At autopsy, gross examination of the heart revealed it to be encased by a fibrocalcific rind, thus confirming the clinical history of chronic constrictive pericarditis. Moreover, the heart had increased dimensions with dilated ventricular chambers and increased parietal pericardial thickness. The coronary arteries were essentially unremarkable without stenosis. Examination of remaining organs was unremarkable. Hematoxylin-Eosin (H&E) -stained histologic sections highlighted a polyvisceral stasis, as well as the presence (in the cardiac samples) of marked fibrotic thickening of the pericardial leaflets with areas of infiltration of white cells. These white cells were also present in the myocardium, disrupting the myocardial architecture. Multiple foci of Contraction Band Necrosis (CBN) involving the sub-endocardial layers were found. To better characterize the myocardial cellular infiltrates, an immunohistochemical evaluation was performed using antibodies against leukocytes (CD45), the main leukocyte subpopulations (i.e., CD3, CD4, CD8, CD20, CD15), and macrophages (CD68). The cellular infiltrate demonstrated strong positivity for CD45 (+++), moderate positivity for CD68 (++), mild positivity for CD8 (+), and negativity for the remaining markers.

Given these results, according to the Dallas criteria, the patient's death was attributed to massive acute myocarditis arising in the setting of chronic constrictive pericarditis. Given the rapidity of the clinical course, the prosecutor determined no malpractice on the part of the physicians; indeed, they had performed multiple diagnostic tests and provided the correct supportive therapy as indicated by the most authoritative literature on the subject.

## H139 Using Culturomics to Investigate the Mouse Thanatobiome

Christi Meyer\*, Yukon, OK 73099; Scott S. Crupper, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** The goal of this presentation is to demonstrate how culturomics can complement the metagenomic investigation of the mouse thanatobiome.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the isolation and identification of living microbes from the thanatobiome will increase understanding of its culturable bacterial diversity. This knowledge will complement existing molecular data to aid in determining if the thanatobiome can provide an alternative to existing methodologies for Postmortem Interval (PMI) estimation.

Forensic microbiology is a rapidly expanding field that has many broad applications in forensic science. Recent advances in DNA sequencing and computing technologies (e.g., metagenomics) have provided researchers with a molecular toolkit to explore a multitude of diverse forensic questions—for example, investigating microbial changes that occur postmortem using next generation DNA sequencing to yield a profile of the thanatobiome, or microbes found associated with internal organs after death. Despite these technological advances and data obtained, many questions remain regarding how to interpret the results and their direct forensic application.

While the use of metagenomics has revealed a complex and diverse thanatobiome that changes with Postmortem Interval (PMI), all interpretations are based on a small piece of DNA and not the organism itself. Indeed, the recent revival of culture-based microbiology, referred to as culturomics, is gaining momentum in the scientific community. Being able to study a living microbe rather than information from a piece of DNA may provide additional opportunities to understand the relationship between the thanatobiome and PMI estimation.

Previously, this laboratory has been examining the usefulness of a mouse model system to study the thanatobiome. Using an Illumina® MiSeq® platform, DNA sequencing of the V3 hypervariable region of the 16S ribosomal RNA (rRNA) gene indicated that *Clostridium* species dominated as early as seven days postmortem. As we continue to gain a better understanding of the mouse thanatobiome and its usefulness in PMI determination, a culturomics-based approach was initiated to start obtaining information based on the direct isolation of microbes from the mouse thanatobiome.

Mice were sacrificed by CO<sub>2</sub> asphyxiation and placed in sealed containers that allowed air flow for up to seven days. Livers were harvested at PMIs of two and seven days. The harvested livers were homogenized in a saline solution and put through a series of serial dilutions. These dilutions were plated on pre-reduced blood agar plates, placed into an anaerobic chamber, and left to incubate at 37°C until bacterial colonies appeared (about three days). Organisms were isolated and total DNA purified using the ZR Fungal/Bacterial DNA MicroPrep kit. Subsequently, the 16S rRNA gene was amplified by Polymerase Chain Reaction (PCR), followed by DNA sequencing. The basic local alignment search tool (Basic Local Alignment Search Tool [BLAST]) was utilized for bacterial identifications.

The obligate anaerobe *Clostridium* dominated the isolations at both PMIs, followed by the facultative anaerobes *Escherichia* and *Shigella*, which could not be discriminated from each other. Less abundant facultative and aerotolerant anaerobes were also identified. Although a limited number of bacterial isolates were examined, this data supports the *Clostridium* effect dominating the culturable thanatobiome, although no discrete trends were seen. Further examination into the non-*Clostridium* population is needed to ascertain if culturomics can support the metagenomic investigation of the thanatobiome and its usefulness in PMI determination.

### Thanatobiome, Culturomics, Postmortem Interval

### H140 An Accidental Asphyxiation by Christmas Lights in a Patient With Schizoaffective Disorder

Corey A. Hornersmith, BS\*, Eastern Virginia Medical School, Norfolk, VA 23507; Wendy M. Gunther, MD, Office of the Chief Medical Examiner, Tidewater District, Norfolk, VA 23510-1046

**Learning Overview:** After attending this presentation, attendees will have reviewed an unusual case of accidental asphyxiation with an atypical ligature and familiarized themselves with the impact of psychiatric illness on mortality, specifically regarding accidental and suicidal deaths.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community in terms of recognition of an unusual ligature not previously reported in asphyxial death, differentiating accidental from suicidal death in persons with psychiatric illness, and evaluating the role of psychiatric illness in a shortened life span and in accidental asphyxia.

Patients with psychiatric illnesses have been shown to have shortened life expectancy and increased rates of mortality from all causes of death. Accidental and suicidal deaths are significantly increased in psychiatric patients, especially those with schizophrenia, when compared to the background population.<sup>1</sup> An illustrative case report is presented.

A 62-year-old woman with multiple psychiatric diagnoses, including schizoaffective and substance use disorders, was found dead by her brother in midsummer in her locked trailer home. Her body was in a condition of moderately advanced decomposition, consistent with the interval observed (i.e., last seen alive five days earlier). Medical and social history included repeated admissions to local inpatient psychiatric wards; she had been the subject of numerous calls to police regarding aggressive or irrational behavior when home. Her brother was her primary caretaker. At the scene, the interior temperature was measured at 105°F. Christmas lights lined the bedroom ceiling, on three of the four walls. The decedent's body was supine on the floor near the bed, entangled in Christmas lights around the neck and torso.

At autopsy, external examination was notable for dried brown-black fluid emanating across the cheeks from each corner of the mouth. The Christmas lights were deeply embedded horizontally around the neck, crossing at the left side of the neck without a knot. One string passed around her upper arm and shoulder; the other string wrapped twice around her torso. After removal of the Christmas lights, a corresponding ligature mark was identified in the exposed dermis; internal examination identified a linear pale area on the undersurface of the platysma muscle and across the superficial strap muscles, without other evidence of injury. Identifiable natural disease included emphysema, atherosclerosis, and remote tubal ligation. Death was attributed to accidental asphyxia from a Christmas light ligature. The contribution of heat was unclear, but likely not significant in the asphyxia. As it seemed likely that she should have been able to untangle the Christmas lights if free of mental illness, schizoaffective disorder was deemed a contributing cause.

Psychiatric illnesses are recognized to place patients at a higher risk of accidental death, as well as suicide and natural death. The literature examining the mortality gap between decedents with and without psychiatric illness has given rise to a number of theories for the discrepancy, including negative side effects of antipsychotic medications, increased tobacco use, unhealthy lifestyle, delayed diagnosis and suboptimal treatment of physical illness, and increased risk of unnatural death.<sup>1</sup> Internet and medical library searches have not identified any previous case reports of intentional or accidental asphyxiation via Christmas light ligature. A case of accidental asphyxial death has been reported in an inebriated 67-year-old man without psychiatric history, who was found dead in a sitting position, with the collar of his sweater hanging off the brake handle of a motorcycle.<sup>2</sup> A schizophrenic woman in her sixties who was judged to have asphyxiated herself on an intraoral handkerchief may have been responding to internal stimuli secondary to her psychiatric illness (suicide) or may have accidentally blocked her airway while attempting to stop the bleeding from a recently avulsed canine tooth.<sup>3</sup> In either scenario, her psychiatric illness was relevant to death. This case report identifies another unusual mechanism of accidental asphyxial death in a woman with psychiatric illness.

### H141 When the Autopsy Is the Only Possibility to Obtain a Diagnosis: The Investigation of a Rare Case of Aortopulmonary Window (APW)

*Alessandro Santurro, MD\**, Sapienza University of Rome, Rome 00161, ITALY; *Cemyigit Deveci, MD*, Akdeniz University, Antalya 07070, TURKEY; *Matteo Scopetti, MD*, Sapienza University of Rome, Rome 00161, ITALY; *Vittorio Gatto, MD*, Sapienza University of Rome, Rome 00161, ITALY; *Federico Manetti, MD*, Rome, ITALY; *Mariantonia Di Sanzo, MD*, Rome 00161, ITALY; *Antonio Grande, MD, PhD*, Forensic Science Police Service, Rome 00173, ITALY

**Learning Overview:** The goal of this presentation is to report the autopsy investigation of a neonatal death due to a rare congenital defect, APW.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by outlining the role of forensic pathology in the management of a difficult task, such as the diagnosis of congenital heart defects.

APW is one of the rarest congenital heart defects, accounting for 0.5% of all congenital heart defects. The malformation is caused by incomplete development of the aortopulmonary septum during fetal life. APW can be isolated or seen as a part of a wide variety of other cardiac anomalies, such as atrial or ventricular septal defects, patent ductus arteriosus, Berry syndrome, pulmonary atresia, aberrant subclavian artery, and tetralogy of Fallot. Patients with APW have increased pulmonary flow, due to the presence of a left-to-right shunt, which leads to pulmonary hypertension in early life and is associated with a poor prognosis in the absence of surgical correction.

This is the report of a case of a male newborn delivered via caesarean section at full-term (39 weeks) who rapidly developed cyanosis, poor reactivity, and hypotonia, necessitating partial resuscitation and oxygen therapy. The quick clinical deterioration resulted in rapid transportation to an advanced hospital where a diagnosis of respiratory distress was made. Despite the intensive care, the symptoms worsened, and the newborn died about 15 hours after birth. An autopsy investigation was performed in order to establish the cause of the symptoms and death.

At autopsy, the cervical, thoracic, and abdominal organs were removed en masse, according to the Letulle technique. After external examination, the heart, lungs, and aorta were separated as a block, and subsequently fixed in formalin. Gross examination after formalin fixation showed an increased heart volume and a pseudo-aneurysmal dilatation of the pulmonary artery. Sectioning of the great vessels highlighted a wide communication between the aorta and pulmonary artery due to lack of an aortopulmonary septum; the defect was located about 3mm before the origin of the left subclavian artery. Main branches of the aortic arch were normal, except for a stenosis of the left subclavian artery approximately 6.6mm from its origin. The findings identified during the postmortem examination made it possible to identify the cause of death as acute cardiopulmonary insufficiency due to a congenital heart defect with a left-to-right shunt (i.e., APW).

Despite advancements in medical technology and practice, congenital heart diseases are still encountered at autopsy of many stillbirths, newborns, and infants. The rarity and the rapid clinical evolution of these conditions—as well as the low likelihood of antemortem diagnosis in many cases—constitutes a challenge for the forensic pathologist. The current case report emphasizes the importance of choosing the appropriate autopsy technique and the need of training in the detection of congenital heart defects, especially in situations of antemortem misdiagnosis or where ancillary methods, such as forensic radiology, are unavailable.

#### Congenital Heart Defects, Aortopulmonary Window, Autopsy Investigation

### H142 A Comprehensive Review of the Pathology of Blunt Traumatic Spinal Cord Injury (TSCI) Resulting in Early Fatality

Declan McGuone, MD\*, Yale School of Medicine, New Haven, CT 06510; Nalin Leelatian, MD, PhD, Yale School of Medicine, New Haven, CT 06510; Kristin Roman, MD, City of New York Office of Chief Medical Examiner, New York, NY 10016

**Learning Overview:** After attending this presentation, attendees will understand the pathologic changes associated with blunt TSCI, as well as the connection between specific pathologic changes and underlying mechanisms of injury.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing an epidemiologic profile for blunt impact spinal cord trauma in a large urban environment and by identifying patterns of injury that may be seen in spinal cord trauma due to blunt impact.

**Introduction:** TSCI is associated with significant neurologic morbidity and mortality. Although the annual incidence of TSCI is estimated at 54 cases per million people per year, data from the National Spinal Cord Injury Statistical Center do not typically include cases with a fatal outcome at the scene of injury.<sup>1</sup> Moreover, the pathologic features of blunt TSCI occurring at the moment of impact are less well-described than secondary changes as a complication of initial tissue disruption. Therefore, characterization of the pathologic changes associated with early lethality is needed to better understand the mechanisms of TSCI.

**Methods:** This study aimed to characterize the neuropathologic profile of blunt impact TSCI resulting in a fatal outcome at the incident location. An electronic database at the City of New York Office of Chief Medical Examiner was queried for all blunt force trauma deaths undergoing full autopsy between 2003 and 2018. All cases with spinal trauma, either in isolation or in combination with other blunt injuries, were identified. Autopsy reports were reviewed by two board-certified forensic pathologists. Exclusion criteria were: (1) any known survival period after injury, (2) any history of spinal disease, and (3) TSCI due to a non-blunt mechanism (e.g., sharp force or gunshot trauma).

**Results:** Two hundred twenty cases of blunt TSCI, resulting in a fatal outcome at the incident location, were retrospectively identified over a 16-year period. The median age was 46.5 years; 77.72% were male and 22.28% were female. Manners of death were accident (80.9%), suicide (10%), homicide (3.7%), and undetermined (5.4%). The most common mechanism of injury was motor vehicle collision (44.1%), followed by fall from standing height (29.5%), and descent from height (12.3%). Ethanol was the most frequent substance on toxicologic testing (33.6%). Atlanto-occipital dislocation was seen in 15.45% of cases and showed an association with transportation-related fatalities in young individuals. Most spinal fractures were single-level injuries (73.6%). Spinal cord findings were available in 83.6% of cases and included an admixture of contusions (32.65%), lacerations (51.7%), softening (31.29%), and crush injury (8.2%). Up to 20.1% of cases had a normal spinal cord on gross examination. Of the 55.9% of cases with available data on spinal hemorrhage, epidural (59.3%) and subarachnoid (25.2%) compartments were the most frequently affected.

**Conclusion:** Presented here is data from a large retrospective series of blunt impact TSCI in association with early lethality in a large urban setting. By broadening the TSCI population to include cases from a forensic setting, a spectrum of findings associated with primary TSCI, that are not typically captured by large TSCI registries, was identified. Also identified was a possible connection between specific mechanisms of injury and the resulting pathology. These findings highlight the role of forensic pathologists in characterizing the spectrum of TSCI with implications for the development of preventative strategies.

### H143 The Histomorphology of Cranial Fracture Healing: Preliminary Observations

*Jered B. Cornelison, PhD\**, Western Michigan University School of Medicine, Kalamazoo, MI 49008; *Carolyn V. Isaac, PhD*, Michigan State University, East Lansing, MI 48824; *Wendy L. Lackey-Cornelison, PhD*, Western Michigan University School of Medicine, Kalamazoo, MI 49007; *Brandy Shattuck, MD*, Western Michigan Homer Stryker MD, Kalamazoo, MI 49008; *Joyce L. deJong, DO*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; *Amanda O. Fisher-Hubbard, MD*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; *Theodore T. Brown, MD*, Kalamazoo, MI 49008; *Elizabeth A. Douglas, MD*, Western Michigan University, Kalamazoo, MI 49008; *Joseph A. Prahlow, MD*, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will have an understanding of important histological features of cranial fracture healing and a proposed method for evaluating them in four differently stained slides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the field's knowledge of how cranial fractures heal and the cells and tissues involved in this process. In addition, this work is laying the foundation for a method to evaluate healing cranial fractures.

Understanding how cranial fractures heal and time-since-injury are important goals of forensic pathology and anthropology, especially as these biological responses relate to the context of accidental versus non-accidental injury. The scientific literature does not provide useful data or methods for estimating times since injury of cranial fractures. As such, this project has two primary research goals: (1) documenting the histomorphology of healing cranial fractures, and (2) establishing histomorphologic phases of cranial fracture healing.

Histologic sections from subadults and adults with known cranial fractures and/or surgical interventions of varying healing times have been collected and stained with: hematoxylin and eosin, Masson's trichrome, alcian blue hematoxylin/orange G, and Russell-Movat pentachrome. These stains were chosen for their ability to highlight different elements of bone healing. Specifically, evaluators are charged with identifying the following cells and tissues associated with bone healing: hematoma, pigment-laden macrophages, fibrin, inflammation, fracture edge morphology, mesenchyme/loose connective tissue, fibroblasts and/or fibrocytes, fibrous connective tissue/collagen, new capillaries, cartilage matrix, bone matrix, bone resorption, woven bone, lamellar bone, and reversal/cement lines.

To prepare samples for histology, the following methodology is employed: a gross sample of the fracture is removed (approximately 20–30mm); the sample is decalcified using either nitric acid, Ethylenediaminetetraacetic acid (EDTA), or Hydrochloric Acid (HCL); sections of the fracture are cut and the tissue is paraffin embedded; four thin sections are cut; and each section is stained and mounted on a glass slide. The slides are digitized and uploaded to a digital microscopy database. Glass slides are placed in four-slide kits and assessed by three randomly selected evaluators. As previous investigators have found variation in bone healing between the outer and inner tables, three different zones were identified for evaluation: the outer table, diploë, and inner table. For each slide, the evaluators assess the presence, absence, and quantity of the cells or tissues listed above. A separate evaluation form is used to assess each zone and stain; as such, each evaluator collects data on 12 different evaluation forms for each sample, resulting in 396 observations on a single sample (and 1,188 total observations by three evaluators per sample). When all slides in a set are assessed, evaluation forms are entered into a database for use in various statistical analyses. Analyses include evaluation of intra- and inter-observer variability; patterns in the presence, absence, and relative quantity of cells and tissues; and correlation of various cells and tissue.

Early findings suggest that HCL is an inferior method for decalcification, compared to EDTA and nitric acid. In addition, the cell and tissue types differ in juvenile versus adult individuals. Additionally, evaluators are noting considerable variability in the type of tissues present in the fracture gap among age-cohorts. Some of these differences include the presence of woven bone and cartilage matrix in juveniles, but these tissues appear to be absent in adult cranial injury healing. As more samples are collected, researchers will be able to provide evidence-based timelines for how different types of cranial bone injuries heal among various age-cohorts. Furthermore, the results of this research will provide a framework for forensic pathologists and anthropologists to sample, document, and classify fractures, as well as provide basic science data for future research goals of creating a method for interpretation of time-since-injury.

*This research project was supported by the National Institute of Justice, Office of Justice Programs, United States Department of Justice. #### Fracture, Histology, Time-Since-Injury

### **H144 Rule Out Trauma: A Five-Year Retrospective Study on Natural Disease, External Trauma, and Manner of Death at the Harris County Institute of Forensic Sciences (HCIFS)**

*Monica B. Patel, DO\*, Houston, TX 77059; Pramod Gumpeni, MD, Harris County Institute of Forensic Sciences, Houston, TX 77054*

---

**Learning Overview:** The goal of this presentation is to evaluate the incidence rate of lethal trauma in decedents when the preponderance of investigative evidence suggests death by natural disease.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating that although a decedent may have some form of external trauma, the severity of underlying internal trauma will determine whether the manner of death is ascribed as natural or accident.

Blunt force injuries are one of the most common injuries evaluated by forensic pathologists. Many decedents will have peri-mortem blunt force injuries, and it is imperative to determine if these are the cause of death or sequelae subsequent to natural disease. Harris County, TX, is the third most populous county in the nation and the most recent HCIFS annual report (2017) showed that 4,731 medicolegal cases were received for examination. Of these, 40.4% were classified as natural deaths, 35.7% were classified as accidents, 11.1% were classified as suicides, 9.6% cases were classified as homicides, 3% were classified as undetermined, and 0.1% were classified as fetal deaths. Greater than one-third of medicolegal cases at HCIFS are natural deaths; however, initially it can be challenging to ascertain if these cases are natural deaths based on the investigative information presented or accident based on the external examination findings. Many decedents who die of natural diseases may have peri-mortem trauma after collapsing or falling. At the same time, some decedents may have a plethora of natural diseases but may die secondary to trauma. The current study investigates how many HCIFS cases with external trauma truly had internal trauma.

A five-year retrospective review of all cases autopsied between the years 2014 and 2018 was performed to identify cases wherein the decedent had external trauma, such as a head laceration or contusion, and an autopsy was performed to rule out internal trauma. Daily case logs containing pertinent investigative information on the circumstances of death were reviewed, and cases were selected based on evidence of concurrent natural disease and peri-mortem trauma, such as a head laceration, contusion, or evidence of a reported fall prior to death. Cases with clear accidental causes and severe external trauma, such as motor vehicle accidents or work accidents, were excluded. Demographic information as well as cause of death and manner of death were then analyzed.

While several of the selected cases in this study did have fatal internal injuries, such as blunt force head injuries or blunt force injuries of the torso, the majority of the decedents died from natural diseases with trauma likely as a secondary result of a sudden collapse/fall. Thus, while peri-mortem injury can lead one to contemplate about accident as a manner of death, it is crucial to correlate circumstantial data along with autopsy findings.

---

#### **Blunt Force Injury, Natural Disease, Peri-Mortem Injury**

### H145 Radically Invasive Projectile (R.I.P.) Ammunition: The Projectile With No Boundaries

Lauren Havrilla, DO\*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27699-3025; Michelle B. Aurelius, MD, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27699-3025

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of R.I.P. ammunition and its potential to create a unique pattern of injury. Attendees will also have insight into the wound tracts that the projectile fragments may take by learning the ballistics of the frangible projectile.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information regarding frangible projectiles and, more specifically, the possible extent of injury with R.I.P. ammunition. This presentation will also impact the clinical community, specifically emergency department and trauma health care providers, by improving their understanding of the potential wound tracts to guide informed medical care decisions.

The R.I.P. ammunition, a newly designed frangible bullet marketed to users of handguns as “the last round you’ll ever need,” is becoming an increasingly popular choice for self-defense rounds.<sup>1</sup> This type of ammunition, from G2 Research, is composed of a base with eight trocars that are intended to fragment upon impact, creating nine individual wound tracts with a radial dispersion.<sup>2</sup> This may create difficulties for first responders, clinicians, and forensic pathologists as the trajectory is different from that anticipated for the main projectile or base. In addition, break-up of the projectile prior to entry may result in more than one entrance wound from a single projectile. The fragmented projectile increases the number of internal injuries, resulting in the need to document and follow several wound tracks and recover multiple small retained fragments.<sup>1,3</sup> If the forensic pathologist or clinician does not have a good understanding of the ballistics of this ammunition, appropriate documentation, medical care, and projectile recovery may be missed. Few case reports have been published on R.I.P. rounds and may be overlooked by the forensic community as these publications are predominantly in the trauma and emergency medicine literature.<sup>3-5</sup>

Six cases in which the decedent had penetrating and/or perforating gunshot wounds from R.I.P. ammunition are presented. Five of the six cases were fatal, with one decedent being remotely shot by an R.I.P. ammunition round. In this latter case, the decedent died of other acute multiple gunshot wounds, thus disproving the marketing motto for this type of projectile. In all six cases, many radio-opaque bullet fragments were seen on postmortem radiographs using a LODOX® scanner. During the autopsy, several fragments were recovered from each decedent and preserved as evidence.

The R.I.P. ammunition used in these cases provides a challenge for forensic pathologists. Postmortem imaging can be extremely useful in identifying the location of each retained trocar and the base. Understanding the ballistics of the R.I.P. ammunition will assist in accurately identifying multiple wound tracts, trajectories, and projectile recovery.

#### Frangible Projectile, Gunshot Wound, Forensic Pathology

### H146 Suicides in Cook County, Illinois: A Four-Year Retrospective Study From 2015 to 2019

Reema Khan, MD\*, Chicago, IL 60612; Stephanie Powers, MD, Chicago, IL 60612; Ponni Arunkumar, MD, Cook County Medical Examiner's Office, Chicago, IL 60612

---

**Learning Overview:** After attending this presentation, attendees will understand the trends seen in Cook County, IL, with respect to the mechanism, seasonal variation, and demographics of suicides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting mechanisms more prevalent in a particular demographic set and preventative measures that could be applied.

According to the Centers for Disease Control and Prevention, nearly 45,000 lives were lost to suicide in 2016 and suicide rates have increased by more than 30% in more than half of the states since 1999. Suicide is the tenth leading cause of death in the United States since 2008. Suicide mortality trends have been proven to be a beneficial public health tool. Determining high risk areas, gender prevalence, and mechanisms could assist in better allocating resources for suicide prevention. Also, this data could potentially be extrapolated and applied to other metropolitan regions as trends at the county level have been largely unexplored to date. The relationship between adverse socio-economic circumstances and suicidal behavior is well established; however, the impact of adverse collective circumstances, such as the socio-economic context where people live, is less well understood.

A retrospective search of the Cook County Medical Examiner's Office database from 2015 through April 2019 was performed for decedents in which "Suicide" was the manner of death. The case files and recorded demographic data, as well as cause of death, mechanism of death, and month of occurrence were reviewed.

**Results:** A total of 2,003 suicide cases were identified from January 2015 to April 2019 in Cook County. The top five most prevalent suicide mechanisms were hanging (673 cases), gunshot wounds (632 cases), overdoses (228 cases), jump from height (111 cases) and train-related fatalities (82 cases). A majority of the suicides occurred in the city of Chicago, as compared to the suburbs. The ages ranged from 11 to 94 years. There was a greater prevalence of suicides in males as compared to females, with 473 females and 1,530 males (1:3 ratio). The number of suicides per year was relatively stable over the course of the study period, ranging from 436 to 481 fatalities. The detailed results of the study will be presented to attendees.

**Conclusion:** Mapping county-level suicide rates provides greater granularity in describing geographic patterns of suicide and contributes to a better understanding of changes in suicide rates over time. Findings may aid in better targeting prevention efforts as well as contribute to future research on community-level risk and protective factors related to suicide mortality.

---

#### Suicide Trends, Demographics, Suicide

### H147 Mississippi Organ and Tissue Recovery in High-Profile Medical Legal Cases

*Mark M. LeVaughn, MD\**, Office of the Chief Medical Examiner, Pearl, MS 39208; *Taylor Phillips\**, The Mississippi Organ Recovery Agency, Flowood, MS 39232

---

**Learning Overview:** After attending this presentation, attendees will better understand organ, eye, and tissue recovery outcomes in a state with an exceptionally high homicide and infant mortality rate utilizing a mixed coroner/medical examiner system.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the results of organ and tissue recovery and transplantation along with the autopsy results with respect to three medical examiner cases.

Since the development and opening of the Mississippi Organ Recovery Agency (MORA) in 1994, a common mindset among coroners regarding homicides, high-profile cases, or infant fatalities had been that donation and recovery of organs and tissues prevented accurate investigation and postmortem findings. This was due to a lack of coroner understanding regarding recovery and postmortem examination procedures. This misunderstanding continued throughout the state for nearly 20 years, which resulted in numerous families robbed of the opportunity to give the Gift of Life and/or honor the wishes of their loved one who had signed the donor registry, a legally binding, first-person authorization.

In 2017, the Office of the State Medical Examiner (OSME) of Mississippi and MORA began to develop protocols regarding the risks and benefits of organ and tissue recovery with respect to medicolegal cases. These protocols followed state statutes in addition to guidelines set by the National Association of Medical Examiners. These protocols reflected the state statutes regarding the responsibilities of the coroners throughout the state. These protocols have been successful in educating coroners and increasing their knowledge that organ and tissue recovery does not preclude an accurate medicolegal investigative process.

Over the past few years, MORA has been able to recover many medicolegal cases, ranging from high-profile homicides, unnatural infant fatalities, and unique circumstantial deaths. Recovery and donation performed by MORA has never disrupted or compromised an investigation in the state of Mississippi. This success has resulted in hundreds of families being able to turn their tragedy into a positive outcome, as well as thousands of lifesaving and healing gifts transplanted to those in need. This positive outcome is due to the support of the OSME and the collaborative protocols put into effect by all three agencies (i.e., MORA, OSME, and coroners). As a result of these protocols, the number of cases shut down by a coroner have decreased by nearly 100%. MORA and the OSME plan to continue these collaborative protocols and share the results of the successful donation outcomes combined with successful medicolegal investigations and prosecutions that were not affected by the recovery of organs, eyes, and/or tissues for the purpose of transplantation or research.

---

### Transplantation, Medical Legal, Collaborative

### H148 Non-Natural Deaths on Hospital Property: A Five-Year Retrospective Review of Cases From Harris County, Texas (2014–2019)

Brooke H. Blake, MD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Science, Houston, TX 77054; Merrill O. Hines III, MD, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will understand the most common scenarios for non-natural deaths on hospital property (including outpatient clinics and doctor offices) in Harris County, TX, which includes the city of Houston and surrounding municipalities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of fatal incidents apart from adverse events of medical care that can lead to death while on hospital property. The forensic community can play a vital role in injury prevention by tracking these deaths and educating the local health care institutions about these occurrences, as well as by identifying and potentially mitigating risk factors.

The current patient safety culture in the hospital setting largely focuses on adverse events (i.e., injuries that occur due to complications of medical management rather than the disease process itself) or falls while in the hospital setting.<sup>1,2</sup> Literature delving into other non-natural deaths occurring in the hospital setting—or while on hospital property—is much sparser.

The database of deaths from the Harris County Institute of Forensic Sciences was searched from 2014 to 2019 using “hospital” as a search term in both the injury address and injury place. Neonates discovered dead, or who remained comatose and eventually were pronounced brain dead following being found unresponsive while in the hospital, were also included.

Study results revealed that deaths from intracranial hemorrhage due to falls remain, by far, the most common cause of non-natural death in the hospital setting; such deaths included falls in hospital parking lots. Suicides, in this study, included both patients recently discharged from psychiatric inpatient settings and those who were not admitted at all, but simply committed suicide on hospital property. In the former case, deaths were usually attributable to jumping from heights, such as parking structures, while in the latter case, deaths typically resulted from gunshot wounds in the parking lot. In this study, recently discharged patients most often killed themselves within hours of their discharge. Homicide deaths due to gunshot wounds occurring inside a hospital were identified but were rare, as were work accidents. Deaths due to airway obstruction (i.e., choking on a food bolus) all occurred during mealtimes.

A steady trend across all five years of the study is accidental death due to acute illicit drug toxicity by admitted patients, the majority of whom were admitted for diagnoses unrelated to acute drug withdrawal or inpatient rehabilitation and brought the drugs with them. This current study suggests that new strategies to help combat illicit drug deaths while in the acute care setting would be beneficial to overall patient safety.

### H149 Autopsy Rates for Injury Deaths by Manner, Cause, and State in the United States From 2015 to 2017

Margaret Warner, PhD\*, Centers for Disease Control, Hyattsville, MD 20912; Marcus B. Nashelsky, MD, University of Iowa Hospital & Clinics, Iowa City, IA 52242; Holly Hedegaard, MD, National Center for Health Statistics, Hyattsville, MD 20782

**Learning Overview:** After attending this presentation, attendees will better understand current trends in autopsy rates and characteristics of deaths in which an autopsy was performed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the characteristics of injury deaths that are most likely to prompt an autopsy examination as well as the variation in autopsy performance practice by state.

The accuracy of cause- and manner-of-death information is dependent on several factors, including whether the decedent had an autopsy examination.<sup>1,2</sup> This study describes variation in autopsy rates for injury deaths by manner of death, cause of death, and state in which the medicolegal death investigation was conducted and a death certificate was completed.

The National Vital Statistics System Detailed Mortality data for the years 2015 to 2017 were analyzed to determine the characteristics of decedents and circumstances of death when autopsies were performed.<sup>3</sup> The query was based on the death certificate item: "Was an autopsy performed?" Response categories on a standard death certificate are "yes," "no," and "unknown".<sup>4</sup> The percent of injury deaths with autopsy status known and reported as "yes" was calculated by age of the decedent, manner and cause of injury-related death, and state. Manner-of-death and cause-of-death categories were defined using the *International Classification of Disease, 10<sup>th</sup> edition (ICD-10) External Cause of Injury Matrix*.

In 2015–2017, 54.5% of injury deaths were autopsied; 43.7% were not autopsied; and 1.8% had an unknown autopsy status. Injury deaths represented 8.3% of all deaths. Of non-injury deaths, less than 4% were autopsied and 5.0% had an unknown autopsy status. For all deaths, 8.0% were autopsied and 4.8% had an unknown autopsy status.

Autopsy rates varied by manner of death with a range of rates between the states. Almost all homicides were autopsied (98.6%, range by state from 90.2% to 100%). In contrast, 54.4% of suicides were autopsied (range by state from 5.7% to 97.2%); 49.6% of unintentional (accidental) injury deaths were autopsied (13.9% to 72.1%); and 83.0% of injury deaths of undetermined manner were autopsied (46.2% to 100%).

Autopsy rates also varied by cause of death. For drug toxicity deaths (all manners), 76.8% were autopsied (23.1% to 97.3%). For motor vehicle deaths, including bicyclists and pedestrians (all manners), 49.5% were autopsied (4.2% to 93.8%).

Among all injury deaths, the percent autopsied was highest for those less than 1 year of age (95.3%) and lowest for those over 65 (22.0%).

Autopsy rates vary by cause and manner of death, age of decedent, and the state in which medicolegal death investigation was conducted and death certified. Variation by state likely reflects differences in state statutes, budgets, and office customs.

### H150 Radically Invasive Projectiles (R.I.P.s) and Other Unusual Ammunition: A Case Series

*Elaine R. Amoresano, MD\**, Office of the Chief Medical Examiner for the State of Maryland, Baltimore, MD 21233; *Patricia Aronica, MD*, Office of the Chief Medical Examiner for the State of Maryland, Baltimore, MD 21223; *David R. Fowler, MD*, Office of the Chief Medical Examiner for the State of Maryland, Baltimore, MD 21223

---

**Learning Overview:** After attending this presentation, attendees will be familiar with the characteristics of the R.I.P. and will better recognize the radiographic and autopsy findings associated with various unusual ammunition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sharing cases of unusual ammunition experienced by forensic pathologists in an urban setting with an exceedingly high rate of gun violence.

The landscape of firearms and ammunition is ever-changing, with different styles of ammunition becoming more readily available and other styles falling in and out of favor. Since recovery and identification of bullets and bullet fragments is an integral part of any death involving a firearm, this presents a challenge for examiners encountering either long-defunct, unique rounds or novel, highly engineered ammunition.

G2 Research's R.I.P. bullets are one such brand of novel ammunition that is rapidly growing in popularity. R.I.P. bullets are solid copper projectiles into which eight trocar spires are machine carved. The trocar design reportedly increases stability while allowing the bullet to function like a saw and effectively pass through solid barriers, such as sheetrock, cinderblock, and metal. When the R.I.P. bullet strikes a soft target, however, the solid base penetrates deeply into the target while the trocar elements break off and bore outward into adjacent structures. The R.I.P. bullet is therefore designed to have the maximum stopping power of a hollow-point bullet with the collateral damage of a frangible projectile. At autopsy, the R.I.P. bullet's design results in atypical wound patterns and paths, which can be difficult to interpret, especially in the setting of multiple projectiles. Awareness of the extremely sharp trocar fragments is particularly important as they can be a hazard to the examiner and the technician performing the case.

While basic knowledge of ammunition is essential for the forensic pathologist, those practicing in an urban setting are increasingly exposed to unique ammunition and need to become more attuned to its distinct characteristics. In most cases, forensic pathologists are initially confronted with these challenging bullets when radiographic imaging is performed, revealing foreign bodies with unusual shapes and contours, sometimes mimicking clothing or personal belongings. Familiarity with the characteristics of unique ammunition, such as the R.I.P. bullet, is indispensable when confronted with one of these challenging cases.

This presentation describes the unique radiographic and autopsy findings in several cases encountered at the State of Maryland Office of the Chief Medical Examiner involving unusual ammunition including: G2 Research's Radically Invasive Projectiles, Taurus Judge .410 bore shot shells, MagSafe® ammunition, PolyCase® ARX composite ammunition, Expanding Full Metal Jacket bullets, #4 buckshot, conical pellet shot shells, black powder rounds, and snake shot ammunition.

### H151 Severe Hemorrhagic Retinopathy and Retinoschisis Associated With Hypoxic Ischemic Brain Injury and Coagulopathy Due to Aspiration of Popcorn Kernels

Patrick E. Lantz, MD\*, Wake Forest University School of Medicine, Winston-Salem, NC 27157-1072; William T. Harrison, MD, Wake Forest Baptist Medical Center, Winston-Salem, NC 27157; Anna G. McDonald, MD, Wake Forest Baptist Medical Center, Winston Salem, NC 27157

**Learning Overview:** After attending this presentation, attendees will learn that extensive Retinal Hemorrhages (RHs) and retinoschisis can occur in young children who have non-traumatic hypoxic ischemic brain, cerebral edema, and coagulopathy due to aspiration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reinforcing the necessity for routine postmortem ocular examinations of children with non-traumatic, hypoxic ischemic brain injury, cerebral edema, and coagulopathy.

Some authors suggest that non-traumatic hypoxic-ischemic brain injury with cerebral edema and coagulopathy does not cause severe extensive RHs or retinoschisis. Presented here is a case of a toddler who aspirated unpopped popcorn kernels and experienced a cardiopulmonary arrest. Return of spontaneous circulation occurred after >60 minutes of Cardiopulmonary Resuscitation (CPR) after which she developed hypoxic ischemic brain injury and coagulopathy. The autopsy findings of this case refute the purported specificity of extensive RHs and retinoschisis in young children for abusive head trauma (shaken baby syndrome).

**Case Report:** A 19-month-old toddler experienced a choking episode at home. Her father gave back blows while her mother called 911. When paramedics arrived, she was unresponsive and in pulseless electrical activity. She received over 30 minutes of CPR with intermittent return of spontaneous circulation. During intubation in the emergency department, food debris and unpopped popcorn kernels were removed from her airway. After an additional 30 minutes of CPR, a return of spontaneous circulation was achieved. Following admission to the Pediatric Intensive Care Unit, she developed coagulopathy with a prothrombin time (>90 seconds), partial thromboplastin time of 174.2 seconds, a fibrinogen of 50mg/dL, and a platelet count of  $171 \times 10^3/\mu\text{L}$ . Given the extent of neurological injury from prolonged cardiac arrest, her family decided to withdraw medical care. She died 15 hours after the choking episode. No clinical fundal examination was recorded in the medical record.

Postmortem indirect ophthalmoscopy revealed bilateral extensive RHs extending past the equators with a large subinternal limiting membrane hemorrhagic cyst (schisis cavity) adjacent to the right inferior temporal vascular arcade. Both fundi had numerous splinter, flame-shaped, dot, and blot RHs plus small wisps of vitreous hemorrhage. An unpopped popcorn kernel occluded her right mainstem bronchus and another popcorn kernel was removed from her oropharynx. Her brain was markedly edematous and contained scattered hypoxic-ischemic neurons. Her retinae exhibited numerous RHs involving the nerve fiber, ganglion cell, inner plexiform, inner nuclear, outer plexiform, and outer nuclear layers; the RHs extended to the ora serrata. The large hemorrhagic cyst over the right fundus consisted of separation of the internal limiting membrane (retinoschisis) with subjacent extravasated blood. Focal intraneural hemorrhage involved the lower cervical spinal cord nerve roots.

This case describes extensive hemorrhagic retinopathy extending to the ora serrata and retinoschisis associated with hypoxic-ischemic brain injury, cerebral edema, and coagulopathy following prolonged resuscitation due to a cardiopulmonary arrest from aspirated popcorn kernels. This study urges caution in interpreting ocular findings out of context since extensive RHs and retinoschisis have been considered diagnostically specific for abusive head trauma (shaken baby syndrome). This case highlights that these ocular findings are not diagnostically specific for abusive head trauma and emphasizes the importance of consistent and thorough postmortem ocular examination in young children with non-traumatic cerebral edema and coagulopathy.

#### Retinal Hemorrhages, Retinoschisis, Hypoxic Ischemic Brain Injury

### H152 A Tale of Two Recreational Mummification Bondage Cases: Undetermined Versus Homicide

*Robyn Parks\*, Los Angeles, CA 90033; Julie M. Huss-Bawab, MD, Los Angeles Department of Medical Examiner-Coroner, Los Angeles, CA 90033-1017; Matthew Miller, MD, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033*

**Learning Overview:** After attending this presentation, attendees will better understand the importance of scene investigation in certifying deaths related to recreational mummification bondage.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of a thorough scene investigation with implications on the manner of death certified in recreational mummification bondage-related deaths.

**Case 1:** A 48-year-old man experienced in bondage sessions and body wraps was found in a residential basement converted to a Bondage & Discipline, Dominance & Submission, Sadism & Masochism (BDSM) -style dungeon after his partner realized he was not responding appropriately. The decedent and partner had known each other for seven months and had regular bondage sessions at the location, the last session two weeks prior to death. According to the partner, the decedent was covered from head to toe by plastic wrap and gaffer's tape with small breathing holes at the mouth and nose. At the scene investigation, the decedent was found nude, supine, with a locked metal chain around his neck, and a penile chastity cage. A trash can in the corner of the room contained plastic wrap and red gaffer's tape that the partner had removed once the decedent was unresponsive. In this instance, video and photos of prior events were not collected into evidence, and reportedly there were no videos or photographs of the event in question. Injuries seen at autopsy included contusions and edema of the genitals, consistent with the male chastity belt, and superficial erythematous horizontal lines on the lower extremities, consistent with the description of being wrapped in plastic and tape. Mild pulmonary congestion and edema were present, and no significant natural disease was seen anatomically. Toxicology studies revealed a low (11mcg/mL) concentration of Gamma Hydroxybutyrate (GHB) in the decedent's blood. Both the GHB, a respiratory depressant, and the restriction of the chest caused by mummification were thought to contribute to an increased risk for respiratory distress. The cause of death was sudden death during recreational mummification bondage due to an undetermined cause after autopsy and toxicologic analysis, and the manner was undetermined.

**Case 2:** A 27-year-old woman was found unresponsive in a hotel room; cellophane, white duct tape, and pink duct tape were in a trash can in the room. Four videos showing the encounter from varying angles were recovered at the scene, depicting the suspect wrapping and striking the decedent; only the decedent's breasts and nose were exposed. The video shows the suspect occlude the decedent's exposed nose, at which time she begins markedly struggling against the restraining tape. The woman becomes unconscious but remains alive, until the suspect removes the tape from the waist down and begins sexual intercourse. After a total elapsed occlusion time of approximately 17 minutes, the man removes the tape from the cyanotic nose, releasing tan-brown fluid from the nares. At autopsy, there were abrasions of the face, neck, left breast, and left thigh; contusions and petechiae of the right and left breasts with patterned contusions of the left breast. Internally, there were scalp contusions and hemorrhages in the neck muscles, though there was no fatal blunt trauma. There was complete occlusion by gastric contents of the right and left mainstem bronchi with near complete occlusion by gastric contents at the level of the vocal cords. No significant natural disease and no lethal drug or alcohol toxicity were present. The cause of death was asphyxia due to smothering and the manner was homicide.

This report of two recreational mummification bondage-related deaths highlights the importance of scene investigation with collection of evidence, including video footage, photos, and detailed histories. Once deemed unresponsive, the bondage tape is often removed during attempts at resuscitation, and the evidence of the events may be lost unless there is a reliable witness or form of event documentation. Without definitive scene evidence, as the findings at autopsy are non-specific, a cause and manner of death should be carefully considered, as an "act of mutual consent" could be taken out of context.

#### **Mummification, Bondage, Asphyxia**

### H153 Two Firework Fatalities in North and Central Texas

Shante Hill\*, Mobile, AL 36617; Tasha Zemrus Greenberg, MD, Tarrant County Medical Examiner's Office, Fort Worth, TX 76104-4919

**Learning Overview:** The goal of this presentation is to educate medical examiners and forensic investigators of the range of findings in firework fatalities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating those involved in investigation of potential firework deaths regarding the range of possible findings.

Upon completion of this presentation, viewers will have gained exposure to rare instances of fireworks fatalities, readily recognize patterns of external injury, and list potential causes of death in these cases. Cases examined by the Tarrant County Medical Examiner's Office, Fort Worth, TX, will be discussed in depth.

Independence Day fireworks displays are a tradition in the United States. Although most accidents involving fireworks result in blast or thermal injuries of varying severity, two cases of accidental death investigated at the Tarrant County Medical Examiner's Office showed additional findings of interest.

