty-stricken countries such as Jamaica and Colombia are recruited and financially compensated to transport drugs to the United States and Europe. Narcotics are usually packed in capsules, condoms, balloons, plastic bags, or fingers of latex gloves and most frequently are swallowed into the stomach or inserted into the rectum or vagina.<sup>1</sup> There are multiple reports of these packages rupturing within the gastrointestinal tract, leading to acute intoxication of the individual.<sup>2-5</sup> Rupture and acute intoxication are the most common causes of death and the risk of package rupture increases with prolonged flight time.<sup>6,7</sup> Medical examiners and coroners need to have a high index of suspicion in cases of sudden death in individuals who have recently traveled from high drug-traffic countries.

Presented here is a much less frequently encountered complication, that of gastric ulceration and perforation, leading to organizing peritonitis, sepsis, and death in a body packer from Africa. This case was unique not only because the mechanism of death was peritonitis rather than intoxication, but also because this individual was elderly and from a country, Ghana, not usually associated with drug trafficking to the United States. In fact, this individual would not have been autopsied except for the fact that he had recently flown into the United States from Africa just a day prior to his death, which led the medical examiner to perform an autopsy to determine whether his death was due to cardiac causes or a pulmonary embolus. The presence of the drugs and his cause of death were both surprising, and somewhat concerning, given that elderly patients that appear to have died of natural causes are not autopsied in many offices around the country. This case illustrates that body packing is used by people of all ages and that without an autopsy, not only is the true cause and manner of death missed, but the incidence of body packing is likely underestimated.

### H110 Anticoagulation and Exsanguination: A Case Series of Fatalities From Superficial Wounds in the Elderly

Abigail L. Alexander, MD\*, Rhode Island Hospital, Providence, RI 02903; Priya Banerjee, MD, Providence, RI 02904

**Learning Overview:** The goal of this presentation is to bring awareness to attendees that when under anticoagulation treatment, and even within the therapeutic threshold, an elderly person can quickly exsanguinate on a superficial wound. The subsequent manner and cause of death can be difficult to ascertain because the scenes can require forensic analysis due to the amount of blood present.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that superficial wounds can lead to fatal exsanguination in the elderly and present as a crime scene.

There has been an unprecedented anticoagulant use in the United States, particularly in the elderly, including treatment for heart disease, atrial fibrillation, and deep vein thrombosis prophylaxis.<sup>1</sup> Since the advent of Direct Oral Anticoagulants (DOACs), warfarin use has fallen but still accounts for roughly 1.6 million quarterly doctor visits.<sup>2</sup> Warfarin's mechanism of action relies on blocking the vitamin K pathway in the liver and is drastically affected by dietary sources, requiring close monitoring. In contrast, dabigatran and other DOACs employ an anti-platelet pathway that does not interfere with vitamin K or require specific testing or close monitoring. Regardless of the therapy used, patients are at increased risk of bleeding-related complications, even when they are in the therapeutic window of treatment. Emergent reversal of anticoagulation with warfarin employs Fresh Frozen Plasma (FFP) and vitamin K, but is very limited when antiplatelet agents are used.

The aim of this presentation is to bring awareness to the potential lethal adverse effects of anticoagulants and that vulnerable populations can suffer mortal complications due to relatively superficial and minor wounds. This case series of three geriatric patients highlights a rare complication of massive exsanguination from rather subtle injuries consisting of puncture wounds or abrasions less than a one-quarter of an inch. The three patients ranged in age from 85 to 89 years. The corresponding death scenes were often so bloody they required careful forensic evaluation to determine manner and cause of death, including exclusion of foul play. The first decedent, an 85-year-old male, was found deceased at home in a puddle of blood on his kitchen floor. It had been apparent he had made several trips to the bathroom and back and upon external examination, the only wound present was a one-eighth-inch abrasion on his ankle. Another patient, an 89-year-old female, died under similar circumstances after apparently puncturing her ankle on a screw protruding from her walker. The puncture wound was also about one-eighth inch in circumference and the only lesion found on her body. Finally, an 89-year-old male bled out from a one-quarter inch puncture wound on his ankle as well. All three patients were known to be anticoagulated for atrial fibrillation. These findings may become more common as there is increasing prevalence of anticoagulant usage with the aging population. It is important for clinicians to weigh the cost versus benefit of putting a patient on anticoagulants, or these unfortunate deaths due to minor trauma with fatal outcomes will only increase.

### H111 2,4-Dinitrophenol Toxicity: A Cause of Death That Is Making a Comeback

Allison Gaines\*, Cobb County Medical Examiner's Office, Marietta, GA 30060; Christopher Gullede, MD, Cobb County Medical Examiner's Office, Marietta, GA 30060

**Learning Overview:** After attending this presentation, attendees will better understand the toxic effects of 2,4-Dinitrophenol (DNP), as well as the antemortem and postmortem evidence associated with its use.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of DNP toxicity and its re-emergence in a culture with increased access to the internet and heightened concerns for body weight and self-image.

DNP is a synthetic chemical that has been used in the production of pesticides, wood preservers, dyes, photographic developers, and explosives.<sup>2-5,7</sup> It acts by uncoupling oxidative phosphorylation, causing the inefficient production of Adenosine Triphosphate (ATP) and increased metabolism of carbohydrates and lipids.<sup>5,7</sup> Because of this, it was introduced into medical practice as a weight-reduction drug in the 1930s, but was later banned due to its potent toxicity and adverse side effects.<sup>2,3,6,7</sup> Despite legislation and warnings of harm associated with its use, reports of deaths due to the use of DNP have increased in the past few years.<sup>2</sup> This may be due to the fact that DNP is readily available online, sold by unregulated vendors and promoted aggressively among the body-building community.<sup>5</sup> There is also increasing concern of usage within vulnerable groups, such as those with eating disorders or young and naïve users who are not fully informed about the drug.<sup>1</sup> The resurgence of DNP-related fatalities could pose a problem for emergency room physicians and medical examiners, as there is no antidote for the compound, and proper diagnosis of DNP poisoning becomes challenging without knowledge of its use.<sup>3,5</sup>

A 47-year-old White male with a past medical history of hypertension was found unresponsive in the bed of his residence by his roommate. The prior night, he experienced fever, labored breathing, and excess sweating. Emergency medical services were contacted, but resuscitative measures were not initiated once postmortem changes were observed. Scene examination revealed a substantial number of stray pills throughout the bedroom and neighboring bathroom. Several prescription medications were located, in addition to vitamins, an empty vial of testosterone, and a used syringe. The decedent had an interest in weightlifting and had a muscular build. Approximately a month after the death, a call was received from the decedent's roommate stating he found evidence to suggest the decedent may have been taking a dietary supplement called DNP at the time of his death. The roommate found email correspondence on the decedent's computer in which he was attempting to purchase the supplement online.

Autopsy findings were significant for moderate pulmonary congestion, focal hemorrhagic gastritis with pill residue in the gastric contents, slight yellow discoloration to the skin of the right arm, and intensely yellow-colored urine. Initial toxicological analysis revealed non-toxic levels of alprazolam, temazepam, oxazepam, lamotrigine, sertraline, and venlafaxine metabolites. After learning of the decedent's potential use of DNP, additional samples were sent to the Center for Forensic Science Research and Education for DNP testing. The samples came back positive for the compound. The cause of death was certified as "2,4-Dinitrophenol Toxicity," with the manner of death being certified as accident.

Given that making a diagnosis of DNP toxicity requires a high index of suspicion and does not present itself in routine toxicological analyses, it is important to understand the factors that may affect an individual's willingness to take this drug, as well as the toxidrome of DNP.<sup>5</sup> This case is presented as an example of how investigative information, autopsy findings, and toxicological analysis must be combined to diagnose DNP toxicity in a deceased individual.

### H112 Death by Intracorporeal Fentanyl Extravasation During the Replacement of an Intrathecal Pump

Luisa Andrello, MD\*, Bellinzona, Canton Ticino 6500, SWITZERLAND; Maria Teresa Pinorini, PhD, Istituto Alpino di Chimica e Tossicologia, Olivone, Ticino 6718, SWITZERLAND; Elia Grata, Fondazione Alpina per le Scienze Della Vita, Olivone 6718, SWITZERLAND; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY

**Learning Overview:** After attending this presentation, attendees will be informed regarding an atypical overdose in a patient undergoing chronic therapy with intrathecal administration of fentanyl and the importance of correctly knowing the distribution and metabolism of fentanyl.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the difficulty of determining toxic values of fentanyl in subjects in chronic therapy and the lack of knowledge by clinical physicians regarding the metabolism of fentanyl and its difficulties in therapeutic management.

A 59-year-old woman with type I neurofibromatosis and chronic radiculopathy causing intense pain was treated with intrathecal fentanyl injection via a continuous-release pump implanted in the left abdomen in 2009. During a routine filling of the pump at 1.00 p.m. on December 7, 2017, there was an intracorporeal fentanyl solution extravasation of about 8.7ml (corresponding to 13,050ug of fentanyl). The woman was treated with immediate clinical monitoring and with naloxone therapy (both in bolus and in continuous infusion for anticipated bradypnea). The woman was then hospitalized for 24 hours of monitoring and administration of low doses of naloxone (0.1mg/h) and oxygen therapy. During hospitalization, there were episodes of bradypnea (with an episode below 10 breaths/minute), episodes of hypotension (68/54mmHg), and some periods of desaturation (average saturation 92%–93% with episodic 75% and 89% drops).

In the morning, the woman was visited and appeared well; the administration of naloxone and oxygen was stopped at 9:00 a.m., and the woman was discharged around 12.00 a.m. on December 8. Notably, at discharge a nurse had measured an oxygen saturation of 75% that was not reported to the doctor. For the passage of the woman from the bed to the wheelchair, a mechanical lift was used with belts located in the abdominal region. The woman returned home, reported being particularly tired and sleepy, and went to bed, where she was found dead at about 7:00 p.m. An autopsy was performed and revealed chronic cardiomyopathy, serous pleural effusions, splenomegaly, chronic liver disease, and multiple cutaneous neurofibromas. The pump for intrathecal infusion was positioned in the abdomen and surrounded by a fibrous envelope; transparent liquid was collected between the pump and the casing. Histologic examination confirmed the macroscopic data and showed microscopic alterations due to pulmonary arterial hypertension.

Interpretation of toxicologic results was complicated by multiple factors, including the absence of reference data regarding toxic/lethal fentanyl concentrations in patients chronically medicated via intrathecal administration. The compendium of all available data, however, ultimately led to certification of fentanyl overdose as the cause of the death. Per literature data, a blood concentration of fentanyl of 25µg/l (i.e., the concentration detected in a sample procured around 12 hours after death) was well above therapeutic values and within the range of toxic and/or lethal values. Furthermore, in this case, fentanyl concentrations detected in organs (i.e., brain, liver, and kidneys) were likewise found to fall into the toxic/lethal range. Analysis of samples taken near the pump (i.e., overlying liquid, fibrous tissue, and adipose tissue) likewise showed high concentrations of fentanyl. The highest tissue concentration was recorded in the adipose tissue underlying the pump (9.0mg/l); in sum, these findings would suggest substance redistribution from the extravasation point to the periphery was still in progress at the time of death. The pharmacokinetics of fentanyl in the present case was not comparable to those of intravenous therapeutic or accidental administration of the substance. It is suspected that drug accumulated initially between the pump and the fibrous tissue that covered it, and subsequently progressively distributed to the surrounding adipose tissue and the periphery—a distribution that was still ongoing at the time of death.

The Public Prosecutor then conducted a thorough investigation with reports by the doctors and nurses who treated the woman, highlighting a fundamental ignorance of the notion of a possible reservoir of the fentanyl in adipose tissue with subsequent progressive release into the body (as a lipophilic substance). The anomalous “delayed” release mechanism, not known in practice, has led to the filing of criminal proceedings against the operating medical staff.

#### Fentanyl, Chronic Therapy, Intrathecal Administration

### H113 “Everybody Hurts”: Fatal Anaphylactic Shock Induced by an Intramuscular Injection of Diclofenac

*Diana Bonuccelli, MD, Department of Legal Medicine, Lucca, ITALY; Marco Conti, MD, Azienda USL Toscana Nordovest, Lucca, ITALY; Sara Niballi, MD, Department of Legal Medicine, Lucca, ITALY; Alberto Mandoli, MD, Department of Legal Medicine, Lucca, ITALY; Benedetta Baldari, MD\*, Rome 00161, ITALY; Stefano D’Errico, MD, PhD, Department of Legal Medicine, Rome 00189, ITALY*

**Learning Overview:** After attending this presentation, attendees will appreciate forensic methodology for the postmortem diagnosis of anaphylactic shock induced by an intramuscular administration of diclofenac in an adult. The increasingly large use of painkillers worldwide represents an alert for the forensic community for complete postmortem investigations in cases of sudden unexpected death.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a case of anaphylactic shock induced by a widely used non-steroidal anti-inflammatory drug. The rarity of fatal events with diclofenac makes this case unusual and interesting for the overall scientific community.

The epidemiological peculiarities of anaphylaxis remain challenging to assess and often the only available data is obtained from hospital admissions. In general, the number of hospitalizations for anaphylaxis is increasing in many countries, with a greater incidence of the phenomenon in the pediatric age group. Prevalence estimates differ worldwide with values varying from 0.3% in Europe to 1.6%–5.1% in the United States. Diclofenac is a widely used Non-Steroidal Anti-Inflammatory Drug (NSAID) derivative of phenylacetic acid. It is commonly used in pain management and preferred by both clinicians and patients because its effect begins in only a few minutes. Safety data from clinical trials in the United States have shown that diclofenac sodium has lower rates of adverse reactions than any of the other comparative NSAIDs. Allergic reactions after intramuscular injection, such as urticaria, asthmatic attack and Kounis syndrome, are commonly reported, while anaphylactic shock is rarely described. A rare fatal case of anaphylactic shock occurring after intramuscular injection of diclofenac is presented here.

A 51-year-old man with a history of severe back pain was prescribed NSAIDs; diclofenac, in particular, had been prescribed two years before his terminal presentation. Acute onset of dyspnea followed by cyanosis of the lips and respiratory failure were described immediately after his most recent intramuscular injection of diclofenac. Unsuccessful rescue efforts included oral administration of betamethasone, intramuscular injection of adrenaline, and cardiopulmonary resuscitation. A complete postmortem examination was performed two days after death. No putrefaction phenomena were evident. External examination was unremarkable. Subpleural petechiae and heavy lungs with white foam in the main bronchi were observed on internal examination. The laryngotracheobronchial tree was unremarkable except for a mild edema of the glottis. The heart appeared normal, with conical shape and epicardial fat mildly represented. Coronary arteries were normal; luminal occlusions were excluded. All tissue specimens were formalin-fixed, paraffin-embedded, and stained with hematoxylin and eosin. Acute polyvisceral stasis, mild cerebral edema, and myocardial interstitial edema were noted. Splenic and adrenal intraparenchymal hemorrhage was observed. Acute pulmonary edema mixed with areas of acute pulmonary emphysema was evident. To estimate the mast-cell population, immunohistochemistry using anti-tryptase antibody as a mast-cell specific marker on 5mm-thick paraffin sections was performed. Pulmonary mast cells were identified and quantified, and a great number of degranulating mast cells with tryptase-positive material outside were observed. Toxicologic analysis on blood and urine therapeutic and non-therapeutic drugs was performed using gas chromatography/mass spectrometry with negative results. Serum levels of mast cell b-tryptase from femoral blood showed serum values of 43.6mg/l (normal value  $\leq 10$ mg/l). The cause of death was certified as cardiorespiratory failure due to anaphylactic shock induced by intramuscular injection of diclofenac.

In conclusion, this is a rare case of fatal anaphylactic shock due to intramuscular injection of diclofenac. This presentation is intended to bring awareness that although diclofenac is a safe and widely used drug, severe and potentially fatal anaphylactic reactions may occur with its use.

## H114 Tri-Allelic Patterns of Short Tandem Repeats (STRs) on D21S11 and Penta D Observed in Three Paternity Testing Cases With Down Syndrome Diagnosed Children

Amir J. Hamuod\*, Baghdad, IRAQ

**Learning Overview:** The goal of this presentation is to show that the use of STRs for DNA profiling can assist in the diagnosis of numerical aberrations of some chromosomes, such as 21 and 18, and as it is considered fast and sensitive, it could be used for prenatal identification of chromosomal trisomy in a short time in comparison with conventional cytogenetic methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that DNA profiling with STR amplification is recommended for a Down syndrome diagnosis, in addition to its main use in paternity and forensic cases.

DNA profiling is a routinely utilized method for determining the paternity and maternity of alleged parents to a child of concern. Many paternity cases are referred to the Paternity and Kinship Division of the Medico-Legal Directorate (MLD) in Baghdad in order to resolve paternity issues and/or to establish identity cards. Blood samples are typically taken from each family member and direct Polymerase Chain Reaction (PCR) is used for DNA amplification; PCR products are then run on the genetic analyzer, and the data is analyzed with GeneMapper® ID Analysis software. The genetic analyses in paternity testing and in forensic casework is based on the detection of STRs, which are small sequences of DNA made up of repeating units of 2–6 nucleotides.<sup>1</sup> Normally, two alleles appear at each locus (i.e., one from the father and the other from the mother; one peak for homozygous genotype and two peaks for heterozygous genotype). Chromosome number aberrations can sometimes be detected during DNA typing. The current study reports three separate cases that were referred to MLD in 2018 for paternity testing; in each case, three alleles appeared at two loci (i.e., D21S11 and Penta D, which is also located on chromosome 21) of the DNA profile for the tested children. The trisomy of chromosome 21 (all or a critical portion) is the most commonly detected form of numerical chromosome abnormality and is the cause of Down syndrome, in which significant intellectual disability and developmental delay with distinctive phenotypic features are seen in affected children. The incidence of Down syndrome is approximately 1/800 newborns.<sup>2</sup>

In 95% of chromosome 21 trisomy cases, the extra chromosome 21 has a maternal origin, while the paternal origin is responsible for the remaining 5%. These cases mainly result from non-disjunction during meiosis II.<sup>3-5</sup> The maternal origin of trisomy 21 is found to be correlated with aging (i.e., >35 years of age).<sup>6,7</sup> Trisomy 21 is known as the most common chromosomal abnormality for the live-born as well as the most prevalent cause of developmental intellectual disability.<sup>5</sup> The use of STRs for DNA profiling has many advantages in forensic and paternity cases.<sup>1</sup> Additionally, the current study shows they can assist in the diagnosis of numerical aberrations of some chromosomes like 21 and 18. Utilizing STRs for DNA profiling is fast, sensitive, and could be used for prenatal identification of chromosomal trisomy in a relatively short time in comparison with conventional cytogenetic methods.<sup>8,9</sup> Cases in which child switching after birth in the hospital is alleged are among the most frequent cases referred to MLD when the child is diagnosed with Down syndrome—yet in the majority of the cases, DNA testing reveals that those children belong to the tested parents. In conclusion, amplification of STRs could be used as a diagnostic technique for trisomy chromosome 21, along with its more standard usage in paternity and forensic cases.

*This study gratefully acknowledges the expert technical support of DNA laboratory in Paternity and Kinship Division/Medico-Legal Directorate, Baghdad/Iraq.*

### H115 A Rare Autopsy Case of Inferior Mesenteric Artery Laceration Associated With Blunt Abdominal Trauma in a Physically Abused Child

*Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University, Osaka 545-8585, JAPAN*

**Learning Overview:** The goal of this presentation is for medical examiners to consider mesenteric artery laceration in addition to liver damage and intestinal rupture in cases of blunt abdominal trauma in physically abused children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting that diverse injuries may develop as a result of blunt abdominal trauma in physically abused children.

There have been few reports of pediatric death caused by blunt abdominal trauma associated with physical abuse—and of those reported cases, the details are often unclear. This presentation will review an autopsy case of hemorrhagic shock due to inferior mesenteric artery lacerations associated with blunt abdominal trauma in a physically abused child. Moreover, the findings of the current presented case will be compared to other reported autopsy cases of blunt abdominal trauma in children.

The patient was a 3-year-old boy with a height and weight of 93cm and 14.3kg, respectively. Subcutaneous bleeding, abrasions, and small scars were observed throughout the body. There was no obvious damage observed on the skin surface in the middle abdomen; however, there was minor bleeding in subcutaneous adipose tissue, and a 6cm × 5cm × 0.5cm focus of hemorrhage within the rectus abdominis muscle was noted. In the abdominal cavity, 450ml of coagulated blood was collected. There were lacerations in the transverse mesocolon and a crush injury measuring 8cm × 9cm × 0.5cm in the mesentery of the small intestine. The inferior mesenteric artery was completely ruptured at 0.5cm from the aortic root. The transverse colon was necrotic, and there was bleeding into the mucosal membranes. Histopathologic examination revealed necrosis, neutrophilic infiltration, and hemorrhage. All organs were hypoglycemic, and the cause of death was certified as hemorrhagic shock due to laceration of the inferior mesenteric artery. Because there was no visible damage on the surface of the middle abdominal skin, strong and/or blunt abdominal trauma by a heel or similar object was suspected as the mode of injury. Based on the visual observations and histopathologic findings in the transverse colon, the subject was determined to have received the injury 3-6 hours prior to the autopsy.

In children sustaining abdominal blunt trauma, injury to organs and bowels is the main concern; moreover, vascular injury should be considered during autopsy. However, in the case of death of physically abused children, visible injury may not be found on the abdominal surface; thus, several modalities, including imaging and biochemical evaluations, should be performed during autopsy to elucidate the cause of death and pathology.

## H116 Neonatal Pulmonary Arterial Hypertension (PAH): A Fatal Case of Noonan Syndrome (NS)

Caterina Bosco, MD\*, Department of Public Health and Pediatrics, Torino 10126, ITALY; Luana Bonaccorso, MD\*, University of Turin, Turin 10126, ITALY; Greta Cena, MD, University of Torino, Torino 10126, ITALY; Lucia Tattoli, PhD, AOU Città della Salute e della Scienza Torino, Torino, Turin 10126, ITALY; Caterina Petetta, MD, University of Turin, Torino 10126, ITALY; Giovanni Botta, MD, Department of Pathology, OIRM Sant'anna, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Dept Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the effects of NS on the respiratory system in association with PAH, which is an uncommon histological feature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting that molecular genetic testing should be performed when newborns develop early severe PAH, an aggressive and often fatal condition.

NS is an autosomal dominant disorder characterized by congenital heart defects, facial dysmorphism, and intellectual disability caused by mutations in genes encoded by proteins of the RAS/MAPK pathway that regulate cellular cycle, differentiation, migration, and apoptosis.<sup>1</sup> This malformation syndrome has an estimated prevalence of 1:1,000–2,500.<sup>2</sup> The main feature of NS is a large spectrum of cardiac defects, including Pulmonary Valve Stenosis (PVS) and Hypertrophic Cardiomyopathy (HCM); the prevalence of cardiac defects in NS is about 80%–90% of cases.<sup>3</sup> Cardiac disease tends to be more progressive in infants with NS, and the earlier the presentation, the more severe the phenotype and the worse the long-term prognosis. Among those patients, there is substantial early mortality, with most deaths occurring during infancy.<sup>4</sup>

The prevalence of pulmonary pathologies in RASopathies is not as well-established as the cardiac and neurocognitive impairments. The development of pulmonary hypertension is generally a gradual and secondary effect of heart malformations.<sup>5</sup> Reported here is a case of uncommon association between NS and early-onset neonatal PAH due to a specific molecular alteration that primarily affects the arterial vessels of the lung.