In July of 2019, a 19-year-old male partook in a deadly game of fireworks war with friends that resulted in his sudden death. The subject ignited his weapon of choice, and an unexpected explosion caused a severe blast injury to his left hand. In addition to the blast injury of the hand, external examination revealed superficial wounds of the central chest, believed initially by some to be attributable to the LUCAS® chest compression device used during resuscitative efforts. Closer inspection revealed a thermal injury in a circular pattern superior to the resuscitation injury. Internal examination exposed fracture with associated hemorrhage of the sternum. Additionally, there was 550mL of blood in the pericardial sac, rupture of the anterior wall of the left ventricle, rupture of the posterior wall of the left ventricle involving the aortic valve, and rupture of the interventricular septum. The cause of death was blunt force injury of the chest due to fireworks explosion. The manner of death was ruled as accident.

A police vehicle dash camera caught the explosion on film; however, it was too far away to show details of the incident. Examination of the scene revealed a cylindrical pyrotechnic device status post-combustion with the clay seal separated. This finding corroborated the witness accounts indicating that he was holding the firework up to his chest, pointing it outward at his friend when it exploded, ultimately providing the mechanism for the pattern of injury on the victim's chest.

In July of 2014, a 51-year-old male was killed in a fireworks incident that resulted in three additional injuries. In preparation for a Kiwanis® event, seven people were unloading fireworks and placing electric matches into six-inch fireworks shells at the rear of a trailer. During the process, a shell became live and detonated. The shell caused other shells to ignite and spread to the open trailer, igniting the majority of the fireworks still in the trailer. The fire then spread to other nearby combustibles, two vehicles, and the trailer. The trailer showed no signs of detonation; instead it had melting of the metal frame, siding and structural components. Investigation could not exclude accidental activation of a defective electric match, improper handling of electric matches or fireworks, or accidental activation of the internal firework fuse by friction caused by metal scissors during the process of installing the electric match.

The decedent was examined at the office and displayed extensive thermal injury, cherry-red discoloration of soft tissues and viscera, and soot in the airways with a carbon monoxide level of 16%. In addition, there was penetration of the neck by a foreign object that injured the internal and external jugular veins at the brachiocephalic vein. There were fragments of laminated pressed cardboard and clear plastic along the wound track. The cause of death was ruled as inhalation of smoke and penetrating injury of the neck due to fireworks explosion. The manner of death was ruled as accident.

In the 2018 Fireworks Annual Report, the United States Consumer Product Safety Commission (CPSC) reported that most fireworks injuries and fatalities seen in emergency rooms occur during the month surrounding July 4.<sup>1</sup> Hospital emergency departments treated approximately 9,100 fireworks injuries. An estimated 62% (5,600) of those injuries treated occurred during the month surrounding Independence Day. The most frequent injuries treated involved the hands and fingers (28%), followed by injuries of the legs (24%) and injuries of the eyes (19%). Only five deaths attributed to fireworks explosions were reported at the time of the CPSC's Annual Report.<sup>1</sup>

### H154 “Who Dismembers Mama?”

*Reema Khan, MD\*, Chicago, IL 60612; Michael D. Eckhardt, MD, Cook County Office of the Medical Examiner, Chicago, IL 60612; Adrienne Segovia, MD, Cook County Office of the Medical Examiner, Chicago, IL 60612*

**Learning Overview:** After attending this presentation, attendees will be familiar with cases involving dismemberment, including the different modes of dismemberment, patterns used to classify them, causes of death, and concealment locations in a large metropolitan area.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by familiarizing death investigators with different patterns of, and implements used in, dismemberment.

Dismemberment is uncommon and is typically performed to hinder identification and/or facilitate the disposal of the decedent. Dismemberment poses specific challenges to the forensic community, including not only in identification of remains, but also in the determination of cause and manner of death. There are different classification systems that describe dismemberment. One classification system encompasses postmortem mutilation and dismemberment. This classification emphasizes the psychology of the perpetrator and describes the postmortem mutilation/dismemberment as motivated by: (1) defensive (disposal of the remains and/or hindering identification), (2) aggressive (outrage and involves mutilation of face and genitals), (3) offensive (necrophilia urge and sexual sadism), and (4) necromanic (necrophilia and retaining a body part as a trophy). Understanding a perpetrator’s motive is useful, but knowledge of specific patterns of dismemberment is also very helpful. Dismemberment patterns can be described as localized (removal of body parts to hinder identification) or generalized (segmenting the body for disposal). Both localized and generalized dismemberment are further subdivided by the method of dismemberment. Patterns can also be described as involving disarticulation, transection by sawing or chopping, or a combination of the two.

In this study, the Cook County Medical Examiner’s Office records were retrospectively searched from 1991 to 2018 to identify cases in which the manner of death was homicide or undetermined, and included the following terms: dismemberment, decapitation, disarticulation, and unidentified bones. Seventeen cases were identified that met these criteria. The dismemberment pattern, cause of death, recovery location, demographic data, type of implements, and other postmortem artifacts were recorded.

The manner of death was homicide in 94% of the cases. An undetermined manner accounted for the remaining 6% of the cases. Female victims accounted for 53% of deaths and their ages ranged from 3 to 81 years. Of the female victims, 44% were black, 44% were White, and the race could not be determined in one case. The cause of death for female victims ranged from sharp force injuries to blunt force injuries with each accounting for 11.1% of the causes of death, for a total of 22.2%. Homicide by unspecified means accounted for 66.7% of the cases. The cause and manner of death was undetermined in 11.1% of the cases.

Male victims made up 47% of the cases, with ages ranging from 2 to 70 years. Of the male victims, 37.5% were Black and 62.5% were White. Cause of death was blunt force injuries in 25% cases. Decapitation, sharp force injury, head trauma, and gunshot wound to the head comprised the remainder of the male victims’ cause of death when one was identified. Each of these four cases accounted for 12.5% for a total of 50%. Homicide by unspecified means made up the remaining 25%.

The entire body was recovered in 52.9% of the cases (i.e., 29.4% of the female victims and 23.5% of the male victims.) Dismemberment and removal-disposal/concealment was an element in 94% of the cases. In only one case was there an element of display rather than concealment. No correlation was found between the cause of death, gender, age, race, or type of dismemberment pattern among the female and male victims. Implements used in dismemberment were identified in 64.7% of the cases. No correlation was identified between cause of death and type of dismemberment/transection pattern (i.e., transection by saw, by chop, or by disarticulation).

Transection by saw predominated. Disarticulation, which appears to be a logical mode of dismemberment, was rare in this and other studies. One can only speculate as to the possible reasons for this; although disarticulation requires less force, it may be more time-consuming and require an understanding of anatomy that an average perpetrator may lack. Additionally, the prevalence of hardware stores and the availability of tools that can be used to dismember a body make transection easier. Recognition of this fact in at least one of the cases reviewed permitted the implements used to be traced to purchases made at a hardware store with subsequent identification of the perpetrators.

### Dismemberment, Disarticulation, Transection

## H155 Pull It Out or Leave It In? Foreign Bodies Discovered During Medicolegal Death Investigation

Christina M. Tengelin, MS\*, King County Medical Examiner's Office, Seattle, WA 98104

**Learning Overview:** The goal of this presentation is to employ case examples to emphasize the importance of applying a multidisciplinary approach in death investigations in which foreign bodies are present as well as to highlight the potential confusion caused when implements are removed and not properly documented prior to the involvement of the Medical Examiner's or Coroner's Office (MEO).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the vastly variable scenarios death investigators experience with the goal of promoting the importance of multiagency communication. The intended result is to instill within attendees a level of caution and consideration when responding to death scenes where foreign objects are present.

Although the characteristics of penetrating wounds can support a determination of what implement caused it, leaving impaled foreign objects *in situ* obviously decreases any potential confusion regarding the implement that can arise. Through a review of six case examples, this presentation will address a series of four considerations from the MEO perspective for outside agencies to review when handling cases with foreign bodies found impaled or inserted into human remains, including during first response. More specifically, the question of scene and responder safety, the importance of documentation, the value in keeping items *in situ* to avoid confounding confusion, and how all of these items come together to support considerations for cause and manner of death will be reviewed.<sup>1-6</sup>

**Case 1:** A 28-year-old male and his brother were in a verbal altercation during which the decedent's brother stabbed the hilt of a handmade metal sword into the decedent's head.

**Case 2:** A 63-year-old female was found deceased in her yard with polytrauma, including a knife stuck in her buttock.

**Case 3:** A 46-year-old male was witnessed to go unresponsive at home during sexual intercourse. An anal plug had been inserted with consent by his wife and remained *in situ* upon the arrival of the MEO.

**Case 4:** A 23-year-old female was stabbed multiple times by her Significant Other (SO). The SO reported that she'd been seated, he'd been standing over her and holding their infant at the time of the stabbing. The knife had been left in the decedent's body by the suspect. However, upon arrival, medics reported noting signs of life so they removed the knife and set it aside to facilitate resuscitative efforts.

**Case 5:** A 32-year-old male was found unresponsive at a bus stop lying in a fetal position. The circumstances surrounding his being there were unclear until the decedent was rolled during his external exam and a syringe was found *in situ* in his arm.

**Case 6:** A 41-year-old male driving a stolen vehicle at slow speeds lost control of the vehicle, which then struck a chain link fence and a utility pole. The top rail of the fence was displaced and impaled the decedent through the mouth and exited through the back of the head.

Reconstruction of injury patterns and determining their instrument of creation is imperative to determining cause and manner of death in cases of penetrating trauma. A thorough death scene investigation includes a multiagency discussion, especially when attempts at lifesaving efforts were made and the original scene was disturbed. In this presentation, it will be suggested that the best way to avoid the potential for confusion in death investigations is to have a set protocol when interacting with first responder agencies in cases where foreign bodies are present.

### **H156 The Importance of Histopathology in Cases of Sudden Death Due to Alleged Electrocution With Inconclusive Autopsy Findings: A Report of Three Cases**

*Siddhartha Das, MD\**, Jawaharlal Institute of Medical Education & Research, Puducherry, Pondicherry 605006, INDIA; *Pampa C. Toi, MD*, Jawaharlal Institute of Medical Education & Research, Puducherry 605006, INDIA

**Learning Overview:** After attending this presentation, attendees will understand the importance of histopathological examination of suspected skin wounds and the heart in cases of sudden death due to alleged electrocution where autopsy findings are inconclusive.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community as attendees will understand the importance of histopathological examination of suspected skin wounds and the heart in sudden death due to alleged electrocution, especially in those cases where the autopsy findings of electrocution are not clear and specific.

The pattern of injuries noted in high-voltage electrocutions is appreciable during autopsy examination. But such clear-cut findings are not found in many cases of low-voltage electrocution. Though joule burns are classically described as the entry wound feature of low-voltage electrocution, they are not seen in many cases. In such cases, doubt may persist in the mind of the forensic pathologist regarding whether to designate them as electrocution entry wounds or not. Similarly, the exit wound may either be absent or else not clearly appreciable via naked eye examination in many cases. In all such cases, histopathologic examination of a suspected entry and exit wound is essential. Ventricular fibrillation is the most common cause of cardiac arrest in electrocution. This most typically occurs when current enters through the right hand and exits through the feet. Hence, histopathologic examination of the heart is also required where death occurs immediately after electrocution.

**Case 1:** A do-it-yourself electrician was repairing a faulty motor pump meant to drain water from a swimming pool. He was accidentally electrocuted and died within few minutes. Suspected electrocution entry and exit wounds were noticed on the right index finger and the heel of the right foot. Tissues from these sites and samples from control sites and the heart were submitted for histopathology. Tissues from the entry and exit wounds showed microscopic features of electrocution. The heart showed features of myofibre breakup. Control site samples were histologically within normal limits.

**Case 2:** A brick kiln laborer was accidentally electrocuted when the metallic rod he was using came into contact with overhead electric wires. Suspected electrocution contact wounds were noticed on the left thumb and the adjoining hypothenar area. No exit wounds were appreciated. Tissues from the suspected entry site and heart were submitted for histopathology. Features of electrocution were observed on microscopic examination of both.

**Case 3:** A welder was electrocuted while at work. A suspected electrocution contact wound in the form of skin reddening was noticed in the hypothenar area of the right hand. A suspected exit wound in the form of a crater 0.3cm in diameter was noticed on the dorsal aspect of the medial right foot about 15cm behind the tip of the great toe. Tissues from the suspected entry wound showed intra-epidermal separation with a dense eosinophilic appearance of the keratin layer. The suspected exit wound had features of sub-epidermal separation and coagulative necrosis of both the epidermis and dermis. A section of the heart showed features of myofibre breakup.

These three cases will be reviewed individually. In alleged electrocution cases, where death is sudden and autopsy findings are unclear, histopathologic examination of the heart and the suspected skin wounds should be mandatory. A final opinion regarding cause of death can be given after collectively considering the history, autopsy findings, circumstantial evidences, and the histopathologic findings.

#### **Alleged Electrocution, Suspected Skin Wounds, Heart Histopathology**

## H157 Developing Novel Microbial Community Metrics for Predicting Manner of Death (MOD)

Sierra Kaszubinski, BS\*, Integrative Biology, East Lansing, MI 48824; Jennifer L. Pechal, PhD, Michigan State University, East Lansing, MI 48824; Heather R. Jordan, PhD, Mississippi State University, Mississippi State, MS 39762; Carl J. Schmidt, MD, Wayne County Medical Examiner's Office, University of Michigan, Detroit, MI 48207; M. Eric Benbow, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will better understand that the community of microbes after death, or the postmortem microbiome, has further forensic utility than postmortem interval estimation. Attendees will see how beta-dispersion profiles, a novel application of the “Anna Karenina Principle,” have predictive power for MOD determination due to the insight postmortem microbiomes provide of antemortem health conditions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic scientific community by presenting how specific postmortem microbiome community metrics may provide a novel tool for MOD determination.

Microbiomes have an important functional role in a host's life, influencing health, development, and disease susceptibility, among many other aspects of human well-being.<sup>1</sup> Microbes also play an important functional role in decomposition after death.<sup>2</sup> Postmortem microbiomes are known to undergo changes specific to anatomical body sites, and follow successional patterns that track the postmortem interval.<sup>2-4</sup> The postmortem microbiome has potential as a tool for postmortem interval estimation. However, the microbial community has additional applications, due to its ability to reflect antemortem health conditions, such as disease state.<sup>3</sup>

As the antemortem microbiome is consistent with the postmortem microbiome within 24 hours after death, microbial community metrics could potentially reveal associations with MOD.<sup>3</sup> The postmortem microbiome is hypothesized to vary depending on a decedent's antemortem health condition related to lifestyle stressors. Stressors that may include, but are not limited to, heart disease, drug/alcohol abuse, and/or a high anxiety lifestyle indicative of certain manners of death (i.e., homicide). This community structure reflected in the postmortem microbiome is thought to vary with the conceptual context of the Anna Karenina Principle. The Anna Karenina Principle asserts that microbiomes of unhealthy individuals have increased beta-dispersion (i.e., microbial community variability) than those of healthy individuals (less variability).<sup>1</sup> The Anna Karenina Principle has shown shifts in microbial communities in living individuals associated with obesity, infection, and smoking.<sup>1,5</sup> Due to the postmortem microbiome reflection of antemortem conditions, the Anna Karenina Principle provides an important conceptual context for quantifying microbial signatures and developing metrics or profiles associated with MOD determinations.

This study sought to determine how beta-dispersion profiles, or beta-dispersion differences associated with certain MODs or antemortem conditions, could potentially be used to confirm MOD assessments—in other words, answering the question: is a postmortem microbiome profile consistent with an MOD assigned in a death investigation? To determine if postmortem microbiomes could be used to answer such a question, 188 United States routine autopsy cases with samples taken from five anatomical sites to test associations of MOD and antemortem conditions, including heart disease, drug use, and gunshot deaths, were reviewed. Previously published amplicon sequence data were analyzed using QIIME2™ (v.2018.11) and beta-dispersion metrics were assessed in R using the *vegan* library to statistically model microbiomes with different MODs and test if the microbial communities varied with the Anna Karenina Principle.<sup>3</sup>

Applying the Anna Karenina Principle to postmortem microbiome beta dispersion profiles resulted in different degrees of dysbiosis and were associated with different MODs, with predictive accuracy that depended on sample type. Preliminary results showed that beta-dispersion differed among body sites, with rectum communities having the highest beta-dispersion, while eyes had the lowest. Across all body sites, natural deaths and suicides had overall higher beta-dispersion than homicides. Also, cases with cardiovascular disease-related deaths had significantly higher beta-dispersion than gunshot or drug-related deaths, while non-violent deaths had higher beta-dispersion than violent deaths. Overall, increased beta-dispersion is more prevalent in MODs associated with disease states (cardiovascular disease and mental health issues) compared to homicides and drug-related deaths. Previous research has confirmed reduced beta-diversity in violent deaths as well as reduced green space access.<sup>3,6</sup> Therefore, the current results support the hypothesis that antemortem conditions are associated with postmortem microbiome beta-dispersion profiles and that such data could have potential utility in death investigations by providing corroborating, or contradicting, microbial evidence of MOD as determined by a reflection of antemortem lifestyle. However, additional studies are needed to confirm and expand these findings.

### H158 The Impact of Confinement in Vehicle Trunks on Decomposition and Entomological Colonization of Carcasses

Stacey L. Malainey, MA, Simon Fraser University School of Criminology, Burnaby, BC V5A 1S6, CANADA; Gail S. Anderson, PhD\*, Simon Fraser University, Burnaby, BC V5A 1S6, CANADA

**Learning Overview:** The goal of this presentation is to inform attendees about the impact on decomposition and insect colonization when confining a carcass inside a vehicle trunk in comparison with exposed carcasses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the differences in entomological colonization and decomposition and delay in colonization caused by confining a carcass inside a vehicle trunk, a common way of disposing of a body. It is important that these differences are understood by forensic investigators, particularly forensic entomologists.

In order to investigate the impact of confinement in a car trunk on decomposition and insect colonization of carcasses, three freshly killed pig (*Sus scrofa domesticus* Erxleben) carcasses were placed individually in the trunks of older-model cars and deployed in a forested area in the southwestern region of British Columbia, Canada (Coastal Western Hemlock Biogeoclimatic Zone, Dry Maritime Subzone), together with three freshly killed similar carcasses that were exposed in protective cages in the same forest. The cages prevented bears and other vertebrates from removing the carrion but allowed insect access. Decomposition rate and insect colonization of all carcasses was examined twice a week for four weeks. At each collection time, the cars were covered with an extensive plastic sheet to prevent egress and ingress of insects while the researcher entered the vehicle for collection.

The exposed carcasses were colonized immediately by *Calliphora latifrons* (Hough) and *C. vomitoria* (Linnaeus) (Diptera: Calliphoridae), followed by *Lucilia illustris* (Meigen), *Phormia regina* (Meigen), and *Protophormia terraenovae* (R.-D.). There was a delay of three to six days before the confined carcasses were colonized, first by *P. regina*, followed by *Pr. terraenovae*. These species remained the sole blow fly species on the confined carcasses. Temperatures were greatly increased inside the vehicles. Despite the delay in colonization, decomposition progressed much more rapidly in two of the confined carcasses in comparison with the exposed carcasses due to the greatly increased temperatures inside the vehicles, with the complete skeletonization of two of the confined carcasses between 9 and 13 days after death. One confined carcass was an anomaly, attracting many fewer insects, supporting fewer larval calliphorids, and decomposing much more slowly than other carcasses, despite similarly increased temperatures. It was later discovered that the vehicle in which this carcass was confined had a solid metal fire shield between the passenger area and the trunk, which served to reduce insect access and the release of odors. These data may be extremely valuable when analyzing cadavers found inside vehicle trunks.

## H159 Estimating the Postmortem Submersion Interval (PMSI) From the Microbiome of Bone in Lacustrine and Riverine Environments in Virginia

Claire M. Cartozzo, MS\*, Richmond, VA 23220; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how different aquatic environments (i.e., freshwater lake and freshwater river) impact microbial community changes across Accumulated Degree Days (ADD).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into the potential use of universal microbial succession on submerged skeletal remains to predict long-term PMSI.

Water-related deaths, criminal activity, and mass disasters occurring over or in water (e.g., boating accidents, ferry disasters, commercial plane crashes, and natural disasters) result in thousands of deaths every year. In Virginia alone, the Office of the Chief Medical Examiner reported that death by drowning (asphyxia) accounted for 91 accidental deaths in 2017.<sup>1</sup> Bodies recovered from aquatic environments are exposed to diverse and changing environmental conditions (i.e., scavengers, microorganisms, temperature, pH, current, etc.). Furthermore, microorganisms, such as bacteria, algae, and fungi, participate in the decomposition of human remains in an aquatic environment. With recent advancements in technology, studies have identified microorganisms as potential estimators of time since submersion (PMSI).<sup>2,3</sup> Unfortunately, a reliable and universal method for determining long- and short-term PMSI has yet to be developed.

To examine the impact of aquatic environments on microbial succession, a freshwater river (James River, Charles City, VA) and lake (Henleys Lake, White Hall, VA) were selected as field sites. Work at Henleys Lake and the James River occurred between November 2016–June 2018 and November 2017–November 2018, respectively. For both sites, fresh pig (*Sus scrofa*) bones (scapulae and ribs) were submerged in cages that were attached to a flotation device or wharf. Waterproof temperature loggers and a YSI Sonde were used to record environmental parameters. Every 250 ADD, five scapulae, five ribs and 500ml of water were collected and stored at either -80°C or 4°C. Sample processing included filtration on 0.22µm filters for water samples and pulverization via liquid nitrogen in a mortar and pestle for bone samples. Both filters and powder underwent DNA extraction and purification using ChargeSwitch® gDNA Plant Kit and DNeasy® PowerClean Pro Cleanup Kit, if necessary. Library preparation and sequencing-by-synthesis of microbial 16S recombinant DNA (rDNA) variable region 4 followed the established Kozich et al. and was performed via Illumina's® MiSeq® 2X300 paired-end sequencing.<sup>4</sup> Data analysis and visualization was completed using the MiSeq® mothur SOP, mothur version 1.35.9, and R studio.<sup>5</sup>

Preliminary analysis suggests that there are significant differences between locations and among sample types at each location. In regard to relative abundance, changes were observed in rib and scapula samples; furthermore, scapula and rib samples at both locations shared Firmicutes and Proteobacteria as the two dominant phyla across time; however, the remaining taxa varied. Both locations also demonstrated significant differences in ordinated space (Bray-Curtis Operational Taxonomic Units [OUT] beta-diversity) for each sample type across ADD. Additionally, curvilinear relationships between shannon diversity and ADD were observed for scapula and ribs at both locations. The aforementioned results suggest that there may be enough similarities between locations to create a long-term PMSI model for Virginia.

### PMSI, Aquatic Environments, Bone Microbiome

## H160 Evaluating the Nearest Weather Station as the Best Representation of Scene Temperature in Forensic Entomology Casework

Michelle R. Sanford, PhD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Si Gao, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will gain appreciation of the difficulty of selecting appropriate weather station temperature data to represent insect development conditions at scenes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting data on long-term comparison between temperatures as encountered at scenes during medicolegal death investigations and the nearest weather stations. These data will also attempt to answer the question of which weather station(s) and temperature data may provide more accurate representation of scene conditions, which directly influence insect development.

Insects are poikilothermic, capable of surviving wide temperature shifts and acquiring much of the heat energy required to complete development from their environment. Forensic entomology depends upon this relationship between insect development and environmental temperature to estimate insect age.<sup>1</sup> Assuming that the insects colonized the deceased following death, the estimated insect age may correspond to the Time Of Colonization (TOC) and a measure of the Postmortem Interval (PMI), depending upon scene conditions and the quality of the underlying data. Recommended practices for forensic entomology rely on collection of weather data from the nearest weather station to feed the calculations underlying insect age estimates.<sup>2</sup> The use of the nearest weather station has been widely assumed to be the most accurate temperature data for a given scene. At outdoor scenes, weather station temperature data appears to be a reasonable surrogate for historical scene temperatures in many scene scenarios. How well the scene temperatures are reflected by the nearest weather station can be evaluated with longer-term scene temperature collections for a calculated comparison and adjustment of the weather station data.<sup>3</sup> However, indoor active temperature modification, away from the nearest weather station temperatures, may be occurring during decomposition and insect development.

This study utilized button temperature sensors to examine the long-term differences between fixed locations, hypothetical scene locations, and the nearest weather stations (Airports: George Bush Intercontinental Airport [IAH], William P. Hobby Airport [HOU], Sugar Land Regional Airport [SGR], Maicai Airport [MCJ], and Conroe-North Houston Regional Airport [CXO]). Furthermore, the study was designed to examine one of the most commonly encountered temperature-modifying effects in medicolegal casework, the effects of being indoors with and without air conditioning/heat. Button temperature sensors recorded hourly temperatures for one calendar year indoors w/air conditioning/heat and outdoors in Houston, TX, and at a location in Conroe, TX, indoors w/out temperature modification and outdoors. These data were then compared to hourly temperature data from five local weather stations at the same times. Regression was used to evaluate the relationship between indoor and outdoor temperatures with the different nearby weather stations.

The results of these long-term evaluations revealed that local outdoor temperatures were informative predictors of indoor temperatures, even in the presence of indoor climate control. Furthermore, the nearest weather station was not always the best predictor of the hypothetical scene temperatures. The results of model validation and evaluation of additional hypothetical scene locations will be presented. Additionally, the potential for directly relating these results to insect development will be discussed.

### Insect, Temperature, Weather Station

## H161 The Impact of Insect Exclusion on Eukaryotic Community Succession on Porcine Remains

Denise Wohlfahrt, BS\*, Virginia Commonwealth University, Richmond, VA 23284; Luisa V. Forger, MS, Dover, DE 19901; Michael Shane Woolf, MS, Charlottesville, VA 22903; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will better understand the eukaryotic community associated with porcine cadavers and how the eukaryotic community changes with time in the presence and absence of insects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving Postmortem Interval (PMI) estimation methods based on these succession patterns.

PMI estimation is a vital part of forensic investigations, yet determination methods for long-term PMI are not reliable. Currently, microbial signatures are being investigated, specifically concentrating on the bacterial or eukaryotic succession patterns as PMI predictors.<sup>1</sup> Insect accessibility to a carrion has long been established as a driving force of the decomposition process.<sup>2,3</sup> Understanding which microbiota are released into these systems, as well as their origins, can aid forensic scientists in establishing robust and reliable PMI estimation methods. While forensic entomology has been useful for long-term PMI estimation, this method does not reflect situations in which remains are not immediately accessible to insects.<sup>4,5</sup>

This study characterized the eukaryotic community associated with porcine remains that were either exposed ( $n=6$ ) or excluded ( $n=6$ ) from insect access, using 18S recombinant DNA (rDNA) MiSeq<sup>®</sup> sequencing. Skin swabs were collected from each cadaver from the lateral thoracic or lateral abdominal regions starting immediately after euthanization, daily for the first 5 days, and weekly after this up to day 61 (1,703 Accumulated Degree Days [ADD]). DNA was extracted using the organic Cetyl Trimethyl Ammonium Bromide (CTAB) extraction method followed by dual-index 18S rDNA MiSeq<sup>®</sup> sequencing on MiSeq<sup>®</sup> FGx platform using MiSeq<sup>®</sup> reagent kit v2 (500 cycles).<sup>5,6</sup> Sequences were analyzed using mothur version 1.39.5 and using SILVA (release 132) as reference data for eukaryotic classification.<sup>7</sup> Statistical analysis was performed using R version 3.5.0.<sup>8</sup>

An Analysis of Molecular Variance (AMOVA) suggested that there is a significant difference between the insect access and insect exclusion groups. However, the major phyla (>1%) differed only in their relative abundance. At the family level, similar patterns in top taxa can be seen. In both the access and exclusion groups, there is an increase in relative abundance of Rhabditida around 209 ADD/7 Days and an increase in the abundance of Dipodascaceae immediately after 448 ADD/15 Days. During the later stages of decomposition, the exclusion group showed much higher relative abundances of Filobasidiales and Trichosporonaceae, whereas the access group showed much higher relative abundances of Diptera, Coleoptera (as expected), and Ascomycota.

In conclusion, this study provides information on eukaryotes associated with porcine remains under both insect access and exclusion conditions. Here, succession patterns in both groups can be useful as predictors of the PMI. Utilizing this information in combination with prediction modeling may aid the forensic science community in filling gaps of extended PMI estimation methods, decreasing the overall rate of erroneous results.

### Insect Exclusion, 18S rDNA, Postmortem Interval

### H162 Understanding the Role of the Thanatomicrobiota in the Decay of “Reproductive Organs” in Human Decomposition

*Gulnaz T. Javan, PhD\**, Alabama State University, Montgomery, AL 36104; *Holly L. Lutz*, University of Chicago, Chicago, IL 60637-1508; *Sheree J. Finley, PhD*, Alabama State University, Montgomery, AL 36104; *Silvia D. Visona, MD*, University of Pavia, Pavia 21100, ITALY; *Antonio M.M. Osculati, MD*, University of Pavia, Pavia 27100, ITALY; *Jack A. Gilbert, PhD*, University of California San Diego, La Jolla, CA 92093

**Learning Overview:** After attending this presentation, attendees will understand how to use 16S ribosomal RNA (rRNA) amplicon sequencing analyses to characterize the thanatomicrobiota of reproductive organs from actual cadavers in criminal cases (e.g., homicide, suicide, and overdose). Specifically, attendees will learn methods to assess the microbial diversity after death using cases with Postmortem Intervals (PMIs) between 3.5 and 240 hours.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing the specific bacterial signatures associated with the uterus and prostate of cadavers with different manners of death. These signatures could help to improve trace evidence regarding characteristics of manner of death for criminal cases.

Human organs decompose at different rates and in different ways. For example, human prostate glands and uteri are the last internal organs to deteriorate during putrefaction. However, the reason for this phenomenon has not been elucidated. To determine whether the bacteria associated with these organs differ from other organs, and to determine whether the taxonomic signature is associated with the PMI, this study applied 16S rRNA amplicon sequencing to tissues associated with 21 prostate glands and 13 uteri collected at autopsy from criminal casework cadavers. The 16S rRNA V4 region was amplified and sequenced from each sample, and non-parametric statistics were used to determine the resulting microbiota profile and its association with cadaver characteristics. Both the uterus and prostate had a significantly greater alpha diversity compared to other organs, as well as maintaining a significantly different microbial composition (beta diversity) as determined by unweighted UniFrac. The prostate was significantly enriched for two 16S rRNA Absolute Sequence Variants (ASVs) associated with the Bacteroidia, one in the family Comamonadaceae (genus *Limnohabitans*) and another in the family Oxalobacteraceae. Uterine tissues were enriched for only two ASVs, including a single ASV in the class Bacilli (family Lactobacillaceae, genus *Lactobacillus*) and a single ASV in the class Gammaproteobacteria (family Enterobacteriaceae, unknown genus). Prostate tissues had a significant underrepresentation of 4C0d-2 ASV (order MLE1-12) and a single Clostridia ASV (family Lachnospiraceae, unknown genus). It is possible that these organisms may associate with differential decay rates. Natural deaths were enriched for class 4C0d-2 (order MLE1-12) and ASVs in the classes Bacilli (family Lactobacillaceae, *Lactobacillus zeae*), Gammaproteobacteria (family Enterobacteriaceae, unknown genus), and Saprospirae (family Chitinophagaceae, genus *Sediminibacterium*). Among victims of accidental death, a single Bacilli ASV (order Lactobacillales, unknown family) and Gammaproteobacteria (family Enterobacteriaceae, unknown genus) were enriched. Homicide victims did not exhibit enrichment of any bacterial taxa. Currently, none of these signals was a significant predictor of manner of death.

### H163 The Postmortem Clostridium Effect: A Thanatomicrobiome Investigation of Cadaver Brain

Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Courtnee Bell, MS, Montgomery, AL 36104; Eloise H. Mikkonen, PhD, Tampere University, Tampere 33520, FINLAND; Sheree J. Finley, PhD\*, Alabama State University, Montgomery, AL 36104; Qiana Matthews, PhD, Alabama State University, Montgomery, AL 36104

**Learning Overview:** After attending this presentation, attendees will have learned how to use the Postmortem Clostridium Effect as a biomarker for forensic microbiology in cadaver brains obtained from criminal casework with a postmortem interval of up to 11 days.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the role of *Clostridium* on the decomposition of human brains from actual criminal cases for forensic science applications.

What happens to the more than 100 trillion bacterial cells and 10 million human cells after a person dies has yet to be determined. It is known that brain cells generally die in as little as three to seven minutes after death. Revealing the diversity of microbial communities located in the human brain using bioinformatics and machine-learning tools have the potential to be a useful biomarker in forensic microbiology. The brain is identified as an intermediate-decomposing body site in the progression of the natural order of decomposition. Human thanatomicrobiome studies have established that putrefactive bacteria have been found in abundance within internal organs of decaying bodies. Of the various types of putrefactive bacteria found in internal body sites, obligate anaerobes of *Clostridium* spp. have been found in highest abundance. According to previous thanatomicrobiome studies, *Clostridium* spp. predominated at both short (4h) and long (up to 10 days) postmortem intervals.

The current study surveyed the postmortem microbiomes of brain tissues from 11 corpses with varying times of death ranging from 29 hours to 11 days. The brains of individuals were collected during autopsy using sterile equipment. Metadata for each cadaver was collected: age, sex, time of death, and cause of death from Official Daily Crime Logs. Total DNA was extracted using the phenol-chloroform method. *Clostridium* genes were amplified and sequenced using primers Clos58-F and Clos530a-R. The influences of case characteristics on microbiome composition, such as beta diversity, were investigated. Following standard demultiplexing and quality filtering using the Quantitative Insights into Microbial Ecology pipeline (QIIME™) and USEARCH global alignment algorithm, *Clostridium* spp. were identified. The output was analyzed using an internally developed Python program that assigned taxonomic information to each sequence. The results demonstrated that age was a significant predictor of the number of observed taxonomic units in brain samples. Furthermore, *Clostridium* and *Escherichia* were the most dominant observed bacterial genera in the study. To date, the results represent the first pilot study to perform *Clostridium* sequencing on postmortem brain tissue from criminal cases and confirm the Postmortem Clostridium Effect in decaying cerebral tissues.

#### PCE (Postmortem Clostridium Effect), Cadaver Brain, *Clostridium* Sequencing

## H164 Postmortem Cardiac-Magnetic Resonance (PMCMR) Protocol in Sudden Cardiac Deaths (SCDs)

Alessandro Santurro, MD\*, Sapienza University of Rome, Rome 00161, ITALY; Giovanni Donato Aquaro, MD, Fondazione Monasterio National Council for Research-Toscana, Pisa 56100, ITALY; Michele Emdin, MD, PhD, Gabriele Monasterio Tuscany Foundation, Pisa 56124, ITALY; Vittorio Fineschi, MD, PhD, University of Foggia, Foggia I-71100, ITALY; Matteo Scopetti, MD, Sapienza University of Rome, Rome 00161, ITALY; Benedetta Guidi, MD, Via Santa Dorotea 1, Pescia, Pistoia 51017, ITALY; Emanuela Turillazzi, MD, PhD, viale degli Aviatori 1, Foggia 71100, ITALY; Marco Di Paolo, MD, Pisa 56100, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the advantages and limitations of postmortem imaging techniques in the study of SCDs. A protocol for an adequate image acquisition and its preliminary results will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by pointing out the importance of PMCMR and its ability to detect pathological myocardial alterations. It will be demonstrated that PMCMR is useful in the study of SCDs, showing a good correlation with autopsy results.

SCD is defined as abrupt and unexpected death that occurs due to cardiac causes, with sudden loss of consciousness within 1 hour from the onset of symptoms when death is witnessed, and within 24 hours of last being seen alive and well when it is unwitnessed. Its main characteristics are related to the non-traumatic genesis and the immediate precipitation of events. Sudden deaths account for 15%–20% of forensic cases. The most frequent causes of SCD are represented by Ischemic Heart Disease (IHD) secondary to Coronary Artery Disease (CAD), followed by primary cardiomyopathies (10%–15%; most frequently hypertrophic cardiomyopathy and arrhythmogenic right ventricular dysplasia), valvular heart disease (5%), and coronary artery anomalies (e.g., anomalies of origin, myocardial bridging). In 5% of cases, no structural cardiac alterations can be documented, but ion channel gene alterations (i.e., channelopathies) can be detected. However, in a minority of cases (5%–20%), the heart appears macroscopically and microscopically normal and no diagnosis can be established (*mors sine materia*).

In order to reduce the cases of death *sine materia*, it is necessary to adopt a correct and rigorous autopsy procedure, collecting and examining the clinical-anamnestic and circumstantial data. Also, Postmortem Magnetic Resonance (PMMR)—in addition to autopsy and classic gross/histological/immunohistochemical investigations—has proven useful in better detecting diagnostic possibilities, especially in the case of SCD.<sup>1</sup> PMCMR has been successfully applied as an ancillary exam to identify myocardial pathological findings, allowing visualization of thin transverse sections of myocardial tissue, which are not possible with routine autopsy and gross examination.<sup>2</sup>

Despite the fact that PMCMR has shown high sensitivity and specificity in the identification of heart diseases, it is currently performed only in a few select cases rather than routinely. The main reasons for its limited application seem to be related to the time of execution and the complexity of the MR technology. Moreover, most of the studies in literature describe PMCMR conducted prior to autopsy with the heart *in situ*. However, examining hearts *ex situ* shows considerable advantages, including overcoming logistical problems of body transport, time constraints, and interference with routine clinical activity. As an adjunct, fixation of the heart in formalin, as required by the autopsy protocol for SCDs, allows for preservation of the organ at room temperature, preserving from postmortem alterations and allowing for PMCMR examination a second time after the autopsy.<sup>3</sup>

Presented is a PMCMR study protocol of the entire formalin-fixed heart *ex situ* using high-resolution 2D-Steady-State Free Precession (SSFP)/3D-SSFP sequences, and T1-weighted (T1w), T2-weighted (T2w), and Proton Density (PD) Fast Spin Echo (FSE) sequences to obtain information on cardiac morphology, to identify ventricular anomalies (e.g., intramyocardial coronary bridging, aneurysms, symmetric or asymmetric hypertrophy of the ventricular wall, papillary muscle abnormalities, valvular anomalies, etc.) and to obtain quantitative parameters (i.e., Left Ventricular/Right Ventricular [LV/RV] mass, ventricular mass, atrial dimensions, aortic and pulmonary root diameters).

### H165 Radiodense Bullet Wipe (RBW) Around Skeletal Entrance Gunshot Wounds: The Frequency of Detection and Evaluation of Decedent, Wound, and Ammunition Characteristics

Ashley Lukefahr, MD\*, *The University of Arizona, Tucson, AZ 85724-5108*; Jennifer M. Vollner, PhD, *Pima County Office of the Medical Examiner, Tucson, AZ 85714*; Bruce E. Anderson, PhD, *Pima County Office of the Medical Examiner, Tucson, AZ 85714*; David C. Winston, PhD, *Pima County Office of the Medical Examiner, Tucson, AZ 85714-2081*

**Learning Overview:** After attending this presentation, attendees will appreciate the prevalence of RBW around skeletal entrance gunshot wounds and the possible significance of bullet caliber, presence of jacket, and range of fire.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by documenting information that may be helpful for the postmortem evaluation of skeletal gunshot wounds.

“Bullet wipe” is the material deposited by a bullet on any surface with which it comes into contact after it is fired. Bullet wipe may contain debris from the gun barrel, including particles of primer and metal fragments from previously fired bullets. X-ray analysis is a non-destructive method by which traces of metallic elements can be visually detected. The analysis of bony defects for RBW is an important technique for assisting in the determination of the presence or absence of perforating gunshot wounds, especially in fragmented, skeletonized remains.

The aim of this current study was to determine the frequency of RBW around entrance firearms injuries that perforated bone. This study prospectively analyzed entrance gunshot wounds for RBW over a three-year period using digital X-ray analysis (KaVo NOMAD™ Pro with DEXIS™ software). The primary rate limiting step was the ability to maneuver the skeletal element for radiography. A total of 59 cases were able to be successfully radiographed. The autopsy reports from these cases were retrospectively reviewed to determine the frequency of RBW by biologic sex, reported ancestry, age-at-death, location of wound, manner of death, range of fire, bullet caliber, and presence of bullet jacket. Data were analyzed by Fisher’s exact test or Chi-square test (GraphPad Prism 8.1.2) with significance levels accepted at  $p < 0.05$ .

RBW was present in 66% ( $n=39$  of 59) of examined cases. Decedent biological characteristics did not significantly alter RBW, including biologic sex ( $p=0.75$ ), reported ancestry ( $p=0.49$ ), and age-at-death ( $p=0.43$ ) when examined by ten-year ranges. Additionally, the location of the bony entrance gunshot wound did not significantly affect RBW detection, including the frontal bone, right parietal bone, left parietal bone, right temporal bone, occipital bone, maxillae (hard palate bones), sternum, and mandible. RBW was not detected from the left temporal bone ( $n=1$ ) nor the rib ( $n=1$ ).

Manner of death did not significantly affect RBW detection, as RBW was found in 67% of homicides ( $n=18$ ) and 72% of suicides ( $n=21$ ). No RBW was detected from cases where the manner of death was classified as accident ( $n=2$ ) or undetermined ( $n=1$ ). Range of fire did not significantly affect RBW detection, as RBW was recovered from 65% of contact range wounds ( $n=22$ ), 69% of intermediate range wounds ( $n=9$ ), and 67% of indeterminate range wounds ( $n=8$ ).

When information was available regarding handgun cartridge caliber ( $n=49$ ), RBW was recovered from 100% of cases involving .22 caliber cartridges ( $n=3$ ), 50% of cases involving .25 caliber cartridges ( $n=1$ ), 64% of cases involving .380 caliber cartridges ( $n=7$ ), 56% of cases involving 9mm caliber cartridges ( $n=9$ ), 75% of cases involving .40 caliber cartridges ( $n=9$ ), 50% of cases involving .357 caliber cartridges ( $n=1$ ), and 33% of cases involving .45 caliber cartridges ( $n=1$ ). In 42 cases, the handgun cartridge was jacketed and RBW was detected in 67% of these cases ( $n=28$ ). All cases involving non-jacketed rounds ( $n=5$ ) showed RBW ( $p=0.30$ ).

Per research, this study is the first to report the frequency of RBW detection from skeletal entrance gunshot wounds.

### H166 Comparing Sinus Fluid Density in Drowning Versus Non-Drowning Victims Using Postmortem Computed Tomography (PMCT)

Zuhha Ashraf, MD\*, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033; Catherine Yim, MD, Olive View Medical Center, Sylmar, CA 91342; Mariam Thomas, MD, Olive View Medical Center, Sylmar, CA 91342; Odey C. Ukpo, MD, Los Angeles County Medical Examiner-Coroner, Los Angeles, CA 90033

**Learning Overview:** After attending this presentation, attendees will understand the implications of measuring the density of sinus fluid in drowning versus non-drowning victims using PMCT.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of comparing sinus fluid density between drowning versus non-drowning victims and between fresh water versus ocean water drowning victims.

Drowning is usually a diagnosis of exclusion but there are characteristic autopsy findings described in the literature, including: presence of fluid in the paranasal sinuses and airways, pulmonary edema, water in the stomach, and mastoid air cell hemorrhage.<sup>1</sup> The content and characteristics of the fluid in the various sinuses are typically not analyzed when determining the cause of death. In PMCT, this anatomic area is easily visualized and the fluid character can be described in Hounsfield Units (HU). Prior studies have evaluated sinus fluid with PMCT. Christe et al. identified the amount and distribution of sinus fluid of 10 drowning cases compared to 20 non-drowning control cases.<sup>2</sup> Kawasumi et al. evaluated sinus fluid density and volume to differentiate salt water versus fresh water drownings.<sup>3</sup> A total of 93 cases (22 saltwater and 71 freshwater) were investigated, and it was found that saltwater drowning had a significantly higher fluid density than fresh water drowning.<sup>2</sup> In both studies, the sinus fluid density in HU was not compared quantitatively between drowning and non-drowning groups.

The goal of this study was to compare the HU of fluid in the sinuses of drowning versus non-drowning victims. PMCT scans from August 2016 to December 2018 were reviewed, and 68 total cases in which fluid was present in the sinuses were examined. Thirty-four drowning deaths were selected for the study group and 34 non-drowning deaths were selected for the control group. The controls included deaths from natural disease, accidents, and homicides. Head trauma was excluded from the controls as blood could be present in the sinuses. An equivalent number of males and females were selected for the drowning (26M, 8F) and control (27M, 7F) groups. The mean ages were 37.0 years (drowning) and 36.6 years (control). Radiologist consultants were blinded to cases and selected the appropriate Region Of Interest (ROI) and measured the average HU of fluid in the sinuses. The mean HU of drownings (25.0936) was lower than the mean HU of controls (30.6895), with a difference of 5.5959 ( $p=0.018$ ). The HU in drownings were compared by location (ocean [11] vs fresh water [23]). The mean HU of ocean (31.0636) was higher than the mean HU of fresh water (22.2384) with a difference of 8.8252 ( $p=0.0082$ ).

There was a difference in the mean HU of the drowning vs. control group, as well as in the ocean vs. fresh water group. While the presence of fluid is not a specific finding, the lower mean HU value in drowning deaths vs. controls represents a lower fluid density, consistent with a more watery fluid. Comparing the mean HU by location shows promising results and may have potential applications such as determining where a victim had drowned or if the body had been moved postmortem.