A 2,150g female newborn was delivered at 34 weeks gestation to a 32 year-old primigravida. Cranio-facial anomalies were found at physical examination. Prenatal routine ultrasound detected polydramnios and biventricular hypertrophy. Family history was negative for congenital anomalies and consanguinity, and exposure *in utero* to teratogens was excluded. Over the next two months, the newborn developed significant hypoxia resulting from recurrent episodes of pulmonary atelectasia with gradual impairment of cardiac function. Echocardiogram and Computed Tomography (CT) scan showed severe HCM with evidence of PAH. Despite intensive neonatal care, the newborn succumbed to complications of acute respiratory failure at four months of age.

The external examination revealed a weight of 4,065g, length of 64cm, and head circumference of 36cm. Multiple dysmorphic anomalies were identified, including dolichocephaly with a square forehead, flat nasal bridge, low-set and posteriorly angulated ears, short neck, and nuchal edema. The internal examination showed severe right and left ventricular hypertrophy of the heart and enlargement of the pulmonary artery and its branches. The histologic examination of the lungs showed pathological changes of pulmonary arterial vessels, including medial hypertrophy, intimal proliferation with plexogenic arteriopathy, and angiomas. These findings were consistent with PAH. A comprehensive panel of genetic testing on blood samples revealed that the infant was heterozygous for the c770C>T mutation in RAF1, which is frequently associated with NS.

Several studies have reported that the RAF1 mutation produces a constitutive activation of the RAS/MAPK pathway with abnormal artery smooth muscle cell proliferation. While patients with this specific mutation are very likely to develop HCM (~85%), it also contributes to the development of an early onset of PAH.<sup>3</sup>

This presentation will provide a better knowledge on the pathogenesis of PAH in NS. An early onset of PAH, especially in newborns, is consistent with a primary genetic alteration of the pulmonary vessels rather than a progressive effect of heart malformation. Comprehensive prenatal screening for RAS/MAPK pathway mutations could allow for possible therapies targeted at the involved pathway, potentially capable of reversing HCM and delaying PAH development.<sup>6</sup>

## H117 Sudden Unexpected Death in Childhood: A Case Report of Fatal Acute Pancreatitis

Fabio Innocenzi\*, Università di Torino, Torino 10126, ITALY; Francesco Lupariello, MD\*, University of Torino, Torino 10126, ITALY; Alessandro Gabriele, University of Turin, Turin 10126, ITALY; Giovanni Botta, MD, Department of Pathology, OIRM Sant'anna, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance of investigating a necrotizing pancreatitis in cases of sudden unexpected deaths in children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding new knowledge about a pathology with little literature data regarding its occurrence in those of pediatric age, thus showing the importance of autopsy and histologic findings in order to understand the features of this rarely reported cause of death in children.

Necrotizing pancreatitis is a complication of acute pancreatitis wherein portions of the pancreas die and may get infected. The primary symptom of necrotizing pancreatitis is severe upper abdominal pain that radiates to the back in 50% of cases. Other related symptoms include swollen abdomen, fever, nausea, vomiting, dehydration, low blood pressure, and rapid heart rate. If left untreated, necrotizing pancreatitis may lead to bacterial infections and sepsis. Necrotizing pancreatitis is diagnosed by symptoms, but the following blood investigations are also helpful: pancreatic enzyme levels, sodium, potassium or glucose, and triglycerides levels. Abdominal ultrasound, Computed Tomography (CT) scan, and magnetic resonance imaging are additionally used to evaluate the pancreas. If these exams show that there is necrosis of the pancreas, a biopsy is necessary to test for infection. Treatments for pancreatitis include intravenous fluids, pain-relieving medication, rest, medication to prevent nausea and vomiting, and nasogastric feeding. According to a 2014 study, the best time to perform surgery is three or four weeks after the onset of the condition. However, if a person is in critical condition, surgery is mandatory to remove the necrotic or infected tissue. Early treatment is the best way to reduce the risk of necrotizing pancreatitis or other complications.<sup>1</sup>

Pediatric pancreatitis has received attention during the past few years. Numerous reports have identified an increasing trend in the diagnosis of acute pancreatitis in children and key differences in disease presentation and management between infants and older children.<sup>2</sup> Acute necrotizing pancreatitis has a variable etiology in children. CT scan is useful for the diagnosis and assessment of its severity.<sup>3</sup> Acute necrotizing pancreatitis accounts for 10% of acute pancreatitis cases and is associated with a higher mortality and morbidity. Necrosis within the first four weeks of disease onset is defined as an Acute Necrotic Collection (ANC), while Walled-Off Pancreatic Necrosis (WOPN) develops after four weeks from the disease onset. The infection of a necrotic pancreas is the most important risk factor contributing to death in severe acute pancreatitis, and it is generally accepted that infected pancreatic necrosis should be managed surgically. An infected or symptomatic WOPN requires drainage. The management of pancreatic necrosis has shifted away from open necrosectomy, as it is associated with a high morbidity, to less invasive techniques.<sup>4</sup> In contrast, the management of sterile pancreatic necrosis accompanied by organ failure is controversial. Recent clinical experience has provided evidence that conservative management of sterile pancreatic necrosis, including early antibiotic administration, seems promising.<sup>5</sup>

In order to contribute to the knowledge of the topic, the case of a 2-year-old toddler brought to the local hospital for severe abdominal pain is presented. There was no significant history reported. Severe abdominal pain, fever, nausea, vomiting, low blood pressure, and rapid heart rate were found at physical examination. Laboratory blood testing showed increased liver enzymes and amylase. The patient suddenly died after 30 minutes, before the medical staff could perform the necessary instrumental investigations.

An autopsy was conducted. The external examination showed broad marbling, especially in the lower limbs. At internal examination, a serosanguinous peritoneal effusion and a 35ml pericardial effusion were detected. Histologic findings included lungs with marked vascular congestion and limited atelectasis, reactive pulmonary hilar lymph nodes, adrenal glands with reduced medullary thickness, kidneys with focal tubular necrosis, pancreas with massive hemorrhagic necrosis, and spleen with reactive foci. The pathologist certified the case as a sudden and unexpected death caused by multi-organ failure due to septic shock in pediatric necrotizing pancreatitis.

In conclusion, this case points out that a careful histologic investigation must always be carried out in order to execute a comprehensive autopsy study, especially in the case of a sudden and unexpected death in childhood caused by a pathology that is scarcely reported in the scientific literature.

## H118 Multifocal Intracranial Hemorrhage in Congenital Neurosyphilis: Autopsy Findings and Literature Review

Michael Harrell, MD\*, Albuquerque, NM 87131; Heather S. Jarrell, MD, Office of the Medical Investigator, University of New Mexico, Albuquerque, NM 87102-4519; Lauren A. Decker, Office of the Medical Investigator, Albuquerque, NM 87131

**Learning Overview:** The goal of this presentation is to review the common clinicopathologic and autopsy findings of congenital neurosyphilis and discuss an uncommon presentation of the disease.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of congenital neurosyphilis and its manifestations.

**Background:** Congenital syphilis occurs by transplacental transmission of the spirochete *Treponema pallidum* from an infected pregnant woman to her fetus. Infection results in a spectrum of clinical manifestations, ranging from asymptomatic infection to sudden death.<sup>1</sup> The central nervous system is rarely affected in infants of treated mothers; however, if untreated, ongoing dissemination of the organism can lead to neurosyphilis.

**Autopsy:** A male infant was born at 29 weeks gestational age via cesarean section for fetal bradycardia. The pregnancy was complicated by intrauterine growth restriction and maternal history of syphilis and alcohol abuse. There were minimal signs of life at delivery, and despite resuscitative efforts, the infant passed away within an hour of birth.

Autopsy revealed a developing and normally formed infant male. The face and chest were involved by a tan-purple maculopapular rash. Small pleural and peritoneal effusions and minimal thymic hemorrhage were present, consistent with resuscitative efforts. An isolated ostium secundum atrial septal defect was identified. Bacterial and viral cultures of the lungs and cerebrospinal fluid were negative, and cultures of the blood showed mixed growth consistent with postmortem overgrowth.

Neuropathologic examination demonstrated a large subdural hematoma overlying the cerebral convexities. Scattered subarachnoid hemorrhage was present, involving the isocortex, brainstem, and spinal cord. Lymphoplasmacytic and histiocytic predominant inflammation involved the meninges. The subcortical white matter and spinal cord demonstrated severe white matter necrosis, edema, and petechial hemorrhage. The lateral ventricles were enlarged. Immunohistochemical staining for spirochetes within the parenchyma of the frontal lobe and cingulate gyrus was positive.

The cause and manner of death were certified as congenital neurosyphilis, natural.

**Discussion:** Congenital neurosyphilis generally manifests as syphilitic meningitis, with early (newborn) and late (1–2 years old) manifestations of the disease.<sup>2</sup> Despite being an acute bacterial infection, syphilitic meningitis is characterized by a mononuclear inflammatory infiltration of the leptomeninges, comprised of plasma cells, lymphocytes, and macrophages. Extension of the cellular infiltrates into brain parenchyma through Virchow-Robin (perivascular spaces), or direct extension into superficial cortex, has been suggested for those with intraparenchymal involvement.<sup>3</sup>

Syphilitic meningitis often progresses to chronic meningovascular syphilis (syphilitic vasculitis) in untreated cases. Inflammation and reparative changes cause cranial nerve palsies and hydrocephalus; over time, the vasculitis may lead to thrombosis, ischemia, and infarction.<sup>4,5</sup> Aneurysm formation and rupture with cerebral hemorrhage can occur; however, this has not been described in premature infants.

Multifocal intracranial hemorrhage represents a novel manifestation of congenital neurosyphilis, an already uncommon disease. The intracranial hemorrhage in this case has numerous potential syphilitic-mediated etiologies.<sup>6</sup> Intracranial hemorrhage has been described in infants with non-syphilitic acute bacterial meningitis and central nervous system vasculitides. Moreover, spontaneous intracranial hemorrhage is a known complication of Disseminated Intravascular Coagulation (DIC), which has rarely been associated with congenital syphilis.<sup>7</sup> Syphilis should be considered in the differential for disease processes that cause meningitis with associated hemorrhage.

### H119 A Peculiar Autopsy Case of Infrarenal Aortic Hypoplasia (AH) and Premature Atherosclerosis in a 13-Year-Old Male

Valentina Rosati, MD\*, Via del Giochetto, Perugia 06126, ITALY; Sara Gioia, MD\*, via Tristano di Joannuccio SNC, Terni 05100, ITALY; Massimo Lancia, MD\*, via Del Giochetto, SNC, Perugia 05100, ITALY; Fabio Suadoni, MD, via Tristano di Joannuccio SNC, Terni 05100, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the case of a young male subject affected by infrarenal AH and premature atherosclerosis with no symptoms of hypertension or lower extremities hypoperfusion, who died from a cardiac tamponade consequent to acute type A aortic dissection with intrapericardial rupture.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of this peculiar and rare pathologic condition.