### H167 Heat-Induced Changes in Charred Human Remains

Antonina Argo, PhD\*, University of Palermo, Palermo 90100, ITALY; Giuseppe F. Lo Re, MD, University of Palermo, Palermo, ITALY; Donatella Piscionieri, University of Palermo, Palermo 90127, ITALY; Ginevra Malta, MD, University of Palermo, Palermo 90100, ITALY; Alessia Vinci, MD, University of Palermo, Palermo 90127, ITALY; Agata Crapanzano, MD, University of Palermo, Palermo 90100, ITALY; Sergio Salerno, University of Palermo, Palermo 90100, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand how heat induces changes on human charred bodies and the possibility of distinguishing peri-mortem and postmortem bone fractures, taphonomic modification, and heat-induced bone changes by macroscopic observation and Postmortem Computed Tomography (PMCT).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results of an observed case (January 2019) of charred human remains in an area (prolonged exposure of the human body to fire) that is very challenging to distinguish peri-mortem and postmortem fractures and by interpreting taphonomic modification and heat-induced bone changes.

Burned human remains in crime scenes are typically difficult to identify, recover, and manage.<sup>1</sup> All of the burned material at the scene, including body tissues, is often modified to a similar appearance. In particular, even though bone is certainly the most resistant to high-temperature exposure, at temperatures above 700°C, it will undergo complete combustion of the organic substances with incineration and recrystallization of the inorganic matter; this phenomenon is termed “calcination.” A charred or calcinated bone is known to be more fragile. The added peri-mortem or postmortem fracture lesion, fragmentation, and bone loss resulting from recovery techniques adds to the difficult task of autopsy and laboratory analysis of burned human remains. This is especially problematic for bone trauma analysis, as its most immediate goal is to distinguish peri-mortem trauma from postmortem alterations and shape lesions from heat-related traumatic lesions. With regard to burning-related changes such as shrinkage, the literature reports that low temperatures (i.e., less than 800°C) of minimal duration produce minimal shrinkage.<sup>2</sup> The characteristics of severely heat-damaged areas of tissue are usually obvious and well-known in forensic practice, but fractures may be challenging to interpret. In cases involving extreme exposure to fire, burned skeletal elements typically exhibit severe fragmentation and fracturing, limiting interpretation and distinction of peri-mortem and postmortem trauma.

In this study, a criminal case occurring on January 2019 and classified as Glassman and Crow level 4/5 male human remains is presented.<sup>3</sup> Color changes, fracturing pattern, bending, shortening, and cracking of all recovered bones by both visual examination and PMCT were analyzed. PMCT allowed for better recognition of cortical thinning and loss of matter, smoothing of the sharp edges, assessment of various alterations of bone marrow density associated with the presence of air, and recognition of thumbnail fractures as an exclusive sign of the burning of bones with soft tissues.<sup>4</sup> Preliminary statistical testing found a significant relationship (p-value <0.005) between the supposed temperature of combustion of analyzed bones within the Shipman color scale and the Hounsfield Units (HU) of bones on PMCT scan. Taphonomic modifications of the human remains were verified after four months and under controlled conditions before burial and are here illustrated.

#### Charred Body, Heat Fractures, Incineration

### H168 Fatal Obstructive Asphyxia: Trans-Pulmonary Density Gradient Characteristic as a Relevant Identifier in Postmortem Computed Tomography (PMCT)

*Wolf Schweitzer, Universitat Zurich, Zurich 8057, SWITZERLAND; Lars C. Ebert, PhD\*, Universitat Zurich, Zurich 8057, SWITZERLAND; Michael Thali, MD\*, Universitat Zurich, Zurich 8057, SWITZERLAND*

**Learning Overview:** After attending this presentation, attendees will understand the key findings that may help identify cases of fatal obstructive asphyxia, such as smothering or manual strangulation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how the forensic identification of fatal obstructive asphyxia may be of relevance when occurring early in the management of a given case. Hence, knowledge of relevant findings and their differential diagnoses may be of significance.

**Background:** The initial qualitative impression had been that obstructive asphyxia typically appeared to correlate with absence or reduced postmortem hypostasis as well as increased pulmonary radiotranslucency. Categories initially included within obstructive asphyxia were fatal aspiration of gastric contents into lungs, fatally blocked trachea or bronchi due to foreign body, fatal ligature strangulation, fatal manual strangulation, and smothering.

**Method:** To investigate the effects of obstructive asphyxia on the Postmortem Computed Tomography (PMCT) appearance of lungs, this study matched 24 cases of obstructive asphyxia with age-sex matched controls. Among the bodies that were examined routinely, there were a number of instances where there had been findings suggestive of some form of obstructive asphyxia: at the death scene, or when documenting the body's position in relation to the death scene, when examining the body. Routinely, such cases are subsequently admitted to this institute for PMCT and medicolegal autopsy upon which further findings emerge that then are evaluated in conjunction with the previous information.

Case selection was performed retrospectively by sampling all cases of 2014 through 2017 using criteria as detailed below. Only cases with full body PMCT, autopsy, and with a full final report were considered. Cases with fatal hypothermia, fatal blood loss, detectable injury of the lungs, or putrefaction with notable gas in soft tissues, vessels, or organs were excluded from the study.

This study manually placed density profile vectors, with a start at positionally dependent locations of each lung to derive PMCT densities for multivariate statistics. For each lung, such a vector was obtained, resulting in two vectors for each case.

As fatal gastric content aspiration cases did not significantly differ from the controls, they were re-grouped into the control group for further testing. The density vectors thus contained pulmonary densities starting from the positionally lowest to the opposite location of each lung.

**Results:** Quantitatively, the obstructive asphyxia case group featured reduced or absent postmortem hypostasis in the lungs and an overall lower density. Linear multivariate statistics (general linear models, linear discriminant analysis) performed relatively poorly, whereas "shallow" neural networks yielded significantly better discrimination. With disjunct training and test sets, neural networks achieved Correct Recognition Rates (CRR) of obstructive asphyxia cases of more than 95%.

**Conclusions:** Within a more narrowly defined collective of obstructive asphyxia, pulmonary PMCT data appears to contain sufficient information to reach a relatively high level of discrimination. This questions the value of an exclusively death scene-focused decision, making for further investigations and may justify a wider use of PMCT. Conversely, obstructive asphyxia remains difficult to diagnose conclusively based on PMCT alone.

#### Fatal Obstructive Asphyxia, Postmortem CT, Forensic Pathology

### H169 Using Postmortem Computed Tomography (PMCT) and Drug Screens to Triage Drug-Related Fatalities

Lauren A. Decker\*, Office of the Medical Investigator, Albuquerque, NM 87131; Sarah Lathrop, DVM, PhD, Albuquerque, NM 87111

**Learning Overview:** The goal of this presentation is to present a novel method to triage drug-related death examinations using PMCT and drug screening.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing an alternative approach to managing the increasing numbers of drug-related deaths in a medical examiner's office without compromising accuracy.

**Background:** In the current context of rising numbers of drug-related fatalities and an overall shortage of forensic pathologists, the current National Association of Medical Examiners (NAME) recommendation that all drug-related fatalities receive a full autopsy may not be the most efficient use of increasingly limited resources. The New Mexico Office of the Medical Investigator (OMI) has devised a new triaging system using a combination of PMCT and drug screens to help alleviate some of the workload while still providing quality care.

**Methods:** Under the new guidelines, drug-related fatalities fall into one of five categories.

**Scenario 1:** The first category pertains to decedents 40 year old and younger, with no medical history, a scene suggestive of drug use, and a negative PMCT. If all of these criteria are met, the case is then triaged based on the results of a Urine Drug Screen (UDS), with a positive screen resulting in a conversion to external examination and a negative screen resulting in an autopsy.

**Scenario 2:** This category includes decedents with significant natural disease, regardless of age, or those that would meet the criteria for an external examination based on age or significant PMCT findings, but who also have some indicators for drug involvement based on history or scene findings. These cases may still receive an external examination with PMCT to document natural disease. A UDS is used in these cases to guide toxicology testing: a positive screen resulting in testing compatible with the positive screen and a negative screen resulting in no additional testing.

**Scenario 3:** The third category addresses decedents with lethal natural disease (i.e., hemopericardium) seen on PMCT or autopsy. The examination type depends on the modality by which the lethal natural disease is discovered. If found on PMCT, an external examination is appropriate. If found at autopsy, the exam type does not change. A UDS is used to guide toxicology testing (i.e., rule out drug involvement).

**Scenario 4:** The fourth category includes decedents with chronic ethanol abuse and significant natural sequelae of such on PMCT, but with some concern for acute ethanol toxicity. These cases may receive an external examination with confirmatory toxicology testing.

**Scenario 5:** The last category relates to all other drug-related deaths that do not fit into the first four categories (i.e., suicidal overdoses). At this time, these cases still receive a full autopsy.

**Results:** Within the period of May 2019 to July 2019, 150 cases were identified as meeting the criteria for one of the first four categories. These cases were triaged according to the above guidelines. During this time period, confirmatory toxicology testing was performed on all cases, regardless of drug screen results. Of those 150 cases, 124 (82%) were converted to external examinations with PMCT. A majority of these cases, 60%, were in Scenario 2, while 34% were in Scenario 1, and the remainder consists of Scenario 3 and 4. Drug screens were performed on 75% of the cases. For those cases with both a UDS and confirmatory toxicologic testing, sensitivity by drug category ranged from 75% to 100%, and specificity ranged from 77% to 100%. To date, of the cases that have been finalized, the UDS was in agreement with cause of death in all but one case. In this instance, the UDS was positive for known medications at therapeutic concentrations, which were determined not to have contributed to death.

**Discussion:** The conversion of 124 of 150 cases to external examinations resulted in an autopsy equivalent decrease from 150 to 57 (when using four external exams per autopsy equivalent). This is not only a significant reduction in workload per pathologist, helping maintain NAME guidelines for numbers of autopsies performed per year, but also reduced technologist labor and morgue resources. Additionally, in nearly 11% of cases with UDS, the drug screens were negative with negative confirmatory testing. In the future, these cases would not have needed confirmatory testing, reducing the cost of toxicology testing overall. The combination of PMCT and drug screens allows for a novel triaging system in which a full autopsy is not necessary for all drug-related deaths, decreasing workload while still maintaining accurate determination of cause and manner of death.

#### Postmortem Computed Tomography, Drug Screen, Autopsy

### H170 The Diagnostic Accuracy of Unexplained Intracranial Hemorrhage as an Indicator of Abusive Head Trauma in the Context of a Coagulopathy

Michael Freeman, MD, PhD, Forensic Research & Analysis, Lake Oswego, OR 97035; Ellen M.F. Strømmer, MPH\*, Salem, OR 97302

**Learning Overview:** The goal of this presentation is to present an analysis of the accuracy of the diagnosis of abusive head trauma when it is based solely on findings of intracranial and retinal hemorrhage and in the absence of any collateral evidence of abuse in a pre-mobile infant with a bleeding disorder.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of a risk-based (i.e., epidemiologic) analysis when the cause of death determination in an infant is entirely dependent on a pathological finding with an unknown positive predictive value for intentional abuse and, thus, an unknown false positive (i.e., error) rate.

The case involved a 4-month-old male infant with no personal or family history of abuse, who was discovered pale, unresponsive, and not breathing by his father, around three days after he had been found to have a bump on the back of his head. Computed Tomography (CT) scan revealed an acute or chronic subdural hematoma and cerebral edema, with no skull fracture. By the time he had died five days later, the child had developed retinal hemorrhage. During the five-day hospitalization, it was found that the child had Factor VII deficiency, and months-later testing of his father revealed the same condition.

An autopsy conducted two days later noted a chronic subdural and subarachnoid hemorrhage, cerebral edema, optic nerve sheath hematoma, and retina hemorrhage. The cause of death was given as “blunt force injuries of the head,” despite an absence of any external sign of trauma. A child abuse pediatrician deemed the finding of both retinal hemorrhage and unilateral shin bruising (from intraosseous catheter) to be consistent with abuse.

Based solely on the fact that he was the caregiver who discovered the child in a non-responsive state, the father was charged with first degree reckless homicide. When confronted with the evidence of Factor VII deficiency, the pediatrician opined that this was secondary to, rather than a result of, the intracranial hemorrhage, noting that extensive personal experience with such injuries was the basis for the conclusion. The pediatrician also claimed that the injuries in the deceased infant, specifically the intracranial hemorrhage and retinal hemorrhage, are only possible due to physical abuse (i.e., shaking with or without impact) or a high-speed traffic crash or fall from at least a two-story height.

A forensic epidemiologic analysis of national hospital data was undertaken to assess the reliability of the claims made by both pediatrician and pathologist.

Data were abstracted from the Kids’ Inpatient Database (KID) and the National Inpatient Sample (NIS). The analysis included all children aged 1 year and under who were admitted to the hospital with intracranial and retinal hemorrhage from 2000 to 2014, inclusive. There were an estimated 9,493 children who met these criteria, approximately 633 infants per year. Coagulopathy was present in 406 (4.2%) of the hospitalized infants, or around 27 per year.

Of the 9,493 hospitalized infants, there were 5,014 (52.8%) who had no other diagnosed injuries that would be consistent with abuse (fractures, burns, internal injuries, etc.), or around 334 per year. Abuse was diagnosed or designated as a cause in 70.9% of the cases where there was no other diagnosed injury. Among the children who did not have a diagnosis of abuse, in the majority for which there was a cause specified, the injury resulted from a low-energy event, such as a ground-level fall or a fall from furniture or a bed.

The analysis revealed the fact that among pre-mobile children who are hospitalized for intracranial and retinal hemorrhage, both with and without coagulopathy, the injury did NOT result from abuse in at least one out of every five cases. Thus, the assertion by the pediatric specialist that, in the absence of a history of a high-speed traffic crash, etc., the injury must have resulted from abuse, was demonstrably false. The conclusion by the pathologist that the injury resulted from “blunt force trauma” was also rejected as factually baseless.

After being presented with the above evidence, in combination with the familial evidence of a coagulopathy, the state dismissed the homicide charge against the father.

#### Abusive Head Trauma, Retinal Hemorrhage, Factor VII Deficiency

### H171 Pediatric Accidental Deaths in Cook County, Illinois

*Serenella Serinelli, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Ponni Arunkumar, MD*, Cook County Medical Examiner's Office, Chicago, IL 60612; *Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the incidence and circumstances surrounding pediatric accidental deaths in a busy, urban medical examiner's office during the past five years.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of pediatric accidental deaths in Chicago, IL, which may be useful in determining risk factors and prevention strategies for the pediatric population.

Accidental injuries are among the most frequent causes of death in children. According to the Centers for Disease Control and Prevention, unintentional injuries represent the fifth-leading cause of death in children <1 year of age and the first cause of death in children between the ages of 1–10 years.

A search of the database of the Cook County Medical Examiner's Office over the past five years (August 2014–July 2019) identified 131 accidental deaths that occurred in subjects between 0 and 10 years old. This represented 15.3% of all deaths occurring in the same period among children of the same age range (131 out of 852 cases).

The mean age was 2 years, and the median age was 1 year. The youngest (two infants) were five days old. The age distribution was as follows: <1 year old (58 subjects), 1 year old (16), 2 years old (13), 3 years old (7), 4 years old (6), 5 years old (13), 6 years old (5), 7 years old (2), 8 years old (2), 9 years old (7), and 10 years old (2). There was a male predominance, with 75 (57%) of the subjects being males and 56 (43%) females. By race, 66 (50%) of the subjects were African American, 58 (45%) were Caucasian, and 7 (5%) were other. Over the period analyzed, the peak incidences occurred in 2015 (35 cases) and 2018 (31 cases).

The cohort was divided into infants (less than 1 year of age) and children (1-10 years of age). The most common cause of accidental death in infants was asphyxia due to an unsafe sleeping environment (45 cases out of 58), followed by motor vehicle collisions, house fires, and drowning. In subjects over 1 year old, motor vehicle collisions, house fires, and drowning represented the vast majority of deaths (53 out of 73), followed by a number of events related to the size of the children and their cognitive and motor development. In particular, deaths associated with the ingestion of solid foods (choking on food bolus) and the capacity to walk autonomously (falls from height, entanglements in window shade cords, etc.) were observed in this age range.

Accidental injury in the pediatric population is frequent, and often a preventable cause of mortality. Prevention strategies rely on a correct evaluation of the causes of death and injury. Forensic pathology can help to identify risk factors and ways to reduce childhood mortality from injuries. This study has the intent to offer information for future intervention plans and a basis for future research.

### Pediatric, Accidental Deaths, Unintentional Injury

### H172 Histologic Findings of the Pancreas in Infant Deaths: A Review of Cases at the State of Maryland Office of the Chief Medical Examiner (MD OCME)

Derek Musgrove\*, Baltimore Office of Chief Medical Examiner, Baltimore, MD 21223; Nikki Mourtzinis, DO, Maryland Office of Chief Medical Examiner, Baltimore, MD 21204; David R. Fowler, MD, Office of Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** After attending this presentation, attendees will have a better understanding of some histological findings that may be seen in cases of infant asphyxia and/or Sudden Unexpected Death in Infancy (SUDI).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by alerting attendees to potential histologic findings in infant deaths attributed to asphyxia and/or SUDI.

SUDI is used to classify those deaths in children 12 months of age or younger with non-specific autopsy findings following a complete forensic autopsy that includes toxicology and radiology, review of medical history, and thorough scene investigation.<sup>1</sup> Most recently, the term SUDI has been used in situations involving infants found in unsafe sleep environments, such as prone positioning, bed sharing, and sleeping on surfaces not designed for infants (plush bedding, large pillows, couches, etc.). Confounding the diagnosis of SUDI, in cases of unsafe sleep environments, is that the risk of suffocation or asphyxia cannot be ruled out as the cause of death. In addition, “gentle” homicides, in particular smothering, can also have similar non-specific findings as SUDI and may be missed, which is why the majority of these cases should be ruled as undetermined.<sup>1</sup>

In a high-volume office such as the MD OCME, a majority of infant cases are ultimately ruled as SUDI, although in situations with strong supporting circumstances, such as a witnessed overlay or wedging, cases may be ruled as asphyxia. During routine review of infant autopsy slides from several autopsies, some sections of pancreas revealed inflammatory infiltrates that seemed independent of any systemic infectious process. Much is included in the literature about examining the histology of major organs, such as the heart and lungs, in cases of sudden infant deaths, but the pancreas is not typically included as a critical organ to sample. This raised the question of how often can such findings be seen in the pancreas on routine histology of infant cases? This led to the primary goal of this study, which was to review the histology of previous infant deaths in order to identify any possible trends. Another objective of the study was to see if there was a correlation between pancreatic infiltrates and the cause of death (i.e., asphyxia versus SUDI).

In order to recognize if pancreatic inflammatory infiltrates are a significant finding in infant deaths, a search of the MD OCME database was performed to identify all cases of infant deaths, ages 0 to 6 months, for the five years between 2013 and 2018. Pancreatic sections from a random selection of cases signed out as either “SUDI” or “Asphyxia” were included in the review. Excluded from the study were causes of death involving blunt force trauma, firearm injuries, and/or other natural disease processes, not inclusive of asphyxia. Per research, only one published article focused on the histopathologic findings in the pancreas in infantile asphyxia.<sup>2</sup> It is hoped that the results of this retrospective review will stress the importance of continually sampling those organs deemed “less important” in the context of sudden infant deaths and to potentially present findings that may force further investigation into these deaths.

### H173 Retinal (RH) and Optic Nerve Sheath Hemorrhage (ONSH), Papilledema, and Spinal Cord Nerve Root/Ganglia Hemorrhage Associated With a Cerebral Cavernous Malformation

*Dongfang Yu, MD, PhD\**, Department of Pathology, Winston Salem, NC 27157; *Ryan T. Mott, MD*, Medical Center Boulevard, Winston Salem, NC 27157-1072; *William J. Beuerlein, DO*, Wake Forest Baptist Health, Winston Salem, NC 27157; *Patrick E. Lantz, MD*, Wake Forest University School of Medicine, Winston-Salem, NC 27157-1072

**Learning Overview:** After attending this presentation, attendees will learn that extensive RHs, ONSH, and papilledema can occur in young children who have increased intracranial pressure, and spinal cord nerve root/ganglia hemorrhages are not specific for hyperflexion-hyperextension injury in young children.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reinforcing the necessity for routine postmortem ocular and spinal cord examinations of children with fatal intracranial hemorrhage, cerebral edema, and elevated intracranial pressure.

RH and ONSH in young children have been considered specific for inflicted traumatic brain injury. Current studies suggest that non-traumatic, markedly elevated Intracranial Pressure (ICP) rarely causes RHs, and when it does, the RHs are few in number and peripapillary. Dorsal root ganglial hemorrhage has been attributed to hyperflexion-hyperextension neck injury (shaken baby syndrome) in infants and young children. A case of a young child with papilledema, bilateral RHs, ONSHs, and spinal nerve root/ganglia hemorrhages associated with non-traumatic intracranial hemorrhage arising from a ruptured left temporo-parietal cavernous malformation is presented. The clinical, autopsy, and investigative findings of this case refute the purported specificity of RHs, ONSHs, and spinal dorsal root ganglial hemorrhages in young children.

**Case Report:** A 5-year-old boy with no significant medical history was found unresponsive at home. At the local hospital, cranial Computed Tomography (CT) revealed a large intraparenchymal hemorrhage. The previous day, he had been diagnosed with Streptococcal pharyngitis and sent home with antibiotics following complaints of fever and headache. On arrival at the tertiary medical center's Pediatric Intensive Care Unit, he had dilated pupils and a Glasgow coma scale of 6. A repeat cranial CT revealed extensive intraparenchymal hemorrhage centered in the left temporal lobe measuring to 6.1cm, extensive surrounding edema and mass effect resulting in 11mm rightward midline shift and crowding of suprasellar cistern concerning for uncus herniation, multifocal subarachnoid hemorrhage along the left convexity, and intraventricular extension of hemorrhage into lateral ventricles with developing hydrocephalus. His family offered no reports of recent trauma. His initial ICP was 67mmHg and remained elevated (40–50mmHg) despite external ventricular drain placement and mannitol treatment. Due to the extent of his neurological injury and high ICP that was refractory to treatment, his parents decided to withdraw care; he was pronounced dead 26 hours after admission. No clinical fundal examination was recorded in the medical record.

Postmortem indirect ophthalmoscopy revealed bilateral papilledema (left > right), numerous splinter, flame-shaped, and dot retinal hemorrhages over the posterior poles and extending past the equators. His autopsy was significant for a 7 x 5 x 4cm intraparenchymal hemorrhage of the left temporo-parietal cortex with associated cerebral edema, left uncus herniation, and cerebellar tonsillar herniation. The intraparenchymal hemorrhage was from a ruptured, thrombosed, necrotic cavernous malformation. Diffuse spinal cord nerve root and ganglial hemorrhages involved the cervical, thoracic, and lumbar regions. The RHs were multilayered and the bilateral ONSH was intradural, subdural, and subarachnoid.

This case describes severe hemorrhagic retinopathy, papilledema, ONSH, and diffuse spinal cord nerve root/ganglia hemorrhages associated with a fatal spontaneous, non-traumatic, intracranial hemorrhage arising from a ruptured cavernous malformation of the left temporo-parietal lobe. The reported ocular and spinal cord findings have been considered diagnostically specific for abusive head trauma (shaken baby syndrome); however, this case illustrates the need for caution in attributing these findings as diagnostically specific for abusive head trauma. This case emphasizes the importance of consistent and thorough postmortem ocular and spinal cord examination in young children with intracranial hemorrhage, cerebral edema, and elevated intracranial pressure.

#### Retinal Hemorrhages, Papilledema, Increased Intracranial Pressure

## H174 Recognizing Congenital Syphilis: The Consequences of the Return of an Epidemic

Jia Jun Guan, MD\*, Los Angeles, CA 90024; Yulai Wang, MD, Los Angeles Department of Medical Examiner/Coroner, Los Angeles, CA 90033; Julie M. Huss-Bawab, MD, Los Angeles Department of Medical Examiner/Coroner, Los Angeles, CA 90033-1017

**Learning Overview:** After attending this presentation, attendees will better understand the epidemiology and findings of congenital syphilis in the neonate.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the potential impact of the current syphilis epidemic on the forensic community and highlight the characteristics of congenital syphilis that can be found at the time of autopsy so an appropriate workup and diagnosis can be made.

**Introduction:** Syphilis, despite being an ancient infection, remains a significant global health concern with newborn syphilis cases reaching a 20-year high in 2017.<sup>1</sup> This study describes an accidental death of a premature infant with concurrent congenital syphilis and amphetamine toxicity. With infection rates rising and neonates of women with poor prenatal care and substance abuse at particular risk, the importance of medical examiner and coroner offices being able to recognize congenital syphilis is pertinent.

**Case Description:** The decedent was a less-than-24-hour-old prematurely born female infant at approximately 34-35 weeks gestation. The mother was unaware of the pregnancy until presenting to an emergency department with vaginal discharge and pain. During the admission, a congenital rash was noted, initiating an infectious workup and a *Treponema pallidum* antibody enzyme immunoassay that was positive. The case fell under medical examiner jurisdiction due to a positive maternal urine drug screen at the hospital. At autopsy, anomalous facies and a diffuse skin rash were present. Congenital pneumonia, acute pancreatitis, and inflammatory skin changes were present in histologic sections, consistent with underlying congenital syphilis. Toxicology studies revealed levels of amphetamine in the blood.

**Discussion:** Syphilis is caused by *Treponema pallidum*, a motile spiral-shaped Gram-negative bacterium, with a steady increase in congenital infections since 2012. Congenital syphilis cases within the United States has more than doubled since 2013, with 918 new cases reported in 2017, including 13 infant deaths, coinciding with increases in rates of primary and secondary syphilis in women; 70% of the cases occurred in Florida, California, Arizona, Texas, and Louisiana.<sup>1</sup> An important risk factor for congenital syphilis is underutilization of prenatal care, with substance use as one of many obstacles to accessing care.<sup>2-4</sup> In congenital syphilis, there is widespread dissemination of spirochetes to almost all organs, with most frequent and severe involvement of the bones, liver, pancreas, intestine, kidney, and spleen. While pathologic changes in the fetus can be seen as early as 15 weeks gestation, two-thirds of live-born cases can be fully asymptomatic, depending on the timing of infection *in utero*. Clinical manifestations of early congenital syphilis appear by three months of age in untreated infants, with most common manifestations including hepatosplenomegaly, mucocutaneous involvement (skin maculopapular eruption, desquamation, and crusting), and skeletal anomalies (periostitis, cortical demineralization, and osteochondritis). Manifestations of late congenital syphilis, arbitrarily defined by clinical manifestations with onset after two years of age, include anomalous facies, interstitial keratitis, Hutchinson teeth, palatal perforation, and anterior bowing of the shins. Congenital syphilis should be suspected in all infants born to women with positive non-treponemal and treponemal tests for syphilis and in infants and children with compatible clinical findings. The diagnosis of syphilis requires direct identification of the bacteria or by positive serologic findings.<sup>5</sup> This case is an example of the impact of the growing syphilis epidemic on medical examiner and coroner's offices and a review of congenital syphilis features.

### Syphilis, Congenital, Rash

### H175 Cervical Vertebral En Bloc Examination in Pediatric Deaths: The New York City Experience (2011–2019)

Rebecca Folkerth, MD\*, New York City Office of Chief Medical Examiner, New York, NY 10016; Anne M. Laib, MD, New York City Office of Chief Medical Examiner, New York, NY 10016; Michelle Stram, New York City Office of Chief Medical Examiner, NY, NY 10016

**Learning Overview:** The goal of this presentation is to inform attendees regarding neuropathologic features of spinal nerve root hemorrhages and associations with other features of trauma, hypoxia-ischemia, or sepsis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating that cervical vertebral en bloc dissection is a proposed means of detecting traumatic spinal nerve root injuries, hypothesized to lead to cardiorespiratory arrest in children suffering shaking and/or impact. Whether Cervical Spinal Nerve Root Hemorrhages (CSNRH) can occur because of hypoxia-ischemia, sepsis, or other non-traumatic etiologies is difficult to study prospectively, as the dissection technique is non-standard, invasive, and thus pursued only in deaths “suspicious” for inflicted trauma. The goal was to evaluate retrospectively the range of findings in all “neck block” specimens since the subject was first published in 2011 and whether traumatic and non-traumatic cases could be discerned.

**Methods:** All pediatric cases from 2011 to the present in which this technique was done were reviewed. The dates of birth, presentation, and death, as well as the findings from forensic autopsy, neuropathology, and microbiology, were analyzed along with final manner of death. Given the exploratory nature of this study, statistical methods were not employed.

**Results:** Over eight years, 43 infants and toddlers (age at death, 1 day to 3.25 years; median 5.3 months) were subject to this protocol because of suspicious or unknown circumstances. Twenty (46.5%) had bilateral, multilevel CSNRH, defined as hemorrhage *within* the spinal nerve root and/or dorsal root ganglion; specifically, 11 had *bilateral* involvement at C3, 4, and 5 (responsible for diaphragmatic innervation). Seventeen of these 20, as well as 12 other cases without bilateral multilevel CSNRH (i.e., 74.4% of the cohort), had other evidence of trauma, including scalp impact, skull/rib/other bone fractures, and/or blunt force abdominal injuries, and were ruled as homicides. Co-occurrence of bilateral multilevel CSNRH, Subdural Hemorrhage (SDH), and bilateral Retinal/Optic Nerve Hemorrhages (RH/ONH) was documented in 19 of the 20. Importantly, four of these cases had *no evidence* of head impact (scalp lesions, skull fractures). In addition to the 20 with bilateral multilevel CSNRH, another 4 had unilateral and/or single level involvement; among these 24, 18 (75%) had Hypoxic-Ischemic Encephalopathy (HIE), associated with resuscitation, life support, and survival >1 day; the remaining 6 of this subset died within one day, without time to develop HIE. Of note, four individuals dying within one day and, therefore, without HIE (3 with bilateral multilevel and one with single level SNRH) also had Amyloid Precursor Protein (APP) immunohistochemical patterns of traumatic axonal injury, further suggestive of torsional force injury to the brain. Among all individuals with HIE ( $N=29$ ), 15 had bilateral multilevel CSNRH; 7 had very limited bleeding around nerve roots (including one infant with confirmed viral sepsis with bacterial superinfection, certified as natural), or foci of endoneurial hemorrhage in a single cervical level. The remaining seven had no hemorrhage whatsoever in or around nerve roots and did not have SDH or RH/ONH (including one infant with suspected sepsis, certified as natural). APP immunostains in 9 of 29 cases (31.0%) with HIE showed mixed patterns of single beaded axons in sites typical for traumatic axonal injury, as well as bundled axon staining typical of ischemia. Of note, however, was the fact that eight of these nine also showed bilateral multiple CSNRH, SDH, and RH/ONH, and were ruled as homicides on the totality of the evidence.

**Conclusions:** Over an eight-year period, this agency adopted “neck block” dissection in pediatric cases with unclear or suspicious circumstances at time of autopsy. Like all other data considered in death certification, neck block findings of bilateral multilevel CSNRH do not “stand alone,” but rather provide additional support for trauma, as they tend to cluster in the majority of cases with objective signs, such as scalp impact, skull/other bone fractures, and abdominal injuries. Particularly remarkable is that, in the absence of evidence of any head impact, bilateral multilevel CSNRH is associated with both SDH and RH/ONH and with markers of diffuse axonal injury, thereby supporting the role of fatal shaking as a mechanism of death. Nearly half of cases with HIE, and the small number of deaths due to sepsis, do *not* show this pattern of nerve root hemorrhage, arguing against non-traumatic pathogenetic mechanisms underlying this phenomenon. Finally, because of the apparent value of this technique to medical examiners in their work-up of suspicious deaths in infants and toddlers, this agency intends to continue its use.

### Abusive Head Trauma, Cervical Nerve Root Hemorrhage, Child Abuse

### H176 Maternal Death Investigation in the Setting of Rising Maternal Mortality in the United States: Trends in Maryland From 2003 to 2019

Colleen Klein, MD\*, Baltimore, MD 21223; Stephanie A. Dean, MD, Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223-2595; David R. Fowler, MD, Maryland Office of the Chief Medical Examiner, Baltimore, MD 21223

**Learning Overview:** The goal of this presentation is to highlight maternal death investigation in the forensic setting, to emphasize the characteristics of this at-risk population, as well as the utility of proper documentation for the benefit of public health.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing awareness to the public health issue that is the increasing United States Maternal Mortality Rate (MMR) by reinforcing the role of medicolegal death investigators, coroners, and forensic pathologists when it comes to investigation of deaths in women of childbearing age.

MMR has been steadily increasing in the United States since 1987, reaching 31.2 maternal deaths per 100,000 live births as documented in 2016, despite the United Nations Millennium Development Goal for a 75% decrease in maternal mortality from 1990–2015. Focusing on “preventable” causes of maternal mortality—those which may have been averted by one or more changes in the health care system related to clinical care, facility management, public health infrastructure, and/or patient factors—is an important step in addressing this national public health issue. Involvement of medical examiner and coroner offices is vital in the initiative to better understand the underlying cause of maternal deaths and explain changes in MMRs.

From January 2003 with preliminary data up to the current date, 345 maternal deaths were reported to the Office of the Chief Medical Examiner (OCME) in Maryland. While relatively uncommon in the forensic setting, these cases highlight characteristics of this at-risk population, as well as the utility of proper documentation for the benefit of public health.

The Maryland OCME records from 2003 onward were searched for reported cases in which the “pregnant in the last year” box was checked—an addition Maryland made to all death certificates in 2001. These deaths were then subclassified as follows: cardiovascular conditions (32.2%), intoxication/substance abuse (16.5%), non-cardiovascular medical conditions (13.3%), homicide (12.5%), injury/accident (12.5%), infection (3.8%), hemorrhage (3.5%), cerebrovascular (2.6%), and suicide (2.9%). One case was classified as undetermined (0.2%).

Pregnancy-related deaths are those which occur within 365 days of pregnancy and are related to or aggravated by pregnancy or its management. Of the 345 deaths reported to the Maryland OCME over a 17-year period, 42% were identified as pregnancy-related (excluding homicide, intoxication/substance abuse, injury/accident, and infectious causes unrelated to pregnancy). Pulmonary embolism was the leading cause of cardiovascular deaths (29%). Beginning in 2013, a shift in the trend was noted in that deaths related to intoxication/substance abuse surpassed those related to cardiovascular disease (26.1% intoxication vs. 20.3% cardiovascular). However, pulmonary embolism (8%) remained the leading cause of pregnancy-related cardiovascular death.

Between two five-year periods (2007–2011 and 2012–2016), the United States MMR increased by 37.2% (reaching 28.4 deaths per 100,000 live births), while the Maryland rate decreased by 7.6% (23 deaths per 100,000 live births). While trends for more recent years in Maryland have improved, there is still work to be done to achieve the national and global goals for maternal mortality rates (target 11.4 deaths per 100,000 live births). In our population, cardiovascular disease remains a leading cause of pregnancy-related deaths, with pulmonary embolism being the most prevalent cause of death in the peri- and postpartum period. Nationally, cardiovascular conditions were responsible for greater than one-third of pregnancy-related deaths from 2011–2015. Globally, obstetrical hemorrhage followed by hypertensive disorders account for the majority. Forensic pathologists and medicolegal investigators need to be aware of these deaths and at-risk populations so as not to misdiagnose and/or misclassify these deaths. Encouraging other providers to report these deaths to medical examiner/coroner offices, as well as proper and accurate documentation on death certificates by forensic pathologists, will help measure the true magnitude of the problem, identify at-risk populations, and allow health departments to focus protective efforts on women who need it the most.

#### Maternal Mortality, Pregnancy-Related Deaths, Reporting Maternal Deaths

### H177 A Histological Study of Persistent Pulmonary Hypertension of the Newborn (PPHN): A Five-Year Retrospective Analysis of a Fatal Cause in Neonates

Caterina Petetta, MD\*, University of Turin, Torino 10126, ITALY; Giovanni Botta, MD, Department of Pathology, OIRM Sant'Anna, Torino 10126, ITALY; Ezio Fulcheri, MD, Istituto Giannina Gaslini, Genova 16147, ITALY; Francesca Buffelli, PhD, MD, Istituto Giannina Gaslini, Genova 16147, ITALY; Niccolò D. Melloni, MD\*, University of Turin, Torino 10126, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Turin, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will be aware of the specific histological features of the lung in PPHN and understand their prognostic significance.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of a disease process that may present as unexplained cardiopulmonary arrest in neonates during and after birth hospitalization, giving rise to medical malpractice litigations and lawsuits.

PPHN is a serious condition that occurs in about 1.8–2 per 1,000 newborns (both term and preterm) in the neonatal intensive care unit, and may significantly complicate the clinical course of approximately 10% of neonates with respiratory insufficiency.<sup>1-3</sup> It is associated with an increased risk of an adverse outcome, including neurologic impairment in 15%–25% of neonates with PPHN who survive after hospital discharge.<sup>4</sup> PPHN is defined as a failure to achieve or sustain the physiological decrease in pulmonary vascular resistance at birth associated with the persistence of the typical *in utero* right-to-left shunt. PPHN may eventually lead to life-threatening circulation failure and is one of the main causes of unexpected death of neonates, with a mortality rate of about 10%–20% of the affected patients.<sup>5</sup> PPHN is often associated with structural or functional disorders of the lungs or systemic diseases, such as diaphragmatic hernia, meconium aspiration, pneumonia, and placental insufficiency.

Clinically, PPHN is characterized by tachypnoea, severe cyanosis, acidosis, and rapidly increasing hypoxemia. PPHN diagnosis is confirmed by echocardiographic evidence of increased pressures in the pulmonary artery and right heart chambers in the absence of evidence of congenital heart disease; however, conclusive diagnosis of PPHN-related death currently relies on autopsy examination. Typically, the clinical manifestations are noticeable leading to the antemortem diagnosis of PPHN. Nevertheless, PPHN arising suddenly and early after birth is usually fatal, despite evidence-based treatment. PPHN remains a challenge in therapeutic management because the complex etiopathogenesis is yet to be fully explained. Moreover, prenatal assessment of PPHN is very difficult and not always possible.

The present study comprised a five-year retrospective analysis of data from neonatal autopsies collected in two hospitals in Northwest Italy (i.e., “Ospedale Ginecologico Sant’Anna,” Torino, and “Ospedale Pediatrico G. Gaslini,” Genova). It entailed thorough identification and analysis of histologic findings in PPHN cases. The aims of the study were to enable better prediction of lung function outcomes in affected neonates and potentially help clarify cases of medical malpractice litigation. From January 2014 to December 2018, the hospital-selected units in Torino and in Genova performed 1,312 and 456 autopsies, respectively, of which 86 and 111 were on neonates. There were 39 autopsies that involved neonates affected by PPHN in life (i.e., 18 in Torino and 21 in Genova). Thus, the average incidence of PPHN as a cause of death among all neonatal autopsies was 19.79% (i.e., 20.93% in Torino and 18.92% in Genova).

Paraffin-embedded tissue sections from the lungs of all 39 autopsy cases were cut in 2- $\mu$ m slices and stained with different histologic and immunohistochemical stains. Specific histologic parameters (i.e., degree of lung development, morphological features of bronchioles, alveolar veins and capillaries, interstitial septae structure, presence of arteriolar layers thickening, hyaline membranes, intralveolar histocytes, interstitial or endoalveolar inflammation, and therapy-induced pulmonary alteration) were reevaluated on light microscopy.

In accordance with the literature, this study showed PPHN is a severe syndrome frequently encountered in pediatric hospitals. Moreover, it is often responsible for the sudden death of neonates during hospitalization after birth. This presentation offers attendees an insight into the importance of an in-depth knowledge of histologic criteria in PPHN that may enhance appreciation of the severity of the disease, guide better management, and help predict pulmonary response. This is fundamental to significantly reduce the rate of neonatal mortality and the associated medicolegal implications.

### H178 The Utility of Postmortem Vitreous Beta-Hydroxybutyrate (BHB) Testing for Distinguishing Sudden From Prolonged Deaths and for Diagnosing Ketoacidosis

*Kristina-Ana Klaric, MD\**, University of Ottawa, Ottawa, ON K1H 8L6, CANADA; *Jacqueline L. Parai, MD*, Ottawa Hospital, Ottawa, ON K1H 8L6, CANADA; *Chris Milroy, MD, LLB*, Ottawa Hospital, Ottawa, ON K1H 8L6, CANADA

**Learning Overview:** After attending this presentation, attendees will better understand the utility of postmortem vitreous BHB levels in prolonged and sudden natural and non-natural deaths and will be provided with values that may be used to establish a diagnosis of ketoacidosis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing postmortem vitreous BHB threshold levels for the diagnosis of ketoacidosis as a cause of death.

Elevated BHB has been used in the diagnosis of Diabetic (DKA) and Alcoholic (AKA) ketoacidosis, with BHB values above 2.5mmol/L in blood often utilized as a threshold. Recently, vitreous BHB has been established as a reliable alternative to blood. It has been shown that vitreous BHB levels above 6mmol/L (with glucose levels above 200mg/dl) are strongly associated with DKA. Slightly elevated levels of BHB have been noted in other stressful states, including infection and hypothermia. The objective of this study was to determine whether elevated postmortem vitreous BHB can be used to predict stressful types of deaths and to establish a vitreous BHB threshold for the diagnosis of ketoacidosis as a cause of death.

A retrospective cross-sectional analysis of vitreous BHB was performed during a two-year study period. Extracted data included history of diabetes mellitus and alcoholism, vitreous glucose, electrolytes and BHB levels, and cause of death, in addition to demographic information. Cases were excluded if the decedent was less than 18 years of age, where collection of samples was not possible, or where the cause of death was not determined. Analysis of BHB was performed using enzymatic quantification by beta-hydroxybutyrate dehydrogenase. Cases were sorted into six categories of death: (1) sudden non-natural death (ST); (2) sudden natural death (SN); (3) prolonged non-natural death (PT); (4) prolonged natural death (PN), (5) DKA; and (6) AKA. Statistical comparisons were made between sudden and prolonged natural and non-natural deaths using the Student's *t*-test. Comparison between alcoholic and diabetic ketoacidosis cases used the non-parametric Mann-Whitney method. Analyses were conducted using Microsoft® Excel® and Minitab® 16.

Nine hundred sixty-seven cases met the inclusion criteria. The mean age was 51.7 years (median=53 years) with a range from 18–97 years. Six hundred twenty-six cases were male and 341 were female. One hundred twenty-two cases had a known history of diabetes and 121 a history of alcoholism (17 cases overlapped). The mean BHB for all cases was 1.67mmol/L (17.4 mg/dl), and ranged from 0.11–18.02mmol/L. For the categories of death, the number of DKA, AKA, PN, PT, SN, and ST deaths were 21, 5, 155, 258, 275, and 253, respectively. Their mean vitreous BHBs were as follows: 11.04mmol/L (DKA), 8.88mmol/L (AKA), 1.56mmol/L (PN), 1.55mmol/L (PT), 1.26mmol/L (SN), and 1.38mmol/L (ST). There was a statistically significant difference between the mean BHBs of the prolonged and sudden natural deaths ( $t=3.54$ ;  $p$ -value <0.001). A significant difference was also seen between the mean BHBs of the prolonged and sudden non-natural deaths ( $t=2.92$ ;  $p$ -value=0.004).

In addition, this study sought to identify a threshold for vitreous BHB levels where ketoacidosis was determined to be the cause of death. BHB levels between 2.5 and 5mmol/L produced specificities in the high nineties and sensitivities above ninety.

While these results show a statistically significant difference of vitreous BHB levels between prolonged and sudden natural and non-natural death, the values do not appear to hold clinical significance. This study has, however, shown that vitreous BHB levels in the range of 2.5–5mmol/L can be set as a threshold for determining ketoacidotic deaths, in line with results previously published for blood BHB.

#### **Beta-Hydroxybutyrate, Vitreous, Ketoacidosis**

### H179 3D Rendering of the Human Body: A Proposal of an Operative Protocol for the Application of Photogrammetry in the Autopsy Room

*Lorenzo Gitto, MD\**, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210; *Laura Donato\**, Rome 00199, ITALY; *Alessandro Di Luca, MD, Roma 00197, ITALY*; *Serenella Serinelli, MD, State University of New York Upstate, Department of Pathology, Syracuse, NY 13210*

**Learning Overview:** After attending this presentation, attendees will have an overview of the benefits of photogrammetry applied to forensic pathology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing an operative protocol that allows accurate and simple data acquisition that can be used during postmortem examinations.

Forensic pathology has evolved in the modern era, thanks to new techniques aimed at improving the bodies' evaluations. The external and internal examinations are still critical to gather information, representing the gold standard for the investigation of the cause and manner of death.

The external examination represents the first approach to the body, allowing the forensic pathologist to gather information about the state of the body and the presence of tissue lesions. Unfortunately, due to the decompositional process, if an injury is missed during the external examination, it can be hard to identify even on subsequent re-examination of the body. At the same time, one of the most relevant issues with the autopsy is that it is an invasive, destructive, and non-repeatable analysis, so that the findings often cannot be accurately re-assessed.