AH is defined as a narrowing of the aortic lumen with consequent hemodynamic obstruction of the blood flow. It is different from coarctation, where the luminal narrowing involves a short tract of the aorta and primary involves the upper descending aorta adjacent to the site of attachment of the ductus arteriosus. While coarctation of the abdominal aorta is extremely rare, AH is an even a rarer condition and has been described both in the thoracic and abdominal aorta.<sup>1-4</sup> The precise etiology of AH is unknown; however, both congenital and acquired (inflammatory and infectious) causes have been proposed.<sup>5</sup> The clinical manifestations are related to the localization of the hypoplastic segment because, when proximal to the renal arteries, it is responsible for the activation of the renin-angiotensin system.<sup>2,6</sup> The infrarenal hypoplasia can result in hypoperfusion of the lower extremities, causing symptoms such as claudication and lower levels of blood pressure relative to the upper limbs.<sup>5</sup>

This presentation reports the illustrative case of a 13-year-old child who died soon after a sudden illness at school. The child's previous medical history was notable for only mild aortic valvular failure along with an ectatic aortic bulb. At autopsy, the main findings were: (1) type A aortic dissection with intrapericardial rupture and hemopericardium (450ml of blood in the pericardial cavity); (2) hypoplastic infrarenal aorta (1.5cm in circumference extending for more than a length of 3cm) with a calcific atherosclerotic plaque deposition; (3) cardiomegaly (heart weight: 480g) with hypertrophy of the left ventricle (left ventricular thickness: 1.8cm; interventricular septum thickness: 2cm); (4) atherosclerosis of the descending thoracic and infrarenal abdominal aorta; (5) pulmonary congestion, and (6) hepatosplenomegaly. Histopathologic examination showed separation of the tunica media layers of the ascending aortic tract with acute hemorrhagic extension and fragmentation of the elastic fibers, as well as atherosclerosis of the infrarenal aortic tract. It also revealed myocardial hypertrophy, hepatic steatosis, and thickening of the renal arteriolar walls.

In conclusion, the described case shows the association between AH of the infrarenal tract and premature atherosclerosis, consistent with the published literature.<sup>5,7</sup> The peculiarity of the case lies in the extreme rarity of this pathological condition in a male subject of such a young age, without antecedent signs or symptoms. Only in the immediate peri-mortem period was there a crushing onset of clinical manifestations, including dyspnea and cold sweating with cardiac arrest shortly thereafter; this was suspected to be due to cardiac tamponade consequent to acute type A aortic dissection with intrapericardial rupture. Ultimately, the dissection (as well as the left ventricular hypertrophy) was the result of prolonged hypertensive stimulation of the cardiovascular system, despite the localization of the aortic hypoplasia to the infrarenal aorta.

## H120 Histopathologic Changes in Placental Tissue Following Misoprostol Administration

Angelina I. Phillips, MD\*, Medical University of South Carolina, Charleston, SC 29425; Daniel C. Butler, MD\*, Medical University of South Carolina, Charleston, SC 29403; S. Erin Presnell, MD, Medical University of South Carolina, Charleston, SC 29425; Evelyn T. Brunner, MD, Medical University of South Carolina, Charleston, SC 29425; Ryan Cuff, MD, Medical University of South Carolina, Charleston, SC 29425

**Learning Overview:** After attending this presentation, attendees will be able to identify the histopathologic placental findings associated with misoprostol administration and utilize the information for the investigation of cases with clandestine misoprostol use.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the methods necessary for recognizing and diagnosing cases of clandestine misoprostol administration.

**Background:** Misoprostol is a prostaglandin analog commonly used alone or in conjunction with other medications to induce abortion.<sup>1</sup> Although misoprostol is only intended for medical abortion in the clinical setting, there is now greater access to the drug through online websites.<sup>2,3</sup> Women may visit these websites and purchase the drug without a prescription, allowing for self-abortions to be performed at home without the supervision of a medical doctor. In one survey, 1.2% of roughly 9,500 patients reported home misoprostol use to terminate a pregnancy, although this number was likely underestimated due to confusion over what misoprostol is and reluctance to report what is considered a crime in some states.<sup>3</sup> In the forensic setting, this fear of committing a crime may likewise contribute to a history of misoprostol use being withheld, leading to death certification as intrauterine fetal demise of unknown etiology in the absence of significant gross or histologic findings, as is often the case. Currently, the literature on the identification of clandestine misoprostol use is limited; however, there is some evidence suggesting tablet preparations of misoprostol when administered vaginally may leave refractile deposits within the placenta.<sup>4</sup>

**Purpose:** The aim of this study is to correlate microscopic placental findings in cases with known misoprostol administration.

**Methods:** A retrospective review of placental cases submitted for surgical pathologic examination over the period of a year was performed. Clinical data was collected through the electronic medical record, including maternal age, gestational history, current pregnancy data (e.g., complications, trimester), and misoprostol administration (i.e., whether administered, dose/formulation, and route of administration). The cohort was then divided into cases with no misoprostol administration, low-dose misoprostol administration, and high-dose misoprostol administration. Surgical pathology slides were reviewed for histopathologic changes, including presence or absence of refractile material, qualitative volume of refractile material present on a scale of 0 (none) to 5 (greater than 50% of tissue with deposits), histopathologic qualities (cotton fibers, amorphous material, etc.), and location of deposits (maternal or fetal surfaces, membranes, or placental disc).

**Results:** Cases with vaginal misoprostol administration were more likely to have refractile, polarizable amorphous material present. The refractile material was commonly associated with purple, dense coral-shaped deposits. The refractile material and deposits when identified were predominantly in the placental membranes and on the maternal surfaces. Refractile material consisting of cotton fibers and other debris were present in nearly all cases at varying volumes.

**Conclusions:** Microscopic examination of the placenta in cases with misoprostol administration consistently show the presence of refractile polarizable amorphous material and/or purple, dense coral-shaped deposits. The deposits described are similar in appearance to that reported for microcrystalline cellulose and crospovidone, both of which represent material used in the manufacture of tablets.<sup>4,5</sup> No standardized toxicological testing procedure is available in the United States for the identification of misoprostol due to its rapid half-life; future study of this data set will include microanalysis of unstained slides containing the refractile deposits with the goal of specific identification of the material and developing a method for confirming the presence of misoprostol in placental tissues.

---

**Learning Overview:** The goal of this presentation is to highlight the importance of fundoscopic and complete spinal cord examinations in young children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reinforcing the necessity for routine postmortem ocular and spinal cord examinations of children in traumatic and non-traumatic deaths.

Interpreting autopsy findings in pediatric deaths can be challenging due to the complicated, evolving, and occasionally conflicting body of literature regarding the specificity of certain findings. Reported here is a case of a fatal, witnessed, canine mauling that highlights the importance of a thorough autopsy to include fundal, brain, and spinal cord examination with inclusion of spinal nerve roots and dorsal root ganglia.

A 6-month-old African American male infant with a past medical history of prematurity was placed and buckled by five-point harness car seat on the living room floor by his babysitter, who then briefly left to unload her vehicle. The infant was subsequently mauled by an adult boxer mix and suffered numerous lacerated puncture wounds of the face and scalp. The mauling was witnessed in its entirety by a relative of the babysitter. He was transported by private vehicle to a local medical center and lost pulses shortly after arrival. He was intubated and return of spontaneous circulation was achieved after approximately 45 to 60 minutes of resuscitative efforts. He was flown to a level one trauma center with loss of pulses en route. He presented in cardiopulmonary arrest and was subsequently pronounced after approximately 45 additional minutes of resuscitative efforts.

External autopsy findings included a combination of lacerated puncture wounds of the face and head consistent with canine bites. Indirect ophthalmologic examination showed retinal hemorrhages of the left eye. There was fracture of the nasal bone and left orbital plate, as well as associated osseous punctures of the left temporal and parietal skull with an obvious concave deformity. Internally, there was patchy subdural hemorrhage, multifocal subarachnoid hemorrhage over the bilateral superior temporoparietal lobes, and puncture wounds of the left frontal and temporal lobes. A complete spinal cord resection with attached dorsal root ganglia by posterior approach revealed multifocal dorsal root ganglia and nerve root hemorrhages of all regions, most pronounced in the lumbar spinal cord, and confirmed in histologic sections.

Some authors previously ascribed specificity to retinal hemorrhages and dorsal root ganglia/nerve root hemorrhages of the cervical spinal cord as it relates to possible abuse head trauma (shaken baby syndrome) with hyperextension/hyperflexion injury of the neck.

With thorough scene investigation and interviews, the witness stated that there was no shaking in the attack, and that the attack simply consisted of frantic biting of the head only with the infant relatively stationary in the five-point restraint car seat. This study proposes that dorsal root ganglia hemorrhages in young children are a non-specific finding and may be seen as a component of hypoxic/ischemic reperfusion injury. This case highlights the importance of routine complete spinal cord examination and fundal examinations in young children and also highlights the importance of being cautious of ascribing diagnostic specificity to retinal hemorrhages or dorsal root ganglia/nerve root hemorrhages.

---

#### Mauling, Spinal Cord, Infant

### H124 The Postmortem Microbiome: An Evaluation of 16S Ribosomal RNA (rRNA) Profiles

*Gulnaz T. Javan, PhD\*, Alabama State University, Montgomery, AL 36104; Sheree J. Finley, PhD, Alabama State University, Montgomery, AL 36104; DeEtta Mills, PhD, Florida International University, Miami, FL 33199*

**Learning Overview:** After attending this presentation, attendees will learn how to use hypervariable regions V1 and V2 of the 16S rRNA gene to determine the postmortem interval.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the determination of time of death using amplicon Length Heterogeneity-Polymerase Chain Reaction (LH-PCR) and capillary electrophoresis.

The ability to quantify the microbial diversity within a human postmortem microbiome is fundamental to the elucidation of molecular functions after a human dies. Before the advent of advanced forensic molecular techniques, the study of the functions of microbial communities has been challenging to investigate due to their different scales (e.g., spatial and temporal). However, with increased use of high-throughput DNA sequencing, combined with bioinformatic analyses, these limitations are quickly diminishing. To date, the “gold standard” of DNA analytical approaches involve a multifaceted process of metagenomic sequencing that is moderately costly and time-consuming to perform. One effective method used to screen microbiomes is to generate a community DNA profile using fluorescent-based DNA profiling methods such as amplicon LH-PCR followed by capillary electrophoresis. Due to the natural occurrence of insertions and deletions within 16S rRNA genes, different length amplicons are generated when the DNA is amplified using universal primers. The hypervariable regions, V1 and V2, demonstrate an extensive range of amplicon lengths that represent the minimum microbial diversity. While any one amplicon could represent different nucleotides, thus different microbial species, it enables forensic scientists to efficiently survey the dynamics of a community under differing postmortem growth conditions. This approach is beneficial because it allows for the rapid production of a genetic pattern, or snapshot, of the bacteria present at the time of sampling, which is an important aspect to consider when choosing samples for downstream metagenomic sequencing.

In the present, first-of-its-kind postmortem microbiome study, 32 samples (brain, heart, liver, and spleen) from eight cadavers of various causes of death from criminal cases were investigated. The results reveal two noticeable trends that affect the number of postmortem microbes and conceivably (1) the frequency of proliferation, (2) the time since death, and (3) the cause of death. Therefore, time-since-death rates of proliferation may prove advantageous for forensic science in determining postmortem interval. LH-PCR is a valid, rapid technique that can monitor these dynamics and, therefore, screen postmortem samples that would be of interest for sequencing analyses. Furthermore, this method is a very inexpensive technique to screen samples to compare community patterns over time and between individuals.

### H125 Simplified DNA Barcoding Strategy for Forensically Relevant Blow and Flesh Flies

Joseph Truppi, BS\*, Harris County Institute of Forensic Science, Houston, TX 77021; Sam Kwiatkowski, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77030; Michelle R. Sanford, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Michael A. Donley, MS, Houston, TX 77021; Katherine Welch, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054; Roger Kahn, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054-2001

**Learning Overview:** The goal of this presentation is to propose a simplified DNA barcoding strategy for identifying insects commonly encountered in casework at the Harris County Institute of Forensic Sciences (HCIFS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a simplified method for DNA barcoding as a tool for medicolegal death investigations.

Accurate insect identification is critical to their use in the estimation of Time Of Colonization (TOC) and Postmortem Interval (PMI) during medicolegal death investigations. Insect specimens are currently identified by evaluating morphologic characteristics as indications of particular taxonomic groups; however, this process is limited because immature life stages typically lack distinguishing morphologies. Identification may be achieved by rearing live specimens; however, this process is time-consuming, labor-intensive, and not always successful.

These deficiencies may be addressed through molecular identification by DNA “barcoding,” wherein DNA sequences from unknown samples are matched to references. This technology enables identification of immature specimens, may be performed without specialized forensic entomology training, and requires equipment common to forensic genetics laboratories. DNA barcoding has been demonstrated in numerous entomological surveys of forensically relevant species; however, the technology has not been implemented for medicolegal death investigations. This is due in part to deficiencies in the technology: no single primer set is capable of distinguishing all of the diverse species important to forensic investigations. Instead, multiple primer sets and sequencing reactions are utilized to maximize the species that may be identified.

Proposed here is a simplified DNA barcoding strategy for identifying insects commonly encountered in casework at the HCIFS. The strategy comprises sequencing and phylogenetic analysis of a single barcoding fragment amplified from the mitochondrial COI locus. Using verified reference specimens, this study shows that the DNA barcoding strategy enables statistically supported identification of species previously encountered in the HCIFS medicolegal death investigations, in particular, members of blow fly genera *Lucilia*, *Calliphora*, *Chrysomya*, *Phormia*, and *Cochliomyia*, the flesh fly genus *Blaesoxipha*, and the scuttle fly genus *Megaselia*, and is effective for immature insect specimens, for example, pupal exuvia, larva, and pupa. Identification is demonstrated for immature specimens collected during past HCIFS medicolegal death investigations for which species-level identification was undetermined by morphology. Future work will include elucidating inter-specific and intra-specific sequence variations of local blow and flesh fly populations to provide further statistical support for identifications and validating the DNA barcoding assay for casework application.

#### DNA Barcoding, Postmortem Interval, Forensic Entomology

### H126 The Effect of Mass-Generated Heat on Larval Development: Implications for Postmortem Interval (PMI) Estimates

Vivienne G. Heaton, PhD\*, Keele University, Keele, Staffordshire ST5 5BG, UNITED KINGDOM; Colin Moffatt, De Montfort University, Health & Life Sciences, Leicester, UNITED KINGDOM; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will better understand the impact of mass size and heat generation on larval development rates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the need for mass temperatures to be incorporated into minimum PMI (mPMI) estimates using larval development.

Observed to arrive at a body within minutes of death, blow flies (Diptera: *Calliphoridae*) are often used by investigators as a tool to aid in the determination of time since death, also known as PMI. Estimating the mPMI based on larval age involves identifying the blow fly species, reconstructing the thermal history at a scene, and modeling the rate of development. Previous research has shown that a strong positive relationship exists between mass size and heat generation, with aggregations composed of as few as 1,200 larvae producing temperatures that are significantly warmer than ambient.<sup>1</sup> Since blow fly larvae are known to experience faster rates of development at warmer temperatures, one would expect the size of the feeding mass to influence the rate of development. However, there are ongoing difficulties with incorporating this concept into mPMI estimates, with very few studies quantifying the relationship between mass size and development. The goal of this research was to determine whether larvae feeding in different-sized masses develop at different rates. The research also identifies which stages of development are most affected by mass size and to what extent.

Aggregations ( $N=21$ ) containing either 300, 1,200, or 2,500 *Lucilia sericata* (Meigen, 1826) (Diptera: Calliphoridae) larvae were reared in a laboratory on racks of lamb ribs at a constant ambient temperature of 22°C ( $\pm 1^\circ\text{C}$ ). A Forward Looking Infrared Radar (FLIR) T425 thermal imaging camera was used to record mass temperatures every five minutes throughout the feeding stages of development. Larvae were sampled every hour and instars were determined by examining the posterior spiracles, which allowed developmental rates to be monitored. At two points during development, 70 hours and the start of the dispersal phase, larvae had their lengths and fresh weights recorded. Data were analyzed using the statistical package R (version 2.12.1).

Results showed a strong positive relationship between mass size and the amount of heat generated by the aggregation ( $p \leq 0.001$ ), with temperatures rising as masses increased in size. While the duration of the egg and 1<sup>st</sup> larval instar phases remained constant regardless of mass size, larvae did show an accelerated rate of development during the 2<sup>nd</sup> and 3<sup>rd</sup> instar when sampled from increasingly larger masses. Accelerated development coincided with the achievement of peak temperatures in the masses. These faster growth rates resulted in the larger aggregations entering the post-feeding phase of development an average of 13 hours earlier than smaller, cooler masses. Physical measurements taken from larvae sampled at 70 hours development showed that individuals feeding in larger masses were significantly longer and heavier than those sampled from smaller aggregations ( $p \leq 0.001$ ), with larvae from the aggregations of 2,500 individuals having a mean length and weight of 13.90mm and 38.81mg, respectively, compared to 12.34mm and 25.99mg in the 300 masses. This provided further evidence of faster growth rates. However, by the time larvae reached the dispersal phase, these differences in length and weight no longer existed ( $p=0.088$ ).

This research highlights the need to incorporate mass temperatures into forensic casework when using larval development to estimate the time of death. Larvae sampled from large masses, particularly during the 3<sup>rd</sup> instar phase, could appear older (re: size) than they actually are due to the accelerated rates of development experienced under warmer conditions. If this is not taken into account, it could result in an overestimation of the mPMI. Future research should focus on identifying how other variables influence heat generation, as well as finding ways to estimate the size of a mass and, hence, its thermal history at a scene.

#### Maggot Masses, Blow Fly Development, Postmortem Interval

### H127 The Impact of Postmortem Microbiota on *Lucilia Sericata* Development

Vadim Mesli, MD\*, Institut Medico Legal, Lille Cedex, Nord 59037, FRANCE; Christel Neut, PhD, Lille 59006, FRANCE; Valéry C. Hédouin, MD, PhD, Lille, Hauts De France 59037, FRANCE; Damien Charabidze, PhD, Univ Lille, Lille 59000, FRANCE; Didier Gosset, MD, PhD, University of Lille, Lille, Hauts de France 59045, FRANCE

**Learning Overview:** After attending this presentation, attendees will have a better appreciation of the impact of selected postmortem bacteria on *Lucilia sericata* development.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the influence of postmortem microbiota on necrophageous insects, which can be of use when evaluating the minimum postmortem interval.

When a putrefied corpse is discovered, several issues arise for the investigators, including providing an estimation of the postmortem interval. Different methods are used to determine an answer to this question, such as the study of the necrophageous insects when they are present. Even though the bacterial communities are abundant on a decomposing body, interactions between insects and the postmortem microbiota are still little known and underestimated. The purpose of this study is to clarify the influence of bacteria that are present during decomposition on the development of *Lucilia sericata* (Meigen) (Diptera: Calliphoridae), a forensically relevant blow fly species.

Several *L. sericata* larvae were sampled on decomposing human corpses and their Excretion/Secretion (ES) fluids were extracted. The bacteria present in the ES fluids were identified using cultural methods and mass spectrometry. Among them, two strains were chosen for confrontation during larval development: *Proteus mirabilis* and *Providencia alcalifaciens*. *L. sericata* eggs were sterilized using successive baths of sodium hypochlorite and 70% ethanol solution. After hatching at 25°C, the larvae were transferred on artificial diets in three different conditions: two groups mono-inoculated with either *P. mirabilis* or *P. alcalifaciens* as well as a control. The diet (Columbia yeast agar) was selected to be as favorable for insects as for bacterial proliferation. Larval development was observed from first instar to puparial stage, which was allowed using sterilized sand around the plates. All insects were followed at 25°C until adult emergence. More than 750 larvae were tracked for every studied condition (the experiments are still in progress). For each replicate of every tested condition, ten larvae were sampled every eight hours during five consecutive days between first instar and post-feeding stage. Larval development and survival were compared between each bacteria and the control. The preliminary results are in favor of differences concerning the early phases of the larval growth, but more replicates are still needed.

During decomposition, bacteria such as *P. mirabilis* and *P. alcalifaciens* (both naturally present in the human intestinal microbiota) are proliferating and interacting with the other present organisms. This study will allow a better understanding of the biotic and abiotic factors involved with decomposing human remains.

### Taphonomy, Postmortem Microbiota, Forensic Entomology

## H128 A Survey of Bacterial Communities in Soil Associated With Porcine Remains

Denise Wohlfahrt, BS, Virginia Commonwealth University, Richmond, VA 23284; Kailey Babcock, BS\*, Richmond, VA 23221; Shane Woolf, MS, Richmond, VA 23220; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will better understand how porcine remains affect the soil microbiome. This information will assist forensic scientists in improving the estimation of the Postmortem Interval (PMI) based on microbial evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the bacterial communities associated with carrion-deposited soil samples and their importance in forensics. This information will help attendees gain a better understanding of carrion resource utilization and improve the precision of PMI estimation using entomological and bacterial evidences.

Estimating the PMI is one of the crucial parts of a death investigation. Immediately after death, algor, rigor, and livor mortis are often used as a PMI estimation method. However, these methods often lose their reliability after 72 hours postmortem. In recent years, soil has become a useful tool in determining this timeline. As bodies are often buried underground or deposited on land, soil may serve as a logical means of estimating time since death. Soil acts as a sink or filter for water, gases, and other resources in the environment, potentially making it a new identifying factor in estimating the PMI. As decomposition progresses to the bloat stage, it releases nutrients and microbes into the underlying soil, altering the soil microbial community composition.<sup>1</sup> Understanding how the microbiome of soil is altered as time progresses will aid the forensic science community in enhancing PMI estimation methods.

This study characterized bacteria associated with carrion-deposited soil samples by using 16S recombinant DNA (rDNA) MiSeq® sequencing. Six porcine cadavers were left to decompose naturally on top of pristine soil. Soil samples were collected directly under the body and three meters away from the body. This repeated each day for a week, then once a week after that for a total of eight weeks. DNA was extracted from the soil samples using the DNeasy® PowerSoil Kit and was amplified and sequenced for Variable region Four (V4) of 16S rDNA using the dual-index MiSeq® sequencing strategy as described by Kozich et al.<sup>2</sup> Sequences were then analyzed using mothur version 1.39.4, and statistical analysis was performed using R version 3.4.0.<sup>3,4</sup>

In general, the total DNA quant value obtained from soil under porcine remains was higher than the DNA quant value obtained from soil at the control sites. After all quality control steps, a total of 4,518,957 sequence reads (average read per sample=55,820) was generated from all samples. Preliminary results show that Acidobacteria and Actinobacteria are among the most prominent phyla observed in soil associated with porcine remains.

## H129 Cranial Hyperostosis and Neuropsychiatric Disorders: Is There a Correlation? A Comparison Between Forensic Cases and a Review of Literature

Orazio Malfa, MD\*, University Magna Graecia of Catanzaro, Catanzaro, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Fabrizio Cordasco, MD, Università Magna Graecia CZ, Catanzaro, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Roberto Raffaele, BE\*, University Magna Graecia of Catanzaro, Crotona 88900, ITALY; Ludovico M. Abenavoli, PhD, University of Catanzaro, Catanzaro, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the role of frontal hyperostosis in the genesis of neuropsychiatric disorders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need to investigate the role of hyperostosis as a potential association and predictive factor of neuropsychiatric diseases.