To overcome these problems, taking photographs of the body before starting the postmortem examination is a crucial part of the medicolegal death investigation process. Photographs must be accurate and detailed since they are taken mainly for legal purposes and are intended to be shown in court. However, even photographs do not allow for a detailed review of an injury or an organ. Their main limitations stand in the 2D rendering of the human body, which has three dimensions, and in their non-repeatability.

Currently, there is an increased interest in "forensic photogrammetry." Photogrammetry is a tool that allows the making of measurements from photographs. It represents an accurate and low-cost method that can be easily implemented in the routine medicolegal death examination.

This study proposes a step-by-step protocol based on a 3D acquisition of the body and applying photogrammetry during the external examination. This technique makes it possible to obtain a 3D graphic reconstruction of the body based on single photographs. Photos must be taken following specific criteria to allow an accurate and reliable photogrammetric rendering. The 3D information is obtained through the acquisition of several partially overlapping photos. After that, a dedicated software recognizes points and areas with similar features and builds a 3D mesh of the body. Although any camera can be used to take photographs of the body (e.g., smart phone), the use of a good-quality camera is highly recommended to obtain the best results. At the end of the image processing, the software will display a 3D rendering of the body, showing the morphology, the texture, and allowing for measurement. The body will be shown as it is observed during the external examination, overcoming potential issues with bad quality single photos or missed lesions. Moreover, it is possible to use photogrammetry to obtain 3D documentation of internal organs or any other element of forensic interest that may be encountered during the postmortem examination.

The advantages of photogrammetry lie in its low cost, simple application, and accurate results. The 3D rendering admits the body rotation on a 360° axis, allowing for a better interpretation and presentation of the features of forensic interest, which can be helpful in court. This is particularly relevant in cases of homicides: in such situations, displaying the 3D images of the deceased to the court will make it easy to show the location and the features of any lesions, allowing a straightforward demonstration of the condition of the body before the autopsy. The main limitation of this technique is that it is time-consuming. A full photographic report requires taking pictures of the anterior and posterior aspect of the body, with an estimated time ranging from 20 to 40 minutes. Moreover, a good source of illumination is needed, and a clean background is preferable to avoid software misinterpretations.

It is believed that photogrammetry is a reliable and useful tool in forensic practice. The application of this protocol allows a simple and accurate 3D documentation of the body during the different phases of the autopsy.

#### Photogrammetry, Autopsy, Protocol

### H180 Electrolytes, Glucose, and Lactate in Postmortem Blood (BL), Vitreous Humor (VH), and Synovial Fluid (SF): A Comprehensive Study

Supawon Srettabunjong, MD\*, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkoknoi, Bangkok 10700, THAILAND; Wantawan Thongphap, BSc, Faculty of Medicine Siriraj Hospital, Mahidol Unive, Bangkoknoi 10700, THAILAND; Anchalee Chittamma, Faculty of Medicine Ramathibodi Hospital, Mahidol, Ratchathevi 10400, THAILAND

**Learning Overview:** After attending this presentation, attendees will better understand the comparative and correlation study of sodium, potassium, chloride, magnesium, glucose, and lactate levels in postmortem BL, VH, and SF of the same subject as well as the correlation study between the constituent concentrations in the fluids and various factors, including gender, age, body height, body weight, body mass index, and Postmortem Interval (PMI), the essential basic knowledge that can fill the current gap in intelligence about using the biochemical substance levels in the fluids to solve any forensic issues in daily practice or further research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as essential knowledge of postmortem investigation of sodium, potassium, chloride, magnesium, glucose, and lactate levels in BL, VH, and SF for forensic applications that have been challenging the forensic community worldwide.

In forensics, sodium, potassium, chloride, magnesium, glucose, and lactate levels in certain human body fluids have been demonstrated to change over time since death. However, there is still controversy regarding their changes in the fluids, and no studies have explored their levels in postmortem BL, VH, and SF simultaneously. Thus, such changes were investigated in the fluids of 52 forensic autopsy cases with an intact body, no metabolic disorders, and no functional or structural abnormality of the eyes or knees, who were autopsied within 15 hours after death. This study also compared and correlated the values from the fluids and determined the effects of gender, age, body height, body weight, Body Mass Index (BMI), and PMI on the parameter concentrations.

Study results showed that BL potassium, magnesium, glucose, and lactate values were significantly higher than the VH and SF values. The opposite pattern was seen for VH sodium levels and VH and SF chloride levels ( $p < 0.001$ ), where SF sodium values were equivalent to the BL values. VH and SF sodium, potassium, chloride, and lactate values had significant relationships with the BL values ( $p < 0.05$ ), but not for magnesium and glucose values. BL potassium and magnesium levels were significantly higher in men than in women, but the opposite pattern was seen with BL chloride levels ( $p < 0.05$ ). Only SF magnesium levels had a negative correlation with the body height of the decedents ( $p < 0.05$ ). This study also found positive linear correlations between BL, VH, and SF potassium concentrations and the PMI as well as between VH and SF lactate concentrations and the PMI, but negative correlations with the PMI for BL sodium, BL chloride, and VH glucose concentrations ( $p < 0.05$ ). Among these relationships, VH potassium has the strongest correlation with PMI ( $r = 0.67$ ,  $R^2 = 0.45$ ), followed by BL potassium ( $r = 0.56$ ,  $R^2 = 0.32$ ) and SF potassium ( $r = 0.49$ ,  $R^2 = 0.24$ ) with respective high prediction index. The parameters that change over the PMI are unreliable indicators of antemortem levels unless the samples are obtained very shortly after death. In addition, the low rates of change of certain parameters with low predictability of PMI make them of very limited use in estimating the PMI. Other parameters served better as biomarkers of underlying conditions or causes of death. The variable effects of the state of the decedents, such as gender and body height, should also be taken into account whenever considering the use of certain biochemical substances for application to specific issues in forensic practice.

#### Postmortem Biochemistry, Postmortem Chemistry, Thanatochemistry

### H181 The Usefulness of a Hand-Held Blood Glucose and Ketone Monitoring Device as a Postmortem Indicator of Diabetic Ketoacidosis (DKA)

Pierre-Antoine Peyron, MD\*, Département de Médecine Légale, Montpellier 34295, FRANCE; Maëlle Plawecki, PharmD, CHU Lapeyronie, Montpellier 34295, FRANCE; Jean-Paul Cristol, PhD, CHU Lapeyronie, Montpellier 34295, FRANCE; Maisy Lossois, MD, CHU Lapeyronie, Montpellier 34295, FRANCE; Eric Baccino, MD, Hopital Lapeyronie, Montpellier, Cedex 5 34295, FRANCE

**Learning Overview:** The goal of this presentation is to describe the preliminary results of a study aimed at assessing the performance of a point-of-care blood glucose and ketone monitoring device in measuring glucose and  $\beta$ -hydroxybutyrate concentrations in postmortem vitreous and blood samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the potential usefulness of hand-held point-of-care devices in screening cases of DKA in a postmortem setting.

**Background:** DKA is a potentially life-threatening complication of type 1 diabetes mellitus. Glucose and ketone bodies such as  $\beta$ -Hydroxybutyrate (BHB) can be measured postmortem in Vitreous Humor (VH) to assess antemortem hyperglycemia and ketoacidosis. However, such analyses may be technically challenging and expensive as they involve sophisticated biochemical methods. As Point-Of-Care (POC) Blood Glucose and Ketone Monitoring Devices (BGMD) are known to provide rapid and accurate results in living patients, they may be used as a reliable and cost-effective approach to screen potential DKA cases at the autopsy, as suggested by prior research.<sup>1</sup> This preliminary study aimed to assess the performance of such a device in measuring glucose and BHB concentrations in postmortem VH and blood samples.

**Materials and Methods:** VH and blood samples were collected from patients known or suspected to be diabetics at the autopsy. VH and blood specimens were collected in dry and lithium heparin tubes, respectively. Glucose and BHB concentrations in VH were measured twice in both eyes, before and after centrifugation (5,000g, 5min), with a commercially-available FreeStyle® Precision Neo BGMD, according to the manufacturer's instructions. BHB levels were also measured in blood using the same device. The results were compared to those obtained with validated biochemical methods. For glucose, reference levels were measured from perchloric acid precipitated VH samples with enzymatic hexokinase/glucose-6-phosphate dehydrogenase method. Values  $\geq 7$ mmol/L were considered to be elevated. BHB concentrations in VH and blood were measured with enzymatic Hydroxybutyrate Dehydrogenase (HBDH) method. Values  $\geq 3$ mmol/L were considered to indicate ketoacidosis. The study was approved by the Ethics Committee of the University Hospital of Montpellier.

**Results:** Forty-five subjects (33 males, 12 females) were included, with a mean age of  $56.1 \pm 13.4$ . Twenty-six subjects were known to be diabetic patients. The postmortem interval was  $3.4 \pm 2.1$  days. No statistically significant difference was shown between both eyes for glucose and BHB levels, and this study observed a high reproducibility of measurements in each eye. Glucose and BHB levels measured before VH centrifugation were not significantly different from those after centrifugation. There was a strong correlation between VH glucose concentrations measured with the BGMD and the validated method ( $R^2=0.74$ ,  $\rho=0.72$ ,  $p<0.0001$ ). The mean values obtained with the BGMD were significantly higher to those obtained with the validated method (7.4mmol/L vs. 5.2mmol/L,  $p<0.05$ ). The sensitivity of the BGMD to detect cases with elevated VH glucose levels was 1.0 and the specificity 0.97 when the threshold value was set to 10mmol/L. No correlation was found between BHB values measured with the BGMD and the validated method, whether in VH or in blood. The sensitivity of the BGMD to detect elevated BHB levels in VH was 1.0 but its specificity 0.38 with a threshold value of 2.5 mmol/L, while they were both 1.0 to detect high BHB concentrations in blood with a threshold value of 3.0mmol/L.

**Conclusion:** This preliminary study confirms that BGMD may be useful in identifying potential DKA cases in postmortem settings. The results obtained so far suggest that glucose can be reliably investigated in VH, regardless of the eye and without any prior centrifugation, whereas BHB analysis should rather be considered in blood. Further analysis on additional samples is underway for confirming these preliminary results and for better delineating appropriate threshold values.

## H182 Lung Weights in Carbon Monoxide (CO) -Related Fatalities

Abigail J. Grande, MPH\*, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Ann K. O'Neill, MPH, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49008; Amanda O. Fisher-Hubbard, MD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will be familiar with the mechanism of death in CO-related fatalities and also recognize the possible effects of CO on the weight of the lungs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by determining if a relationship exists between the presence of postmortem carboxyhemoglobin and the weight of the lungs at autopsy in CO-related fatalities.

CO is a colorless, odorless gas that is produced from the incomplete combustion of organic fuel.<sup>1</sup> It causes hypoxia by preferentially binding to the hemoglobin molecule in place of oxygen, producing carboxyhemoglobin.<sup>1</sup> Commonly recognized as a “silent killer,” CO is the most common lethal poisoning in the United States.<sup>2</sup> While suicides constitute the majority of CO-related fatalities, over 2,200 deaths resulted from unintentional CO poisoning from 2010 to 2015 in the United States.<sup>2,3</sup> Non-smokers generally have carboxyhemoglobin concentrations of less than 3% at baseline, depending upon the setting in which they live (e.g., urban versus rural).<sup>1</sup> However, smokers may have a slightly higher hemoglobin concentration, though usually less than 10%.<sup>4</sup> Therefore, carboxyhemoglobin can be detected in the blood of decedents who die under a wide variety of circumstances, from the 50-pack-a-year cigarette smoker with chronic obstructive pulmonary disease to the arson victim found dead in his home. Other than the “cherry-red lividity” and the bright red viscera often seen on examination, the autopsy findings in acute CO toxicity are not well characterized.<sup>2</sup> As it can act as a central nervous system and respiratory depressant, similar to opioids, which are frequently associated with pulmonary edema at autopsy, lung weights in CO-related fatalities were evaluated.

This study retrospectively reviewed cases of CO-related fatalities. A search was completed using an online database of deaths investigated by medical examiners and/or coroners from several counties in Michigan and Indiana from 2008 to 2019. This study restricted the search to include the following terms in any portion (a, b, c or d) of the immediate cause of death on the death certificate: *carbon monoxide, inhalation, exhaust, and combustion*. It was also restricted by type of examination, as this study required cases with a full autopsy in order to review the postmortem lung weights. In addition, cases were excluded if carboxyhemoglobin testing had not been completed.

Twenty-eight cases of CO-related fatalities were identified, not including those due to fire exposure. In a study by Molina and DiMaio, average normal lung weights were determined by evaluating postmortem lungs in sudden, traumatic deaths of adults.<sup>5,6</sup> On average, normal male right lungs weighed 445g and left lungs weighed 395g, while normal female right lungs weighed 340g and left lungs weighed 299g. Of the 28 CO-related deaths, 22 were male, ranging in age from 20 to 74 years, and 6 were female, ranging in age from 19 to 71 years. The right lung in the deceased males ranged in weight from 450g to 1,120g, while the left lung ranged in weight from 270g to 1,040g. This resulted in an average of 782g for the right lung and 710g for the left in males. The right lung in the deceased females ranged in weight from 350g to 660g, while the left lung ranged in weight from 370g to 640g. This resulted in an average of 536g for the right lung and 493g for the left in females. The average percentage of postmortem carboxyhemoglobin was 56.7 among all male and female CO-related deaths.

Compared to the aforementioned normal lung weights, the right and left lungs in male CO-related fatalities were both 1.8 times heavier and in female CO-related fatalities were both 1.6 times heavier. As this data continues to be evaluated, fire-related fatalities that include a component of CO inhalation will be examined for comparison.

### H184 Unrecognized Anatomical Larynx Variants May Lead to More Than 70% of False Larynx Fractures

Joao E.S. Pinheiro, PhD, MD\*, Instituto Nac Medicina Legal e Ciências Forenses, Coimbra, Beira Litoral 3000-213, PORTUGAL; Jose L. Cascallana, PhD, Instituto de Medicina Legal da Galicia, Lugo, SPAIN; Benito Lopez de Abajo, MD, Institute of Legal Medicine of Galicia, Santiago de Compostela, SPAIN; Xose L. Otero, PhD, Department of Statistics and Operations Research, Santiago de Compostela, SPAIN; María Sol Rodríguez-Calvo, PhD, University of Santiago de Compostela, Santiago de Compostela, SPAIN

**Learning Overview:** After attending this presentation, attendees will acquire a greater understanding of anatomical laryngeal variants, as well as their impact on the diagnosis of fractures of the hyoid bone and thyroid cartilages.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the pitfalls associated with anatomical variants in strangulation cases. Additionally, the estimation of the incidence of false laryngeal fractures based on the prevalence of these variants, already established for a Galician population (Northwest Spain), will also be of interest to the scientific community.

Misinterpretation of fractures of the hyoid bone and thyroid cartilage due to anatomical laryngeal variants are common because the variants are usually unknown or poorly recognized. This comes as no surprise considering that forensic textbooks and the forensic literature have failed to pay attention to these anatomical variants, namely with epidemiologic studies assessing their prevalence.<sup>1,2</sup>

After having identified in 207 consecutive autopsies the most frequent anatomical laryngeal variants (i.e., triticeal cartilage (52.7%), terminal segmentation of the thyroid horns (11.7%), ectopic superior thyroid horns (8%), lateral thyro-hyoid ossification (5.3%), and calcification of the stylohyoid ligament (1.4%)) this study devised a mock exercise to quantify the impact of these variants on the diagnosis of either thyroid or hyoid fractures.<sup>3</sup>

In order to achieve this objective, a case-by-case evaluation exercise was carried out by two experienced pathologists. Taking into account the particular characteristics and specific location of each variant, its potential misinterpretation was recorded. An estimation of the false positive rate was calculated considering the number of anatomical variants possibly misclassified as fractures to all samples in the study.

The results showed 71.5% potential errors (false positives) of the 207 cases studied.<sup>3</sup> Triticeal cartilages were the most important variant affecting the diagnosis of laryngeal fractures, with a rate of potential errors of 46.4%, followed by the terminal segmentation of the thyroid horns (7.3%), ectopic superior thyroid horns with 6.3% of possible errors, and the lateral thyrohyoid ossification (4.4%). In addition to the isolated variants, in 6.8% of the individuals, there were more than one anatomical variant with the potential to influence the diagnosis.<sup>3</sup> The most frequent association was the terminal segmentation of the thyroid horn with triticeal cartilage that may lead to 3.8% of false fracture diagnoses. It should be noted that only 28.5% of the cases would be totally exempt of any negative influence of anatomical variants.

These results demonstrate the necessity for forensic pathologists to be aware of laryngeal anatomical variants in order to avoid erroneous interpretation of autopsy findings. Apart from the increasing use of X-ray and computed tomography as ancillary techniques, the manual dissection of the neck, with observation and palpation of the fractures, remains the major tool for forensic pathologists worldwide. This reinforces the importance of these results and the need for a correct interpretation of the anatomical variants when identifying laryngeal fractures in strangulation.

## II Demons and (Mis)Diagnosis: A Cultural Case Study of Sleep Paralysis

Melissa Piasecki, MD\*, Reno, NV 89509; Elizabeth Phelan, BA\*, Washington University in St. Louis, St. Louis, MO

**Learning Overview:** The goals of this presentation are to: (1) review the core symptoms and prevalence of Sleep Paralysis (SP) with hypnagogic hallucinations; (2) describe the impact of cultural context in the interpretation of SP symptoms; and (3) identify the potential errors in psychiatric diagnoses of patients with SP.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping attendees appreciate the varied manifestations of SP in different cultural settings, allowing for accurate diagnoses and referrals. Attendees will increase cultural competency, avoid erroneous diagnoses, and effectively consider SP in the differential diagnosis of hallucinations.

SP is a relatively widespread phenomenon in which individuals awaken and are unable to make voluntary muscle movements. This phenomenon is frequently accompanied by hypnagogic hallucinations, often of a threatening figure or presence. SP is considered a parasomnia, a sleeping disorder, if it recurs frequently and is distressing. SP has a lifetime prevalence rate of 7.2%, with students and psychiatric patients experiencing SP more frequently.<sup>1</sup> It often accompanies other sleeping disorders, such as narcolepsy.

Interpretation of SP, especially the hallucination of an evil being, varies between cultures and countries. The “hag” in Shakespeare’s *Romeo and Juliet* is considered to be a manifestation of SP, while in Brazilian tradition, there is the character of Pisadeira, an old woman who lurks on rooftops and crushes sleepers’ chests.<sup>2</sup> More recently, individuals interpret their hallucinations during SP as part of an alien abduction.<sup>3</sup> The cultural context of interpreting the symptoms of SP has a significant impact on the way individuals seek and receive treatment for SP; due to cultural stigmas, they may turn to confidential sources (such as herbalists and shamans) for help rather than seek treatment at medical institutions.<sup>4</sup>

Forensic evaluators routinely assess for the presence of psychotic symptoms but may not consider SP as an etiology. The differential diagnosis of hallucinations typically focuses on primary psychotic disorders, such as schizophrenia or substance-induced psychosis. *The Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5)* does not include SP in the differential diagnosis of psychotic disorders, but does include schizophrenia in the differential diagnoses of narcolepsy.<sup>5</sup> Accordingly, an evaluator’s index of suspicion for a sleep disorder may be low in the context of bizarre and threatening hallucinations. An evaluator may err in diagnosing a major psychotic disorder or attributing “atypical” symptoms to malingering instead of referring an evaluatee for a sleep study. Errors in diagnosis may expose an individual to unnecessary treatment or result in a damaging label of “malingerer.” This presentation illustrates the potential for error with a forensic case study of a man who interpreted vivid SP-related hallucinations as an evil demon spirit that threatened him. He interpreted the hallucination as a signal of his need to improve his religious practices. His family, who attended the same Baptist church, endorsed this interpretation. However, forensic evaluators concluded he was malingering and did not refer him for further treatment or evaluation.

### I2 A Mystic Religious Figure Who Became an Actress—From a Man of God to a Showgirl: A Particular Case of Circumvention of the Mentally Incapable Perpetrated Against a Couple, as Well as Crowds of People

Ignazio Grattagliano, PsyD\*, University of Bari, Bari 70124, ITALY; Antonello Bellomo, MD, Via Latilla 16, Bari 70100, ITALY; Carla Piccininni, MD, Università degli Studi di Foggia Italy, Foggia 71121, ITALY

**Learning Overview:** After attending this presentation, attendees will more fully appreciate the importance of knowing how to recognize the various signs of circumvention of the mentally incapable and the need to take the necessary steps, both in its prevention and in response to it.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that circumvention of the mentally incapable comes in many forms, some obvious and others not so obvious. New ways to address this phenomenon must be formulated and put into practice.

In Italy the offence of circumvention of the mentally incapable is defined in art. 643 of the Penal Code as follows: “*whoever, to gain profit for himself or others, abuses the needs, passions or inexperience of a minor, or abuses the state of infirmity or psychic deficiency of any person, even not subject to interdiction or declared mentally incapable, and induces this person to accomplish an act that has any harmful judicial consequences on himself or others, is punished ...*”

Victims of such crimes are people who normally conduct a normal, well-adapted existence, but who may be affected by some fragility, unexpressed desires that have not been fulfilled, traumas, unresolved problems that have not been processed, or even psychopathologic traits, characterized by a tendency for dependency, low self-esteem, or a highly suggestible personality. An examination of the relationship between the perpetrator and victim in these types of crimes is essential during the related clinical and legal investigations.

**The Case:** In a rural area in southern Italy, where daily fears and hopes for the future seek an ear and reassurance against the background of the anguish of their daily life, Mr. B. and Mrs. D. came to this study’s attention, bound by a marriage that was over in all but name. They had been selected by a self-proclaimed seer and mystic as the “adepts and beneficiaries” of his “powers.”

The circumstances of “P. the mystic” are those of the last born of a large family living on a single salary, a minor and self-proclaimed seer, who over time built up a reputation for monthly apparitions of Our Lady, attracting crowds of the faithful and huge donations for fantastic projects aimed at saving the world. He came to know the above-mentioned couple and promised intercession with God to allow them to create a family and receive the blessing of children.

“P. the mystic” gained the trust of both, and love of both at different times, sometimes purely carnal, also in a homosexual relationship, and at others involving profound submission, obedience to making love to the person indicated, and total credulousness, as when instructed to believe in a pregnancy in the man. The financial (about two million euro) and emotional costs (two relationships outside marriage for each of them), presented as the means to happiness, mark an episode that is in its own way unique, exceptional, and terrible, as curious as it is unlikely, unhappy and distressing for the parties.

Manipulations and suggestions ensnared them. Data on reality were freely interpreted in a mystic-grandiose manner in a type of delirious trance. True events were afforded the same credibility as parables or prophecies. The absolute remission to the “divine will” appears more as the expectation of a Messianic destiny to which fears and responsibilities are continually subordinated than as a true, aware act of faith.

**Conclusions:** In this view of the world, often driven by a preponderant belief in magic that is seen as a form of religion, it is reasonable to suppose that the suggestions insinuated could have achieved the dual function of reassurance and credibility.<sup>1</sup> It is well known that religions in general, to respond to these needs and be presented as meaningful systems, are proposed as communication systems built on narratives, social forms, and actions.<sup>2,3</sup> In particular, by offering shared beliefs, stories, and meanings, religions contribute to confer order to social reality, proposing various forms of “communicative contract,”<sup>and</sup> how the destinies of such proposals accept them opens up ample scenarios offering different possibilities and positions.<sup>4,5</sup>

### I3 Mental Health and Stress Relating to Crime Scene Investigators (CSIs): A Lack of Training, Support, and Resources for CSIs

*Melanie Walchek, MFS\*, Glendale Police Department, Glendale, AZ 85301; Ismail M. Sebetan, MD, PhD\*, National University, La Jolla, CA 92037-1011; Paul Stein, PhD\*, National University, La Jolla, CA 92037*

---

**Learning Overview:** The main goal of this presentation is to compare self-perceived stress between civilian CSIs and sworn officers, the impact on their mental health, as well as the available stress management tools. After attending this presentation, attendees will have a better understanding regarding the inconsistencies about reporting and recognition of occupational stress experienced by civilian CSIs and their sworn law enforcement counterparts. Significant differences apparently exist in the training, screening, coping strategies, and stress management between the two groups. There are also different standards in place to contend with exposure to traumatic events and related stress exposure and availability of resources for stress management for these professionals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community and the agencies employing CSIs by demonstrating the need for more awareness of the occupational stress regarding this group, more open mental health discussions, and research to address these concerns. This is especially relevant for civilian CSIs, where stress and mental health support is nearly non-existent.

The plan of this study was to use a 28-question anonymous survey that collected responses about the stress perceived and experienced on the job; the training and education regarding stress management and coping skills; and the awareness of resources, policies, and support once stress or trauma is experienced. Participants within this study included CSIs ( $N=12$ ) and sworn law enforcement officers ( $N=46$ ) whose duties included responding to scenes of death, violence, dangerous, or emotionally sensitive scenes.

The results indicated that both groups were statistically similar in reporting that their agencies or employers offer programs of peer support, assistance, or critical incident stress management, with 100% of respondents having acknowledged that the services existed. Another area of the study evaluated the perceived stress experienced by both groups during the course of their duties. The results demonstrated there was a two-fold difference in reporting stress for the CSIs compared to the sworn officers. The self-reported scaled responses were also statistically analyzed and showed twice as many CSIs having experienced vicarious stress as compared to sworn officers. The topic of training and education in stress management within the first year of hire demonstrated 75% of CSIs did not feel they received adequate training compared to 30% of sworn officers. The perception of similar resources for assistance once stress was encountered showed 75% of CSIs thought they did not receive assistance, compared to sworn officers (28%).

In conclusion, the survey responses from this study suggest CSIs feel they are experiencing stress and trauma at similar levels as sworn officers and that sworn officers appear to have been given more training and education to cope with the stress encountered.

---

#### Crime Scene Investigation, Mental Health, Stress

## I4 A Rare Case of Psychotic Serial Killing by Poisoning

*Ilaria Rossetto, PhD\**, Residences for Execution Safety Measures, Castiglione delle Stiviere 46043, ITALY; *Filippo Franconi, MD*, Sistema Polimodulare di REMS Provvisorie, Castiglione delle Stiviere 46043, ITALY; *Alan R. Felthous, MD*, Saint Louis University School of Medicine, Saint Louis, MO 63104-1027; *Giancarlo Di Vella, MD, PhD*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY; *Stefano Ferracuti*, La Sapienza University, Rome 00185, ITALY; *Giovanni De Girolamo*, IRCCS Fatebenefratelli, Brescia 25125, ITALY; *Marco Lagazzi*, Studio Lagazzi, Milan 20124, ITALY; *Felice F. Carabellese, MD*, University of Bari, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will know the atypical case of an Italian serial poisoner and how the case has been analyzed in a forensic context.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the rare possibility that cases of intoxication can result from criminal behavior and of the complexity of a forensic psychiatric assessment.

There is no recent international literature on serial poisoners and, historically, this criminal behavior has been described more commonly in females than in males.<sup>1,2</sup> This is the atypical case of a 27-year-old Italian man who killed three members of his family (grandfather, grandmother, and uncle) and poisoned four other members of his family by the hidden administration of thallium. The thallium was ordered from an Italian pharmaceutical company, bought directly and paid for in cash. In recent months, the man developed his plan to kill seven members of his family, not including his parents. The man was arrested by the police after a brief investigation. Upon detainment in jail, he talked to the psychiatrist about the reasons for his crimes: he had to punish them by death for their “idolatry,” which in his mind was their poor sense of decency. This consisted of behaviors such as wearing more comfortable clothing at home. He said that he tried to convince his family to change and adapt their behavior to “conform to the will of God,” but they did not listen to him, so he was forced to kill them. He also mentioned having heard voices that ordered him to punish his family members for their indecent behavior. He was finally voluntarily admitted to a psychiatric acute ward, treated with antipsychotic drugs, and discharged to prison after several days with a diagnosis of “Delusional Disorder.” He underwent to a brain Computed Tomography (CT) scan to exclude a significant organic disorder.

For the previous three years, he had been showing significant social withdrawal, loss of external contacts, and initiated a concentrated study of religious texts without any basis in real life or recognized religious authority. Based on these observations, the judge requested a psychiatric evaluation to assess, as allowed by the Italian criminal law, his capacity to stand trial, his mental state at the time of the murders, and the presence or absence of social dangerous. He was evaluated by four psychiatrists and tested by a psychologist. Two psychiatrists were requested by the prosecutor, one by the defendant’s advisor, plus there was the judge’s advisor. Thus three different forensic psychiatric assessments were produced: two assessments supported Not Guilty by Reason of Insanity (NGRI) and one identified only a diminished responsibility. During the evaluation, the defendant told his story again and remained inflexible with respect to his murderous intents, showing lack of empathy toward his victims and his parents. In this regard, he showed no remorse and said that he did not poison his father and mother only because he did not want to draw attention to him. The presence of a delusional disorder with a mystical-religious theme was clear and part of a complex psychotic disorder that brought him to consider himself a type of “avenger” of the will of God. The patient is currently hospitalized in a secure forensic unit.

**Conclusions:** This rare case of a serial poisoner provides an opportunity to examine how an offender’s ability to plan and execute an antisocial act with some apparent “lucidity” during the action should not exclude a possible diagnosis of schizophrenia. In such cases, the motive for murder is often revenge, triggered by persecutory delusions.

## I5 Big Data and Machine Learning: Changing the Risk Assessment Landscape

*Casey Upfold, BA\*, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA; Gary A. Chaimowitz, MD, Saint Joseph's Healthcare-McMaster University, Hamilton, ON L8N 3K7, CANADA; Mini Mamak, EdD, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** The goal of this presentation is to provide attendees with an introduction to the process of machine learning and the available models as well as an overview of the potential ways in which it can be implemented into forensic psychiatry practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of machine learning and the benefits of incorporating machine learning into forensic psychiatry. In addition, attendees will gain insight into the application of machine learning in the risk assessment process and future directions for using this type of analysis.

The risk assessment field has seen little change since the introduction of actuarial and structured professional judgement tools in the 1990s. At the time of their introduction, these tools greatly improved risk assessment practice and outcome. However, for the past 10–15 years, other than tools being tweaked and new versions being released, there has been no notable advancement in the field. Information technology and data storage have greatly advanced research practice in a number of fields in recent years, and machine learning and the use of big data have the potential to change the risk assessment landscape.

Big data consists of a large amount of data, created at a high velocity and of a wide variety of types. Given how complex these datasets are, it is unpractical to use traditional statistics to analyze them. Moreover, statistical analyses identify risk factors at a group-level instead of an individual level and often do not deal well with the comorbidities and heterogeneity of psychiatric disorders. Machine learning analysis can be used to extract value from big data and transform it into applicable information. Machine learning is a field of artificial intelligence that includes analyzing current and historical trends to make predictions on how unseen cases will behave as well as identifying patterns of human behavior to detect trends. The primary aim is to allow the algorithms to learn automatically and adjust the actions accordingly, with minimal human intervention.

The use of traditional statistical models has often focused on group effects, which makes it hard to extrapolate what is found to a specific individual, and are often used in conjunction with theoretical frameworks in order to confirm prior assumptions. However, because machine learning is data-driven and looks at patterns underlying the data itself, it provides the opportunity to identify predictors and automatically adapt and customize them on an individual level and potentially display patterns that are very useful that were previously unexpected.

While still in its infancy, research utilizing machine learning and big data in psychiatry are showing great promise. Predictive models may help to develop tailor-made interventions for patients and a better allocation of resources from the health care system. The process of machine learning and the data-driven models will be highlighted, as well as their application in forensic settings, as these models have the potential to identify individuals at a higher risk for an outcome of interest and can aid in the prediction of violent behavior, criminality, and social rehabilitation.

---

### Machine Learning, Big-Data Analytics, Forensic Psychiatry

### I6 The Electronic Hamilton Anatomy of Risk Management-Forensic Version (eHARM-FV): Launching the Fifth Generation of Risk Assessment

*Casey Upfold, BA, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA; Gary A. Chaimowitz, MD, Saint Joseph's Healthcare-McMaster University, Hamilton, ON L8N 3K7, CANADA; Mini Mamak, EdD\*, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will have been provided with an introduction to the eHARM-FV tool, the patient analytics function, and the role of the eHARM-FV in improving patient outcomes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by ensuring that attendees have acquired a better understanding of the eHARM-FV tool, the application of it in practice, and the potential benefits of using data analytics in forensic psychiatry.

The HARM-FV is a structured professional judgment tool that was developed in an effort to enhance the short-term risk assessment and risk management processes in forensic psychiatry. The HARM-FV combines static and dynamic risk factors to facilitate team discussions of risk and guide treatment planning, privilege requests, and risk management. By guiding through relevant risk factors, the HARM-FV facilitates a continuous process, eventually guiding the team to make an informed judgment regarding risk.

After nearly a decade of successful use and given the richness of the data captured by the HARM-FV and the potential for research advancement, the functionality of the HARM-FV was increased through the development of the innovative eHARM-FV. The eHARM-FV was developed in an effort to bridge the gap between psychiatry and technology by combining the risk assessment and risk management processes with built-in analytics to enhance and inform these processes. The use of technology to measure, monitor, and assess risk and change would have a significant impact for key stakeholders within psychiatry, including patients, care providers, and the community.

The eHARM-FV automatically generates individual , which allows users to easily track changes at an individual level. A patient's progress can be viewed on specific risk factors, aggressive incidents, and to track changes in clinical risk ratings over multiple time periods. These patient analytics using real-time data are accessible to the team at any point during or after a risk assessment and consequently allow users to target treatment and potentially enhance everyday clinical practice. Users can refer to the analytics during an assessment as a way to track decompensation or improvement and inform the assessment process. These analytics may also allow teams to better distinguish antecedents to specific incidents or behaviors, then use this information to inform future treatment or interventions. Thus, the eHARM-FV combines the risk assessment and risk management processes with built-in analytics to enhance and inform these processes in a way never before seen by forensic psychiatry.

The eHARM-FV has been successfully implemented in several psychiatric settings in Canada, with additional versions, translations, and training opportunities now available. Through this presentation, an overview of both the patient tool and patient analytics will be provided, and learning regarding the use of analytics in forensic psychiatry and the ways in which such a tool can enrich clinical practice in this setting will be discussed.

---

#### Violence Risk Assessment, Data Analytics, eHARM

### I7 **Advancing Risk Assessment and Risk Management Using Analytics: The Electronic Hamilton Anatomy of Risk Management-Forensic Version (eHARM-FV)**

*Casey Upfold, BA, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA; Gary A. Chaimowitz, MD\*, Saint Joseph's Healthcare-McMaster University, Hamilton, ON L8N 3K7, CANADA; Mini Mamak, EdD, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** This presentation will provide a demonstration of the eHARM-FV aggregator and database functions as well as results from analyzing eHARM-FV-based data with machine learning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by imparting knowledge about the eHARM aggregator and how eHARM-FV-based data can be analyzed using machine learning.

The eHARM-FV is the first risk assessment strategy to incorporate and use internal analytics and “big data” capabilities and thus introduces the fifth generation of risk assessment. With the capability of the eHARM-FV to store data, an additional tool, the aggregator, was created. The development of the aggregator tool added a significant degree of functionality that heightens the usefulness of the eHARM-FV. By loading multiple eHARM-FV patient files into the tool, the aggregator allows for large-scale analysis at the group level and within moments, trends can be viewed across diagnosis, risk factors, treatments, and interventions. For instance, users can easily identify which programs have the highest number of referrals, greatest involvement, longest waitlists, and least engagement to inform program planning and resource allocation. Moreover, this data may be cross-referenced with aggressive incidents or risk ratings to determine where a need exists for a given program or unit. Thus, the eHARM-FV database can inform risk management, research, service planning, and quality management.

In addition, the aggregator tool allows users to download imported data into a de-identified database that includes each existing eHARM-FV report for each patient selected. The database derived from the eHARM-FV is generated at the clinical interface, avoiding additional data collection or entry and the potential for errors, and increasing the ecological validity of studies that use the eHARM-FV-based data. This function of the aggregator presents a step toward machine learning and big data analysis within forensics as it creates a rich database consisting of an extensive variety of relevant variables at numerous time points, alongside accurate, longitudinal, and historical data about risk, treatment, and outcome variables.

Big data and analytics are rapidly changing health care and enabling a degree of measurement and quality improvement not previously seen. For a variety of reasons, including the limited number of quality indicators in mental health care, psychiatry has been late to the game. Forensic mental health has a few advantages in that there are recordable indicators within the behaviors that are monitored and measured. Use of technology to measure, monitor, and assess risk and change would have a significant impact for key stakeholders, including patients, care providers, and the community. Analytics offers an opportunity to increase our understanding of the forensic population, target effective programs and interventions, and direct more personalized care at the critical intersection of risk assessment and prediction—risk management. The eHARM-FV takes advantage of the capabilities afforded by big-data analytics to enhance the assessment, monitoring, and management of risk at the clinical interface, as well as the opportunity to use machine learning in forensic psychiatry. Through this presentation, the aggregator tool will be demonstrated and preliminary findings using machine learning to analyze eHARM-FV-based data will be discussed.

---

**eHARM, Data Analytics, Forensic Psychiatry**

## I8 An Overview of Forensic Patients Within the Ontario Review Board (ORB) Patient Database

*Casey Upfold, BA\*, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA; Gary A. Chaimowitz, MD, Saint Joseph's Healthcare-McMaster University, Hamilton, ON L8N 3K7, CANADA; Mini Mamak, EdD, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA; Heather Marie Moulden, PhD, Forensic Psychiatry Program, Hamilton, ON L8N 3K7, CANADA; Katelyn Mullally, St. Joseph's Healthcare Hamilton, Hamilton, ON L8N 3K7, CANADA*

**Learning Overview:** The goal of this presentation is to provide attendees with an overview of the Ontario forensic psychiatry system and with a representative profile of individuals who are under the jurisdiction of the ORB.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by expanding current knowledge and answering a number of key questions in regard to individuals in the forensic psychiatry system who have been found Unfit to Stand Trial (UST) and Not Criminally Responsible (NCR), as well as the implications for decision-making in forensic psychiatry.

The purpose of this study was to provide a representative profile and increase the understanding of forensic patients who are under the jurisdiction of the ORB. In Canada, those who are deemed UST or NCR on account of mental disorder are placed under the jurisdiction of a Review Board. There is a Review Board in each province, each of which assumes the role of determining the custodial status of the UST and NCR accused.

In Ontario, individuals found UST or NCR are placed under the jurisdiction of the ORB. Consequently, these individuals become the subject of annual review board hearings, in which hospital reports are prepared for board members to review; these include personal, family, psychiatric, and criminal history as well as treatment response, progress, and risk profiles. These reports are provided to assist the review board members in determining whether the accused should remain incarcerated or receive a conditional or absolute discharge. In making these decisions, the review board members are required to take into consideration the need to protect the public, the mental condition of the accused, and the reintegration of the accused into society.

The ORB, hospital staff, and the field of forensic psychiatry, in general, are responsible for the tremendously difficult task of identifying at-risk individuals, making decisions regarding one's ability to be tried for and held responsible for their criminal actions, and making decisions regarding an individual's ability to live safely in the community. It is imperative that institutions and tribunals are as informed as possible in making these decisions, which can only occur with sufficient empirical research and evidence.

At St. Joseph's Healthcare Hamilton, a total of 1,241 annual ORB hospital reports from the years of 2013–2015 were collected from ten forensic psychiatry facilities and coded to create the ORB Patient Database. The database includes male (86%) and female mentally ill offenders, all of whom are over the age of 18 years ( $M=42.54$ ,  $SD=13.33$ ). All individuals in the database were either found UST (3%), NCR (78%), permanently UST (5%), or previously UST and subsequently found NCR (13%) for a violent (70%), non-violent (20%), or sexual (10%) index offense. The primary objectives of this study were to use the ORB Patient Database to: (1) describe historical profiles of ORB patients, (2) identify trajectories, (3) examine index offense characteristics, (4) evaluate reported risk levels and assessments, and (5) psychiatric profiles.

In order to best inform and enhance the decision-making progress of the ORB, it is imperative to understand who the forensic psychiatry population is, what factors predict specific outcomes, and how to improve trajectories within the system. The current study will aid in expanding current knowledge and answering a number of key questions, including, but not limited to, those listed and informing forensic decision-making for years to come. Further results and implications from the current study will be discussed.

### Review Board, Forensic Psychiatry, Mental Disorder

## **I9 Is the Canadian Review Board Effective? An Evolving Forensic System Depending on Case Laws**

*Sebastien S. Prat, MD\*, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3R2, CANADA; Gary A. Chaimowitz, MD, Saint Joseph's Healthcare-McMaster University, Hamilton, ON L8N 3K7, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will be aware of how the forensic psychiatry system functions in Canada. Attendees will know the power that the Review Board has to ensure community safety and allow psychiatric rehabilitation. Attendees will also be aware of how the Review Board and the Forensic Psychiatric programs interconnect to achieve these goals. Attendees will be aware of the case laws that have defined the roles of the Review Board and that have recently changed some of its functioning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a system that is based in Canada to an audience that will likely be international. As the Canadian Review Board is a system that is focused on psychiatric rehabilitation, this presentation shows the efficiency but also the difficulties that professionals in forensic mental health may encounter.

The Canadian Review Board system has comprehensive procedures to allow individuals who suffer from a mental disorder and have committed a crime for which they were found to be not criminally responsible based on a mental disorder or permanently unfit to stand trial to be rehabilitated. Even though the “paramount” criterion is community safety, the Review Board has to order dispositions that will permit the patients to attend programs that will benefit their rehabilitations, notably therapeutic interventions that will address their risk factors. Based on a federal legislation, the Review Boards and its applications are described in the Criminal Code of Canada. Each hearing held by the Review Board allows a thorough analysis of the patients' situations. Its members are part of a multidisciplinary panel (lawyers, clinicians, and public members), allowing for the acquisition of several view points on the situation to decide about the most appropriate dispositions, tailored to the clinical requirements for both the community and the patient.

Case laws have been instrumental in refining the legal requirements and prerogatives of the Review Board. This presentation will highlight the legal mechanisms under which the Review Board operates. It will also present how some of the most recent decisions of the Court of Appeal have changed some outcomes and how the evidence needs to be presented. This presentation will provide a description on how the Review Board system operates and stimulate a discussion with attendees that will likely offer some international perspectives.

---

### **Criminal Code of Canada, Forensic Psychiatry, Risk Mitigation**

## I10 The Legalization of Cannabis in the Canadian Review Board System

*Natalie M. Raso, MD\*, St. Joseph's Healthcare Hamilton, Hamilton, ON L9C 0E3, CANADA; Sebastien S. Prat, MD, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3R2, CANADA*

---

**Learning Overview:** The goal of this presentation is to discuss how legalization of cannabis may have an impact on conditions of discharge of individuals previously found not criminally responsible due to a mental disorder. Attendees should learn how a shifting landscape in terms of cannabis legalization and adoption of harm-reduction techniques may influence the discharge conditions of individuals in the forensic system.

**Impact on the Forensic Science Community:** This presentation will have an impact on the forensic science community by informing attendees about how legalization of previously illegal substances could lead to changing tolerance of substance use for individuals previously found not criminally responsible due to a mental disorder.

In the Canadian Review Board system, when a person is found not criminally responsible for a crime due to a psychiatric disorder, the Review Board may prohibit them from the use of any illegal substances if they are known to have abused substances in the past. Often the clause on an individual's disposition will dictate that the individual abstains from all illicit or illegal drugs. Up until recently, that clause encompassed cannabis use. In recent months, however, this prohibition has become more complicated, as cannabis is no longer considered an illegal substance in Canada.

As a result of this change, there has been a recent shift in how the Review Boards consider substance use prohibitions for individuals found not criminally responsible. One consequence of the legalization of cannabis has been individuals and their physicians seeking that prohibitions around substances be amended to exclude legal substances, thereby permitting individuals to use cannabis when they are prohibited from using other recreational substances.

This presentation will report three separate cases in Ontario, Canada, in which physicians sought amendments to substance use prohibitions set out by the Review Board to allow individuals to use cannabis legally (while still being prohibited from using other illicit substances). This presentation will explore the various arguments used to request such an amendment to an individual's disposition as well as the varying decisions made by Review Boards in response to these new requests.

This presentation will also discuss the "harm reduction" approach that is used as a basis in many of these recommendations to the Review Board. Specifically, this presentation will discuss the harm reduction literature around cannabis in the forensic psychiatry system.

This presentation seeks to review a shift in the Canadian forensic Review Board system following the country's legalization of cannabis in 2018, specifically that drug prohibition clauses are being amended to permit the use of cannabis for some individuals, where other substances remain prohibited. This presentation will aim to provide context for forensic professionals practicing in other jurisdictions that may have recently legalized cannabis or may do so in the future.

---

### Cannabis, Legalization, Not Criminally Responsible

## I11 An Increasing Demand for the Psychological Evaluation of Asylum Seekers

Collin Lueck\*, Los Angeles, CA 90232

**Learning Overview:** After attending this presentation, attendees will learn: (1) the definition of “asylum” and the routes to obtaining asylum; (2) the details of the psychological evaluation of asylum seekers, including screening for symptoms, writing affidavits, and collaborating with legal organizations; and (3) the role that forensic psychiatrists can play in this process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by teaching attendees about the psychological assessment of trauma and mood symptoms in asylum seekers and about the current laws related to asylum.

There were more than 70 million forcibly displaced people (those who leave their home countries fleeing war or other conflict) worldwide at the end of 2018.<sup>1</sup> This number has risen steadily over the past ten years, driven upward by conflicts in Syria, other parts of the Middle East, and Sub-Saharan Africa. Some displaced people seek asylum in the country to which they immigrate, often when faced with deportation. Asylum refers to protection given to people who fear persecution in their home country due to their race, religion, nationality, political opinions, or membership in a particular social group.<sup>2</sup>

Most asylum applicants in the United States emigrate from China and Central and South America. The United States granted just over 26,000 asylum applications in 2017, according to the most recent data available. Those who are denied may face deportation.<sup>3</sup> As immigration has become a central factor in the polarized political climate of the United States, asylum regulations are rapidly shifting and are now an area of intense media scrutiny.<sup>4</sup>

In order to obtain asylum, applicants must demonstrate that they fear death or persecution and that this fear is “credible.” To demonstrate that their fears are well-founded, many asylum seekers will undergo psychological evaluations by psychiatrists, physicians of other specialties, or other mental health clinicians.<sup>2</sup> These professionals may write affidavits concerning the facts and psychological evidence related to persecution suffered by the asylum seeker. These affidavits can substantially affect the likelihood that an asylum application is granted.

Given the rising number of displaced people worldwide, as well as recent media attention given to asylum-seekers and other immigrants to the United States, professionals of multiple medical and mental health specialties may take interest in performing psychological evaluations and writing affidavits. It is important that this work be performed in a thorough, sensitive, and culturally informed manner. Although many asylum-seekers have experienced deeply traumatic events, their psychological responses to these experiences may be different than that traditionally seen in the United States.<sup>5-7</sup> Forensically trained psychiatrists can play a special role in performing evaluations, training others to do so, and raising awareness of the role of mental health clinicians in the asylum process.

This presentation will provide an introduction to conducting an asylum interview and will outline the key components that asylum evaluators should elicit during their examination. Those who attend will gain information about developing an asylum affidavit, and about the role that forensically trained psychiatrists can play in the asylum process during this global refugee crisis. In addition, attendees will gain a broader understanding of assessing trauma and mood symptoms in other patient populations.

### Asylum, Trauma, Immigration

## I12 Recent/Proposed Legal Changes in Asylum Law and the Implications for Mental Healthcare

*Joseph Chien, DO\**, VA Portland Health Care System, Portland, OR 97239; *Will Frizzell, MD\**, Oregon Health and Science University, Portland, OR 97239

**Learning Overview:** After attending this presentation, attendees will appreciate recent changes/attempts to change the political asylum process by the current administration. Attendees will learn about the potential impact of these changes/proposed changes on mental health providers and forensic practitioners who work with refugees and others seeking asylum.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by updating forensic practitioners on recent political events impacting those seeking political asylum in the United States. This presentation will also promote awareness of different levels of racism that may affect the treatment of minorities and disadvantaged people.

Mental health professionals play a key role in assisting applicants for political asylum to the United States.<sup>1</sup> Political winds during the current Trump administration coupled with unprecedented numbers of asylum seekers at the southern border have spurred recent attempts to fundamentally alter the asylum process. Specifically, this presentation will discuss: (1) Attorney General William Barr's July 29, 2019, order in "Matter of L-E-A," prohibiting asylum seekers from using the status of "immediate family member" as constituting a "particular social group" eligible for asylum in the United States; (2) the "Secure and Protect Act of 2019 (S.1494)," a Senate Bill sponsored by Senator Lindsey Graham introduced on May 15, 2019, which proposes changes that would, among other things, increase the amount of time children could be detained by their families and allow Border Patrol to quickly send unaccompanied minors back to Central America under certain circumstances.<sup>2,3</sup> This presentation will discuss the implications of these changes/proposed changes to asylum seekers and psychiatrists working on political asylum cases as well as the potential ill effects on mental health that these changes may have on asylum seekers, many of whom have already led lives affected by trauma.

A second goal of this presentation is to explore concepts of racism, including overt, covert (i.e., implicit bias), and institutionalized racism and debate whether the abovementioned changes represent a shift toward a more racist United States. It will be argued that policy changes like those presented above, while perhaps not inherently racist in themselves, potentially represent the institutional legitimization/codification of racist ideas. Increased awareness of the forms of racism that pervade our society will help ensure the fair treatment of individuals we treat and assess.

### Asylum, Racism, Forensic Psychiatry

## I13 A Neurological Condition and Forensic Psychiatry: A Case Report

*Sebastien S. Prat, MD\*, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3R2, CANADA; Aline-Claire Huynh, BHSc, McMaster University, Hamilton, ON, CANADA; Jasreen Cheema, MD, University of Toronto, Toronto, ON, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand the concept of risk management with unconventional conditions. Attendees will also understand why clinical details are important, notably to make the proper diagnosis and offer solid evidence to the legal professionals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting a rare case report. As this clinical situation is not widely described, it will allow forensic professionals to be more familiar with the diagnosis-making process and how this can be defended in a court setting.

**Introduction:** Typically, individuals found to be not criminally responsible on the account of a mental disorder integrate the Canadian forensic system, due to suffering from a schizophrenia or bipolar disorder. Mitigating the patients' risk and promoting their rehabilitation are the focus of the forensic psychiatry team. The difficulties in achieving significant positive results and allowing patients to be released and later discharged into the community result from treatment-resistant psychiatric symptoms. Although this is an unconventional situation, this may occur when someone presents with a psychotic disorder due to a medical condition. Indeed, this medical condition may not have a good response profile to the medication usually used in psychiatry that deals with delusions and behaviors. Moreover, the evolution of this condition, or its day-to-day management, may be quite different from what is usually expected from a common psychiatric condition.

**Case Report:** Based on a case report, this presentation highlights the difficulty in providing a diagnosis of psychotic disorder due to a neurological condition in the forensic context. For instance, this relates to a case of multiple sclerosis with psychotic features. In this case, ruling out differential diagnoses, primarily psychiatric, was not an easy task due to the presence of a comorbid personality disorder. In addition, as multiple sclerosis extremely rarely presents with psychosis as its main symptom, the diagnosis was not easy to make. Moreover, due to the presence of delusional thinking in relation to the cause for the brain lesions, adherence to treatment and follow-up was poor.

**Discussion:** When someone is deemed not criminally responsible on account of a mental disorder in the court, it states that the individual's mental disorder is associated with deviant behaviors. The role of the Review Board in Canada (forensic system) is to make dispositions that will mitigate the risk and enhance rehabilitation. Making the appropriate diagnosis is essential to offer the optimal treatment response and assess its efficacy, notably on the risk profile. It is notably relevant in forensic psychiatry because evidence gets scrutinized, not only at the initial hearing, but also during upcoming hearings through the Review Board system. Moreover, inappropriate medical management will lead to risk for the patient (due to the progression of the disease inadequately treated) and risk for the community (due to the ongoing risk of safety). This case also shows how difficult risk mitigation is achieved and how risk formulation is performed because of an unstable neurological disease. Moreover, in this particular situation, the impact of propaganda that in this particular occurrence was detrimental to the patient's rehabilitation by increasing the patient's paranoid symptoms will be presented.

### Neurological Condition, Propaganda, Risk Management

## I14 Differences Between Readmitted and Non-Readmitted Patients Discharged From Italian Psychiatric Security Facilities

Filippo Franconi, MD\*, *Sistema Polimodulare di REMS Provvisorie, Castiglione delle Stiviere 46043, ITALY*; Ilaria Rossetto, PhD, *Residences for Execution Safety Measures, Castiglione delle Stiviere 46043, ITALY*; Alan R. Felthous, MD, *Saint Louis University School of Medicine, Saint Louis, MO 63104-1027*; Giancarlo Di Vella, MD, PhD, *University of Torino, Department of Public Health Sciences, Torino 10126, ITALY*; Massimo Clerici, *Bicocca University, Milan 20126, ITALY*; Felice F. Carabellese, MD, *University of Bari, Bari 70124, ITALY*

**Learning Overview:** After attending this presentation, attendees will know the characteristics of a group of psychiatric patients discharged between 2008 and 2018 from a psychiatric security facility in northern Italy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of important clinical aspects, especially the differences between patients readmitted and not readmitted after discharge.

There is substantial international literature on the clinical and criminological characteristics of patients discharged from forensic hospitals.<sup>1-3</sup> In Italy, unfortunately, there are few studies on this topic.<sup>4,5</sup> In order to fill this gap, this study gathered the clinical and criminal data of 543 male psychiatric patients discharged from the only secure psychiatric facility in the Lombardy Region of Italy between 2008 and 2018. Among this group of patients, the prevalence of readmission into the forensic facility is 11.6% with an average of 22.7 months after discharge. The prevalence of post-discharge violent offending in this population was 3.5% within an average of 28 months after discharge. This study focused on the differences between the patients discharged and not readmitted (first group) and the patients readmitted at least once (second group). This study found that the median duration of inpatient treatment was longer in the first group than in the second (28.2 vs. 19.6 months). It was then noticed that the average age at the time of discharge was higher in the first group (43.2 vs. 38 years old). Moreover, the prevalence of psychotic spectrum disorders as the primary diagnosis was higher in the not readmitted group (53% vs. 44%) and the prevalence of personality disorders as the primary diagnosis was higher in the readmitted group (30% vs. 44%). In regard to substance abuse, a known major risk factor for violent behavior, having substance abuse as a secondary diagnosis was more frequent in the second group (26% vs. 42%). As far as the type of index crime was concerned, the patients who were not readmitted were more likely to have committed violent crimes (homicide and attempted homicide). In summary, this study found retrospectively that patients discharged and readmitted into an Italian forensic psychiatric facility were younger at the time of the first discharge, had a shorter length of the stay, most likely had a personality disorder as a first diagnosis, and had substance abuse as a secondary diagnosis, compared to patients who were not readmitted during the study period.

**Conclusions:** Some clinical implications arise from these findings. First, they suggest that we should make a more accurate risk assessment and risk management in young patients with personality disorders and substance abuse, because these are the patients who will most likely be readmitted. Furthermore, in these types of patients, the length of stay should be considered as an important prognostic factor when evaluating the possibility of discharge.

**Learning Overview:** After attending this presentation, attendees will better understand risk and protective factors of violent behavior inside the forensic psychiatric facilities in Puglia and Basilicata, Italy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating, once identified, the risk and protective factors of violent behavior in socially dangerous subjects with specific treatment proposed.

**Introduction:** Over the past few years in Italy, the treatment of psychiatric offenders has undergone profound changes, following a series of court and legislative interventions that have radically changed the forensic psychiatric treatment panorama. The process of overcoming and closing judicial psychiatric hospitals (Ospedali Psichiatrici Giudiziari [OPGJ]), presented to the Decree of the President of the Council (D.P.C.M.) on April 1, 2008, with the transfer of health competencies related to detainees to the Ministry of Health over a period of less than ten years, led to an approach strongly based on the regionalization of the treatment of forensic psychiatric patients. This change involved, among other things, the establishment of the Residences for Execution of Security Measure (REMS) and the transfer to regional psychiatric facilities all patients with a profile of being socially dangerous in a psychiatric sense so as not to require a correctional-type security measure.

Law 81 of May 30, 2014, sanctioned the final transition to different treatment models for the socially dangerous offender. All Italian regions have therefore involved themselves in identifying and creating structures to welcome people deemed socially dangerous from the psychiatric point of view. At the same time, it has become a regional task to plan the social reintegration of acquittees with infirm minds coming from OPGs that are closing, whose social and health assistance have been entrusted to mental health departments.

This was also the case for the Puglia Region, where a special commission planned the discharge of the internees in the OPGs originating in the region, providing, in addition to the REMS already activated, ten dedicated communities (communities for patients with safety measures) for offenders with mitigated socially dangerous profiles.

In this regard, the welfare reorganization of the mentally ill offender presents a series of critical issues related to the estimation of the levels of social danger and the adequacy of the different structures for the treatment and rehabilitation of patients with specific profiles, as well as to the safety and protective needs of the community.

Considering the lack of empirical data in this regard, the acquisition of greater knowledge on risk and protective factors within the specific and particular Italian psychiatric-forensic treatment reality is essential.<sup>1-5</sup>

This study aims to evaluate the recurrence rate of new violent behaviors and/or crimes in forensic psychiatric patients subjected to a security measure and entrusted for treatment to mental health departments (DSMs) in any form of treatment (REMS, dedicated community, therapeutic-rehabilitative community, outpatient treatment, etc.) and to evaluate the effectiveness of treatments and the relative differences in reducing violent behavior.

**Conclusions:** The main expected result is the identification of risk and protective factors for aggressive and/or violent behavior within the specific forensic psychiatric population under study after the closure of high-security Italian hospitals. The second expected result is the estimation of criminal recidivism rates, as well as aggressive and violent behavior in the study population and the relative differences in comparison with the control group. The initial data obtained one and one-half year after the beginning of the present research show how aggressive and/or violent behaviors are present in the experimental group in only a negligible percentage. The rehabilitative approach with these types of patients seems to be effective.

### Risk Factors, Protective Factors, Violent Behavior

## I16 Women and Men Who Committed Murders: Male/Female Psychopathic Homicides

*Felice F. Carabellese, MD\**, University of Bari, Bari 70124, ITALY; *Alan R. Felthous, MD*, Saint Louis University School of Medicine, Saint Louis, MO 63104-1027; *Gabriele Mandarelli, MD, PhD*, University of Rome “Sapienza,” Rome 00100, ITALY; *Domenico Montalbò*, Polignano a Mare 70044, ITALY; *Fulvio Carabellese*, p.za G. Cesare, 11, Bari 70124, ITALY; *Donatella La Tegola, PhD*, University of Bari, Bari 70124, ITALY; *Ilaria Rossetto, PhD*, Residences for Execution Safety Measures, Castiglione delle Stiviere 46043, ITALY; *Filippo Franconi, MD*, Sistema Polimodulare di REMS Provisoria, Castiglione delle Stiviere 46043, ITALY; *Roberto Catanesi, MD*, Bari 70124, ITALY

**Learning Overview:** The goal of this presentation is to examine gender differences in psychopathic homicides.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by redefining the concept of female psychopathy and, consequently, of the available diagnostic tools.

**Introduction:** The relationship between the psychopathic dimension and homicide is controversial. The origins of psychopathy and its psychopathological position are still controversial. This disorder is characterized by manifestations that involve the subject’s emotional drive and interpersonal sphere, as well as the lack of respect for other people’s rights and for social rules. This is an important risk factor for antisocial and violent acts. Moreover, this increases criminal recidivism and hinders therapeutic change.

Psychopathic homicide, according to the psychopath’s personality traits, are either committed to obtain a personal benefit (e.g., money, sexual opportunities, status enhancement) or they are a result of a sadistic and predatory behavior, which is frequently associated with substance abuse. Moreover, some gender differences can also be observed in the homicide phenomenon regarding victims, weapons, and psychopathic dimension.

**Methodology:** This study involved male and female murderers suffering from a mental pathology with excluded and partial criminal responsibility who had been interned in the Residence for the Execution of Security Measures (REMS) of Castiglione delle Stiviere, Puglia, and Basilicata as a security measure to prevent the risk of criminal recidivism, together with male and female prisoners of Calabria, Basilicata, and Puglia convicted of murder with full criminal responsibility from March 2015 through the end of 2017. The sample consisted of 39 female and 48 male perpetrators of homicide and attempted homicide.

The entire sample of male and female murderers was assessed by the Structured Clinical Interview for *DSM-5* (SCID-5) and the Personality Inventory for *DSM-5*—Informant Form (PID-5 IRF) (per the American Psychological Association [APA], 2015), which were recently validated for the Italian population to determine major psychiatric disorders and personality traits, respectively, and can also be used by an examiner. In addition, the validated Italian version of the Psychopathy Checklist-Revised (PCL-R) was used.

**Results:** This study analyzed the total scores of the PCL-R and scores for Factor 1 and Factor 2. In the overall analyzed sample, this study found an average score of 13.18 (standard deviation (sd): 7.19); in the male group, 12.29 (sd 6.36); and in the female group, 14.28 (sd 8.05). Therefore, in all cases, an average value was found that was below the threshold that defines the condition of psychopathy. Statistically significant was the difference between the two groups of homicide/attempted homicide committed by men or women in regard to the distribution of Factor 1 scores, which evaluated the interpersonal/affective aspects. Here, the total average score obtained from the entire sample was 6.65 (sd: 4.22). However, this study obtained an average of 5.54 (sd: 3.49) for men and a higher value for women, with an average of 8.02 (sd: 4.65).

The differences observed for Factor 2, which concerns the aspects of social deviance, were less significant. Therefore, the average in the total sample was 6.19 (sd: 3.77); in the group of men, 6.48 (sd: 3.77); and in the group of women, 5.85 (sd: 3.79).

**Conclusion:** This study allowed reflection on how psychopathic traits are expressed when they are associated with the maximum expression of social deviance: homicide and attempted homicide. Therefore, based on the results obtained, it is possible to state that: (1) contrary to expectations, from an epidemiological point of view, the psychopathic dimension in this sample was not pronounced in crimes such as homicide and attempted homicide; and (2) there are differences in the phenotypic manifestations of the psychopathic dimension in this sample between the male and female genders. In women, expressions of psychopathy are more closely related to interpersonal/affective disorders, rather than to antisocial behavior, which is more frequent in men.

Finally, it is important to point out that, although the PCL-R represents an accurate assessment tool for women as well as men, its theoretical construct would require a “feminine” review, especially for Factor F1, which concerns the affective-interpersonal manifestations of women. Indeed, in line with other international surveys, this research indicates the existence of gender differences. Therefore, some work is required to redefine the concept of female psychopathy and, consequently, of the available diagnostic tools.

### Murders, Gender, Psychopathic

## I17 Sex Offenders and Psychopathy: A Study of an Italian Sample

Donatella La Tegola, PhD, University of Bari, Bari 70124, ITALY; Ilaria Rossetto, PhD\*, Residences for Execution Safety Measures, Castiglione delle Stiviere 46043, ITALY; Filippo Franconi, MD\*, Sistema Polimodulare di REMS Provvisorie, Castiglione delle Stiviere 46043, ITALY; Adriana Zito, MD, Bari, ITALY; Fulvio Carabellese, p.za G. Cesare, 11, Bari 70124, ITALY; Fabio Ferretti, MD, Siena, ITALY; Anna Coluccia, MD, Siena, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the presence of psychopathy in subjects who have committed sexual offenses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying the presence of psychopathy in subjects who commit crimes of a sexual nature and will assess the possible influence on criminal recidivism.

**Introduction:** Sexual offenses are among the crimes that cause great social alarm. Thus, attention to intra- and extra-prison treatment perspectives for perpetrators of deviant sexual behaviors has increased in recent years.

In the face of legislation in force in Italy, attentive to respect and safeguarding the personal rights of the victims and severe with regard to those responsible for the abuses, the institutional initiatives aimed at the prevention of this type of crime seem to be few, other than that they can be characterized by very high, specific relapse rates, as is the case with programs and initiatives with treatment and re-socialization purposes.<sup>1,2</sup>

Violent antisocial behavior is characterized by typicality of thought, denial, and minimization of damage to the victim and suspension of empathic abilities. One of the persistent characteristics in sexual offenders is denial. Denial is a personality trait or a conscious or non-conscious strategy that the subject adopts to protect himself and is supported by different cognitive dimensions. When complete negation is not present, minimization is often present, (i.e., the subject can admit the crimes committed and his own responsibility, but minimizes other aspects, such as the seriousness of the consequences on the victim).<sup>3</sup>

This study has identified two types of negation: total negation and partial negation.<sup>4</sup> Minimization is subdivided into minimization of the aggression in terms of frequency and gravity, of responsibility, of damage, of premeditation, and of fantasies. The primary function of these mechanisms is self-protection, that is, to stop denying means to suffer social and legal sanctions, while denial allows the aggressor to safeguard an acceptable image before others, the family, and himself. Denial protects him from unpleasant feelings of shame, guilt, and self-denigration and can help save himself and his family from following the admission of guilt.<sup>4</sup>

Some authors have conducted research focusing on the cognitive distortions of sex offenders.<sup>5</sup> These authors define cognitive distortions as a system of beliefs that in sexual offenders would involve opinions about children, women, the world, and themselves. The justifications, perceptions, and judgments would be used by the offender to rationalize his behavior as a molester. These beliefs, moreover, would allow the maintenance of the sense of self-esteem and the avoidance of negative consequences, thanks to a shift of responsibility from internal causes to one's own deviant behavior, but also to reduce the discomfort felt (for having carried out an unacceptable behavior), the guilt, and the shame, with the outcome that this behavior can be repeated.

The evaluation, in particular, focused on the coping resources and strategies of offenders and on personality characteristics, particularly psychopathic. Scientific literature reports that psychopathic traits characterize criminal behaviors, especially the violent ones. Psychopathy is also considered a risk factor with respect to the recurrence of sexual crimes, even if the relationship between psychopathy and sexual violence is rather complex.<sup>6</sup>

In light of the data reported, a research project was started in collaboration with the Bari Prison and the Altamura branch aimed at identifying the possible presence of psychopathy in this sample. These are 16 definitive prisoners who committed sexual crimes that gave their consent to their involvement in the present.

The first data obtained show that the sample had a rather low average total Psychopathy Checklist-Revised (PCL-R) score ( $M=14$ ;  $SD=8.3$ ) with higher mean values for Factor 1 (Interpersonal/Affective) ( $M=7.68$ ;  $SD=4.78$ ) greater than the Factor 2 (Social Deviance) ( $M=5.5$ ;  $SD=3.89$ ). Among the most significant data obtained on the different items of the PCL-R was that it is possible to detect higher scores with regard to talkativeness and superficial charm ( $M=1.5$ ;  $SD=0.79$ ), the sense of grandiosity ( $M=2.62$ ;  $SD=5$ ), the need for stimuli and the propensity to boredom ( $M=1.3$ ;  $SD=0.84$ ), and the manipulative style ( $M=1$ ;  $SD=0.86$ ). Also relevant are the scores of items regarding emotional and sexual relationships: promiscuous sexual behavior ( $M=1.56$ ;  $SD=2.91$ ) and numerous short-term relationships ( $M=2.3$ ;  $SD=3.6$ ).

### Sex Offender, Psychopathy, Risk Factors

## I18 Sexual Addiction and Deviant Sexual Behavior: Are They Comorbid Disorders?

Ingrid Bertsch, MA\*, Centre Hospitalier Régional Universitaire de Tours, Tours 37170, FRANCE; Sebastien S. Prat, MD, St. Joseph's Healthcare, McMaster University, Hamilton, ON L8N 3R2, CANADA; Servane Barrault, PhD, Université François Rabelais de Tours, Tours, FRANCE

**Learning Overview:** After attending this presentation, attendees will be aware of the co-occurrence of sexual addiction and sexual deviant behavior. Attendees will know about the therapeutic strategies and how to address these conditions in clinical practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by looking into a topic that has been understudied but has the potential to help better rehabilitate sexual offenders.

Sexual behavior is part of human behavior and naturally exists among each human being. Societies have drawn a lot of concerns in relation to sexuality, even when it relates to non-deviant sexuality. Mental health clinicians are confronted with addressing this topic as sexuality has the potential to cause a lot of distress. The main sexual disorders that have been studied for decades are hypersexual behavior and deviant sexual behavior.

Although these two sexual behaviors appear to be of different types, some studies highlighted that they may be comorbid. Indeed, it is not uncommon to identify individuals with a paraphilic disorder who also present with hypersexual behaviors.<sup>1</sup> In addition, some individuals with addictive sexual behavior tend to develop non-conventional, deviant, and/or illegal sexual behavior as a means to increase their sexual excitement (voyeurism, exhibitionism, and rape, for example). Also, epidemiological studies have shown that two-thirds of patients suffering from sexual addiction also suffer from a paraphilic disorder.<sup>2</sup>

For some sexual offenders, focusing on sexual behavior is interpreted as a way for them to cope with their psychological difficulties, both cognitive and emotional, which may also be explained by the fact that they present with a sexual addiction. North American studies showed that 35% to 55% of individuals who have sexually offended suffered from a sexual addiction.<sup>3,4</sup> In addition to finding that these two conditions are present among the same population, studies have shown other psychopathological similarities, such as personality disorder, relationship difficulties, cognitive distortion, and other types of addictions.<sup>2</sup> Therefore, if these two conditions may be comorbid, it becomes relevant to look into common therapeutic interventions (assessment tools, types of therapeutic programs, attitude of the clinicians, and expected efficacy).

The principle aim of this presentation is to offer a screen shot of the current scientific knowledge related to sexual addiction and sexual violent behavior as comorbid conditions, in terms of their common clinical signs and therapeutic interventions. Clinical vignettes will be used to highlight the data of the literature review and the possible therapeutic options.

### I19 The Personality Assessment Inventory (PAI): Treatment Scales and Interpersonal Characteristics in a Sample of Men Charged With or Convicted of a Sexual Offense

Alden Parker\*, Clemson, SC 29631; Emily D. Gottfried, PhD, Medical University of South Carolina, Charleston, SC 29407

**Learning Overview:** The goal of this presentation is to inform those who are involved in the assessment and treatment of persons who have sexually offended of considerations related to treatment prognosis and personality characteristics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the ability of evaluators of sexual offending behavior and treatment providers to make treatment recommendations based on information obtained from psychological testing.

This presentation will focus on the relationship between the Personality Assessment Inventory (PAI) interpersonal personality traits of dominance and warmth and PAI scales associated with treatment motivation and process.<sup>1</sup> The PAI Treatment Rejection (RXR) scale assesses treatment motivation levels with low scores indicating high motivations for treatment and high scores indicating low motivation for treatment. However, since motivation for treatment does not always equal a positive outcome, the PAI Treatment Process Index (TPI) is composed of 12 features that indicate levels of obstacles that may be present within treatment, such as hostility, low motivation, defensiveness, and low social support, as well as correlate highly with withdrawal, hostility, and alienation. It was hypothesized that RXR and TPI would be negatively associated with the PAI scale assessing Warmth (WRM) and positively associated with the PAI scale assessing Dominance (DOM). In other words, it was expected that individuals with lower levels of WRM and higher levels of DOM would be less motivated for the treatment process and were predicted to experience a greater amount of challenges within treatment.

Data were collected from 101 men who underwent comprehensive evaluations of sexual behavior after being charged with or convicted of a sexual offense or sexual boundary violation. After invalid PAI data were removed, the final sample was 92 men who ranged in age from 19 to 80 years old ( $M=44.84$ ,  $SD=14.79$ ). The current presentation will discuss the relationship between several PAI scales and the relationship between the PAI scales and number of prison disciplinary infractions, age of examinee, self-esteem rating, victim(s)' age and sex, history of parental mental illness, substance abuse, and criminal offending; prior mental health or substance use treatment; and prior sexual behavior treatment. This presentation will assist clinicians who perform assessment and provide treatment to individuals with problematic sexual behavior in using the PAI and other psychological testing in making treatment recommendations.

## I20 Frontotemporal Dementia and Sex Offending: Neurological Neuropsychiatric and Legal Issues

Mohan Nair, MD\*, Seal Beach, CA 90740; Manish Fozdar, MD\*, Triangle Forensic Neuropsychiatry, PLLC, Raleigh, NC 27609; Wesley Maram, PhD\*, Orange, CA 92868; Dean De Crisce, MD\*, Coast to Coast Forensic Associates, Union, NJ 07083; Jaime Coulter, JD\*, Law Offices of Lloyd & Coulter, Orange, CA 92868; Andrew LLOYD, JD\*, Law Offices of Lloyd & Coulter, Orange, CA 92868

**Learning Overview:** The goal of this presentation is for mental health professionals and those involved in the criminal justice system to recognize how the neurological disorder Frontotemporal Dementia (FTD) can be a factor in new onset sexual offending in middle-aged and older subjects

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a basic understanding of FTD. Attendees will have greater sensitivity to the presence of this condition in first-time middle-aged, and older offenders, will learn how to use expert witnesses more effectively in such cases, and will have a basic understanding of diagnostic methods.

FTD is an increasingly recognized brain disorder that begins to manifest in the mid-40s. Second only to Alzheimer's disease in prevalence, FTD accounts for 20% of early onset dementia cases. The signs and symptoms of FTD often go unrecognized as a brain disorder and may be mistaken for psychiatric symptoms.

Neurodegenerative diseases can affect executive function (i.e., higher-level decision making, social emotional processing, and self-awareness resulting at times in inappropriate sexual and violent behaviors). This can lead to antisocial and criminal behaviors that first appear in middle-aged individuals or in later life.

This presentation aims to educate attendees how the behavioral variant of FTD (bvFTD) is of compelling medical/public health and jurisprudence relevance. FTD is often missed by psychiatrists and neurologists. The predominant symptoms being social, emotional, and behavioral makes it less likely to be recognized as a neurological disorder; given the lack of overt cognitive problems, unlike other forms of dementia such as Alzheimer's, psychiatrists may often misdiagnose it for bipolar disorder or some form of impulsive control disorder.

Six clinical features identify bvFTD: (1) disinhibition; (2) apathy/inertia; (3) loss of empathy; (4) perseverative and compulsive behaviors; (5) hyperorality, especially of sweets; and (6) dysexecutive neuropsychological profile. At least three features must be present to diagnose possible FTD.

BvFTD does not have to show overt cognitive impairment (i.e., intellect, reasoning, memory). What that means is that individuals with early bvFTD may continue to work, but only become behaviorally and emotionally unstable.

A 2015 University of California San Francisco retrospective medical record review study found that within the subgroup of FTD, more than a third of people had acted out with criminal behaviors.<sup>1</sup> A 2002 study of Swedish court-ordered forensic psychiatric evaluations noted that sexual offenses were most typical of older offenders with dementia. Hypersexual behavior may be present in as many as 20% of those with bvFTD.

Hypersexuality and inappropriate sexual behavior may be the first symptom of the disorder within a subgroup bvFTD. This hypersexuality is not believed to occur purely from poor impulse control or frontal disinhibition but from alterations in the sexual drive from lesions in the right temporal and limbic areas. These sexual behaviors can include new onset involvement in pornography, including child pornography, voyeurism, chatlines, prostitutes, and hands-on sexual behavior and public masturbation. Temper tantrums, binge eating, and lack of empathy to people and animals may be concurrently present.

Given the age of onset (i.e., in mid-40s), FTD may manifest in the prime of professional and family life. Sexual misbehaviors that emanate from FTD can have devastating consequences on individuals and families. This is complicated by the fact that individuals with FTD may appear cognitively intact *and even acknowledge* that their behavior is inappropriate but appear to lack remorse and control over their actions.

Establishing bvFTD as a cause or a factor in criminal actions may be exculpatory or mitigating. Instead of being identified and punished as sex offenders, subjects with neurodegenerative diseases, such as bvFTD, could be treated differently by the legal system. For example, providing appropriate neurologic evaluation and channeling subjects to palliative and medical institutions.

Dysfunction of the orbitofrontal and ventromedial cortex may be identified by neuropsychological testing. Routine neuropsychological batteries are not adequate. Tests such as the Iowa Gambling Task and tests used from autism/moral reasoning/theory of mind tests such as Faux Pas Recognition Test may be more helpful.

Neuroimaging can be helpful in evaluating new onset criminal behavior in adults and should always be considered. Positron Emission Tomography (PET) scans in the early stages and by Magnetic Resonance Imaging (MRI) scans in later stages can help identify FTD and separate it from psychiatric disorders such as bipolar disorder. PET can help with the diagnoses of bvFTD and has recently been authorized for use by Medicare.

Among the subjects covered in this presentation are: educating attendees on the neurological and neuropsychiatric aspects of bvFTD; the evaluative process and management of such cases; the relevance of specialized psychological and physiological testing (penile plethysmography and polygraph) in such cases; discussion of the role of expert witness use and testimony in such cases; and a prosecutor's perspective on dealing with sexual criminal defendants with brain disorders.

### Frontotemporal Dementia, Behavioral Variant, Sexual Offending

### I21 When Crime and Illness Overlap: California's New Mental Health Diversion Plan, Assembly Bill 1810

*Torri L. Montgomery, MD\*, University of Southern California Institute of Psychiatry, Law, and Behavioral Science, Los Angeles, CA 90033*

**Learning Overview:** After attending this presentation, attendees will be familiar with: (1) recently enacted California Assembly Bill (AB) 1810 that implements Mental Health Diversion; (2) the primary purpose of this legislation concerning the disproportionate representation of persons with mental illness in jail; (3) evidence and opinions for and against AB 1810; and (4) suggested recommendations for community mental health professionals working with this specific population.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community in several ways. It will expand clinicians' knowledge and interpretation about a relatively new California mental health diversion law. In addition, this presentation will discuss existing programs designed to treat those individuals who qualify under this new law and identify the need that will arise for the development of treatment programs across a continuum of community care.

Assembly Bill 1810, also known as "Mental Health Diversion," was implemented in June 2018. This bill was in response to a bed space shortage at the California Department of State Hospitals (DSH) and jail overcrowding due to the growing population of persons with mental illness. The DSH shortage was attributed to an increasing population of those found "Incompetent to Stand Trial (IST);" namely, there was a 60% increase from 2013 to 2018 of individuals deemed IST and sent to state hospitals. Moreover, it was estimated that from 2010 to 2017, there was an 86% increase in the number of inmates in the Los Angeles County jail system with mental health problems.

Although AB 1810 promotes three major changes, it also incorporates a broader perspective: (1) increased diversion of individuals with mental disorders to mitigate their entry and reentry into the criminal justice system while protecting public safety; (2) allows counties discretion and flexibility in the development and implementation of diversion for individuals with mental disorders; and (3) provides diversion for this population across a continuum of care settings that addresses their unique mental health treatment and support needs.<sup>1</sup>

Proponents of the bill cite that about one-third of inmates in California's jails suffer from serious mental illness.<sup>2</sup> They highlight that prior to AB 1810, California criminal courts had limited options to rehabilitate persons with mental illness charged with felonies.<sup>2</sup> This bill allows the court to order mental health treatment, counseling, and medication adherence for those whose mental illness played a role in the alleged misdemeanor or felony offense. However, certain criminal charges preclude an individual from consideration under this bill; that is, murder, manslaughter, rape, and other sex offenses.

Opponents of the bill express a number of concerns focused primarily on unclear and vague operational details. The roles and collaboration between courts, law enforcement, and community mental health treatment providers are not well defined. Further, counties may not be required to create or pay for new treatment facilities or programs, thus relying on pre-existing resources in community-based mental health treatment.<sup>2</sup> Care will potentially default to community psychiatric facilities and providers who may not be trained or willing to work with this unique forensic population.

This presentation will not only discuss AB 1810 but will also highlight its impact on those with mental illness who are charged with crimes, community mental health systems, the criminal justice system, and the public. Recommendations will be discussed for ways to deliver the necessary mental health services and structure for this unique population.

### I22 False Allegations of Sexual Abuse and Malpractice in Child Custody: A Big Court Case in Italy

*Laura Volpini, PhD\**, Rome 00174, ITALY; *Giuseppe Troccoli, MD\**, Mental Health Services, Bari 70122, ITALY; *Luigi Mignogna, MD*, Ciampino, Lazio 00043, ITALY

---

**Learning Overview:** After attending this presentation, attendees will be more skilled in how to assess a malpractice scenario regarding child custody and allegations of sexual abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting solutions that could prevent malpractices scenarios in child custody settings and allegations of criminal child abuse.

This presentation will take the Case of Bibbiano, a small city in the center of Italy into the Emilia Romagna region, as an icon of malpractice. Code named “Angels and Demons,” this case presented a disturbing picture of psychological violence toward children and their parents. Seventeen people, including medical doctors, social workers, and psychologists, were arrested by the Italian police. They are accused of submitting false reports regarding the family situation of children and also of having modified their drawings by adding genital attributes. Finally, they are accused of having brainwashed children with false memories of abuse.

Despite not yet being confirmed, these facts had a huge impact on the international press, causing questions about the entire Italian child custody system, allegations of sexual abuse system, and the competence of Italian psychologists, social workers, and medical doctors.

The crucial point of this presentation will be to clarify the Italian guidelines about child custody practices, about cases of allegations of sexual abuse, and the differences between them, in addition to clarifying what happened in the “Angels and Demons” case.

Italian legislation applies child custody to foster families or group homes only as a residual solution, and not as the final choice as happened in Bibbiano. Also, according to law number 172/2012 of the Italian penal code, in criminal offenses involving minors, the presence of an expert who acts as an assistant to the judge is required, but the assessment of sexual abuse always belongs to the judge him/herself. Despite what allegedly happened in Bibbiano, the expert has no legal status to decide whether a sexual abuse occurred or not.

Following what law n. 24/2017 of the Italian penal code states, the expert has to follow accredited guidelines, such as “La Carta di Noto,” the Italian national guidelines for child abuse allegations and can be neither suggestive nor manipulative during child interviews. These guidelines are totally antithetical to the presumed facts of the Bibbiano case where experts brainwashed children and used therapy to create fake abuse memories. Overall, it appears extremely important that the judge could ask the expert witness to use the standard methods for this type of case.

Next, the Juvenile Court and social services must build intervention systems, aimed at promoting residual family resources, to allow the child to live in a context that could prevent risks to his psychological development. Moreover, in cases of alleged abuse or maltreatment, law n.154/2001 has provided that the suspect should be removed from the family unit instead of removing the minor, as seems to have happened in the Bibbiano case.

It is hoped that in the future, the Juvenile Court, starting from these facts, rather than delegating to the social services will involve technical experts with specific training on the assessment of parenting skills. It is also hoped that, through this presentation, awareness of the need for specific training and specific technical skill may grow, beginning with social workers and psychological experts, up to judges themselves.

---

#### **False Allegations of Sexual Abuse, Malpractice, Child Custody**

## I23 Brain Imaging in Death Penalty Mitigation

Mohan Nair, MD\*, Seal Beach, CA 90740; Rob Friedman, JD\*, Tallahassee, FL 32301; Manish Fozdar, MD\*, Triangle Forensic Neuropsychiatry, PLLC, Raleigh, NC 27609

**Learning Overview:** After attending this presentation, attendees will have learned about various types of brain imaging and the evolving application in criminal cases and will have a better understanding of how to be sensitive to the possibility of mitigation and the appropriate use of experts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding of the possibilities, use, and misuse of brain imaging techniques as they apply to criminal defenses.

Brain imaging techniques, such as Magnetic Resonance Imaging (MRI), Computed Tomography (CT) scans, functional MR imaging, diffusion tensor imaging, perfusion imaging, Positron Emission Tomography (PET), and Single-Photon Emission Computed Tomography (SPECT), have increasing applications in clinical settings

Increased reporting in the peer-reviewed literature and clinical evidence has demonstrated sensitivity and specificity for even the more recent techniques, such as Diffusion Tensor Imaging (DTI). In regard to its use in evaluations of Traumatic Brain Injury (TBI), Hulkower noted, “Despite significant variability in sample characteristics, technical aspects of imaging, and analysis approaches, the consensus is that DTI effectively differentiates patients with TBI and controls, regardless of the severity and timeframe following injury. Furthermore, many have established a relationship between DTI measures and TBI outcomes.”<sup>1</sup>

Increasing advances in brain imaging will compel the legal system to determine which imaging techniques have probative value from prejudicial and misleading ones.

The track record for the success of functional neuroimaging in exculpating specific-intent crimes, such as murder, is not a good one. However, presentation of functional brain imaging has fared better in the mitigation of the death penalty in some capital offenses.

In November of 2002, just five months out of prison, 32-year-old Coy Evans was charged with first-degree murder of a police officer, two counts of armed robbery, armed burglary, kidnapping, and possession of a firearm by a convicted felon. Evans was later convicted of fatally shooting Sgt. Dale Green, a 13-year veteran of the Tallahassee police department, while the officer was investigating a home-invasion robbery. The jury spared Evans from the death penalty. A Single-Photon Emission Computerized Tomography (SPECT) brain scan may have been a factor in the jury’s decision

Approximately 44% of the neurobiological (genetic/neurological) claims raised were attempts to mitigate sentencing.<sup>2</sup> Failing to adequately investigate the probability of a brain abnormality may constitute ineffective assistance of counsel. Failure to obtain brain imaging studies in a first-time older offender may be an example, given increasing evidence that the behavioral variant of frontotemporal dementia may be a factor in their offending.

The defense (in plaintiff cases) and the prosecution (in criminal cases) have generally been successful at portraying much brain imaging evidence as “junk science.”<sup>3</sup> However, in 2018, the United States District Court for the Southern District of Florida ruled that DTI satisfied the *Daubert* standard for admissibility in *Marsh v. Celebrity Cruises, Inc.*, a personal injury claim for mild traumatic brain injury. The Court concluded that a lack of a standardized protocol for the acquisition and interpretation of DTI results did not make DTI technology “junk science” nor render the opinions of a board-certified neuroradiologist unreliable. In arriving at their opinions, the Court appears to overlook elements of *Daubert*, (i.e., known or potential error rate; the existence and maintenance of standards controlling its operation; and possibly whether it has attracted widespread acceptance within its relevant scientific community). This lack of adherence to established evidentiary standards has not stopped the increasing use of DTI in the courtroom.

### I24 You Saved My Butt: A Change in Jurisdiction for a Threat Against a Judge, and Why Forensic Psychiatrists Exist

Vivian Chern Shnaidman, MD\*, Princeton, NJ 08540

---

**Learning Overview:** After attending this presentation, attendees will understand the myriad of issues that occur when mentally ill plaintiffs and defendants are let loose in the civil arena as *pro se* litigants. Attendees will understand how the legal world, as well as the rest of the medical world, is sorely lacking in the understanding of the mental health field. Through the detailed analysis of one specific custody case, including the threats to one judge's life and the resulting change in jurisdiction of the trial that did not lead to new charges, attendees will begin to identify every step at which potentially dangerous individuals may be diverted toward treatment, and every juncture where a forensic psychiatrist might "first do no harm." The ethical, moral, and legal implications of our field will be discussed within the framework of one real case.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the many opportunities forensic psychiatrists and psychologists have to intervene in the trajectory toward dangerousness. This case illustrates the long-term decompensation of one individual, his multiple encounters with both the medical and the criminal justice systems, and every instance in which his mental illness was ignored. It culminated with a death threat against a judge that was handled via a change in venue, which could have resulted in the death of that judge. This case is a perfect teaching case to help the forensic mental health and legal communities understand our roles in preventing acts of violence and could theoretically result in new legislation.

The case of DS began as a routine family spat. DS claimed to be educated and appeared to be intelligent. When he could not hold a job and did not appear to behave like other young husbands, his wife asked him to please go for counseling. His refusal led to a series of unfortunate events, culminating in a divorce. As time went on, DS began to behave in more and more bizarre ways. Despite the numerous episodes of imminent danger to his children and the existence of one reliable parent, the laws surrounding the requirements of equitable distribution of parenting time led to the courts permitting DS to have ongoing access to his two very young children and to continually put them in harm's way.

This case presentation will examine the story of this case and the legal system that ignores mental illness at every turn. Attendees will also see how other medical specialties minimize and marginalize psychiatry, how psychiatric illness is misunderstood, and how, when this case culminated in a clear and convincing threat to a judge's life in open court, this judge's only recourse was to send the case to another jurisdiction. (What she said in the title was only the punch line, years later!)

Cases similar to this one enter the legal system every day and are disposed of in similar ways, often resulting in much more catastrophic outcomes. Some will be presented via their published decisions as a part of this presentation. This presentation will include discussion about how to inform both the legal community as well as the general population via the media about every opportunity to stop meaningless violence by addressing mental illness in the community. This case is a fantastic example; because of every dropped opportunity, it illustrates and offers the chance to brainstorm some ideas for the future, supporting the theme of this year's meeting, *Crossing Borders*, where we may finally cross the border between psychiatry and law and bring the two disciplines together in a way that would truly serve society as well as individuals.

---

#### Death Threat by Mentally Ill, Change in Venue, Prediction of Dangerousness

## 125 The Influence of a Juror's Note-Taking on Other Jurors' Memories for Testimony

Caitlin A. Pratt\*, Edmond, OK 73034; Jaclyn K. Maass, PhD, University of Central Oklahoma, Edmond, OK 73034

**Learning Overview:** The goal of this presentation is to discuss how jurors who take notes during a trial may be able to heavily influence the opinions of jurors who did not take notes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to the limited body of literature that exists on this topic and by bridging theories from the fields of forensic science, cognitive psychology, and social psychology.

This study seeks to investigate how a juror's memory for testimony may be influenced by a fellow juror who took notes during the trial. The non-note-taking juror may rely on the memory of the note-taking juror. If that is the case, could this juror's memories actually be altered? Research suggests that being exposed to misinformation after an event can alter a person's memory of that event, especially if it comes from a "reliable" source.<sup>1-3</sup> In addition to unconsciously altering memories, we sometimes choose to conform (i.e., change our opinions based on what others around us believe). When our decision is based on evidence provided by others, this is known as informational influence.<sup>4-5</sup> This influence may be of particular importance in jury deliberations.