Cranial hyperostosis is an idiopathic condition characterized by an increase in skull thickness. Frequently, it involves the frontal bone and the anterior fossa. Hyperostosis, and particularly Hyperostosis Frontalis Interna (HFI), has been described in association with psychosis, depression, Parkinsonism, executive function disorders with memory loss, and inappropriate behavior. Only case reports are published in forensic literature. A correlation has been hypothesized with the so-called Morgagni-Stewart-Morel (MSM) syndrome, characterized by HFI and metabolic and neuropsychiatric disorders.<sup>1</sup> However, to date, there is no general agreement on the existence of the MSM syndrome as the pathogenesis of the phenomenon remains unclear.

The aim of this study is to examine the possible correlation between cranial hyperostosis and neuropsychiatric disorders, comparing the published literature to the findings in three forensic autopsy cases. In each case, the morpho-volumetric analysis of bone structure and brain was performed at autopsy (i.e., measuring thickness of the skull, diameters of the cavities, presence of bone spurs, weight and size of the brain, thickness of the cortex, and brain analysis by Virchow cutting). Toxicologic analysis was performed. An investigation was carried out regarding previous hospitalizations and psychiatric disorders, incorporating information from family doctors and psychiatrists. Finally, a literature search was performed utilizing the PubMed<sup>®</sup> National Center for Biotechnology Information (NCBI) search engine and the key words “cranial hyperostosis” and “psychiatry” OR “psychiatric disorders.” Obtained literature was reviewed.

**Case 1:** A woman suffering from diabetes and schizoaffective disorder (depressive type) suffered an exacerbation of delirium, hallucinations, and dysphoria over the past few months. She required assistance, support, and continuous reassurance from physicians; she was not reliable and was unable to function effectively independently. She died following a suicidal fall from a height. At autopsy, HFI was noted with the presence of multiple, diffuse bone spurs, located in the anterior cranial fossa, which protruded toward the brain. The absence of fractures was due to greater resistance of the bone structure of the skull. The brain weighed 1,090 grams with softening areas and punctiform hemorrhagic areas on the thalami and the cerebellum.

**Case 2:** A woman suffering from severe dementia and diabetes was admitted with a pertrochanteric fracture of the left femur after an accidental fall. Reportedly, her dementia had diminished her cognitive abilities significantly enough that it compromised her ability to perform daily activities. She died due to massive pulmonary embolism following the femur fracture. At autopsy, frontal cranial hyperostosis was noted. The brain showed a flattening of the cerebral convolutions and a reduction in the thickness of the cortex (1,040 grams).

**Case 3:** A man was found dead due to a suicidal gunshot injury. At autopsy, Diffuse Cranial Hyperostosis (HCD) was evident with an overall reduction in brain volume (approximately 1,000 grams). There was a large subarachnoid and intracerebral hemorrhage due to the firearm. His clinical history was significant for depression with suicidal ideation.

These cases highlight disorders arising in the context of hyperostosis, including prefrontal syndrome, depression, and neurodegenerative diseases (dementia). These disorders coincide with those described in the literature, except for suicidal behavior.<sup>2,3</sup> Literature review showed that the potential role of frontal hyperostosis in the genesis of neuropsychiatric disorders so variable in their etiology, pathophysiology, and symptoms is still controversial. The most accepted hypothesis is that an abnormal release of hormones (e.g., estrogens) has a decisive role in the genesis of a “neurometabolic” syndrome. The overproduction of estrogens results in the growth of frontal bone (a known hormonal target), neuropsychiatric disorders, and metabolic diseases with greater prevalence in women.<sup>1</sup> In the current study, two of the three reported cases involved women suffering from diabetes. Additionally, the growth of sharp bone spurs on the endo-cranium could also exert a “disturbing” role on the frontal and prefrontal lobes, contributing to the prefrontal syndrome associated with the hyperostosis. In the context of neurodegenerative disorders, literature review also showed a correlation between HFI and a decrease in brain volume.<sup>4</sup> The current study illustrates the need for a statistical large-scale collection of anatomic data in psychiatric patients. Such a survey could prove critical in establishing structural anatomical data as a potential predictor of psychiatric disorders, such as prefrontal syndrome, dementia, and depression with suicidal ideation.

## H130 Patient Misinterpretation of Findings Leads to Suicide

Jack Stover\*, Kalamazoo, MI 49009; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** The goal of this presentation is to emphasize the importance of performing an autopsy in the wake of an unconfirmed medical diagnosis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the importance of post-suicide autopsy as it pertains to patient-physician communication and its role in a tragic suicide.

Approximately 14 in every 100,000 people commit suicide every year.<sup>1</sup> In 2008, 22.6% of suicides were attributable to physical health problems.<sup>2</sup> This represents a particularly relevant avenue of intervention for health care professionals. Physicians are privy to patients' most intimate health information and thus should be aware of a possible mental health crisis. When handling such matters in particular, physicians' words carry great weight. Occasionally, physicians can become numb to the sway they have on the lives of patients. Patient misinterpretation of their doctors' words can have devastating consequences. This concept is crystalized in the case of a patient who, due to a misunderstanding of information provided, committed suicide because she presumed she had been told she had cancer.

A 75-year-old woman with a history of chronic obstructive pulmonary disease, atrial fibrillation, emphysema, and hypertension presented to an Emergency Department with complaints of worsening constipation, epigastric pain, and nausea of three-days' duration. Physical exam was non-specific. A computed tomography scan revealed bilateral cystic and solid adnexal masses concerning for ovarian neoplasms. She was referred to an oncologist. Two days later, before meeting with the oncologist, her husband tried to wake her—only to find her dead in her bed, with a suicide note present. It read: "SORRY DEAR NO MONEY FOR CHEMO WON'T DO ANY GOOD I LOVE YOU! GET WELL." Subsequent medicolegal autopsy revealed a relatively healthy elderly woman. The cause of death was the toxic effects of multiple drugs, including propafenone. The manner of death was suicide. The ovarian tumors were benign cystadenofibromas, characterized by benign fibrous stroma and cysts lined by serous-type or mucinous epithelium, with no evidence of borderline or malignant cells.

In order to prevent similar tragic deaths, more patient-to-provider information checkpoints should be implemented. This would entail having patients repeat back their understanding of their diagnoses. Patients can also overestimate their understanding of care information. An interactive communication loop helps mitigate these gaps.

One technique for this is Ask Me 3, which identifies three main questions the patient should be able to answer at the end of a healthcare visit: (1) What is my main problem?; (2) What do I need to do?; and (3) Why is it important for me to do this? Use of the Ask Me 3 technique incorporates important attributes of adult learning—multiple modalities, reinforcement, and personalization—and has been linked to better health outcomes.<sup>3</sup>

In addition to communication concerns, the presented case demonstrates the importance of performing an autopsy when a patient has received a recent unconfirmed medical diagnosis, particularly if that diagnosis somehow played a role in death. A breakdown in physician-patient communication was uncovered as a result of a postmortem examination. Knowledge of the autopsy findings will alert the physician to a possible need for communication adjustment.

Some might argue that an autopsy in the case of a suicide is unnecessary in the presence of an obvious mechanism of mortality. This is true to an extent, but, in general, it does not apply to suicides by overdose. According to the Forensic Autopsy Standards promulgated by the National Association of Medical Examiners, autopsies should be performed on cases of suspected drug overdose.<sup>4</sup>

Forensic pathologists should consider performing autopsies in cases of sudden death occurring in situations with ambiguous medical diagnoses, particularly if such diagnoses may have precipitated a suicide. In addition to either confirming or refuting the decedent's supposed underlying pathology, performing autopsies in such cases may assist in revealing any possible lapses in communication between health care providers and patients.

### Communication, Suicide, Autopsy

### H131 Colonization Rates of Barnacles (Crustacea: Cirripedia) on Different Fabrics as a Tool for Forensic Investigation of Human Remains in a Marine Environment

Elysia Tingey, BS, Canning Vale, Western Australia 6155, AUSTRALIA; Jennifer Verduin, PhD, Murdoch University, Murdoch 6152, AUSTRALIA; Ian Dadour, PhD\*, Murdoch University, Perth, Western Australia 6151, AUSTRALIA; Paola A. Magni, PhD, Murdoch University, School of Vet & Life Sciences, Murdoch, Western Australia 6150, AUSTRALIA

**Learning Overview:** After attending the presentation, attendees will understand how long barnacles require to colonize four different fabrics (cotton, velvet, satin, and neoprene) in marine waters off the coast of Perth, Western Australia. The outcome of this research identifies which fabric was the most desirable substrate for colonization.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information pertaining to the colonization, settlement preference, and growth of barnacles on various types of clothing in a marine environment. This research will contribute toward increasing the accuracy of the minimum Postmortem Submergence Interval (minPMSI) of clothed human remains in a marine environment.

**Background/Introduction:** The estimation of the time since death (i.e., minimum Postmortem Interval [minPMI]) is an important aspect of a forensic investigation in a terrestrial environment and is even more challenging when a body is found submerged or floating in a marine environment. Human remains discovered on land involve an estimation of the minPMI based on the presence of carrion insects, generally blow flies (Diptera: Calliphoridae). In the marine environment, the time spent underwater by the body (minPMSI or Floating Interval [FI]) is required for an accurate minPMI. The presence of barnacles (Crustacea: Cirripedia) are one parameter that have come under recent scrutiny, due to their colonization and permanent settlement on human remains and accompanying items, such as shoes and clothing. Research on the useful nature of barnacles in forensic investigations is scarce and, to date, has not considered the different clothing materials that may be associated with human remains.

**Objectives and Methods:** The current research is focused on the colonization, settlement preference, and growth of barnacles on cotton, velvet, satin, and neoprene. Polystyrene Floats (PF), covered with four types of fabric, and uncovered Polystyrene Float Controls (PFC) were submerged over a period of six months. The investigation was located off the coast of Perth, Western Australia. The aims of this research were: (1) the identification of marine species colonizing the fabrics, with special attention paid to barnacles; (2) the identification of which fabric provides the most desirable environment for colonization; and (3) the understanding of which fabric affects the growth rate of the different species of barnacles.

**Results and Discussion:** Results revealed the presence of three species of barnacles, in varying numbers and sizes. *Balanus trigonus* Darwin was found to be the most abundant and frequently present. The two other species, *Amphibalanus reticulatus* (Utinomi) and *Amphibalanus variegatus* (Darwin), were less abundant. The colonization process of the barnacles happened rapidly, with colonization observed in the first month (28 days) on neoprene and PFC. Statistical analyses were used to determine significant relationships between barnacle diameter (measure of growth) and fabric. Overall, the most favorable substrates that were colonized by barnacles were neoprene and PFC, followed by satin. Cotton showed a low colonization rate, possibly due to the partial deterioration of the material over time, and velvet showed an inconsistent colonization rate. The settlement preference of barnacles on all fabrics and the PFC was on the bottom half of the floats (away from sunlight exposure) and areas where the fabric folded. This study is the first to provide data to support the estimation of PMSI of clothing fabrics that may be associated with human remains in Australian marine waters.

#### Barnacle, Colonization, Postmortem Interval

### H132 The Applicability of FLIR® Thermal Imaging of Swine Decomposition During the Louisiana Summer

Helen R. Carter, BS\*, Hammond, LA 70401-7095; Erin J. Watson-Horzelski, PhD, Southeastern Louisiana University, Hammond, LA 70402

**Learning Overview:** After attending this presentation, attendees will have gained insight on the use of thermal imaging in forensic entomology and taphonomic studies. The goal of this presentation is to characterize the thermal sources and effects of external (ambient and carcass surface) and internal heat units (maggot mass heat, carcass tissues) on blow fly development and postmortem estimations. This presentation will illustrate the potential differences between observed thermal heat units and those hypothetically available at Cadaver Decomposition Islands (CDIs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the incorporation of FLIR® C2™ thermal imaging can provide real-time documentation of thermal units at CDIs and human remains recovery sites.

Postmortem estimations based on insect evidence are often determined by the summation of thermal units at a crime scene to predict the energy budgets required to complete specific insect life stages present on human remains. Forensic entomology studies have increasingly focused on improvements to accumulated degree day calculations and thermal summation models, with particular emphasis on: (1) biological thresholds for growth; (2) maggot mass metabolic heat; and (3) the curvilinear portion of insect development.<sup>1,2</sup> The aim of this research was to incorporate infrared thermal imaging to field studies of large vertebrate carrion, as well as to illustrate the potential usefulness of FLIR® thermal imaging to both decomposition research and law enforcement communities.

Louisiana has a humid subtropical climate with long, hot, humid summers and short, mildly warm winters.<sup>3,4</sup> Whereas, summer daily ambient temperatures typically exceed 32°C with carcass temperatures often approaching biological maximums for blow fly development when large maggot masses are present (greater than 50°C). FLIR® infrared thermal imaging can provide real-time documentation of carcass surface temperatures, as well as areas of elevated internal temperatures due to maggot mass metabolic heat. A preliminary study utilizing infrared imaging as a “non-invasive tool” for documenting maggot mass temperatures on swine carrion in Australia was conducted in 2014.<sup>5</sup> However, those authors briefly studied only one juvenile swine carcass in the field (7d) and one juvenile swine in a temperature-controlled room (9d).

This research was conducted using three fresh adult swine carcasses (~45–60kg each) placed on the ground in a hard-bottom flatwoods forest at Southeastern Louisiana University’s Outdoor Classroom in July 2019. Each sampling event included manual sampling of insects, digital photography, and multiple temperature measurements within the CDI. Temperature data included: (1) FLIR® C2™ compact professional thermal imaging system (infrared camera) to document carcass surface temperatures and maggot mass activities within the carcass; (2) dual digit temperature probe for internal carcass temperatures, maggot mass heat, soil-carcass interface, soil and ambient temperatures; and (3) climatology data from Hammond Municipal Airport weather station. Accumulated degree day estimations were calculated for multiple indicator species using both observed thermal units and regional airport climatology data. Earliest blow fly colonizers for all three swine carcasses included: *Chrysomya megacephala* (F.), *Cochliomyia macellaria* (F.), *Lucilia coeruleiviridis* Macquart, and *Phormia regina* (Meigen).

The FLIR® C2™ infrared camera provided the following for each sampling event: (1) infrared images (isotherms); (2) relative humidity isotherms; and (3) digital photographs for comparisons. All infrared images were analyzed using FLIR® Tools+ Imaging Software (2016). Nine to ten carcass and CDI regions were analyzed per sampling event: mouth (anterior), ear (dorsal head), forelimbs, abdomen, hind limbs, posterior, beneath the carcass, wounds, and adjacent ground/leaf litter (control). Thermal recordings from digital temperature probes were analyzed against the FLIR® output and isotherms were compared for humidity levels. The addition of FLIR® Tools+ output contributed valuable information to the overall understanding of the microenvironment of CDIs and the role of temperature and humidity throughout vertebrate decomposition.

### H133 Maternal Death by Fire and Fetal Carboxyhemoglobin Levels

*Nicole D. Lee, MS\*, Western Michigan University, Kalamazoo, MI 49007; Theodore T. Brown, MD, Kalamazoo, MI 49008*

**Learning Overview:** After attending this presentation, attendees will understand: (1) the physiology of acute carbon monoxide exposure and carboxyhemoglobin levels, (2) the existing research from animal models and limited case studies on maternal carboxyhemoglobin levels and concurrent fetal levels, (3) how paired maternal and fetal carboxyhemoglobin levels vary based on the type of carbon monoxide exposure, and (4) how the findings from the present case fit into prior findings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a better understanding of the significance of carboxyhemoglobin levels in mothers and fetuses in the setting of both acute and chronic carbon monoxide exposure.

The effect of maternal carbon monoxide exposure on fetuses is an underreported topic. The relationship between maternal carboxyhemoglobin levels and fetal carboxyhemoglobin levels has yet to be fully explained, especially in cases of acute, non-smoking-related exposures. Data from animal model experiments on rabbits and ewes demonstrated a lag in rising fetal carboxyhemoglobin levels after acutely exposing the mother to carbon monoxide. Eventually, over several hours, the fetal levels exceed the mother's and reached equilibrium approximately 10% higher. A search of previously published studies on humans only revealed seven paired reports of maternal and fetal carboxyhemoglobin. Presented here is a pregnant female involved in a residential fire where carboxyhemoglobin levels were tested in both the mother and fetus.

An 8-month pregnant, 35-year-old woman died in a house fire caused by an overloaded extension cord. Postmortem examination documented extensive fire-related changes, which included singed hair, diffuse charring of the skin, skin splits, and soot deposition of the airways. The skin splits were predominantly on the forehead, left temple, perioral region, chin, upper chest, bilateral upper extremities, and lower abdomen. There was dense soot in the nares, oral cavity, and trachea, and scant soot in the bilateral mainstem bronchi and proximal esophagus. The muscles, body cavities, and organs had a bright red-pink discoloration. The decedent's carboxyhemoglobin level was elevated at 51.3%. Her cause of death was inhalation of products of combustion and thermal injuries. The fetus had neither trauma nor malformations. Fetal heart carboxyhemoglobin level was 4.9%.

The research on what fetal carboxyhemoglobin levels occur at certain maternal carboxyhemoglobin levels is unclear. While there are some studies on chronic maternal exposure to carbon monoxide (mostly through smoking) and paired fetal and maternal carboxyhemoglobin levels, there are very few case studies available regarding acute carbon monoxide toxicity and concurrent maternal and fetal carboxyhemoglobin levels. The levels found in this case provide insight into this relationship by corroborating previous findings that demonstrated a lag between acute and severe maternal exposure and a corresponding rise in fetal levels.

#### Carboxyhemoglobin, Pregnant, Fire

### H134 The Mouse Thanatomicrobiome Is Highly Variable in Early Postmortem Intervals

Taylor L. Smith\*, Emporia State University, Emporia, KS 66801; Molly B. Still, MS, Topeka, KS 66604-1514; Scott S. Crupper, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** The goal of this presentation is to present data regarding the mouse thanatomicrobiome and discuss its application as a potential alternative to current postmortem interval determination. This presentation will also provide evidence the mouse model system may be applicable to human thanatomicrobiome studies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a potential alternative to current postmortem interval determination. This is especially relevant as determining an accurate postmortem interval is a key component of many crime scene investigations.

The postmortem microbiome of internal organs is referred to as the thanatomicrobiome, and microbial changes that occur within may have potential forensic applications. As compared to microbes on the surface of a decomposing body (epinecrotic microbiome), microbial signatures associated with internal organs are less susceptible to environmental changes and may represent a valid means of determining a postmortem interval. Although the thanatomicrobiome remains poorly understood, recent advances in the field of metagenomics have provided the necessary technology to better investigate the microbiome of this complex environment.

This laboratory previously investigated the mouse liver thanatomicrobiome to determine if it would be a suitable model system comparable to a human. Using 7–21-day postmortem mice, a *Clostridium* effect was observed similar to that reported in human cadavers. Furthermore, as the postmortem interval increased, the species richness of the liver also increased, suggesting that decomposition is mediated by a wide variety of microorganisms. However, questions remained regarding the makeup of microbial signatures in earlier postmortem intervals. To fill this gap of knowledge, the liver thanatomicrobiome of pre-seven-day postmortem mice was examined.

Mice were sacrificed using CO<sub>2</sub> asphyxiation and immediately placed in covered containers maintaining proper air flow to allow the natural decaying process to take place. Three separate time intervals were analyzed: one, three, and five days postmortem, in addition to control groups (zero and seven day postmortem). Livers were dissected and stored at -80°C until DNA was extracted with a Zymo Research Tissue/Insect Miniprep kit following the manufacturer guidelines. Subsequently, the V3 hypervariable region of the 16S ribosomal RNA (rRNA) gene was amplified and sequenced on an Illumina MiSeq® platform. Bioinformatic analysis of the resulting data identified predominant organisms present down to the level of genus.

Day one postmortem mice consistently revealed *Escherichia* and *Bacteroides* predominated. *Escherichia* levels were extremely variable (61-1%) while *Bacteroides* levels were much more consistent (3-4%). Although day three mice consistently demonstrated that genera in the family *Clostridiaceae* increased along with *Bacteroides* as its predominant members, this trend did not continue as the day five postmortem mice demonstrated high levels of *Escherichia*. At day seven postmortem, the *Clostridium* effect was widely seen as earlier determined. The observed variability seen in days one through five extended into the Shannon Species Diversity Index, which measures species richness. Values obtained were extremely variable, and no discrete trends were observed as compared to the 7-21 day postmortem mice. Taken together, these data suggest the liver thanatomicrobiome is highly variable in the initial days postmortem and individual host differences may significantly affect the rate of decomposition.

#### Thanatomicrobiome, Postmortem Interval, *Clostridium* Effect

### H135 A Fatal Hemorrhage From a Periumbilical Wound: A Case of Stabbing or a Rare Bleeding From a Caput Medusae?

*Francesca Frigiolini\**, Genova 16143, ITALY; *Sara Lo Pinto, MD*, University of Genova, Genova 16146, ITALY; *Fiorella Caputo, MD\**, Department of Legal and Forensic Medicine, Genova 16132, ITALY; *Rosario Barranco\**, University of Genova, Department of Legal Medicine, Genova 16132, ITALY; *Giulio Fraternali Orcioni, MD*, Department of Clinical Pathology, Genova 16132, ITALY; *Alessandro Bonsignore, MD, PhD\**, University of Genova, Genova, Liguria 16132, ITALY; *Francesco Ventura, MD\**, Department of Legal Medicine University of Genova, Genova 16132, ITALY

**Learning Overview:** After attending this presentation, attendees will have learned about a rare complication of portal hypertension in a context of Hepatitis C Virus (HCV) -related liver cirrhosis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing attention to the importance of conducting a complete autopsy examination, supported by histological studies, in all patients with portal hypertension in order to identify skin wounds that could be a sign of an ectopic varix rather than a case of stabbing. This presentation will also raise awareness in the clinical community for understanding a complication of portal hypertension which, without a proper treatment, could be fatal.

Portal hypertension is a serious complication of chronic liver disease. Varices are the most common clinical manifestations, and variceal bleeding is the predominant cause of mortality in patients with portal hypertension. The most common site of varices is the lower esophagus, but they may occur at any location where there are portosystemic anastomoses, including the periumbilical venous plexus. Periumbilical varices are known as “caput medusae.” Deaths due to exsanguination from periumbilical variceal rupture are rare with only two such fatalities reported in the literature.

A 55-year-old man was found dead in a hotel room. He was lying on the floor near the bed in a prone position. The body was surrounded by a large pool of blood that extended (in drips and stripes) to the bathroom floor. The pattern of blood suggested that the man had moved from the bathroom to the bedroom, where he then died. The external examination of the body revealed a small round wound close to the umbilicus. On pressing the abdomen, blood was seen to flow from the wound, thus establishing the origin of the hemorrhage. No further injuries were detected. A review of the decedent’s medical history revealed that he was affected by type II diabetes mellitus, HCV-related liver cirrhosis, and portal hypertension. He also had a liver tumor, which had been treated with chemotherapy, and was waiting for a transplant.