Some research specific to jury settings does suggest that jurors may be influenced by opinions of other jurors who have taken notes.<sup>6-7</sup> However, these studies are relatively dated, and further research is needed to investigate whether a juror's actual memory of the testimony is influenced or just their judgement of the verdict.

This study will see how the opinions of a juror who takes notes during a trial influences the opinions of other jurors. Attendees will watch a video of a witness testifying at a mock trial. They will be sent to "deliberate." A confederate will have notes with inaccurate details about the testimony. Attendees will be tested again on their memories to see if the participant incorporates the other juror's inaccurate details. It is hypothesized that attendees' verdicts will be changed by the opinion expressed by the note-taking confederate, and that attendees' memories of the trial's details will be changed.

Jurors may believe that by choosing to trust the opinions of someone who has written details from the trial, they are more likely to have an unbiased, accurate memory of the trial. It is important that individuals know what outside sources may affect their memories and opinions, and this study will provide additional information in this field.

### I26 The Evaluation of Psychological Trauma of Individuals Who Escaped From Turkey Due to Human Rights Violations: Post-Traumatic Stress Disorder (PTSD)

*Alper Keten\**, Institut für Rechts-und Verkehrsmedizin, Heidelberg, CA 69115, GERMANY; *Johannes Nicolakis, MD*, Heidelberg Institute for Forensic and Traffic Medicine, Heidelberg 69115, GERMANY; *Ramazan Abaci, PhD*, Köln University, Köln, GERMANY; *Sarah Heinze, MD*, University Hospital Heidelberg, Heidelberg, Baden-Wuerttemberg 69115, GERMANY; *Kathrin Yen, MD*, Heidelberg University, Heidelberg, GERMANY

**Learning Overview:** After attending this presentation, attendees will be informed about the impact of psychological trauma on a well-educated group of people who migrated to Germany from Turkey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the human rights violations and migration in Turkey over a well-educated group of people who migrated to Germany from Turkey.

**Introduction:** Post-Traumatic Stress Disorder (PTSD) shows specific symptoms and may arise after witnessing traumatic events, including death or death threats, serious injury, or encountering a situation that threatens the physical integrity of the individual. The latter is one of the most common causes of PTSD. One of the most common reasons for disrupting physical integrity is the pressure exerted on citizens by repressive states or regimes. After the 2016 coup attempt in Turkey, thousands of public officials (teachers, academics, doctors, engineers, etc.) were dismissed or imprisoned. A large number of well-educated citizens escaped from Turkey and sought asylum in other countries. Germany is a favored destination for Turkish asylum seekers. Since 2015, approximately 40,000 Turkish citizens have applied for asylum in Germany. The aim of this study was to analyze PTSD in Turkish asylum seekers in Germany and to discuss the obtained results.

**Materials and Methods:** Turkish citizens aged 18 years and over who sought asylum in Germany after the failed coup d'état in Turkey in 2016 were included in this study. Recruitment was performed via announcement in a mobile messaging group that functions as a support group for Turkish citizens in Germany. One hundred ninety-nine people responded to the announcement. The PTSD Checklist for *DSM-5* (PCL-5) scale, a questionnaire consisting of 25 questions (5 of them related to demographic information), was used to measure PTSD. Google® Forms was used to present the questionnaire in a survey application, which was sent to the study participants via mobile messaging applications. A descriptive analyses on the obtained data was conducted.

**Results:** One hundred ninety-nine people completed the questionnaire. 119 participants (59.8 %) were male, and 80 (40.2 %) were female; 118 participants (59.3 %) were in the age range of 26 to 35 years; 174 participants (87.4 %) were married, 25 (12.6 %) were divorced or single; 113 participants (56.8 %) have been in Germany for 7–19 months prior to participation in this study, while 15 (7.5 %) have been in Germany for 6 months and less; 177 participants (88.9 %) scored more than 33 points on the PCL-5 scale and were preliminary diagnosed with PTSD, while 12 participants (6.0 %) scored 22–33 points.

**Discussion:** PTSD is the most common type of psychiatric disorder after physical and mental trauma. In this study, the ratio of PTSD cases was higher than in similar literature. This may be a consequence of enduring repressive practices in Turkey or during migration. In order to minimize trauma and to provide rapid rehabilitation, it is important to develop new policies considering PTSD in rehabilitation practices for refugees. As the study only included a relatively small number of participants, additional studies are needed to draw definite conclusions and to avoid sampling bias.

#### PTSD, Detention, Refugees

## 127 The Forensic Analysis of the State of Health in Prisoners: Is It Possible to Prevent Psychiatric Diseases and Suicide Risks in Prison?

Fabrizio Cordasco, MD\*, Università Magna Graecia CZ, Catanzaro, ITALY; Carmen Scalise, MD, University of Catanzaro, Catanzaro, ITALY; Isabella Aquila, MD, PhD\*, Institute of Legal Medicine, Catanzaro, Italy 88100, ITALY; Matteo A. Sacco, MD\*, Chair of Legal Medicine, University of Catanzaro, Catanzaro 88100, ITALY; Francesco Sicilia, MD, University Magna Graecia of Catanzaro, Catanzaro 88100, ITALY; Orazio Malfa, MD, University "Magna Graecia" of Catanzaro, Catanzaro, ITALY; Cristoforo Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Luigi De Aloe, MD, Institute of Legal Medicine, Catanzaro 88100, ITALY; Santo Gratteri, MD, Catanzaro 88100, ITALY; Silvia Boca, Viale Europa, Catanzaro, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance of using a protocol that can prevent psychiatric diseases in prison and reduce the suicide risk in the prison population.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the importance of surveillance systems in order to reduce the prevalence of psychiatric diseases and suicide in prisoners.

There are about 10 million prisoners in the world, of which 6 million are held in United States prisons.<sup>1</sup> From 2016 to 2018, there was a reduction in Europe in the detention rate estimated at 6.6%, while in Italy the prison population is growing: this phenomenon is linked to the increase in organized crime. As of June 2019, there are 23,442 prisoners in Italian prisons.<sup>2</sup> Due to the worldwide importance of the phenomenon in the public health, it is necessary to investigate the relationship between detention and prisoner health as well as the change in the psychophysical state of a subject after a period of incarceration. The scientific literature shows that in prisoners, there is a higher incidence of psychiatric diseases compared to the general population.<sup>3</sup> A systematic review of the literature shows that the prevalence of depressive disorders in prisoners is higher by 10%–12 % and almost half are affected by personality disorders. Suicide is the main cause of death among prisoners, and it causes over half of the deaths in prisons. The main risk factors are alcohol or drug abuse, family conflict relationships, and low socio-cultural status.

A review of the scientific literature was performed. The results were compared with the cases of Institute of Legal Medicine of Catanzaro, consisting of 30 forensic medical reports relating to the health of prisoners and their compatibility with detention. Prisoners were subjected to medical history collection and clinical examination. The clinical diary, laboratory, and/or instrumental investigations were analyzed. The most frequent pathologies were: anxious-depressive disorder (50%), gastrointestinal diseases (50%), osteoarticular diseases (40%), endocrine diseases (40%) and migraine (30%). The anxious-depressive disorder is reactive in all of cases and is a consequence of the detention and change of daily routine. Furthermore, gastrointestinal disorders and migraine may be expressions of an important anxiety somatization.<sup>4</sup>

In order to reduce psychiatric disorders and suicide risks, it is necessary to perform a medical and psychological evaluation for each new prisoner. In this way, it is possible to know the health status of each prisoner and to schedule a periodic monitoring of the diagnosed diseases. This evaluation requires specialized medical personnel able to set up an appropriate treatment. This study shows that prisoners suffering from psychiatric diseases are subjected to drug therapy without a complete diagnosis. It is important to adopt strategies in order to safeguard the mental health of prisoners. A mental health management protocol is not yet adopted in prisons worldwide. First, a risk stratification of the development of psychiatric diseases (for healthy subjects) or suicide risks (in subjects with known psychiatric pathology) must be conducted. A careful case history is needed, with investigations about the age of the subject, history of alcohol or drug abuse, familiarity with psychiatric pathologies, previous suicide attempts, type of relationship with family (a subject isolated from his/her own family has a higher risk of developing psychiatric pathologies). Once the medical chart of each prisoners is completed, it is necessary to schedule periodic updates to assess any worsening of health conditions. Furthermore, it is essential to train prison custodians in the recognition of signs of mental suffering (feelings of guilt, shame, despair, isolation). Periodic meetings must be scheduled between prison police and prison medical staff. During the meetings, updates concerning each prisoner are reported. The application of this protocol could reduce suicide episodes and allow for the early identification of risk signals.

### Forensic Science, Prison, Mental Disorders

### I28 The Charleston Mother Emanuel African Methodist Episcopal (AME) Church Shooter: Debating the Psychiatric Experts' Competency to Stand Trial Reports

Christopher Fields, MD\*, Medical University of South Carolina, Charleston, SC 29407; Emily D. Gottfried, PhD\*, Medical University of South Carolina, Charleston, SC 29407; E. Thomas Lewis, MD\*, Medical University of South Carolina, Charleston, SC 29407; Diana Mullis, MD\*, Medical University of South Carolina, Charleston, SC 29407

**Learning Overview:** After attending this presentation, attendees will gain experience in approaching complex competency to stand trial cases by participating in a debate and discussion of the evaluation reports by psychiatric experts in a mass murder trial. Attendees will investigate a racially motivated perpetrator and gain an understanding of arguments for and against adjudicative competence. Additionally, relevant literature and case law involving competency to stand trial will also be incorporated into the discussion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating a racially motivated perpetrator and will further understanding of arguments for and against adjudicative competence.

Psychiatric experts provide critical information to the trier of fact in assessing competence to stand trial.<sup>1</sup> How do opposing experts examine the same information and reach different conclusions regarding psychiatric diagnoses and opinions about competency? In this complex case, how an autism spectrum disorder may impact competency to stand trial is explored. There is developing case law and literature addressing individuals with autism spectrum disorders who perpetrate violence and engage in criminal behavior.<sup>2</sup> Diagnostic differences between severe personality disorders and primary psychotic disorders are explored in relation to their potential impact on competence. Young adults with social difficulties that could be suggestive of prodromal psychotic symptoms may be particularly difficult to evaluate with regard to the extent their symptoms interfere with the ability to work with an attorney on a defense strategy. Questions remain regarding how much ability constitutes sufficient present ability to consult with an attorney.

This presentation will describe the church shooting that occurred at the Mother Emanuel African Methodist Episcopal Church in Charleston, SC, and provide context for Mr. Roof's history, psychological functioning, and psychiatric symptoms. The three competency reports authored by two psychiatric experts and the psychological evaluation conducted on Mr. Roof will be reviewed and their findings will be debated. Additionally, Mr. Roof's desire to represent himself in trial and how this impacted the opinions regarding his competency to stand trial will be explored. Finally, relevant literature and case law involving competency to stand trial will also be incorporated into the discussion.

## I29 Competence in Competence: Myths, Misconceptions, and Avoiding Pitfalls

George D. Annas, MD\*, State University of New York Upstate Medical University, Syracuse, NY 13202; Corina Freitas, MD\*, Syracuse, NY 13202

**Learning Overview:** The goals of this presentation are to improve knowledge and expertise in competence to stand evaluations and improve knowledge regarding common myths and misconceptions of Competence to Stand Trial (CST) evaluations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing those in the forensic field outside of mental health a better understanding of competence evaluations and improved skill in navigating interdisciplinary interactions in these areas.

Competency hearings in criminal proceedings are among the most common of the forensic mental health examinations, and the numbers are on the rise.<sup>1</sup> But what exactly occurs when a CST evaluation is ordered for a criminal defendant? Many in the field of forensic mental health regularly perform these types of evaluations for the courts, making them seem “simple” or “easy” for those who do this on a day-to-day basis. However, it can be easy to lose perspective and expect that all of the court officers are experts in this matter as well.

Even more frustrating can be interacting with an attorney who reaches a roadblock in dealing with a client and concludes the person must be “crazy.” In fact, experts in the mental health field find it surprising to learn that attorneys often do not understand the core concepts behind a defendant’s CST. This is often due to the fact that competency hearings are relatively rare occurrences and, therefore, few have regular experience with them. Since mental health experts are the ones doing these evaluations, perhaps this presentation can share some knowledge regarding how the process is approached and hopefully shed some light on the core concepts involved.

However, we should not forget that many of our colleagues have difficulty with these evaluations as well. Evaluating a criminal defendant’s CST can often seem so routine and mundane that some can forget the degree of skill it takes to perform these examinations adequately. It is not uncommon to come across CST reports that are inadequate in their conclusions, poorly worded, and poorly reasoned. However, even experienced evaluators are not always immune to making critical errors in this process, especially in the face of difficult interviews.<sup>2</sup>

Through case scenarios, sanitized from actual evaluations from firsthand experience, this presentation will address some common but challenging scenarios that can arise during these interactions with defendants. Examples will include, but are not limited to: how to deal with the defendant who says “I don’t know” to every question, how to differentiate delusions from incidental bizarre utterances, and some of the strategies one can use to determine when a defendant with a mental illness is “unwilling” vs. “unable” to participate in the evaluation. Also addressed will be a basic review and understanding of malingering and some of the ways in which this can be detected in this type of examination. Also addressed will be some proposals aimed at helping to prevent mistakes that are common among trainees and some that even experienced evaluators may fall prey to.

This presentation seeks to both provide a unique perspective in this “bread and butter” part of the world of forensic mental health and to hear the perspectives of those in the legal field.

### Competence to Stand Trial, Criminal Competence, Forensic Psychiatry

### I30 Schema-Focused Therapy (SFT) in Forensic Patients With Personality Disorders: A Theoretical Model and Recommendations for Best Clinical and Preliminary Findings of a Multicenter Randomized Clinical Trial in the Netherlands

Melania Lugli, PhD\*, Science & Method, Reggio Emilia 42124, ITALY; Vivian Shnaidman, MD\*, 10 Vreeland Drive, Skillman, NJ 08558; Ariel V. Tabachnik, BS, Rutgers Robert Wood Johnson Medical School, Piscataway, NJ 08854; Alessandra Draicchio, PsyD\*, Science & Method, Reggio Emilia 42124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand, from a psychotherapy model, a forensic modification of SFT and will be equipped to make recommendations for its implementation in forensic clinical practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing how availability and development of SFT could be an effective treatment for severe personality disorders in forensic patients. The analysis includes three years' work with treatment professionals in the Netherlands to adapt and integrate SFT (also known as "Schema Therapy") in their work with forensic patients.

**Introduction:** SFT was developed by Jeffrey Young as a treatment for patients with personality disorders and other difficult-to-treat problems, who often show poor outcomes in other forms of therapy. In a multi-center randomized clinical trial that was completed in the Netherlands, patients with borderline personality disorder who were given SFT showed substantial improvements in their symptoms and functioning over a three-year course of treatment, as well as over subsequent one-year follow-up intervals. It was in this spirit that Bernstein, Arntz, et al. undertook the project of adapting and testing the efficacy of SFT methods in forensic patients with personality disorders.<sup>1</sup> Patients with severe personality disorders, such as those often seen in forensic settings, present special challenges because of their fluctuating emotional states. In the SFT model, these states are conceptualized as "Schema Mode." Recent research suggests that standard cognitive and behavioral approaches are only of limited effectiveness in forensic patients with personality disorders. SFT may provide a more effective alternative for forensic patients with personality disorders.

**Results:** From a SFT perspective, one can understand a forensic psychiatric institution as a complex group dynamic in which the patient's Schema Modes evoked corresponding Schema Modes in various staff members, including the therapist.

Schema Mode Work is the preferred form of SFT practice with more severe personality disorders, such as antisocial, borderline, narcissistic, and paranoid personality disorders, which are the most prevalent personality disorders in forensic settings. It is proposed that the Schema Mode model be expanded to include four new Schema Modes that appear to be common in forensic patients, beyond the 11 original modes that were proposed by Young and colleagues. Schema Modes often play themselves out in a predictable pattern. In some instances, these temporal sequences of unfolding Schema Modes may help to explicate the events leading up to and culminating in the commission of crimes.

From a Schema Mode perspective, it is hypothesized that highly psychopathic patients make prominent use of some of the most maladaptive and destructive Schema Modes; particularly predator, conning, self aggrandizer and bully and attack.

SFT principles and methods have been integrated into each phase of treatment from intake to discharge. The goal of Forensic SFT is to reduce the patient's reliance on maladaptive coping modes by: breaking through the patient's emotional detachment to access and heal their "Vulnerable Child Mode." The findings are preliminary, but they suggest that SFT may be a promising form of treatment for forensic patients with personality disorders. The apparent success of SFT patients in getting permission for leave is an important clinical indication that they are being judged to have a lowered level of risk.

**Conclusion:** This study's adaptation of SFT for forensic patients and recommendations for clinical practice represent a work in progress. They will need to await the findings from their complete sample before making more definitive recommendations regarding triage to SFT for forensic patients with antisocial, borderline, narcissistic and paranoid personality disorders. The ongoing research will provide more insight into the mechanism that explains the apparent effectiveness of SFT in forensic personality disorders patients, including some psychopathic patients. The group is engaging in a board research program to answer questions about the effectiveness of SFT in forensic populations, such as which patients benefit the most from SFT. It is hoped that this study inspires others to investigate other promising forms of therapy for forensic patients with personality disorders. Randomized clinical trials remain the goal standard for investigating the effectiveness of treatment. Without them, there is likely to be little progress in determining what is effective for this highly challenging group of patients.

## I31 Suicide in a Mountainous Territory: A Ten-Year Retrospective Survey

Serena Maria Curti, MD\*, Azienda USL Valle d'Aosta, Quart 11020, ITALY; Pasquale Beltempo, MD\*, Azienda USL Valle d'Aosta, Quart, Valle d'Aosta 11020, ITALY; Anna Maria Beoni, MD, SC Psichiatria, Azienda USL Valle d'Aosta, Aosta 11100, ITALY; Maurizio Castelli, MD, Azienda USL Valle d'Aosta - SC Medicina Legale, Quart 11020, ITALY; Valerio Ricci, MD, PhD, SC Psichiatria, Azienda USL Valle d'Aosta, Aosta 11100, ITALY; Mirella Gherardi, MD, SC Medicina Legale, Aosta 11100, ITALY

**Learning Overview:** After attending this presentation, attendees will understand a suicidal trend in the Italian region “Valle d’Aosta” during a ten-year-long retrospective survey.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about unusual aspects of a suicide phenomenon in a mountainous territory that can be a predisposing factor to social isolation and difficulty in health care access.

Italy is ranked 128<sup>th</sup> worldwide for suicide with 4.7 suicides per 100,000 people per year. Since 2013, the leading region for suicidal events in Italy is the “Valle d’Aosta,” a small mountainous area in northwestern of Italy. It is the least densely populated Italian region with only 39 residents per square kilometer. The majority of the population lives in an urban area along the central valley that leads to France and Switzerland, while secondary lateral valleys have only remote rural villages, which are frequently isolated during the long, harsh winters.

This presentation reports data about the total number of suicides in “Valle d’Aosta” from January 2009 to June 2019 collected through the analysis of death certificates and external examination reports archived in the Aosta Office of the Medical Examiner. Resulting data were checked with medical records of the regional hospital to identify cases with a psychiatric history.

The research yielded a total of 159 suicides (20.8% of all the violent deaths): in 43 cases, the decedent was female (27%) and in 116 male (73%) with an average age of 58.6 years (range 17–93 years). The greatest percentage of suicides occurred in the age group of over 65 years (44%). This figure was markedly higher than the national statistics (33%). For this reason, this study compared the older suicidal population (Group 3) with two younger groups (Group 1, aged 17–4 years, and Group 2, aged 35–64).

The male-to-female ratio was 12:1 for Group 1, 1.73:1 for Group 2, and 3.37:1 for Group 3. These data confirm sociological studies: there are distinct sex differences in suicide mortality and suicidality (i.e., ideation and/or attempt). Females report higher rates of attempting suicide, yet males are more likely to die from suicide, possibly because males use more lethal means.<sup>1</sup>

The suicide rate in the lateral valleys was significantly higher in the youngest group compared to the oldest one ( $p=0.0207$ ), probably due to social isolation and lack of a future outlook, more difficult to cope with by a younger population. Seasonality showed a slight homogeneous prevalence of suicides during spring, consistent with the literature on the subject.<sup>2</sup> Leading suicidal methods were hanging (53.8%), fall from height (19.2%), and railway suicide (11.5%), with no firearms cases, for Group 1; hanging (47.6%), fall from height (15.9%), and drowning (14.3%) for Group 2; and hanging (45.7%), fall from height (15.7%), and firearms (15.7%) for Group 3. Hanging is worldwide one of the most common suicidal methods, while the constancy of fall from height as second-most common suicidal method in the present sample can be related to the peculiar morphology of the mountainous territory with cliffs and bridges across waterways.

Among the decedents, psychiatric records were found in 19.2% of Group 1 (mostly bipolar disorder), 34.9% of Group 2 (mostly depression), and 18.6% of Group 3 (slight prevalence of depression over bipolar disorder). The leading method chosen by the psychiatric population of Group 3 was—by far—fall from height (53.8%). This can be explained with the major physical and mental impairment of this subgroup of psychiatric and elder subjects, as fall from height only requires a residual ambulatory ability and minor planning of the act. In all the psychiatric subgroups, no cases of firearms suicides were observed; this is consistent with the strict Italian statutory requirements for firearms licenses. The suicide place was more frequently the decedent’s home for all the groups. While home (70%) outdistanced the other suicidal places in Group 3, such as waterway (8.6%), and bridge (5.7%), in the other groups, the prevalence was slighter. The choice of an intimate place to commit suicide can be related with a higher sense of discretion in the elder population.

This presentation provides attendees with a greater awareness of the importance of social and geographical factors in the forensic reconstruction of the suicidal act.

### Suicide, Social Isolation, Elderly Population

### I32 Maternal Filicide: A Descriptive and Follow-Up Study of 17 Women Hospitalized in a French Secure Unit Over a 23-Year Period

*Sophie Raymond, MD\*, Umd Henri Colin - Hôpital Paul Guiraud, Villejuif Cedex, Val De Marne 94806, FRANCE*

---

**Learning Overview:** The goal of this presentation is to provide an analysis of maternal filicide and to specify the psycho-criminological profile of mentally ill filicidal mothers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving the understanding of maternal filicide associated with mental illness.

**Background and Goal:** Maternal filicide is defined as child murder by the mother. Many classification systems have been proposed, based on underlying motives such as altruism, mental pathology (often acute psychosis), an unwanted child, fatal maltreatment, and spousal revenge. Pathological filicide refers to cases in which the perpetrator has a major psychiatric illness. Related literature is sparse, especially concerning the evolution of offenders. The present work seeks to identify the main characteristics of mentally ill filicidal mothers and to assess their socio-clinical evolution after the filicide.

**Method:** Studied first was the sociodemographic, clinical, and forensic characteristics of all filicidal mothers admitted to France's Henri Colin secure unit between 1996 and 2018 (17 patients). The evolution of these patients was assessed after discharge from the secure unit, using questionnaires sent to the prisons or the psychiatric hospitals where the patients were transferred.

**Results:** Most filicidal mothers had a dysfunctional childhood, marked by emotional neglect, intra-familial violence, or social isolation. They were mostly married, with a mean age of 32 years. There was a history of abusing their own children in one-third of the cases. The victims' mean age was 6.2 years, and in several cases, multiple siblings were murdered. Half of the filicidal mothers had a history of psychiatric disorder. Three different diagnoses were found in this study: a mood disorder (41.2%), schizophrenia (41.2%), or a personality disorder (17.6%). The analysis of the act allows us to distinguish two subgroups of motivational profiles. In the first group, filicide is a defensive reaction to a perceived threat: the murder is committed under the influence of hallucinations or delirium. In the second group, filicide is linked to a context of separation, real or imagined. Several forensic and psychopathologic features associated to each profile are detailed. Concerning the evolution of these patients, this study underlines the suicidal risk (even years after the offense), therefore requiring long-term supervision.

**Conclusion:** The results of the present study on 17 mentally ill filicidal mothers are consistent with the literature. Two psychopathologic profiles are described. Several biases in this study disallow the generalization of these findings, and further studies are needed.

---

**Filicide, Infanticide, Forensic Psychiatry**

### I33 White-Collar Criminals: A Breed Apart?

Matthew W. Motley, MD, PhD\*, University of Southern California Institute of Psychiatry and Law, Los Angeles, CA 90050

**Learning Overview:** After attending this presentation, attendees will understand: (1) what crimes qualify as “white-collar;” (2) historical models of white-collar criminal behavior; (3) the differential treatment of white-collar criminals from other types of criminals; (4) the evidence basis for the notion of a distinct white-collar criminal; and (5) considerations relevant to evaluating defendants charged with white-collar crimes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) improving understanding of white-collar criminal behavior, and (2) attendees gaining confidence in performing forensic evaluations of white-collar criminals.

The phrase “white-collar” traditionally denotes professionals and others from the upper strata of society. This is reflected in the Federal Judiciary’s use of the term, which first appeared in a Federal decision in the 1930s, referring to a class of workers. In 1947, the United States Supreme Court used the phrase “white-collar” in *Fay vs. New York* to draw a distinction from the “manual laborer.”<sup>1</sup>

Edwin H. Sutherland, the sociologist who is generally credited with coining the phrase “white-collar crime,” defines it as “crime committed by a person of respectability and high social status in the course of his occupation” in his 1949 monograph, *White Collar Crime*.<sup>2</sup> The book highlighted these crimes because, Sutherland observed, they have a great cost to society and were absent from the study of criminology. *White Collar Crime* “ridiculed theories of crime which blamed such factors as poverty, broken homes, and Freudian fixations for illegal behavior.”<sup>3</sup> Sutherland observed that existing theories of criminal behavior were based on biased statistics and specifically neglected “business and professional men.”<sup>2</sup>

Following the publication of Sutherland’s highly influential book, white-collar criminals were no longer ignored. The term “white-collar crime” entered the vernacular. Sutherland’s direct influence on the Federal Judiciary is reflected by the fact that its very first use of the term is a citation of Sutherland’s book in the 1955.<sup>4</sup> Since the publication of *White Collar Crime*, the Federal Judiciary has generally accepted the importance of preventing and prosecuting white-collar crimes.

Ironically, despite Sutherland’s goal of a unified theory of criminality, over time, the idea of the white-collar criminal as a separate class of criminal—a breed apart—has proliferated in the popular imagination. There is the conception of white-collar criminals as typically “ingenious” (so described by the 2<sup>nd</sup> Circuit Court of Appeals in 1961) or even as criminal masterminds (for example, the presentation of Bernard L. Madoff in the media).<sup>5</sup> The idea of white-collar criminals constituting a separate class had become so widely accepted that in 1964, District Court Judge John W. Oliver wrote, “the past sentencing practices of the District Courts of the United States have, I think, not unreasonably produced a longstanding conviction that there is some sort of a distinction between ordinary crime and White Collar crime.”<sup>6</sup> The downside, for defendants, of the idea of white-collar criminals as being a breed apart from “ordinary” criminals is that it may sabotage potential defenses. To wit, a mastermind by definition understands the consequences of his/her actions.

Recently, when examining the 2008 United States financial crisis—an event that uncovered numerous examples of white-collar crime—scholars have rediscovered that such criminal behaviors can be motivated by factors common to other types of crime, including impulsivity, environmental influences, and rationalization. Only time will tell if this conceptual shift foreshadows increased prosecution of white-collar crime or, on the flipside, more successful defenses in terms of mitigation.

## I34 Pathways to Readmission: Investigating Patient Perspectives in a Forensic Psychiatric Setting

Shannon Kelley, PhD\*, William James College, Newton, MA 02459; Natalie Armstrong Hoskowitz, PhD\*, Bridgewater State Hospital, Bridgewater, MA 02324; Kerri Kane, MA\*, William James College, Newton, MA 02459

**Learning Overview:** The goals of this presentation, in addition to adding to the literature of this understudied population, are to provide a theoretical framework through which readmission issues may be viewed, provide a methodology for other facilities to follow in order to identify patterns to readmission, and present any results from this site that may be applicable and useful to other facilities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a theoretical and practical framework by which to identify and address patterns in forensic hospital readmission rates so that attendees may apply this information in their individual settings.

The average rate of readmission following discharge from a secure forensic psychiatric hospital is high, both in the United States and abroad.<sup>1</sup> This trend is associated with significant financial costs to involved systems, as well as substantial economic, social, and emotional ramifications for readmitted psychiatric patients and their caregivers, such that there is a critical need to better understand and respond to contributing factors. However, the circumstances of readmission to forensic hospitals have received relatively limited scholarly attention, particularly in comparison with the vast body of literature on violence risk. This is concerning given that rates of readmission are much higher than rates of violent offending among discharged forensic psychiatric patients.<sup>2</sup> Furthermore, existing research has largely focused on individual difference variables, and additional investigation is needed to identify potential environmental and systemic factors that may explain pathways to readmission and identify areas for intervention.<sup>3</sup> Prior research suggests that high-risk psychiatric patients are able to prospectively estimate their risk for future violence with a level of accuracy comparable to the leading violence risk assessment instruments.<sup>4</sup> Given that patient self-perceptions are a promising method of improving violence risk assessment, they are likely also a rich source of meaningful information on a broad range of factors relevant to risk of readmission. The purpose of the proposed study is to collect and analyze data from a pilot sample of forensic psychiatric inpatients in order to identify themes regarding the actual and perceived distal and proximal reasons for their readmission to a New England state hospital. The study aims to replicate previous research on individual characteristics of patients at risk for readmission and expand our understanding of the different trajectories and outcomes of forensic inpatients by investigating potential environmental and systemic risk factors.

Data will be obtained from qualitative analysis of in-person interviews of male inpatients from a strict security, New England state hospital. Data collection will likely be ongoing at the time of presentation. Interview questions were designed to capture individual factors that are theoretically and empirically linked to risk for readmission (e.g., substance use, symptom severity), as well as potentially relevant systemic and environmental factors (e.g., access to mental health resources, financial/housing issues, family discord). Data from the subject interviews will be analyzed using one or more qualitative approaches, including a thematic content analysis. This involves reviewing subject responses to define and name common patterns and to identify implicit as well as explicit themes. Results (as available) will be discussed in the context of practical applications for attendees, including how this methodology and any findings may be applicable to other sites for replication or for guidance in how to maximize community reintegration upon discharge. Limitations and future directions also will be presented.

### Readmission, Forensic Hospital, Patient Perspectives

## I35 Shame Among Forensic Patients and the Potential Moderating Roles of the Social Determinants of Health

Rusan Lateef, MSW\*, McGill University, Montreal, PQ, CANADA; Amina Ali, MD\*, New York, NY 10036; Fiona Moloney, BS\*, Toronto, ON M6J 1H1, CANADA

**Learning Overview:** After attending this presentation, attendees will have gained insight into the levels of shame among forensic psychiatry patients diagnosed with a psychotic disorder compared to psychiatry patients who are not involved in the forensic system. Additionally, attendees will understand the potential of various social determinants of health in moderating the levels of shame among these populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by allowing attendees to gain a deeper understanding of the complex social factors that contribute to feelings of shame among forensic psychiatry patients. By acknowledging the prominence of shame, as well as the socioeconomic factors that may contribute to shame, researchers and practitioners within the forensic community will be able to consider certain issues that they encounter with forensic psychiatry patients through a more holistic perspective. Considering shame and socioeconomic factors as part of treatment programs may help reduce levels of shame and, in turn, improve clinical outcomes by allowing patients to advocate for themselves and maintain a sense of hope throughout treatment.<sup>1</sup>

Shame is a painful feeling and experience of believing one is fundamentally flawed and involves a desire to hide the perceived damaged self from others.<sup>2,3</sup> Having a mental health diagnosis can increase the levels of shame a person feels, in part due to stigma surrounding mental illness, and more specifically stigma around psychosis.<sup>4,5</sup> Among individuals with schizophrenia, shame has been associated with negative clinical consequences, including increased paranoia and decreased adherence to treatment.<sup>6,7</sup>

Forensic psychiatry patients comprise a subgroup of individuals with psychotic illnesses who have been less studied with regard to shame. Due to possible further stigma related to contact with the criminal justice system, it was hypothesized that forensic patients diagnosed with a psychotic disorder would have higher levels of shame than patients diagnosed with a psychotic disorder without criminal involvement.

A multitude of socioeconomic factors can impact a person's life and health. These factors are known as social determinants of health, and negative experiences with a number of these factors, such as poverty, have been associated with increased levels of shame.<sup>6,7</sup> It is hypothesized that positive experiences with these factors will lower the levels of shame a patient feels, and negative experiences will increase levels of shame.

This presentation will present findings on levels of shame among patients with schizophrenia and other psychotic disorders, measured using the Test of Self-Conscious Affect (TOSCA-3S). Levels of shame will be compared between patients with a diagnosis of a psychotic disorder who are in the forensic system versus those who are not. Results from moderating analyses will present the impact of the social determinants of health on levels of shame. These results will help clinicians in forensic psychiatry to better tailor treatment programs to their forensic psychiatry patient populations.

### Shame, Schizophrenia, Social Determinants of Health

### J1 A Fast Examination of Counterfeit Pharmaceutical Packaging Through Laser-Induced Breakdown Spectroscopy (LIBS) and Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) Spectroscopy

Emily A. Haase, BA, BS\*, West Virginia University, Morgantown, WV 26506; Mandy Ho, BS, West Virginia University, Oglebay Hall, Morgantown, WV 26506; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** The goal of this presentation is to inform attendees about the advantages, feasibility, and preliminary classification ability of LIBS and ATR/FTIR for the purposes of counterfeit pharmaceutical packaging examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a fast, portable, non-invasive, sensitive technique for the examination of counterfeit pharmaceutical packaging. In analyzing counterfeit and authentic pharmaceutical packaging, this technique has shown correct classification rates of over 90% using quadratic discriminant analysis for a variety of ink colors and paperboard substrates. These rates indicate that this technique is an encouraging possibility for the analysis of counterfeit pharmaceutical packaging as well as pre-established visual examination methods.

The global production and sale of counterfeit pharmaceuticals present a substantial health and economic risk, affecting thousands of people and costing billions of dollars every year. While covert and overt anti-counterfeit technologies (such as Radio Frequency Identification [RFID], holograms, and security ink) exist to prevent the accurate replication of authentic pharmaceuticals, their cost considerably prevents widespread implementation. As sophisticated counterfeit pharmaceuticals become more difficult to discriminate from their authentic counterparts by simple visual inspection, there is a need for alternative spectrochemical methods for the identification of counterfeit pharmaceuticals and the associated packaging. These spectrochemical methods should ideally have a fast, accurate, and mobile instrument available for rapid on-site detection. LIBS and ATR/FTIR are quick, sensitive, portable techniques to identify the chemical composition of the packaging and packaging ink. LIBS is an inorganic, quasi-non-destructive technique, where only a very small portion of the sample is ablated from the surface, while ATR/FTIR is entirely non-destructive and detects the organic compounds within the sample. Current methods for the examination of suspected counterfeit pharmaceuticals involve the analysis of the Active Pharmaceutical Ingredient (API) and of the pharmaceutical packaging. The investigation of the packaging itself, as opposed to the pharmaceutical, is particularly important in cases of bulk suspected counterfeit pharmaceuticals in which the pharmaceuticals are missing, or when only the packaging has been altered.

In this study, over 150 counterfeit and authentic pharmaceutical packaging samples were analyzed using LIBS and ATR/FTIR. Seven different colors of ink (brown,  $n=21$ ; pink,  $n=45$ ; green,  $n=31$ ; red,  $n=46$ ; yellow,  $n=74$ ; blue,  $n=92$ ; and black,  $n=122$ ) and the paperboard material of the packaging ( $n=147$ ) were analyzed. Each sample was run with eight replicates in different locations to account for variation within the sample; duplicate control samples analyzed on different days were used to assess inter-day and intra-day variations; and samples from the same lot or printed with the same ink/paper/printer system were measured to assess the intra-lot variability. The study included the analysis of packaging from common pharmaceutical products, including hormones, antibiotics, and analgesics. Six machine learning and statistical methods ( $k$ -nearest neighbors, neural network, naïve Bayes, random forest, quadratic discriminant analysis, and linear discriminant analysis) were used to evaluate the methods' capabilities to differentiate between the authentic and counterfeit sample sources and to correctly classify the samples. Fifty percent of the samples were used to train the machine learning classification algorithm; the other half were used to test the classification algorithm. For combined LIBS and ATR/FTIR, the successful classification rate within same-color datasets was over 70% for all techniques and over 90% for the quadratic discriminant analysis technique. These correct classification rates indicate that a combined LIBS and ATR/FTIR technique is auspicious for the non-invasive, rapid (few minutes), on-site examination of pharmaceutical packaging.

#### Counterfeit Pharmaceuticals, LIBS, ATR/FTIR

## J2 Surface Roughness Measurement Techniques Using Pen Pressure Measurement in Signatures and Usability for Determination of Identity

Dilara Oner, MS\*, Istanbul University-Cerrahpasa, Istanbul, Fatih 34098, TURKEY; Gursel Cetin, PhD, Istanbul University-Cerrahpasa, Istanbul, Fatih 34100, TURKEY; Derya Dispinar, PhD, Istanbul Technical University, Istanbul, TURKEY

**Learning Overview:** After attending this presentation, attendees will have better understand the contributions of measuring pen pressure numerically with microscopes measuring surface roughness in determining signature identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the usage of pen pressure measurement, which has an important place in the field of writing and signature examination, and by providing a study on an important subject, the measurement with 3D microscopes.

One of the diagnostic methods used in forensic signature examination and determination of identity is the depth analysis of the stroke and the changes in that value of depth.<sup>1,2</sup> Generally, the methods used to evaluate the depth and depth changes of the stroke do not yield numerical values but rather remain at the level of subjective evaluation.

In this study, the aim is to investigate the use of microscopes that are generally used in the field of engineering for surface roughness measurement and to determine whether the numerical values obtained can play a role in identifications in forensic signature investigations.

The Leica® DVM-6 3D microscope was used to measure the depth of the stroke in this study. Eleven participants were selected, and one was asked to sign their signature three times in three different conditions to create the questioned signatures. A clipboard was used as the first substrate under a blank paper. After that, one paper was placed on the same clipboard as a second condition. Finally, as the third condition, two papers were placed on the clipboard under the blank paper. Five female and five male subjects were asked to imitate the questioned signature three times by only looking at it—freehand simulation. This imitation was performed in all three conditions. Then, three dots were selected from the genuine signatures—those of the person who was imitated them. The maximum depth of the stroke was determined by measuring from these points. The maximum value of the stroke depths was determined for each subject separately by measuring at the same points in the imitation signatures. For each subject, it was investigated whether the values determined from the same points of the signature showed a statistically significant difference with the questioned signature. The data obtained were analyzed in *t*-test using SPSS 23 software. The calculations were performed within a 95% confidence interval.

In the three signatures of the first condition, statistically significant differences were found in six subjects compared to the questioned signature in measurements made from three points (total nine points). In the three signatures from the second condition, statistically significant differences were found in three subjects compared to the questioned signature in measurements made from three points (total nine points). In the three signatures from the third condition, statistically significant differences were found in four subjects compared to the questioned signature in measurements made from three points (total nine points). The mean of all three conditions (mean of 27 points in total) shows statistically significant differences in seven subjects compared to the questioned signature.

It is never possible to reach definitive conclusions in determining the identity of signatures. As matter of fact, when experts write the results, they never say that this signature is the product of a particular person's hand. One of the criteria used in this determination is the depth of the strokes that make up the signature. In addition, it is important to show this depth numerically with the changes created by depth. In practice, experts will never be able to decide on the identity of a signature with the values they achieve. However, they will have an important criterion in establishing an opinion. Herein, it is necessary to evaluate the values obtained, together with other findings, and to interpret them correctly.

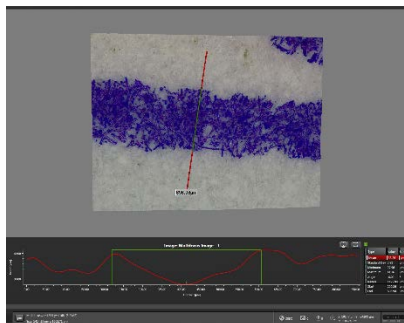

Figure 1: Pen pressure depth analysis sample result that was used in study.

### J3 Use of Raman Spectroscopy in Forensic Sciences to Authenticate Artworks Seized by Operation Lava Jato

*Carla D. Feliciano\**, Federal University of Paraná, Curitiba, Paraná, BRAZIL; *Evaldo Ribeiro*, Federal University of Paraná, Curitiba, BRAZIL; *Ismael Heisler*, Federal University of Paraná, Curitiba, BRAZIL; *Matheus Radaelli*, MS, Federal University of Paraná, Curitiba, BRAZIL; *Marco A. Geus*, Technical Sector of the Federal Police, Curitiba, BRAZIL; *Ricardo Mascarenhas*, Technical Sector of the Federal Police, Curitiba, BRAZIL; *Fernando Comparsi*, Technical Sector of the Federal Police, Curitiba, BRAZIL; *Fábio A.S. Salvador*, PhD, Brazilian Federal Police, Curitiba, Paraná 80030370, BRAZIL

**Learning Overview:** The goal of this presentation is to bring awareness to attendees regarding investigating a money laundering and bribery scheme involving numerous public figures, and state and private companies.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that samples that present luminescence are currently being discarded as an evaluation method. This study proposes that through the luminescence presented in the Raman spectra, it is possible to differentiate works of art.

As has been widely reported by national and international media, Operation Lava Jato is a set of investigations underway by the Brazilian Federal Police, aimed at investigating a money laundering and bribery scheme involving numerous public figures as well as state and private companies.

During the operations conducted, the number of works that were seized in the past four years were greatly highlighted. By 2016, around 230 works of art had been seized, indicating that the use of works of art has been recurring as a form of money laundering. The choice of works of art in this scheme may be due to the value given to a certain work, the value that can be obtained in an auction, and the lack of technical criteria to say if these works are genuine or not, because the sales market is not regulated as it should be.

After the large number of apprehensions, there was the need to look for techniques in which it was possible to analyze the authenticity of the works. In the past, this work was performed by art specialists, who through visual analysis determined whether a work was authentic or not; but the Federal Police realized that just a visual analysis was not enough, and that it was necessary to use a method that would not be challenged in the future and that would maintain the integrity of the work in question. The Technical Scientific Sector of the Federal Police Superintendence Paraná, headquartered in Curitiba, sought qualified people from universities in optical techniques, preferably non-destructive, such as the Raman spectroscopy technique. A partnership was then made between the Technical Sector of the Federal Police (STPF) and two universities: the University of São Paulo (USP) and the Federal University of Paraná (UFPR).

The work in question was performed by the Federal Police's Scientific Technical Sector with the UFPR, and dealt with the analysis performed on four works of art that have been questioned by the Federal Police regarding their authenticity with a possible signature of the painter and diplomat, Sergio Telles. These works, called Questioned Frames 34, 35, 36, and 113, are under the custody of the Oscar Niemeyer museum, also located in the city of Curitiba in Paraná.

Samples were collected by scraping using a 30G ½ needle. The Raman scattering experiments were performed using a Raman Witec Alpha 300 confocal microscope with an excitation laser operating at 532nm and focused by a 50x lens.

Analyses of the various samples were performed, visually searching for similarities between the pigments of the four frames. The presence of the pigments was identified as: blue, white, orange, brown, and green in both frames; there were cases of a frame having more colors than those mentioned, which were not discarded, because there is future intention of creating a database of national pigments. After determining the colors present, the analysis was performed by color similarity.

In some cases, the Raman spectrum was clearly visible, but in most of the spectra, the luminescence was present, so by analyzing the line shape and the light emission peaks, this study could find other components present in the paintings, as in the case of yellow, orange, red, and green contributions in the samples.

In cases in which the spectrum was clearly visible, it was possible to identify the similarity to the violet diaxazine pigment, which was present in several of the samples. The oranges and browns in two of the works show a great chance of compatibility, in addition to the white present in three paintings, which presented a luminescence characteristic already expected to be this pigment.

From the analysis performed, it is possible to state that there are great similarities between the pictures. The next step to be taken is to perform measurements related to the standard frame, certified by Sérgio Telles himself, compare these with the results already obtained by the questioned frames, and use the Raman technique with infrared excitation laser to decrease the effect of luminescence.

#### Authentication, Artworks, Operation Lava Jato

### J4 The Authenticity of Questioned Pretty Good Privacy (PGP) -Signed Digital Documents

Martin S. Olivier, PhD\*, University of Pretoria, Pretoria, GP 0028, SOUTH AFRICA

**Learning Overview:** The goal of this presentation is to question the authentication of digitally signed documents and whether they will stand the test of time based on a case study involving 55 PGP-signed documents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the many problems encountered (primarily obtaining a public key or finding grounds for trusting a public key). This presentation also points toward basing trust in keys on known good exchanges where the key was used.