Autopsy revealed a cirrhotic liver with firm parenchyma. Evidence of portal hypertension included dilatation of the vena cava, splenomegaly, and intact esophageal varices. No blood was recovered from either peritoneal cavity, nor was evident in the gastrointestinal tract. A relevant finding was the presence of abnormally dilated and convoluted veins in the subcutaneous tissue of the umbilical region (i.e., caput medusa). The abdominal wound depth was established with the help of a probe, showing that the injury extended deep into the subcutaneous fat and the periumbilical veins. All these autopsy investigative findings served to exclude a stabbing injury. Histologic sections showed that the abdominal wound consisted of epidermidis located on top of an ectatic venous vessel with a focally interrupted wall. In the subcutaneous tissue, there was a widespread presence of ectatic vessels of medium to large caliber. These histologic findings confirmed that one of the periumbilical varices had ruptured and connected with the overlying skin through a fistula that was likely formed due to inflammation. Ultimately, the cause of the death was attributed to massive hemorrhage due to periumbilical varix rupture with cutaneous fistula formation in a patient with portal hypertension attributable to HCV-related liver cirrhosis.

In conclusion, only by careful and complete autopsy—including histologic analysis, medical record review, and circumstantial scene investigation—is the correct final diagnosis obtained in extremely rare and complicated cases such as this. Moreover, this case highlights the importance of evaluating for the presence of possible varices in less-common locations when dealing with patients affected by portal hypertension.

#### Caput Medusae, Portal Hypertension, Fatal Hemorrhage

### H136 Brain Damage and MicroRNA (miRNA) Dysregulation: An Experimental Study

*Francesco Sessa, MS\**, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY; *Luigi Cipolloni, MD, PhD*, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; *Monica Salerno, MD, PhD*, University of Catania, Forensic Medicine, Catania 95123, ITALY; *Pietrantonio Ricci, PhD*, University of Catanzaro, Catanzaro, ITALY; *Cristoforo Pomara, MD, PhD*, Catania, Foggia, ITALY

**Learning Overview:** After attending this presentation, attendees will have a better comprehension of miRNAs as a useful tool, both in the clinical setting and in medicolegal investigation. Particularly, this experimental study focused on brain damage, analyzing the miRNAs expression values in four selected groups of cadavers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing evidence about the expression levels variation of the specific miRNAs (miR-21, miR-34, miR-124, miR-132, and miR-200b) involved in the control of important target genes that regulate the neuronal apoptosis and neuronal stress-induced adaptation.

Brain damage and/or dysfunction as a sequelae of multiple different conditions is considered an important field of research for the scientific community. Recent studies have focused on side effects related to aging of the Central Nervous System (CNS). Moreover, a growing number of investigations have been conducted, analyzing the CNS effects of stroke and drug use/abuse. The identification of specific circulating and/or tissue biomarkers that could indicate brain injury remains challenging, however. Since 2007, miRNA technology has become an integral part of research; the scientific community has frequently investigated utilizing miRNA as potential molecular biomarkers for several diseases. Today, miRNA dosage has become an essential tool in several clinical applications.

This experimental study focused on miRNA expression in cases of brain injury. MiRNA is a well-known diagnostic tool, both in the clinical setting and in medicolegal investigations. Previous studies have demonstrated that specific miRNAs (i.e. miR-21, miR-34, miR-124, miR-132, and miR-200b) control important target genes involved in neuronal apoptosis and neuronal stress-induced adaptation. Thus, in this experimental setting, their expression was evaluated in four selected groups of decedents in which five males were selected for each group (i.e., Anabolic Androgenic Steroid [AAS]; propionate testosterone) abuser, drug abusers (cocaine), ischemic-stroke-related deaths, and aging damage in elder decedents who died from other neurological causes).

Total RNA, including miRNAs, was isolated from Formaldehyde-Fixed Paraffin-Embedded (FFPE) samples using the RecoverAll™ Total Nucleic Acid Isolation Kit with minor modifications. For miRNA profiling, the TaqMan Advanced miRNA Assay was used. Complementary DNA (cDNA) was obtained following TaqMan® Advanced miRNA Assays User Guide (Publication number 100027897 Rev. C). Quantitative Real-Time Polymerase Chain Reaction (qRT-PCR) was performed using the StepOnePlus™ Real-Time PCR System, and raw data were analyzed using the relative software (version 2.3). Expression fold changes were computed using the  $2^{-\Delta\Delta Ct}$  calculation.

Study results demonstrated that drug abuser and AAS abuser groups showed a higher expression of miR-132 and miR-34, suggesting a specific pathway in consumption-induced neurodegeneration. Conversely, miR-200b and miR-21 dysregulation was linked to age-related cognitive impairment. Finally, ischemic stroke-related deaths were associated with an alteration in miR-200b, miR-21, and miR-124; significantly higher levels of this last expression were strongly sensitive for ischemic damage. Moreover, these results suggest that these expression patterns could be studied in other biological samples (e.g., plasma, urine) in subjects with brain injury linked to aging, AAS abuse, drug abuse, and stroke to identify reliable biomarkers that could be applied in clinical practice. Further studies with larger samples are needed to confirm these interesting findings.

### Anabolic Androgenic Steroids (AASs), Brain Injury, MiRNA Dysregulation

### H137 Under Pressure: A Small Italian Town Under Attack

*Michela Ferrara, MD\**, Department of Forensic Pathology, Foggia 71122, ITALY; *Francesca Maglietta, MD\**, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; *Margherita Neri, MD, PhD*, University of Ferrara, Ferrara 44100, ITALY; *Luigi Cipolloni, MD, PhD*, Department of Forensic Medicine Sapienza Rome, Rome 00161, ITALY; *Stefania De Simone, MD*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; *Francesco Sessa, MS\**, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; *Giuseppe Bertozzi, MD\**, Department of Forensic Pathology, Foggia 71121, ITALY

**Learning Overview:** The goal of this presentation is to report the case of a young girl killed in front of her school by the explosion of a rudimentary bomb. The application of a multidisciplinary forensic approach showed the death was due to a primary blast lung injury.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reporting an example of an analytic approach to guide the forensic pathologist in the diagnosis of primary blast injury in explosion deaths, which are increasing events in civilian populations.

Blast injuries are physical traumas due to explosions. They are a frequent event in war zones, but may increasingly be seen in civil settings due to terrorist attacks. Primary blast injury is defined as being attributable to the blast wave effects. Air-filled organs, such as lungs, the gastrointestinal tract, and middle ears, are most frequently affected because the blast wave easily compresses them. The diagnosis of primary blast injury can be challenging for the forensic pathologist as the absence of external injuries may lower the suspicion for investigating internal lesions.

This presentation reviews the death of a 15 year-old girl secondary to the explosion of a handmade bomb. The event occurred at around 7.45 a.m. in front of a high school in an Apulian town in Italy,. The bomb was hidden behind a garbage can placed near the school gates and was operated remotely. A group of nine students were wounded; among them, a 15 year-old girl who died shortly after arrival at the hospital. An autopsy was performed. However, before autopsy the forensic pathologist requested a total body Computed Tomography (CT) scan, which documented the presence of multiple pulmonary lacerations and contusions of the right lung, bilateral pleural effusion, and a massive left pneumothorax with hypexpansion of the left lung. External examination showed multiple excoriations spread over the body and particles of a blackish color fixed in the facial epidermis. Internal examination confirmed the CT findings and revealed the presence of fractures of the posterior arches of the eighth and ninth left ribs and a fracture of the left scapula. Histologic investigations performed on the lungs with hematoxylin-eosin staining showed pleural lacerations, subpleural hemorrhages, acute pulmonary emphysema, acute alveolar septal ruptures, and massive endoalveolar hemorrhages. The immunohistochemical examination of skin samples, performed using anti-Heat Shock Protein (HSP) antibodies (i.e., HSP 27, HSP 70, HSP 90), confirmed the presence of heat alteration of the skin. Skin samples stained with Perls' histochemical method (to demonstrate the presence of iron) and with the sodium (Na) -rhodizonate solution (to demonstrate the presence of lead, barium and antimony), were observed in polarized light and in phase contrast microscopy, using a quantitative analysis of images. The reactions were positive.

The absence of significant external lesions, in conjunction with the pulmonary histologic alterations and immunohistochemical evidence, led to the conclusion that death was due to acute respiratory injury secondary to the architectural subversion of the pulmonary parenchyma as a direct consequence of the detonation of an explosive bomb (i.e., primary blast lung injury). The perpetrator responsible for the massacre claimed to have triggered the bomb in anger due to a scam he suffered. The prosecutor's office identified the event as a terrorist act; the perpetrator was sentenced to life imprisonment. No other cases like this one have been reported in Italy.

In cases of explosions, decedents should undergo radiologic evaluation prior to the autopsy examination. Such examination allows for the identification of several findings that may not otherwise be evident during the autopsy (e.g., pneumothorax) and can guide the forensic pathologist in focusing on organs of interest. In suspected primary blast lung injury, histologic studies are mandatory to confirm typical evidence (e.g., diffuse alveolar overdistension and interstitial hemorrhage). Immunohistochemical methods may provide additional information about the biochemical changes that can occur after the heat damage, which are in other ways complicated to analyze; additionally, this method can provide information about the chemical elements contained in the explosive mixture. Overall, the diagnosis of blast injury-related deaths can be challenging because of their low frequency in the civil population and non-specific presentation that can mislead forensic pathologists inexperienced in this type of case. This presentation aims to propose a model of an analytical approach to these types of deaths.

### Blast Injury, Explosions, Analytical Approach

### H138 A Cold Bone Heart: A Rare Case of Death Due to Acute Myocarditis in a Subject Suffering From Chronic Constrictive Pericarditis

Lorenzo Spagnolo, MD\*, Department of Forensic Pathology, Foggia, Foggia 71122, ITALY; Francesco Sessa, MS\*, University of Foggia, Forensic Pathology, Foggia 71100, ITALY; Francesca Maglietta, MD\*, University of Foggia, Forensic Pathology, Foggia 71122, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Alessandra Radogna, MD, University of Foggia, Legal Medicine, Foggia 71122, ITALY; Santina Cantatore, Foggia 71100, ITALY; Irene Riezzo, MD, PhD, SC di Medicina Legale, Foggia 71100, ITALY; Giuseppe Bertozzi, MD\*, Department of Forensic Pathology, Foggia 71121, ITALY

**Learning Overview:** The goal of this presentation is provide a suitable methodological approach to cardiac-related death due to suspected myocarditis occurring in subjects suffering from chronic constrictive pericarditis instrumentally ascertained. This study focuses on macroscopic and histological findings used to reach the diagnosis of the cause of death, with particular regard to the immunohistochemical assessment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the methodological approach employed in rare cases of fatal acute myocarditis in subjects with diagnosed chronic constrictive pericarditis and the importance of conducting an exhaustive immunohistochemical study with CD45, CD3, CD4, CD8, CD20, CD15, and CD68 antibodies in order to obtain a reliable postmortem diagnosis of myocarditis.

Myocarditis may present with a wide range of symptoms, ranging from mild dyspnea or chest pain, resolving without specific therapy, to cardiogenic shock and death. The onset of acute myocarditis in a substrate of patients with pre-existing chronic constrictive pericarditis is a sporadic occurrence.

A 48-year-old man with a history of chronic constrictive pericarditis of unknown etiology presented to his family doctor with respiratory difficulties, asthenia, and fever with shivering. The doctor prescribed antibiotic therapy, recommending a second evaluation after a few days. However, the day after, the patient was taken to the hospital due to a sudden drop in blood pressure. Electrocardiogram showed diffuse ST elevation, while laboratory tests showed increased levels of cardiac necrosis markers. Echocardiogram revealed the presence of a hyperechoic calcific pericardial formation that circumferentially enveloped the heart, as well as ventricular hypertrophy with a deficit in lateral kinetics and an ejection fraction of 30%. Cardiac ventriculography confirmed the circumferential pericardial calcifications, while coronary angiography revealed no arterial stenoses. Notwithstanding the diagnostic efforts of the physicians, the patient died the following day of unclear causes. Following a complaint of medical malpractice to the judicial authority, a complete autopsy was performed.