In principle, authentication of digitally signed documents is a simple computational process. PGP was created in 1991 as a cryptographic tool that enabled users to communicate privately, but also to achieve a range of other functions, including the ability to sign documents.<sup>1</sup> For over three decades, PGP (or PGP-compatible software) was a standard tool for users who wanted to encrypt and/or sign documents. The open source implementation (the GNU Privacy Guard [GnuPG]) is based on the OpenPGP standard.<sup>2</sup> This presentation uses the term PGP to refer to any implementation PGP of functionality.

While other (better) solutions than PGP have been developed, none have achieved the widespread acceptance and name recognition PGP has. The shortcomings of PGP are well known, but when used correctly, PGP remains useful.<sup>3</sup>

One question about authentication of digitally signed documents is whether they will stand the test of time. This presentation presents a case study in which 65 documents signed with PGP have been examined to determine whether their authenticity can (still) be established. The dates of these documents range from July 22, 1998, to May 15, 2018. The primary tool used for signature examination was Gpg4win—an implementation of GnuPG for Microsoft® Windows®. Gpg4win version 3.1.10 released on July 14, 2019, was used.

The 65 documents were not selected randomly; thus results cannot be generalized. Moreover, problems encountered can be seen as predictable, based on PGP critiques. However, an empirical case study provides insight into the relative prevalence of such expected problems.

The selection of older documents was intentional: The forensic document examiner is often confronted by authenticity of older documents, such as a last will or an old contract. The first problem (predictably) stemmed from the age: the signatures were associated with defunct email addresses.

Consider a specific example: one of the files examined was signed by the signator on October 19, 1998. The key remains available on public key servers, even though the associated address has not been used for well over 15 years. The key is not signed by a third party; the signator removed the key long ago from his keyrings. Backups were found, but were corrupted. Two options existed (claim ownership or sign the key). However, both rely on the signator's recollection of key authenticity. Both lead to "successful" verification of the document.

Some general remarks can be made about observations in this case study. About half of the keys used to sign documents were available from key servers. However, none of the keys were signed by third parties. Hence, key servers were not useful to find a chain of certificates between any key used and the a signator's key. Availability of about half of the public keys made it possible to proceed with verification if grounds existed to trust the public key.

As noted, many keys are linked to obsolete email addresses, which complicates signer identification. Users arguably do not have much information available. In any case, relying on the user's cooperation enables repudiation. Web searches were performed for key fingerprints but yielded no useful information for any search.

Another problem: about half the keys found on key servers had expired. Gpg4win in such a case reports "The signature is invalid: Signing certificate is expired." GnuPG 1.4.20 and GnuPG 2.1.11 on Linux® produced potentially more useful results (with the caveat about trusting the key). It reports "Good signature", but warns the user (twice) that the key had expired.

The problem of key authenticity is pervasive. One promising possibility remains: where the key has been used in other exchanges known to be valid, such knowledge may be used as grounds to trust the key. An email interchange between two users who know one another is one possible example.

#### Digital Signatures, Questioned Digital Documents, PGP

### J5 What's Old Is New Again: Portable Instant Photo Systems and Questioned Documents Redux

*Javaid Khan\*, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will have a more thorough understanding of currently available instant photo technologies and features associated with those prints.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) increasing awareness of instant photo technology; (2) offering insight into photo production processes; and (3) illustrating how these prints could be identified in questioned documents.

Invented in the 1940s by Edwin Land, Polaroid® dominated the instant film market for decades, up until it was uprooted by 35mm film and emerging digital formats in the 1990s. After an extended lull in popularity, the incorporation of digital photography with modernized printing technologies led to a resurgence of an updated form of the once-considered vintage instant film system. Although Land's invention has had staying power in today's society, the reality remains that the newer generation of document examiners may have limited experience with instant photography systems. As the potential for improved technology in this area continues to evolve, there is a need for this knowledge gap to be addressed in order to ensure thorough examination of identification documents.

Documents associated with identity often include a photograph. The properties of these documents are dependent on a number of factors, including the issuing country, the requirements at the time of issuance, and the document's purpose for use. Exposure to a broad range of document types has increased due to the breadth and accessibility of international travel and migration, which has in turn led to the necessity of examining all types of unfamiliar identity documents. In the event that a document becomes questioned, identification of production technologies is often required. To properly analyze the value of any findings, awareness of currently available print process technologies, including instant films and their associated features, should be taken into account.

The availability of these low-cost and high-quality instant film systems provides examiners with another factor for consideration as to how a document might have been constructed. Traditional instant film development was based on silver halide exposure with reagent development, producing the expected low-quality instant print. The more current instant photo systems utilize digital photography with integrated reagent development film, or form factor thermographic print processes producing higher-quality images. As a result, more regard should be given to alternate sources of photograph production.

The scope of this presentation will be limited to technology suitable for portrait photo production, as is typically encountered in identity documentation. A non-exhaustive selection of form factor printer devices will also be used, limited to popularity of use. This presentation will provide attendees with an overview of currently available portable instant print photo systems, including portable instant printers, the properties associated with these various technology types, and features that could be used to aid in identifying these products.

---

#### **Questioned Documents, Instant Photography, Print Process**

### J6 Delving Into Digitally Processed Documents: How Does Optical Character Recognition (OCR) Impact Documents?

*Nina Harnarine, BSc\*, Forensic Examiners Inc, Toronto, ON M4W 3H1, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will understand the impact of OCR technology on various documents containing signatures, writing, different writing instruments, and text typed on a typewriter.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on how OCR technology may impact a document that is being examined.

OCR or optical character reader is the process of converting images containing text into machine-encoded text. The images can be scanned or photographed, and a software application converts all text components. OCR integrates three research fields: pattern recognition, artificial intelligence, and computer vision.

In the digital age of artificial intelligence and automation, OCR has become popular for various applications. Documents containing text that have undergone OCR processing can be electronically searched, edited, stored, and uploaded. In addition, this digitized text can be used in machine processes, such as cognitive computing, text-to-speech, machine translation, and text mining.

Forensic Document Examiners (FDEs) may be asked to examine digitally processed documents. Some businesses are shifting toward becoming paperless. This shift within some businesses has resulted in FDEs examining more digitally processed documents. With the aid of technology, four individuals from four corners of the globe can all sign one document without ever having to sit around the same table. Signatures from four different individuals would require digital processing of the document, likely scanning and re-scanning of the document. What does this document look like after undergoing multiple digital processing steps?

This research sets out to determine how OCR technology impacts documents with text. There are numerous OCR software applications available. The documents in this research project were processed with the OCR function in Adobe® Acrobat® Pro DC. How does Adobe® Acrobat® Pro DC OCR read different signature styles? How are these same styles of signatures reproduced when scanned and converted into a text document using the Adobe® Acrobat® Pro DC?

Documents can be written using various writing instruments. Is there any difference in how the Adobe® Acrobat® Pro DC OCR function reads and converts the text for different writing instruments?

Some documents contain a combination of typed and written text. How does Adobe® Acrobat® Pro DC OCR read cursive or printed or mixed (both cursive and print) text? How are these same writing styles reproduced when scanned and converted into a text document using the Adobe® Acrobat® Pro DC?

One may want to digitize their old records, including documents that have been composed on a typewriter. How does Adobe® Acrobat® Pro DC OCR read typewritten documents? How are typewritten documents reproduced when scanned and converted into a text document using the Adobe® Acrobat® Pro DC?

This research will also examine some of the mobile OCR applications, including Scanbot®, Dropbox®, Adobe® Scan, Microsoft® Office Lens, and Google® Keep.

In this digital age, FDEs should be cognizant of how digital processing techniques such as OCR may impact documents. Artifacts and digitization can be observed in digitally processed images. Understanding how the artifacts or digitization occur is important. If no original document is available, the best available copy should be requested. If only a digital file is available, the digital file in its original file format should be submitted for examination. An FDE may be asked to examine a hard copy of a document that has undergone multiple digital processing. It is important that FDEs understand the evidence that digital processing applications, such as OCR, may leave behind on the document and how the digitally processed document may differ from the original or even the first-generation copy.

#### Optical Character Recognition (OCR), Document Processing, Scanned Document

## Questioned Documents—2020

---

### J7 Application of the “Value of Evidence” Approach in Forensic Document Examination

*Miriam Angel, MS\*, Los Angeles Police Department, Questioned Documents, Los Angeles, CA 90032*

---

**Learning Overview:** The goal of this presentation is for attendees to acquire a working knowledge of how the “value of evidence” approach can be applied to document casework through illustration of theory basics and mock case examples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing modifications to the current interpretation method and reporting conventions that can help elucidate the evaluation process and advance forensic document examination as a science.

Numerous publications in the scientific, academic, and legal communities have described the need for forensic conclusions to be scientifically justified, with an aim toward balance and transparency. The widely suggested method for evaluating and reporting forensic findings requires that the examiner consider the value of evidence in terms of the likelihood of observing the evidence given at least two competing propositions, within the framework of the case information. This is opposed to expressing opinions on the likelihood of the propositions themselves. It is advisable that examiners be familiar with the logic behind the different types of conclusion verbiage so they can speak intelligently when this topic inevitably finds its way into the courtroom.

This presentation will involve discussion of the theory behind the “value of evidence” approach and how evaluation under this method would differ from the traditional method of evaluating document evidence. Sometimes referred to as the “logical approach,” interpreting evidence and expressing conclusions in terms of the “value of evidence” means the examiner considers the likelihood of the evidence given each of a pair of propositions and then weighs the difference in the magnitude of support for each of those propositions. By explicitly considering each proposition, the examiner makes clear that each side of the dispute was given due attention as well as how much support was qualitatively assigned to each.

Using a mock case, attendees will be guided through each step of the examination process, from stating the relevant propositions to outlining the expectations of observations under each proposition to evaluating the likelihood of the evidence given each proposition, and then, finally, to expressing an opinion. Assigning individual likelihoods and consolidating those likelihoods into a logically based conclusion statement will be discussed. How those assignments can be justified will also be advised. In this presentation, the “value of evidence” conclusion will be given in qualitative terms rather than numerical ones.

---

#### **Evaluative Reporting, Conclusion, Document Examination**

### J8 Characteristics Observed in Impressions Produced by Signature Stamps

*Jan Seaman Kelly, BA\*, Forensic Dynamics LLC, Las Vegas, NV 89147*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the various materials used for stamp dies and the characteristics observed in the impression of a signature stamp.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating attendees of the materials used for the dies of facsimile signature stamps. Having an understanding of the characteristics observed in an impression may assist the examiner during the examination in determining the type(s) of rubber stamp(s) that could have produced the signature stamp impression.

The definition of signature has changed as it was limited to a handwritten name or mark made by the individual onto a document as proof of identity and intent. The legal requirement that a signature had to be handwritten was changed when facsimile signature stamps began to be used in business. With the development of the computer, electronic and digital signatures are heavily relied upon to complete business transactions. The impact of digital technology has impacted the manner in which individuals sign their signature on personal and business documents. Even though this has impacted the number of facsimile signature stamps being used, the forensic document examiner may encounter a case involving a facsimile signature stamp as this remains a viable option to sign one's name to a document.

Facsimile signature stamps are used to sign a myriad of documents, including business or personal letters, checks, invoices, legal documents, certificates, etc. Signature stamps are easy to use and guarantee a perfect impression of the signature every time. The use of a facsimile stamp signature on a document implies the same intent and legality as if it was an original inked signature manually produced by the individual. The advantage of using a facsimile stamp instead of manually signing the signature is one of convenience. The disadvantage of using facsimile stamps is the stamp can be stolen, duplicated, and used for criminal activities.

The examination of a signature stamp impression or a facsimile signature stamp is within the scope of forensic document examination. The dies of facsimile signature stamps include laserable rubber, photopolymer, and flat die. Water-based stamp ink is primarily used for rubber and photopolymer dies while flat die stamps use oil-based ink. Characteristics observed in the signature stamp impression can be clues as to the type of die used to produce the impression. For example, laserable rubber and photopolymer dies are raised and can leave an outline or "squeegee" appearance on the edge of each letter in the signature while the flat die stamp will not leave an outline.

In modern business, one acceptable method of signing a document is the facsimile signature stamp. This presentation will discuss the types of die materials used and the related characteristics and defects that can be present in the stamp signature impression.

---

**Forensic Document Examination, Signature Stamp, Stamp Die Material**

### J9 Testing the Perceptual Accuracy of a Subject's Ability to Identify Their Own Handwritten Numbers and Words

*Jacqueline Joseph\*, Portland, OR 97205*

**Learning Overview:** After attending this presentation, attendees will understand that some people cannot recognize their own handwriting and handwritten numbers. This presentation will illustrate an original research method that acquires data for use in overcoming a general assumption that people can successfully recognize their own handwriting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering insights about a person's subjective statement of "That's not my handwriting" or "It looks like my handwriting, but I don't remember writing it" by applying forensic handwriting identification methodology to show evidence that it is their handwriting. This presentation will illuminate the issue of eyewitness error in which a subject is unable to identify their handwritten words or numbers in records and other documents.

This presentation will illuminate the issue of eyewitness error when a subject denies, is unable to, or mistakenly identifies his/her handwritten words and/or numbers in cases involving: (1) altered medical records; (2) employment logs/timesheets; (3) legal documents; and (4) other questionable handwritten entries. Knowing these insights may become the basis of serving the truth when a subject cannot recall or is unable to accurately recognize and successfully identify the questioned handwritten numbers and/or words.

Warned of the unreliability of eyewitness testimony, someone may be confounded when comparing the statement of his suspect, "That's not my handwriting" with the proffered expert opinion of "The suspect wrote it," or vice-versa. Outside the specialty of Forensic Document Examination (FDE), some people believe that they can successfully identify their own handwriting.

Prompted by credibility challenges of expert handwriting opinion, a small population study with 23 subjects was designed and conducted for the purpose of securing data on the success of subjects and their ability to recognize their handwriting and handwritten numerals.

Handwritten numbers are written similarly in various languages; therefore, they cross borders, allowing subjects of many nationalities to participate in the study. Additionally, the following confidence choices were included: "I'm 100% certain," "I'm fairly certain," "I'm guessing/I don't know," and "My writing is not observed on this exhibit."

In summary, the results of this study revealed that 98% of the subjects successfully identified their handwriting, while 50% of the subjects failed to successfully identify their handwritten numbers. The handwritten numbers used for this study included: "April 15, 2007," "1948," "78910."

In conclusion, because the Forensic Document Examiner's expert opinion is tested for reliability based on the sufficiency of evidence coupled with the examiner's skill, knowledge, and experience, the awareness of the results of this study may become an important factor for use as the basis for forming a reliable opinion.

There is much to be gleaned from this study. For example, statistics regarding the subjects' confidence choices may be tabulated for an expanded version of this study. Additionally, it would be insightful to acquire the subjects' confidence choices before the study's purpose was revealed, and prior to the handwriting of the phrases and numbers. Furthermore, subjects' bias or intentional disguise could factor into the overall dilemma of conflicting opinions on the same evidence.

The preliminary data from this small population study suggests additional research would be fruitful.

---

#### **Eyewitness Error, Opinion Conflict, Handwriting Perception**

### J11 Education and Training in Forensic Document Analysis Offered as an Elective Course to Undergraduate Forensic Science Students in Turkey

*Sevil Atasoy, PhD\*, Uskudar Universitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY; Zekai Genç, PhD, Üsküdar University, Istanbul, Üsküdar; Kaan Yilancioglu, PhD, Üsküdar University, Istanbul, TURKEY*

**Learning Overview:** After attending this presentation, attendees will understand how an elective course in the field of forensic document analysis has been offered at Istanbul's Uskudar University to undergraduate forensic science students by academicians with a professional expertise in the field for more than 20 years.

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community by presenting details about the one and only teaching and training program about document analysis at the undergraduate level in Turkey.

In Turkey, as with every developed country, it is necessary to instruct any interested candidate well equipped with knowledge and experience in forensic science at the undergraduate level to prepare them for conducting scientific research, for developing novel methods and instruments, or for future positions, such as private or government crime laboratories. Transforming expert establishments, whether private or governmental, and crime laboratories into organizations that are accredited and well-known in Europe and around the world, and enabling the export of high technology heavily depends on the aforementioned. The Forensic Science program under Uskudar University's Faculty of Engineering and Natural Sciences is the first and still the only one in Turkey, offering BSFS degrees. The learning content was prepared in accordance with the Forensic Science Education Programs Accreditation Commission (FEPAC). FEPAC is a body of the American Academy of Forensic Sciences (AAFS), founded in 1948, which currently has more than 6,500 members and is the only association in the world that accredits undergraduate and graduate education.

Efforts to strengthen the reliability of the methods of forensic practitioners have led to attempts to create standardized teaching and training programs, especially in the field of pattern recognition; document analysis and signature identification is one such field. An elective course is offered in the fifth and sixth semester to teach the basics of this field and train the students accordingly. The course does not train the student as a document examiner and in no way certifies or qualifies the student to conduct questioned document analysis for the court. The syllabus encompasses: (1) the functions and responsibilities of questioned document examiners in the criminal justice system; (2) the process for obtaining exemplars, types of document examination (e.g., handwriting, typewriting, inks, erasures), collection and preservation of evidence as well as courtroom procedures; (3) the theoretical and practical aspects of handwriting as forensic evidence; and (4) the production of normal and false handwriting, variables in handwriting production, standards of comparison, identification theories, examination methodologies, expression of conclusions, and challenges to professional practice. Students have hands-on training according to the best practice manuals, standards, and guidelines published by the Scientific Working Group for Forensic Document Examination (SWGDOC), the American Society for Testing and Materials (ASTM) E1732, and the European Network of Forensic Science Institutes (ENFSI) and will learn the operation and practical use of various instrumentation used in the field, such as the Video Spectral Comparator (VSC) 8000 and Leica® Z6 Stereo Macroscope and Leica® FSC Comparison Microscope.

#### Document Analysis, Signature Identification, Forensic Science Education

### J12 Investigating the Interlaboratory Reproducibility of Magnetic Flux Measurements of Toners

*Carrie Polston, BA\**, Sam Houston State University, Huntsville, TX 77341; *Williams Mazzella, PhD*, University of Lausanne, Lausanne-Dorigny, 0 CH-1015, SWITZERLAND; *Patrick Buzzini, PhD*, Sam Houston State University, Huntsville, TX 77340

**Learning Overview:** After attending this presentation, attendees will better understand the potential for use of a quantitative magnetic flux measuring device to differentiate between black and white toner-printed documents from different sources. Attendees will gain an understanding of the magnetic characteristics exhibited by toner-printed documents and how to employ magnetic flux measurement techniques during comparative examinations between questioned and reference printed texts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a method for rapidly screening black and white toner-printed documents, offering the opportunity to evaluate the subsequent need for more time-consuming or destructive methods.

This study was conducted to address questions raised by previous research into the magnetic properties of toner and the use of magnetic flux measurement devices. Specifically, this research addresses questions related to the reproducibility of numeric magnetic flux measurement results between different analysts from different laboratories using similar instrumentation. The hypotheses advanced were that the difference in magnetic flux measurement values produced by different devices is not significant, or alternatively significant, when applied to the same sample.

To test the hypothesis of interest, samples were prepared that contained a standardized test site with a grid of squares of known area and controlled properties to minimize the chance of hysteresis and other induction current spatial effects. The study sample set consisted of three toner samples for each participating laboratory as well as a standardized negative quality control sample. These samples were analyzed by the issuing laboratory and three participating laboratories using a standardized methodology guide optimized to control for hysteresis and to minimize operator-introduced random error. Following this methodology guide, each laboratory conducted testing on positive and negative quality control samples at instrument startup before collecting 28 replicate measurements on each toner sample. The toner samples were measured by the originating laboratory prior to issuance to the participating labs to facilitate the direct comparison with the results of the participating laboratories. The values obtained for each toner sample by each participating lab were then compared with the values obtained for that same sample by the issuing lab via a paired *t*-test to check for significant variation in the results before and after performing comparisons between the results of all of the laboratories and using Analysis Of Variance (ANOVA).

It was found that there was a significant difference in magnetic flux measurement capability between similar devices, and the values produced for the same sample were significantly different. Some of the participating laboratories were not initially able to follow the standardized methodology guide when it was presented, as the software and sensor versions for their instruments were significantly different and not originally set to conduct the requested measurements. These investigations have found differences in the instrument serial number to be a significant source of variability in magnetic flux measurement data. For effective implementation of magnetic flux measurements in forensic laboratory settings, it is advisable to ensure that measurements are conducted using the same device when their numeric results will be the basis for comparisons. Numeric measurements of the magnetic flux of toners can be of value for questioned document examiners due to their non-destructive nature and their rapid collection; however, it is important to ensure that the methodology used controls for sources of variation, including differences in the device and software design.

#### Questioned Documents, Toner, Magnetic Flux

### J13 Decipherment of Latent Handwriting Impressions: Point/Counterpoint

Thomas W. Vastrick, BS\*, Apopka, FL 32703

---

**Learning Overview:** After attending this presentation, attendees will understand what should be expected of a forensic document examiner concerning the decipherment of images raised through an Electrostatic Detection Device (EDD) or special lighting, what they should be able to do, and what limits they should impose, if any.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing a consensus methodology for use in everyday casework involving the decipherment of latent handwritten images so that the resulting conclusions will be more reliable and more uniform. In addition, accuracy will be increased by a consensus understanding of the limitations imposed on such procedures.

Forensic document examiners commonly, but not exclusively, conduct examinations of latent handwriting impressions utilizing an EDD. This device is the best practice for examinations in which use of the device is possible. Lighting from various angles are also used as an enhancement to the use of EDD and sometimes, by various necessities, as a substitute. Either method is applicable to the theme of this presentation.

The Scientific Working Group for Forensic Document Examination (SWGDOC) is an organization dedicated to developing and publishing discipline-wide standards in forensic document examination. One such standard is titled *SWGDOC Standard for Indentation Examinations*. In this standard are statements as to decipherment of indentations of latent handwriting impressions in Section 8.3 as follows: 8.3.—once examinations and evaluations have been completed, reports may include the following types of conclusion(s), opinion(s), or finding(s): 8.3.3.—the text of deciphered indentations.

A question arises as to: (1) whether a forensic document examiner is trained to decipher handwriting; (2) whether the experience of a forensic document examiner qualifies one to decipher writing; (3) whether there are any proficiency studies to establish that a forensic document examiner has a superior ability through either training or experience to decipher handwriting; and (4) whether there are limitations that should be placed on this process. It is the purpose of this presentation to address these specific four issues and initiate a debate concerning any needed modifications to the published standards if it is deemed necessary.

Attendees will be exposed to various opinions and ideas as to decipherment. It is the purpose of this presentation to present both sides objectively and moderate a discussion with attendees. As a result, attendees should come away from this presentation with a better understanding of the foundational bases for stating conclusions or limiting conclusion statements in regard to decipherment of latent handwriting impressions.

One position is that forensic document examiners are trained in the decipherment of latent handwriting impressions. In the standard titled *SWGDOC Standard for Scope of Work of Forensic Document Examiners*, Paragraph 4.2.2 (concerning forms of examinations) states: Other problems are the decipherment and sometimes the restoration, alteration or additions to document and relationships of documents. Some of the considerations as to a separate expertise in decipherment involve: (1) the specific training in decipherment; (2) the impact of the examination of large quantities of writing as a foundational basis for decipherment; (3) study of indentation obstructions and their impact in impressions; and (4) study of various forms of writing to include date formats, time formats, diacritics, etc.

Since this research is unaware of any proficiency studies as to decipherment capabilities of professional forensic document examiners versus a control group, a discussion of the design of research and a search for willing researchers will be a part of the general discussion. Next, there will be a short review of various form variations, such as date entries, phone numbers, time, etc. The purpose of this section is as a refresher to understanding that alternative forms must be considered in any decipherment process. Finally, this discussion will seek to reach a consensus as to report terminology that accurately reflects both the findings and the limitations to the noted examination data.

---

#### Handwriting, Indentations, Decipherment

### J14 Infrared (IR) Luminescence With Different Paper Substrates

*Dennis J. Ryan, MBA\*, Applied Forensics LLC, East Meadow, NY 11554*

---

**Learning Overview:** The goal of this presentation is to determine if different paper substrates have any effect on the visualization of luminescent pen inks.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how an examiner must be cautious in drawing any conclusions when different paper substrates are involved.

The paper substrate variables included brightness, weight, brand, and type of paper. The preliminary research determined that there was a significant variability within one level of brightness (92, 98, 102, etc.), so the research was predominately restricted to only 98 brightness paper. Eighteen different pens were used with numerous different paper substrates. Individual pieces of 98 brightness paper was used. These pieces varied by weight, type, and brand. The size of the piece of paper remained constant. One straight ink line was drawn with 18 different pens of varying colors and types. Each pen used was known to have ink with luminescent properties. The different pens were broken down into 3 rollerballs, 2 fountain pens, 1 felt tip, 11 ballpoints, and 2 gel pens. This study used the following 98 brightness papers: four color copy papers, seven multipurpose papers, six laser papers, and one inkjet paper. A Foster & Freeman Video Spectral Comparator (VSC) 40/HD was used to detect the IR luminescent properties of the different pens. Eighteen pens were used, but data was analyzed for only 17 pens; one of the pens ran out of ink. Significant variations were seen when comparing multipurpose to color copy paper.

Caution should be exercised when examining the IR luminescent properties of inks over different substrates. The findings showed that the type of paper may have a significant effect on the visualization of luminescent inks. Inks luminesced at lower wavelengths on laser and color copy papers than the same ink on multipurpose papers. No correlation could be made between paper weight and ink luminescence because no consistent pattern was observed. No one brand of paper consistently affected the visualization of the luminescence. Erroneous conclusions may be reached when examining inks over different paper substrates (i.e., unlined white paper enclosed in a white envelope).

Some preliminary results were obtained from 96 brightness white paper, 100 brightness, and color copy paper. The results from the 96 brightness paper was consistent, if not identical, to the results found to the same type and weight. Some pens luminesced under slightly lower wavelengths on laser and color copy paper on the 96 brightness paper. The results for the 100 brightness papers was less conclusive because there were as many different paper substrates on the commercial market as there is in the 96 and 98 brightness range.

---

#### IR Luminescence, Ink Examination, Paper Substrate

### J15 X-Ray Cabinets Applied to Forensic Document Examination

*Samiah Ibrahim, BSc\*, Ottawa, ON K1S 1R1, CANADA; Tobin A. Tanaka, BS\*, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA*

**Learning Overview:** After attending this presentation, attendees will learn how X-ray cabinet radiography can be used in examinations of questioned documents and the materials used to produce documents.

**Impact on the Forensic Science Community:** The presentation will impact the forensic science community by demonstrating how X-ray cabinets can be used in a variety of examinations in the questioned document laboratory.

Questioned document examination is one of the oldest areas of forensic science, spanning more than 100 years, coincidentally emerging around the same time frame as when X-rays were first reported in the scientific literature by W.C. Röntgen.<sup>1</sup> Documents may take many forms, for example: single sheets of paper, bound books, packaging, and plastic cards. The increase in the different types of materials, such as ink, toner, papers, and polymers that may be used in making documents, is also diverse. Consequentially, the range of instrumental techniques and technologies used in their examination is equally diverse.

X-rays are commonly used in non-destructive examinations of objects in industry, medicine, dentistry, and materials science. It follows that its use in forensic science will apply to many situations where similar types of non-destructive examinations may be beneficial, such as those encountered in questioned documents. Forensic document examination has used radiography and in particular “soft” X-rays to reveal the inner structures of documents and the materials used to make them. While specific application of X-rays to document examination has been published at least as early as 1953, it has not always been straightforward to obtain suitable radiographs.<sup>2</sup> The difficulties are not always solely due to the time taken for film processing but to the fact that most X-ray equipment is not well suited for low-density materials, such as documents. Many instruments are not capable of producing X-rays of low enough energy to disclose these subtle radiographic densities. As a result, many X-ray devices and sources are too powerful, resulting in poor contrast radiographs. Other challenges include requiring specialized knowledge to operate certain devices and shielded areas for health and safety regulatory requirements.

The characteristics of X-ray exposure and nomenclature will be reviewed. This will educate the document examination community on how radiograph exposures are described in terms of factors such as: X-ray tube voltages and current, exposure time, beam diameter, sensor capability, and geometric magnification. Some basic physics on X-ray interactions with matter will provide insight into what happens when an object is subjected to X-ray radiation. These interactions include scattering, transmission, and absorption, and these may pose radiograph imaging problems, especially when the shape of objects is irregular.

Many practical lessons on successful implementation of X-ray radiography of documents can be drawn upon from the conservation and restoration community. Objects including documents and books are subjected to X-ray radiography in a similar fashion to what may be desired for matters pertaining to forensic document examination.<sup>3</sup>

Modern cabinet X-ray devices afford the convenience of instant results, flexibility in setup, and safety and convenience of digital radiographs, permitting adaptable post-processing for optimal viewing. This presentation will include several examples of different document types along with discussion on how this type of non-destructive examination can provide valuable insights into document construction, alterations, and materials differences. Digital radiograph formats including the Digital Imaging and Communications in Medicine (DICOM) will be explained as will the advantages and disadvantages of each.

## Questioned Documents—2020

---

### J16 Practice Management Software: The Key to Staying Organized

*Linda L. Mitchell, BS\*, Forensic QDE Lab, LLC, Escondido, CA 92025-4116*

---

**Learning Overview:** The goal of this presentation is to introduce the concept of practice management software and illustrate the advantages of keeping communications, evidence copies, examination records, and billing information in one place.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a user-friendly method of evidence management to keeping records clean and organized. This presentation is directed toward experts of all types in private practice.

Experts in forensics find themselves in an age where documentation and data storage methods are crucial to their credibility. No longer can one put a file on the hard drive for later retrieval without first making it easily retrievable. Important work product and related documents are sometimes required at a moment's notice, not to mention that the file system of one's personal hard drive poses many challenges when trying to locate important information.

In the attorneys' world, a great number of software programs have been developed to help keep evidence, case law, and work time sorted out. Over the years, it has become more inclusive of communications, work product, and time tracking, allowing the attorney to keep all the documents related to a case sortable and searchable. These developments have inadvertently served adjunct legal professionals, such as expert witnesses.

Experts have the same challenges as attorneys, particularly those who are engaged in private practice. While not as closely monitored as certified document labs, private practitioners should be providing a similar regimen of data maintenance and retrieval. Further, there should also be a secure means of transmitting work product and any other data to clients rather than using Gmail® or Yahoo®.

Practice Management Software (PMS) for attorneys has provided solutions to organizing the date management problem in the office. From the intake information to the final billing, PMS will consolidate every part of the expert's work. The only part of everyday work that is not included is Marketing and Internal Finances, which is necessarily separate from the work that is performed in the forensic lab.

The purpose of this presentation is to stimulate the thought processes of the private practitioner toward streamlining and consolidating his or her work product so it is searchable for future projects and for conflict checks, available for other cases that involve similar issues or questions, and provide an accessible database for historic work that could be useful as resources.

This presentation is an introduction to the software used in law offices as it applies to expert witness work. While not an endorsement of any one brand of software, this presentation will discuss the potential for every expert to consolidate his or her data, evidence, work product, time tracking, and communications into one easy-to-use location that is more secure than the open internet. Each of the software applications that are being presented have been used and there will be discussion on the pros and cons of each. Other software options will be included, but all software in this genre are not necessarily mentioned.

---

**Practice Management, Evidence Management, Private Practice Software**

## J17 Forensic Document Examination: Early Incorporation of the Forensic Intelligence Paradigm

Samiah Ibrahim, BSc\*, Ottawa, ON K1S 1R1, CANADA

**Learning Overview:** After attending this presentation, attendees will better understand the relatively new academic pursuit of forensic intelligence, as well as gain insight into how, throughout the history of forensic document examination, laboratories have practically worked with this concept.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community because, ultimately, attendees will take away a sense of how they can apply the principles of forensic intelligence into their research and casework.

Forensic science is simply defined as the application of scientific knowledge to legal matters. Traditionally, the results of forensic analyses are used to help resolve criminal investigations; however, with modern advancements, many of the scientific techniques used in forensic analyses are now common and necessary parts of investigations in both the private and public domain and can be applied from the earliest moments.

Intelligence is the end result of the collection and subsequent analysis of information assembled from myriad sources. The purpose of gathering intelligence relates directly to the directive or mandate of the organization collecting the information. Worldwide, intelligence-gathering agencies draw upon the gamut of their resources in order to render a more complete model during investigations. The use of science and, in particular, forensic science, has long been a part of these resources; however, this does not preclude other organizations from employing forensic analyses in the development of their intelligence product.

Forensic intelligence has been defined in the literature as the accurate, timely, and useful product of logically processing forensic case data for investigation and intelligence purposes.<sup>1</sup> This literature, courtesy of various academic groups working to establish processes and models to exploit forensic case data, highlights excellent examples of intelligence derived from the various forensic disciplines.<sup>2-7</sup>

Forensic examination of the materials, substances, and objects seized from seemingly random or disparate instances or events may identify links between suspects, activities, or items and their involvement in criminal activity. This approach, to look to the collective data generated by these many forensic analyses in new ways to discern non-obvious linkages, will bolster our current practices to create better product and ultimately make better, more-informed decisions throughout the international law enforcement continuum. Ultimately, a mature forensic intelligence approach may provide data prior to an event, particularly in a criminal environment with a serial/recurring component.

This presentation will introduce the topic of forensic intelligence and establish how forensic document examination, from the earliest times, has incorporated these ideas into casework. Further, over the past many years, various data collection tools have been developed by forensic document laboratories around the world with the express purpose of providing ways to link disparate casework. This presentation will highlight some examples of these tools and how they have been used in forensic document examination, as well as to shine a light on the potential to use these same tools to generate data that could input the investigation of other crimes not typically thought of as being in the realm of forensic document examination.

### J18 Crossing Borders: Issues From Inter-Jurisdictional Casework

*Linton Mohammed, PhD\**, Forensic Science Consultants, Inc, Burlingame, CA 94010-2017; *Thomas W. Vastrick, BS\**, Apopka, FL 32703; *Tobin A. Tanaka, BS\**, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA; *Samiah Ibrahim, BSc\**, Ottawa, ON K1S 1R1, CANADA

---

**Learning Overview:** After attending this presentation, attendees will be aware of the inter-jurisdictional nature of questioned document examination casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by educating attendees about the challenges and limitations that are associated with inter-jurisdictional work in forensic document examination.

Forensic science has been inter-jurisdictional in nature from earliest times in the various disciplines. As one of the original forensic disciplines, Questioned Documents has myriad examples of this. Some of the earliest reported cases of forgery are accounts of counterfeit travel documents from the far reaches of the world. In approximately 450 BC is the first mention of a written letter from a Persian official requesting safe passage from “the governors beyond the river” as he crossed their lands.<sup>1</sup> Consequently, throughout history, documents such as laissez-passer, passports, currency, and other official documents from foreign jurisdictions have had to be forensically examined to determine authenticity and veracity.

In more modern times, there has been a broadening of the inter-jurisdictional nature of forensic work to include training and other collaboration. Forensic document examination has matured as a discipline over the past century in North America, Europe, and select other areas of the world. Recently, there has been a concerted effort to promote international standards in the examination of documents, including providing training to forensic scientists from all corners of the globe. Further, venues such as the American Academy of Forensic Sciences and other forensic conferences provide opportunity to share knowledge across borders. This learning is multi-path as traditional examiners learn equally from examiners of foreign scripts, for example. It has become commonplace to receive requests for forensic document examination services from foreign entities, about foreign entities, and concerning documents of foreign origin, source, manufacture, etc. This may bring certain elements of challenge and limitation to the examination.

Another issue in working on inter-jurisdictional casework involves the basic logistics of physically receiving the case (continuity of evidence included), or establishing where items will be examined. This may perhaps involve remote field examinations that pose other specific challenges from technical (such as power supply and ventilation) to space requirements and security.

There are examples of inter-jurisdictional cases that involve the prosecution of suspected war criminals and those charged with crimes against humanity in which security concerns add a real element of danger that may be foreign to the traditional forensic document examiner.

A daunting challenge to inter-jurisdictional work is the assurance that the forensic opinions issued in a report are received and understood with the same weight as they were written and intended. Clarity of message is crucial in all forensic reporting; this challenge is increased considerably if there are differences in language, legal system, customs, and culture.

Each of these challenges will be touched upon in this presentation by those who have worked in some regard on the international scene. With the increase in inter-jurisdictional casework, it is important to share experiences within the forensic document examination community so that our work is clearly understood by clients and stakeholders, regardless in which and for which jurisdiction the work is conducted.

### J19 Developing a Frequency of Occurrence Proportion-Based Database in Forensic Science: A Template Using the Handwriting Database

*Thomas W. Vastrick, BS\*, Apopka, FL 32703*

**Learning Overview:** The goal of this presentation is to provide attendees with a template for how to create a frequency of occurrence database for their location and for their discipline through the experiences and lessons learned developing a handwriting database over the past ten years. Attendees will learn about each step used by one of the founders and leaders of the template project.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by knowledge transfer of the experiences gained through the entire development process of one such database. As such, the worldwide forensic science community will have the benefit of the successes and failures in methodologies utilized and the reasons behind the results.

In 2010, a team of forensic document examiners and statisticians undertook to develop, from scratch, a database of frequency of occurrence proportions. This project was funded by the National Institute of Justice, United States Department of Justice with a research grant. The results were formally presented at the 2015 American Academy of Forensic Sciences Annual Scientific Meeting in Orlando, FL. Subsequent to that, team members headed two further studies that broadened the database to include numerals. To date, there are more than 800 features in the database.

Because there had been few similar studies ever conducted, the team needed to establish several protocols. These protocols, by design, were based on statistical standards as it was determined that best practices dictated that this was to be a statistically driven study concerning forensic science rather than a forensic science study using statistics. The protocols incorporated published information and procedures utilized in other areas. The areas of procedures that were addressed included population sampling, quality control, data selection, system development, reporting, potential for abuse, and integrity of the data.

The statisticians employed a multi-strata system of population sampling based on factors that had been published concerning intrinsic and extrinsic factors that affect handwriting. The team reviewed each factor and determined the best method to address the factors individually. Next, the team used recent census reports to establish the strata goals, set at 80% of the census numbers. The other 20% were permitted to be collected randomly in order to take advantage of randomness and to further address factors that may not have been considered. The population sampling method will be addressed in great detail in this presentation and implications to developing sampling protocols for regions that may have significantly less homogeneity will be discussed.

Another aspect of population sampling was the physical collecting of specimens. Again, standard methodologies needed to be followed and the method with which the team executed this aspect of the study will be discussed in detail.

Data selection was a complex process that required a significant amount of time and processes. First, features were initially selected by subject matter experts based on being deemed objective in nature, as opposed to subjective. The reason was to establish reproducibility in data entry from the many data entry personnel. The method of testing involved use of an Attribute Agreement Analysis (AAA). This presentation will go into the published AAA standards and both the successful and unsuccessful methods used in its implementation.

The system developed for the input and use of the data was complex and unique. Efforts were made to create a system that could be expandable and flexible so that future additions would be easy and use in actual casework could be applied on a national level of targeted subgroups. This presentation will discuss this in detail and demonstrate the various software programs that were developed.

Since population sampling is not precise to the entire population, but rather an estimate, it is important to know how to report results in the most accurate manners possible. This presentation will discuss how the handwriting database deals with this issue.

Finally, procedures were created to minimize the potential for any bias by the separation of duties and the restricted access to data by the forensic specialists. Conversely, the entire team contributed to ideas of potential misuse and abuse of the process and agreed that it was important to address these issues upfront. These issues will also be discussed in the presentation.

---

#### Frequency, Statistics, Database

### J20 Statistical Analysis of Handwriting: Probabilistic Outcomes for Closed-Set Writer Identification.

*Amy M. Crawford, MS\*, Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011; Alicia L. Carriquiry, PhD, Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011; Danica Ommen, PhD, Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011*

---

**Learning Overview:** The goal of this presentation is to provide insights into features of handwritten documents that are important for statistical modeling with the task of writer identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing ongoing forensic statistics research to practitioners in the field. Collaboration and communication is fundamental to the success of emerging research. All statistical methods and code are open-source and available to the community.

The objective of this work is to develop a statistical model that takes all styles of writing (cursive, print, and connected print) and gives a probabilistic evaluation of a closed-set writer identification as well as variability estimates. Such probabilistic statements have potential to support examiner conclusions and be used by the community to provide free and open-source methods for searching a collection of documents.

When forensic examiners compare handwritten evidence, they often focus on small details of writing. Likewise, this statistical approach to the comparison of such documents begins by decomposing writing into small meaningful connected pieces of ink, often corresponding to letters. The R package *handwriter*, developed at the Center for Statistics and Applications in Forensic Evidence, handles this processing task. The small pieces are treated as graphical structures, and graphs are grouped using a novel dynamic method that is based on the similarity of their shapes. The frequency at which graph types appear in writing, along with measurements taken on the small graphs, serve as data for a Bayesian hierarchical model. This study considered measurements such as slopes, lengths, centroid locations, and loops and compared the measurements within groups to investigate their ability to discriminate between writers. Measurements that separate writers well in a numeric capacity will be useful for the statistical model.

There are a few notable insights that arise through the modeling process. First, the model that takes all styles of writing as inputs is able to separate print and cursive writings through a latent variable. Next, through a multivariate over-dispersion calculation, one can evaluate intra-writer variability as it relates to the model.

The statistical model is ultimately used to perform a closed set writer identification analysis. Data for the analysis come from the first 100 writers in the Center for Statistics and Applications in Forensic Evidence (CSAFE) handwriting data collection. In this data collection, study participants were asked to transcribe three writing prompts: the “London Letter,” a short excerpt from *The Wonderful Wizard of Oz*, and an even shorter common phrase. Each prompt was written three times during each of three data collection sessions. This study investigated writer identification performance under varying amounts of known and questioned writing.

*This work was partially funded by the CSAFE through a Cooperative Agreement between the National Institute of Technology (NIST) and Iowa State University, which includes activities carried out at Carnegie Mellon University, University of California Irvine, and University of Virginia.*

## J21 The Creation of Forged Promissory Notes Using the Signature Which Was for Different Purposes: A Case Report

*Dilara Oner, MS\*, Istanbul University-Cerrahpasa, Istanbul, Fatih 34098, TURKEY; Abdi Ozaslan, MD, Istanbul University-Cerrahpasa, Fatih, Istanbul 34098, TURKEY; Gursel Cetin, PhD, Istanbul University-Cerrahpasa, Istanbul, Fatih 34100, TURKEY*

**Learning Overview:** After attending this presentation, attendees will have seen an interesting example of one of the forgeries in the field of forensic document examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating an example that will raise awareness in the field of forensic document examination.

In recent years, frauds have been frequently encountered by printing promissory notes on the upper side of a signature that was written for a different purpose and unjustly charging the person. In a case given by the court to experts, a forged promissory note was arranged to use the space on the right side of the signature for other purposes. Therefore, the case was found interesting and useful for presentation and discussion.

At first glance, the localization of the signature in the document subject to review is remarkably close to the left edge. In addition, when the signature is compared to the other signatures of the person, it is seen that the signature is left-leaning. In the examination, it was found that the top and bottom edges of the document were 20.5cm and the right and left edges were 9.6cm. When the top and right sides of the document were examined under a stereomicroscope, it was found that the images were compatible with each other and the signs of wear were relatively high. In addition, when the bottom and left sides of the document were examined under a stereomicroscope, it was found that the images were compatible with each other and the signs of wear were relatively low.

**Findings:** It was seen that there was text on the upper side of a paper whose size cannot be determined at present, and the lower right side of this text is signed as approving the text (Figure-1a). Then the text was turned 90 degrees to the left (Figure-1b) and the paper was cut between the signature and the text. The paper was cut again by the bottom of the signature (Figure-1c), a blank signed paper (Figure-1d) was added to the space at the top of the existing text, and, as a result, the document was made available. (Figure-1e).

In the Turkish legal system, a document must contain certain elements in order to create a promissory note; however, there is no standard regarding the size, color, and printing format of the promissory note. Therefore, in cases where there are elements such as the date of arrangement, the due date, and the amount of money, all types of papers and sizes will be valid. In this way, a forged promissory note can be produced by using a signature on blank paper that was written for other purposes. If there is too much space between the text that is located on top and the signature, between the signature and the bottom of the paper, or on the sides as in this case, the paper can be cut from the top, bottom, or sides, and a forged promissory note can be printed on the rest of the blank.

As in the case presented, the person who qualifies as a debtor in such a situation can state that he/she did not sign such a bill and declare an objection to the signature. When the expert's examination, commissioned by the court, naturally states that the signature belongs to him/her, a complex situation arises. Therefore, the court and the experts in counterfeiting should be careful and focus on not only the objection to the signature.

In particular, all documents that are not printed or printed with computer printer output, electric typewriter, typewriter, or handwritten should also be examined in terms of the cut edges of the printed paper, the layout format of the promissory note, text, line ranges, and whether toner waste in laser printer output is above wet-signature lines.

**Figure-1:** Stages of creation of a counterfeit document

**Figure-1a:** The text above is signed by the person

### J22 Writing Instrument Developments: Hybrid Pens, Rollerball Pens, and Mixable Fountain Pen Ink

*Tobin A. Tanaka, BS\*, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA*

---

**Learning Overview:** After attending this presentation, attendees will be aware of three evolutions in writing instruments: (1) hybrid pens; (2) roller ball pens that are compatible with fountain pen ink; and (3) mixable ink for fountain pens. Examples of the physical and optical characteristics of these pens and inks when examined with a variety of instrumentation including hand magnifiers, microscopes, spectral examinations, and scanned images of the writings will be shown.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of these developments in the writing instrument industry. This presentation will provide information on the features that may be observed if examining such writings or inks.

Far from being a static industry, the writing instrument world continues to develop new and evolving products that may be used in writing. Although document examiners may not always need to precisely identify the type of writing instrument used in the production of writing, there is a need for an awareness of the ever-increasing types of writing instruments in use. Standards, such as those from the Scientific Working Group for Forensic Document Examination (SWGDOC) and the European Document Experts Working Group (EDEWG) outline some instances in which observations may disclose evidence that must be considered as part of an examination.<sup>1-4</sup>

Hybrid pens utilize a combination of ballpoint and gel ink. The intention of the manufacturer is to provide a longer-lasting ink supply typical of ballpoint pens, with the benefits of smooth writing as often experienced with gel pens. Differentiating between hybrid pen lines and those of ballpoint or gel can be very challenging.

Most rollerball pens are supplied with rollerball refills, but a few are designed to take fountain pen ink. Even when chemical analysis is permitted, there is the potential for misinterpretation of the writing instrument type if too much reliance is weighted on the chemical composition alone.

Ink manufacturers advise against the blending of fountain pen inks. The reason being that blending different inks may result in coagulation of the ink and clogging of the pen; other more adverse chemical reactions have been known to occur. Mixable ink is formulated to permit the blending with variable proportions to make a wide variety of desired colors.

This presentation will provide some indication of what features may be reliable indicators of hybrid ink writing and rollerball pens that use fountain pen ink. For mixable fountain pen inks, this presentation will highlight how well the inks blend together, the homogeneity of any such mixture, and the evidence that may indicate to a document examiner that the written line may be the result of blended fountain pen ink.

### J23 Detecting Backdated Documents Through Line Layout Approaches to Font Identification

*Thomas W. Phinney, MS, MBA\*, Portland, OR 97206*

---

**Learning Overview:** After attending this presentation, attendees will learn the utility of font identification in detecting backdated documents. Attendees will learn about font dating and its use in detecting backdated documents, as well as both traditional methods of font identification and newer methods based on glyph spacing, which are suited to automation and capable of yielding results even with very poor document reproduction.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by not only covering widely used tools but also giving attendees new tools for detecting document backdating and identifying an area for more research.

**How Font Identification Can Demonstrate Forgery:** Identifying a font used in a document, when combined with information about when the font was designed and made available to the public, can be supportive or conclusive in proving that the document was not created on a date claimed. This can not only prove backdating, but in cases where the purported author was deceased before the font was available, can be evidence of forgery.

**Traditional Methods and Resources for Font Identification:** A variety of books, manuals, and web sites provide visual references and information on font classification and earmarks. Many of these approaches require some degree of expertise for reliable results.

**Complications for Font Identification and Timelines:** Although a font may be officially released on a given date, that does not mean it was completely unavailable before that date. Especially for fonts bundled with operating systems and office suites, the availability of pre-release and beta versions can complicate the story by creating a gray area of time, when a new font was not yet used by the average person, but still available to some people outside the company. Calibri illustrates this issue, with its increasing availability to outside testers for a period of almost two years before its formal and full release with Windows® Vista and Office 2007.

Another complication, for at least some common typefaces, is the existence of (later) lookalike fonts, sometimes called “clones” or “knockoffs” of the original. This generates the potential for false negatives, or less commonly, false positives.

**Line Layout Methods for Font Identification:** Except for traditional typewriters and fonts of that same style (such as Courier, Prestige Elite, and Consolas), wherein all letters take the same amount of space, most fonts are “proportional”: each letter is allocated a different amount of space. Aside from some proportionally spacing typewriters and a few fonts created to imitate the spacing of earlier fonts, the spacing of fonts is generally unique, like a fingerprint.

This spacing is revealed by cumulative character width, especially with non-justified (ragged right) text. Even with a very poor document reproduction, one can use this method by comparing line breaks and especially ragged line endings. Any large-enough sample of such lines is like a fingerprint: the relationship of where each ragged line ends, relative to the adjacent lines, uniquely identifies a particular proportional font. Because this method is based on *relative* line endings, it does not require duplicating the original document and is unaffected by distortions that can occur when documents go through copying, faxing, scanning, etc.—even multiple generations of reproduction.

An employee of Adobe® at the time made this observation in 2004, in regard to the Bush National Guard memos. This concept, when applied in an automated way by a computer program, became the basis of a patent application. The concept was subject to internal peer review, and the patent was granted by the United States Patent & Trademark office and expires in September 9, 2025).

That this technique can differentiate different fonts has been thoroughly demonstrated on a small scale, with handfuls of fonts at a time. However, no testing has been done on a larger scale, to further validate the methodology or determine the statistical reliability of the method. Such testing can be done manually; if automated, it would presumably require either licensing the patent or waiting for patent expiry in 2025.

*The presenter has no financial interest in Adobe® Systems nor in licensing the patent.*

---

### Forgery Detection, Font Identification, Document Authentication

### J24 The Interaction of Writing Profiles and Automated Scoring Rules

*Cami Fuglsby, MS\*, South Dakota State University, Brookings, SD 57007; Michael Caligiuri, PhD, University of California, San Diego, CA 92093; Danica Ommen, PhD, Iowa State University-Statistics, Ames, IA 50011; Christopher P. Saunders, PhD, Brookings, SD 57006; JoAnn Buscaglia, PhD, Federal Bureau of Investigation Laboratory, Counterterrorism and Forensic Science Research, Quantico, VA 22135*

---

**Learning Overview:** After attending this presentation, attendees will better understand the importance of statistical invariance as it relates to the development of automated scoring rules for handwriting verification systems. The Random Non-Match Probability (RNMP) is the chance that two writing samples written by the same writer are declared a non-match by a given biometric scoring method. Some important questions that arise are whether or not this chance is the same for every writer in a population of writers and whether or not it is affected by the number of words in the writing samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by delving into the design and validation of automated handwriting identification systems to writing samples, the statistical methods, and interpretations based on scores.

**Hypothesis Statement:** Designed studies of handwriting will allow researchers to identify scoring rules that have an RNMP that varies as a function of a writing profile.

In the construction of Automated Handwriting Identification Systems (AHIS), pairwise scoring rules play an important role associated with characterizing the performance metrics of the system. Most AHIS for forensic source identification are optimized to recommend the order in which an examiner should search a candidate list of known writers to identify the source of a writing sample with an unknown writer. In effect, they recommend the source of a writing sample that an examiner will then verify. A natural measure of the performance of a scoring rule is the associated Random Match Probability (RMP). The RMP is the chance that two writing samples from different writers are declared a match—this is analogous to the “likelihood of a chance match” in the logical approach to handwriting analysis. Unfortunately, most handwriting AHIS are not optimized for minimizing the RMP and are instead focused on minimizing the time to find a writer in database of writers. This means that, if one wishes to compare two writing samples in a head-to-head comparison to measure the similarity with a given AHIS, then the researchers will usually need to design a strategy for encoding the output of the system in order to develop an interpretable scoring rule (by interpretable, this study means that a score has meaning that is consistent across writing profiles, or that the RNMP for two writing samples written by writer A is the same as two writing samples written by writer B). This work will discuss various strategies for constructing pairwise dissimilarity scores and characterizing the performance of the resulting scoring rules.

Using writing samples collected under a National Institute of Justice (NIJ) -funded research project, this study explores the properties of various pairwise scoring rules for the results of the FLASH ID system. This study also focuses on the scores’ dependence on the amount of handwriting (in each writing sample) that is made available to the system. Another important focus of this research is on the visual display of the statistical methods to convey the performance of the scores.

---

#### Source Identification, Handwriting, Biometric Performance Metrics

### J25 Writer Classification of Handwritten Characters Using a Neural Network

*Yoko Seki, MA\*, National Research Institute of Police Science, Kashiwa-shi, Chiba-ken 277-0882, JAPAN; Yoshinori Akao, Kashiwa, Chiba, JAPAN; Shigeru Sugawara, PhD, National Research Institute of Police Science, Kashiwa-shi 277-0882, JAPAN; Yoshiyasu Higashikawa, PhD, National Research Institute of Police Science, Kashiwa-shi 277-0882, JAPAN*

**Learning Overview:** After attending this presentation, attendees will understand the results of writer classification using a neural network and the necessity of the future research on a neural network using various data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the validity and the problems of the application of a neural network to handwriting identification.

Machine image recognition technique along with deep learning has been advancing rapidly, and its application to forensic document examination has also been expected. A writer classification experiment using a neural network, which was conducted as one of the feasible studies, is reported in this presentation.

Writer classification using the neural network LeNet was conducted. Samples used for the experiment were 26 uppercase Latin alphabetical letters, 26 lowercase letters, 26 Hiragana characters, and 26 Kanji characters, written five times respectively by ten people. Each letter and character was originally written in a 1cm x 1cm square box in handprint. Then, an 8-bit grayscale image of each sample was obtained under conditions in which the image size was 32 pixels x 32 pixels with a resolution of 85 dots per inch (dpi).

Writer classification using LeNet was conducted on the following four categories: uppercase Latin alphabetical letters, lowercase letters, Hiragana characters, and Kanji characters. Image data were divided into two groups: training data and validation data. Four out of five samples per letter or character were used for training and the remaining one was used for validation. Thus, there were 1,040 samples (26 characters x 4 samples per character x 10 writers) used for training and 260 samples (26 characters x 1 sample per character x 10 writers) used for validation per category. Training was done under conditions in which the batch size was 64 and epoch was 50. After training was completed, validation samples were classified into any of ten writers respectively, and the accuracy ratio was calculated on four categories.

The accuracy ratio was 0.7615 for uppercase letters, 0.6500 for lowercase letters, 0.7500 for Hiragana characters, and 0.7769 for Kanji characters, which was higher than expected. The average accuracy ratio of respective letter or character (training samples: 4, validation samples: 1, batch size: 8, epoch: 50, trials: 104 (26 letters or characters x 4 categories)) was 0.5897, and the expected accuracy ratio of each of the four categories was around 0.7000 before the experiment. These results may show the importance of the number of samples in the application of the neural network. Recall ratio per writer varied the largest in lowercase letters (0.0769–0.9230), which explained the reason of the lower accuracy ratio. In these classification experiments, feature extraction of individuality from each writer's handwriting was conducted on all the training samples, and this means a writer's features extracted were expected to be common to all letters or characters used. Thinking that the comparison of documents in forensic document examination is performed on the same letters or words and that forensic document examiners have knowledge and experience with the feature extraction from one's handwriting, these results are interesting. The results may suggest that a person writes various letters and characters in a constant and unique manner.

Two writers showed a high recall ratio (over 0.9000) in all four categories, and their handwriting samples were unique in size, shading, or the location of the handwriting in the box, which may be the primary features for the neural network classification in this experiment. Forensic document examiners do give weight to these features, but they give more weight to graphic features of a handwriting, such as slope, angularity, relative relationship between strokes in writer classification, or identification tasks.

Several findings on the application of a neural network to writer classification were obtained from these experiments. More experiments, such as classification using samples of the same graphic form with augmented samples, using image data with higher resolution, or using more complicated algorithm, will be necessary for the future study.

#### Handwriting, Writer Classification, Neural Network

## J26 Availability of Measurement of Ascender and Descender Parts of Letters in Determining the Gender of the Writer

Dilara Oner, MS\*, Istanbul University-Cerrahpasa, Istanbul, Fatih 34098, TURKEY; Gursel Cetin, PhD, Istanbul University-Cerrahpasa, Istanbul, Fatih 34100, TURKEY; Omer Kurtas, MD, Kocaeli University, Kocaeli, TURKEY

**Learning Overview:** After attending this presentation, attendees will have gained information about the results obtained in a study in Turkey about the measurement of certain parts of letters, which is one of the methods used in determining whether a manuscript belongs to a woman or a man, and how the possibility of applying the same method will arise in different countries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the tests of a study conducted in Turkey based on numerical values and usability to determine whether a manuscript belongs to a woman or a man.

One of the findings used when determining whether a manuscript belongs to a female or a male is to compare the length ratios of the parts by measuring some letters. The goal of this study was to determine the differences between female and male writings by measuring the parts of the same letters in the same words on the same texts written by females and males.

For this purpose, manuscripts that were written by 20 females and 20 males whose age range was 22–63 years (average 32.7 years) and whose educational background was either university students or graduates, who were Turkish citizens living in the same geographic region (Istanbul, Turkey) were analyzed in Adobe® Photoshop® software using the letter “d” in “başladı, derken, uyandım” words, the letter “t” in “lokantada, seyrettik, papatyalarım” words, the letter “p” in “akıp, papatyalarım” words, the letter “k” in “yaklaşan, sığındık, katıldı” words, the letter “y” in “dinmesiyle, yol, ayrıldım” words, the letter “b” in “İstanbul, boğaz, bulutlar” words, the letter “f” in “ferah, film” words, the letter “g” in “gibi, gökyüzü, gitmeye” words, and the letter “h” in “sabahına, hoş, bahar” words. The data obtained were analyzed with *t*-test in SPSS 23 software.

It was found that ascender and descender parts of all letters were the higher length value in male participants and the difference was statistically significant in all letters except “y,” “f,” and “g” (p value <0.05).

It is stated in related literature that the handwritings of females and male differs from each other.<sup>1,2</sup> Objective findings to be used to reveal this difference should be based on numerical measurements. In this study, significant differences were obtained in some selected letters. Also, if the measured number of letters, the range between words, the range between letters, and the number of measurements is further increased, much more reliable findings can be obtained in the differences between females and males.

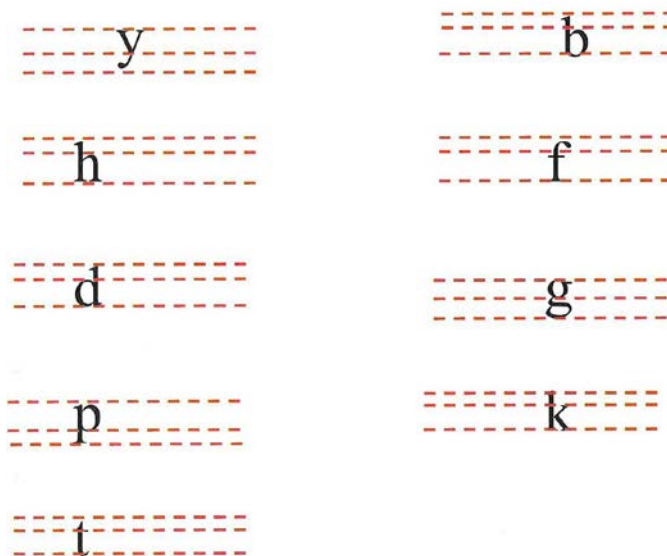

Figure 1: Measurement zones in letters

### J27 A Study of the Impact of a Primary Learned Handwriting Language on a Secondary Language

*Amanpreet Kaur, MSc\*, Punjabi University, Patiala, Punjab 147002, INDIA; Rakesh Kumar Garg, PhD, Forensic Science Department, Patiala 147002, INDIA*

---

**Learning Overview:** After attending this presentation, attendees will be able to understand how a primarily learned handwriting language affects the handwriting in the secondary learned language. The significance of the analysis is further represented with the help of various statistical tools.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a key aspect in the field of handwriting examination. This is the prevalent aspect in the field because people around the globe are being attracted to learning new languages, but their native language always has some impact on the later learned language.

Identification of handwriting found on a disputed document by comparison with the known handwriting samples of the suspect still comprise the problem that is most commonly referred to a forensic document examiner. One of the important scientifically established principles that govern such analysis and identification is the “Principle of Comparison,” which explicitly states that, for obtaining correct results, like has to be compared with like; meaning, thereby, that the expert has to analyze and rely upon similar letters and combinations between the questioned and the standard handwriting samples and, consequently, the problems in which similar handwriting samples in the same script have not been provided for comparison usually fall outside the scope of forensic document examination. However, in this field, like any other human activity, perfect and ideal conditions are hard to achieve.

Handwriting is an acquired motor skill and combined output comprised of visual perception and activity, comprehension of form, activity of the central nervous system, the anatomy and physiology of bones, muscles of the hand and arm, and, most commonly, the script used by a person in common and its effect on his secondary language. Linguistic diversity among different world populations is a well-established and recognized fact. Throughout the world, thousands of languages exist that are written in hundreds of different scripts.

As we know, India is a polyglot country as there are a total 122 languages and 234 mother tongues. Only 22 languages have gained official status by the Constitution of India. From prior studies, it was demonstrated that the mother tongue has a great impact on the language that we learn later in life. In a similar way, the language that one uses primarily for writing purposes affects the secondary language. Rendering an expert opinion has become highly difficult and problematic in cases in which a questioned document in one language and a standard document in another language are available for comparison. Handwriting examination in these types of cases is of foremost importance because these features may lead to the nationality and locality of the writer of the handwriting in question and may help the document examiner compare the handwriting samples, irrespective of the script.

This study is basically focused on the similarities found in the class as well as individual characteristics of the Mother tongue and secondary learned language. One hundred individuals were selected for the study and eight handwriting samples for both languages (Punjabi [the Mother tongue of the Punjab region] and English) were collected with the consent of the subjects. Results obtained were statistically analyzed, and it was revealed that an earlier learned language affected the secondary language significantly. In 68% of the cases, there is a similarity between the individual and class characteristics of the two languages. Apart from this, the given study also reveals that script independent comparison of handwriting is possible when basic elements of strokes (for instance, grapheme) are considered.

#### Language, Script, Primary Language

### J28 Comparing Latin With Cyrillic Script in Handwriting Identification

*Andrea Ledic, MS\*, Croatian Forensic Science Centre "I. Vucetic," Zagreb 10000, CROATIA*

---

**Learning Overview:** After attending this presentation, attendees will better understand handwriting analysis of documents written in different alphabets.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a unique study in which documents written in different alphabets were analyzed as well as by teaching attendees about the methods for handwriting and signature examination of documents written in different alphabets.

Identifying handwriting has always represented a challenge as there is no such instrument that could identify the writer in a clear and unambiguous way. In fact, identification has to be made by a handwriting expert, while instruments are used only as tools in his or her work. Even though forensic examination of handwriting has an established and worldwide accepted methodology; its application may differ depending on the script that is examined. The goal of this presentation is to examine the possibilities of handwriting analysis of documents written in different alphabets (Latin vs. the Cyrillic alphabet, and vice versa).

The professional standards used for evaluating handwriting and signatures in the Latin alphabet can also be applied to those in the Cyrillic alphabet. The most important element is the movement of a writing instrument on a writing surface, leaving a trace on the paper that has an important role in identifying the writer.

When an expert witness analyzes text in the Cyrillic alphabet, such as Russian, Serbian, Bulgarian, Ukrainian, or other languages in which some letters are similar to the letters of the Latin alphabet, while others are completely different, he or she has to take into consideration all possible variations of the alphabet. Also, the fact that in the Cyrillic alphabet, it is more difficult to evaluate printed than cursive letters, so the expert has to have access to writing samples from that particular country or region.

The Croatian Latin alphabet has 30 letters, and 27 of them contain one character only. The Cyrillic alphabet has 30 to 40 letters, depending on the language using it. If the lists of letters of both alphabets are compared, one can notice that there are also letters whose form is the same, both in the Latin and Cyrillic alphabet, but they are pronounced in different ways. However, the fact that there are some letters that are the same but have a different meaning makes the comparison of two alphabets easier.

In order to answer research questions, testing and an analysis have been conducted of the handwriting of 12 volunteers from the Vukovar area (a locale in Croatia near the Serbian border) who use both alphabets on a daily basis. In order to collect handwriting samples, every person was asked to copy the same text both in the Latin and the Cyrillic alphabet. Every sample in the group written in the Latin alphabet matched the sample in the Cyrillic alphabet that had been written on the same day with the same instrument, consisting of exactly the same text.

In the first phase of the research, a preliminary analysis was performed to check whether the collected handwriting samples meet handwriting analysis professional standards regarding their quality and quantity as is the standard practice under International Organization for Standardization (ISO) 17025. Next, a detailed examination of general and individual handwriting features was conducted on all handwriting samples written in the Latin and the Cyrillic alphabet for each person individually.

The above-mentioned features of the Latin and the Cyrillic alphabet handwriting samples were examined in terms of their degree of similarity as well as dissimilarity using the comparative method. A stereomicroscope and video spectral comparator were used to compare handwriting samples as well as for the capture of images and for measurements of the size of letters and handwriting in general. Each feature's degree of similarity and dissimilarity was rated by two experts independently. The obtained results have shown that it is possible to evaluate samples of handwritten text written in different alphabets. However, when interpreting the results, one should take into consideration all the limitations suggested by handwriting and signature analysis professional standards, (e.g., photocopies, quality and quantity of materials, similarities in handwritings of various writers, diversity of the content, etc.).

Finally, it should be emphasized that the present research is only a case study. In order to draw universal conclusions, one would have to conduct an experiment on a large group of individuals and real case subjects.

### J29 The Forensic Document Examiner (FDE) Forum

*Carl R. McClary, MS\*, Bureau of Alcohol, Tobacco, Firearms and Explosives, Atlanta, GA 30345; Samiah Ibrahim, BSc\*, Ottawa, ON K1S 1R1, CANADA; Jan Seaman Kelly, BA\*, Forensic Dynamics LLC, Las Vegas, NV 89147*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the state of forensic document examination through hearing attendee opinions on various current topics. The purpose of this forum is to engage attendees on their thoughts on current issues facing forensic document examiners. Topics will be chosen by the forum presenters and presented to the attendees to then discuss. These topics can range from standard methods to training to opinion terminology. Progress of any discipline depends on feedback from stakeholders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing members and non-members alike, as stakeholders, the opportunity to provide their thoughts on topics current in the field of forensic document examination.

The concept of the FDE Forum is not new to the Questioned Document community. It was a concept first utilized at the Southeastern Association of Forensic Document Examiners (SAFDE) meetings in the early 1990s as a method of opening up certain topics of concern to their members. At these meetings, there was a discussion starter on subjects upon which there may have been disparate opinions. Through forums of this type in other organizations, there have been many lively discussions on topics such as the strength of opinions on examinations involving photocopies or rubber stamp impressions. Other topics that could be considered are opinion terminology, board certification, standard training, or specific requirements found in our standard methods. A popular theme in the past has been what type of evidence is required in order to achieve a particular conclusion in handwriting examination (for instance, the elimination of a subject).

Not all discussions must necessarily be centered on issues facing forensic document examiners. Some discussions could focus on attendees' thoughts on and interpretations of quotes from texts in the field by authors such as Harrison, Osborn, and Hilton. Other discussions could begin with the opinions of some of these authors, and other discussions could be in criminal and civil cases of notoriety, past and present. This type of forum is an excellent way to poll attendees on their preferences on methods of testimony, court presentations, and laboratory requirements regarding testimony. Any topics that could relate to international issues and our theme "Crossing Borders" would be appreciated.

---

#### Forensic Document Examination, Forum, Stakeholders

## K1 Identification of Fentanyl and Fentanyl Analogs by Using High-Resolution Mass Spectrometry and Machine Learning

Yufei Chen, PhD, North Attleboro, MA 02760; Xinyi Sui, MS\*, North Carolina State University, Raleigh, NC 27606; Nelson R. Vinuesa, PhD, North Carolina State University, Raleigh, NC 27695

**Learning Overview:** After attending this presentation, attendees will be familiar with the fragmentation pattern of fentanyl as well as its derivatives under Collision-Induced Dissociation (CID). Attendees will also be introduced to a new methodology where the structure of major fragmentation ion could be predicted by Konstanz Information Miner (KNIME) workflow.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel KNIME workflow that is capable of predicting the major fragmentation ion as well its structural similarity against the reference based on the input tandem mass spectrum.

Fentanyl is a type of synthetic opioid that was originally developed as a pain management agent for cancer patients. Because of its stronger addictive reaction over morphine or heroin, it was diverted into a type of abused drug, which largely contributed to the current ongoing opioid crisis. One special emerging issue regarding the detection of fentanyl is the rapid evolution of fentanyl derivatives, as the analytical standards in the forensic laboratory may not be able to keep up with the development of newer fentanyl derivatives.

KNIME is a free and open-source data analytics and mining platform developed by a team of software engineers at the University of Konstanz in 2004. Compared with other data mining software such as Statistical Package for the Social Sciences (SPSS) and Statistical Analysis System (SAS), KNIME was chosen in the study for its user-friendliness as well as its versatility. Traditional cheminformatics platforms rely on command line interfaces to operate, which considerably hinders their application as they require the operator to have certain training in command-line language. KNIME, on the other hand, has a Graphic User Interface (GUI) and modular functionality, which greatly facilitates the operation as well as the modification of calculation as the operator could change the functionality of the whole workflow by connecting and disconnecting nodes. Datasets obtained from different sources could be integrated into one workflow. Currently, KNIME is widely used in biological as well as pharmaceutical applications.<sup>1</sup>

Regarding the techniques used in this study, quadrupole Time-Of-Flight (qTOF) Mass Spectrometry (MS) was used to obtain Tandem Mass Spectrometry (MS/MS) spectra and the design of workflow was performed on the KNIME platform. MS has become one of the leading techniques in multiple fields, including forensic science, because of its sensitivity and versatility. Reinforced by the capability of performing structure elucidation via CID, hybrid mass spectrometer such as qTOF/MS has become a powerful tool in the study of controlled substances, including fentanyl derivatives. In CID, pure nitrogen gas is pumped into the collision cell where it collides with the targeted ion, causing fragmentation of this ion, which could provide useful information for structure elucidation as different molecules will fragment differently depending on their structure.

Thus, in this study, a novel KNIME-based workflow was created based on a series of CID MS/MS spectra from unmodified fentanyl as well as five additional fentanyl derivatives, including benzyl carfentanil, cyclopropyl fentanyl, cyclopentyl fentanyl, furanyl fentanyl, and acryl fentanyl.<sup>2,3</sup> Preliminary results suggested that two common fragmentation patterns could be observed on the fentanyl ion, including product N-phenylpropionamide ( $m/z$  188) and a neutral loss of cyclohexylamine (149 Da). Across a total of five different fentanyl derivatives, either one of these patterns could be observed and the appearance of fragmentation pattern is related to the structure of fentanyl derivative. Fentanyl could be considered as the structural combination of an N-phenylpropionamide with a cyclohexylamine and functionality modifications could be on either part. If the main product ion of  $m/z$  188 showed up, this fentanyl derivative should have modification on the side of N-phenylpropionamide. If the neutral loss is 149 Da, it should be a fentanyl derivative that had a modification on the cyclohexylamine. By utilizing this observation, a KNIME workflow could be established based on the fragmentation pattern of fentanyl derivatives obtained from MS/MS on an Agilent® G6520B qTOF mass spectrometer. This KNIME workflow was able to read MS/MS spectrum file (in form of a CSV file) from different software vendors and determine the structure of major fragment ion by  $m/z$  and mass difference based on a set of preset rules. It could also predict structural similarity as a numeric factor of Tanimoto coefficient by calculating the proportion of common functional groups between unmodified fentanyl and fentanyl derivative.

## K2 An Evaluation of Screening for Drug Use Using Postmortem Prolactin (PRL) Levels in Serum and Cerebrospinal Fluid (CSF)

Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School Legal Medicine, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN

**Learning Overview:** The goal of this presentation is to show the significance and practicability of measuring PRL as a drug screen by means of a biochemical examination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the utility of drug screening examinations using PRL as an index.

**Introduction:** PRL is a hormone primarily secreted by lactotrophs in the anterior pituitary gland. PRL secretion can be controlled by PRL-inhibiting factors such as psychiatric drugs, including anti-dopamine agents. The use of Dopamine (DA) antagonists to increase PRL levels may lead to hyperprolactinemia under clinical circumstances. On the other hand, as a screening method for drug use, detection of the drug in question has been the main approach to date, and reports using hormone levels in body fluids as indices have been lacking. It is speculated that PRL would offer a marker in autopsy cases with unknown details of drug abuse. The goal of this study was to investigate postmortem PRL levels in serum and CSF as potential markers of drug abuse in autopsy cases.

**Materials and Methods:** One hundred twenty-one autopsy cases were examined, after excluding cases involving acute hypoxia/ischemia such as asphyxia, because PRL concentrations are reportedly increased under hypoxic conditions. Detected drugs were classified as DA antagonists ( $n=10$ ), stimulants (e.g., methamphetamine and amphetamine;  $n=10$ ), psychotropic drugs other than DA antagonists ( $n=23$ ), other non-psychotropic drugs ( $n=28$ ), and no detected drugs ( $n=50$ ). Samples comprised of blood collected from the right heart chamber and CSF. PRL was measured by chemiluminescent enzyme immunoassay. *PRL* gene expression in the anterior pituitary of autopsy cases was analyzed by Reverse Transcription-Polymerase Chain Reaction (RT-PCR). The PRL-positive cell ratio in the anterior pituitary gland was measured by immunohistochemical analysis. Gynecomastia was also evaluated using Computed Tomography (CT), and compared with serum and CSF levels of PRL.

**Results:** Serum PRL levels in the present cases, except for DA antagonist cases, were similar to clinical reference levels (3.1–29.3ng/mL). PRL levels in serum and CSF were higher in DA antagonist cases (serum: range 18.8–200ng/mL, median 41.0ng/mL; CSF: range 11.7–394ng/mL, median 34.1ng/mL) than in other cases (serum: range 1.99–217ng/mL, median 20.3ng/mL; CSF: range 1.23–97.2ng/mL, median 9.26ng/mL). Significant differences in *PRL* gene expression in the anterior pituitary were evident between DA antagonist cases and other drug cases ( $p < 0.0001$ ). However, no significant difference in immunohistochemical PRL-positivity ratio in the anterior pituitary gland was evident between drug-detected and drug-undetected cases. PRL levels in serum and CSF correlated with *PRL* messenger RNA (mRNA) expression in cases with abuse of DA antagonists. No relationships were identified between serum or CSF PRL level and gynecomastia using CT in any groups using drugs.

**Discussion:** Use of DA antagonists increased PRL levels in both serum and CSF from autopsy cases. High RT-PCR expression of *PRL* with high serum and CSF levels of PRL were suggested to be controlled by *PRL* gene expression response. These results suggest that postmortem measurements of PRL may prove useful for diagnosing cases of DA antagonist use.

### Prolactin, Dopamine Antagonist, Drug Screening

## K3 Metabolism and Estimation of Intake of Intravenous Nicotine Injection

*Alissa M. Shida, BS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School Legal Medicine, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN*

**Learning Overview:** The goal of this presentation is for attendees to better understand the distribution of nicotine in the body and the pathophysiology of acute nicotine poisoning.

**Impact on the Forensic Science Community:** Estimating the details of nicotine intake based on its distribution of nicotine and its metabolite, cotinine, in the body could be expected to be helpful for not only forensics, but also treatment for acute nicotine poisoning.

A rare case of death involving nicotine poisoning through an intravenous injection was experienced; the metabolism of nicotine in the body was analyzed and the intake was estimated based on the results.

**Case History:** A young Asian female was found by her husband in cardiorespiratory arrest in a hotel room. She was brought to the hospital, but was subsequently declared dead. About 36 hours later, a forensic autopsy was performed to identify the cause of death. A syringe, liquid nicotine, and hydrogen peroxide water were found in her hotel room.

**Autopsy Findings:** The subject was an adult female (height: 153cm; weight: 45.3kg). She had dark reddish-purple hypostasis and her face was moderately congested. The palpebral conjunctivae were congested, with few petechiae. Injection marks running along the course of the blood vessel with subcutaneous hemorrhage were seen on the left elbow fossa, left forearm, and right upper arm. Both left and right heart blood contained dark red blood with liquidity. The brain (1,285g) was edematous and swollen, and the lungs (left: 380g; right: 385g) were moderately congested with parenchymal hemorrhage. The other organs were also congested.

**Results and Discussion:** The present case was considered acute poisoning. Toxicologic examination clarified the presence of nicotine, which reached the lethal level in blood. Further examination was performed in other body fluids and organs, and a high level of nicotine was detected in the tissue around the injection mark on the right upper arm. Cotinine, the metabolite of nicotine, was quantified, but a low level was indicated, except for in the tissue around the injection mark on the right upper arm. Hydrogen peroxide was also quantified, and the results were within the normal range of a healthy person. For these reasons, it was concluded that the cause of death was acute nicotine poisoning by intravenous injection. Nicotine absorbed into the body migrates to the liver to be metabolized and discharged from the kidneys. Based on the half-life of nicotine and cotinine, it appears possible to estimate the amount and the time passed since intake, but this is extremely difficult because of individual genetic and racial differences in the metabolism of nicotine. Therefore, much more data must be collected from individual samples and analyzed in terms of the efficiency of nicotine metabolism. The quantification of nicotine and cotinine in cases involving nicotine poisoning could be useful to estimate the amount, route, and time of intake.

### Nicotine, Injection, Toxicology

## K4 A Validated Method for the Quantitative Determination of Anabolic Steroids in Urine by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Shaiju Vareed, PhD\*, *Expertox, Inc, Deer Park, TX 77536*; Ernest D. Lykissa, PhD, *Expertox, Inc, Deer Park, TX 77356*

**Learning Overview:** After attending this presentation, attendees will better understand a validated method for the quantification of anabolic steroids in urine by basic hydrolysis, liquid-liquid extraction, and LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a method validation to rapidly and simultaneously confirm 12 anabolic steroids in urine.

Anabolic steroids are the synthetic analogues of testosterone. These drugs have high abuse potential and are most often used by males to increase muscle mass and enhance athletic performance. Abuse of anabolic steroids can lead to early heart attacks, strokes, liver tumors, kidney failure, and psychiatric problems. Also, stopping use of these drugs can cause depression, which in turn can lead to resumption of use. Unlike many other drugs of abuse, these drugs are often injected; therefore, users who share needles or use non-sterile injecting techniques are also at high risk for contracting dangerous infections such as viral hepatitis and HIV.

Most of the methods for the detection of steroids are currently based on Gas Chromatography/Mass Spectrometry (GC/MS) analysis. These methods involve lengthy extraction procedures followed by derivatization of steroids and metabolites. Additionally, GC/MS methods are used to detect steroid metabolites instead of the parent drug due to their lower sensitivity. An LC/MS/MS method was recently developed for the detection, identification and quantification of 12 anabolic steroids (testosterone, boldenone, fluoxymesterone, clostebol, oxandrolone, formestane, clenbuterol, dihydroepiandrosterone, epitestosterone, methandrostenolone, stanozolol, and 3-hydroxystanozolol) in urine samples. Briefly, the method involved hydrolysis of glucuronide metabolites of steroids using  $\beta$ -glucuronidase followed by liquid-liquid extraction. The dried extracts after reconstitution with organic/aqueous solvents mixture were injected onto an Agilent® 6460 QQQ LC/MS/MS in positive ionization mode. Separation was achieved on an Agilent® ZORBAX® Eclipse® XDB-C18 column (4.6 x 100mm, 1.8um) with a flow rate of 0.3mL/min of 0.1% formic acid in H<sub>2</sub>O (A) and 0.1% formic acid in methanol (B). The gradient was initiated at 50% B, increased to 60% B over 2min, held at 60% B until 9min, increased to 100% B until 12min and held at 100 % B until 15min, decreased to 50% B at 15.1min, for a total run time of 19min. Method validation was conducted according to the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines.

Sample preparation involves basic hydrolysis followed by liquid-liquid extraction. Good linearity and reproducibility were obtained for all steroids and metabolites with a coefficient of determination  $R^2 > 0.99$ . Limits Of Quantification (LOQ) ranged from 1ng/mL to 5ng/mL for various steroids and metabolites. Excellent imprecision and accuracy were achieved (CV <15%) for all steroids and metabolites. Twenty-five urine samples collected from international competitors were tested using this method. Stanozolol, boldenone, testosterone, epitestosterone, and clenbuterol were the major positive steroids found in this study.

### Anabolic Steroids, LC/MS/MS, Drug

## K5 Cocaine Overdose: A Fatal Record

Adriano Acella\*, Bari, Puglia 70124, ITALY; Carmelinda Angrisani, MD, Institute of Legal Medicine, Bari, ITALY; Giuseppe Strisciullo, BES, University of Bari, Bari 70124, ITALY; Francesco Introna, MD, Dim Sezione Di Medicina Legale, Bari 70124, ITALY; Antonio De Donno, PhD, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand how high human tolerance can be to cocaine in chronic consumers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community due to the extraordinary case reported: a blood cocaine concentration of 333mg/l was found, the highest recorded concentration of cocaine ever found in overdose death.

The decedent was a 48-year-old White male who police reported had a long history of cocaine abuse; he was found dead in his bathroom between the toilet bowl and the shower, with the door of his house closed from the inside and no evidence of a break-in. Furthermore, his ex-wife reported that he hid drugs under his shoe insoles. Police also discovered some white powder on a bathroom cabinet, which was determined to be cocaine.

The autopsy revealed pulmonary edema and generalized visceral congestion, no foreign body in the airways, and no violent injuries on the corpse. White crystals were found on the decedent's nostrils. A nasal swab and a pulmonary artery blood sample of 25cc were taken and stored at -20°C. Both samples were submitted to the toxicology laboratory of Bari for analysis; samples of vitreous humor, urine, hair, and abdominal fat were taken for further testing.

Due to appropriate fluidity and the suitable quantity of blood taken, the blood sample did not require any dilution in order to be tested. Standard screening protocols were applied during blood testing: Headspace/Gas Chromatograph/Flame Ionization Detector (HS/GC/FID) was used to search for alcohol and the immunochemical method was used to search for drugs (cocaine, methadone, cannabinoids, opiates, barbiturates, benzodiazepines, amphetamines, and tricyclic antidepressants). Positive results were found for cocaine and further testing was conducted by Gas Chromatography/ Mass Spectrometry (GC/MS); a blood concentration for cocaine of 333mg/l, Ecgonine Methyl Ester (EME) of 35.1mg/l, and Benzoyllecgonine (BE) of 69.1mg/l was reported. Testing on the nasal swab by GC/MS/FID resulted positive for cocaine, EME and BE, confirming that the drug was administered (or possibly self-administered) intranasally.

The outstanding concentration observed prompted a review of scientific literature to compare it with the ones previously reported. Spiehler and Reed measured blood cocaine concentrations exceeding 20mg/l in three fatalities.<sup>1</sup> Mittleman and Wetli found a blood cocaine concentration as high as 30.9mg/l in their review of 60 cocaine-related overdose deaths.<sup>2</sup> Amon et al. reported a blood concentration of 211mg/l after an ingested bag of cocaine broke in a victim's intestine.<sup>3</sup> The highest blood concentration reported so far in literature was by Peretti et al. of 330mg/l, 1.5 times greater than Amon et al., found in a young woman who had a long history of cocaine abuse.<sup>4</sup>

The last case mentioned jointly with the present one, which records the new highest cocaine blood concentration, offer new insights on human tolerance to cocaine in chronic consumers. Analyzing literature, it seems that nobody but chronic consumers could tolerate doses of cocaine in the order of 10<sup>2</sup>mg/l. To confirm this hypothesis, it would be appropriate for the scientific community to report cocaine intoxication cases as much as possible.

### Cocaine Overdose, Toxicology, Highest Blood Concentration

## K6 The Identification of Xylazine in a Patient Who Presented for Heroin Withdrawal

Colin Appleford\*, Royal Oak, MI 48073; Michael P. Smith, PhD, Beaumont Health System, Royal Oak, MI 48073

**Learning Overview:** The goal of this presentation is to present a recent case of a patient whose toxicology studies revealed the presence of xylazine and to inform the audience about xylazine as a drug adulterant and drug of abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness about a less well-known veterinary medicine and providing information about how to detect the drug in human samples.

**Introduction:** It is important not to overlook veterinary medications as possible drugs of abuse. Having an awareness of these medications is crucial for physicians, forensic pathologists, and toxicologists. Xylazine is a sedative used in veterinary medicine and there are few reports of it being used as a drug of abuse or a drug adulterant in the literature. Detection of xylazine in human samples can be performed by using Gas Chromatography/ Mass Spectrometry (GC/MS).<sup>1</sup> This is a case report of a woman who presented to the emergency department in Royal Oak, MI, for heroin withdrawal, and urine toxicology tests revealed the presence of xylazine.

**Case Presentation:** A thirty-two-year-old female presented to the emergency department with a chief complaint of nausea, intractable vomiting, and tremors. She has a past medical history of Intravenous (IV) drug abuse, alcohol abuse, anxiety, depression, and hepatitis C. Physical exam findings revealed that the patient had tachycardia (heart rate=139bpm) and multiple skin lesions and scars on the upper and lower extremities. A complete blood count revealed that the patient was anemic (hemoglobin=11.8g/dL) and had neutrophilia with a left shift (neutrophils=14.9bil/L). A comprehensive metabolic panel showed an elevated blood glucose (134mg/dL) and an elevated aspartate aminotransferase (45U/L). During the patient interview, she stated that she used heroin the night before she came to the hospital. The patient was admitted to the hospital for heroin withdrawal and was started on IV fluids and antiemetics.

A comprehensive drug analysis was performed and the patient's urine was positive for codeine, morphine, hydromorphone, and 6-acetylmorphine. GC/MS was performed on the urine, which revealed a lidocaine metabolite, nicotine and metabolites, diphenhydramine, xylazine, ondansetron, fentanyl, and acetyl-fentanyl. The patient ultimately left against medical advice two days after coming to the hospital.

**Discussion:** Xylazine is an alpha-2 adrenergic agonist and is used as a sedative, muscle relaxant, and analgesic in veterinary medicine. It is administered to animals intravenously, intramuscularly, and subcutaneously. It has been reported that xylazine has been used on its own as a drug of abuse and as an adulterant for heroin. This medication has also been reported to be used as an adulterant with speedball (a mixture of heroin and cocaine).<sup>2</sup> A study published in *Forensic Science International* in 2014 reviewed the literature and found 43 cases of xylazine intoxication. Out of those 43 cases, 22 of them were fatal.<sup>1</sup>

When xylazine is used alone as a drug of abuse, the main route of administration is injection. However, there have been reports of xylazine being inhaled or taken orally. The physical exam findings for a patient who has overdosed on xylazine include lethargy, miosis, hypotonia, respiratory depression, and hypothermia. The clinical presentation of a patient who has overdosed on xylazine will look similar to a clonidine or opioid overdose. For patients who are intoxicated with xylazine, the treatment plan is supportive. Health care providers need to be aware of the need for endotracheal intubation for respiratory depression.<sup>3</sup> Analytical techniques to identify and quantify xylazine in human samples include GC/MS and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).<sup>1</sup> It's important to note that standard hospital drug screens will not detect the presence of xylazine, like most other Novel Psychoactive Substances (NPSs). The approach that this health system has adopted is designed to be able to confirm the ingestion of NPSs in patients that are still in the emergency room. This has allowed the physicians to attribute certain presenting signs and symptoms to NPSs and treat the patients more appropriately, as well as adding important information regarding local drug surveillance data.

## K7 An Unusual Case of Suicide by Fluvoxamine Poisoning

*Jessica Quaiotti, MD, Department of Public Health, Pavia 27100, ITALY; Matteo Moretti, MD\*, University of Pavia, Pavia 27100, ITALY; Claudia Carelli, Cossato, ITALY; Silvia D. Visona, MD, University of Pavia, Pavia 27100, ITALY; Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Claudia Vignali, University of Pavia, Public Health Experimental, Pavia, ITALY; Luca Tajana, University of Pavia, Pavia 27100, ITALY; Luca Morini, Pavia, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY*

**Learning Overview:** After attending this presentation, attendees will be aware of a particular case of fluvoxamine fatal poisoning.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing blood concentrations of fluvoxamine and other drugs in a fatal intoxication case; these data could be useful in the interpretation of further cases of death.

This case regards a 48-year-old woman with psychiatric disorders, who died in the protected community where she lived. She suffered from obsessive-compulsive disorder, personality disorders, and mild mental retardation.

The patient was treated daily with: haloperidol 2mg/mL (10 drops twice a day); fluvoxamine tablets (150mg); clonazepam (2.5mg/mL; 20 drops three times a day); gabapentin tablets (300mg twice a day); propranolol hydrochloride tablets (40mg); and, when needed, clonazepam (100mg/mL; 20 drops) was also administered.

The woman was found unconscious by the paramedical staff of the protected community at about 3:00 p.m. in the bathroom of her room, where she was heard alive through the closed door at 11:30 a.m. of the same day. After trying to call the woman several times, the health care workers opened the door using a special key. They found the patient sitting on the toilet, her mouth smeared with pink-colored vomit. In her mouth, in her hands, and on the floor there were also many sheets of toilet paper, pink in color. Resuscitation attempts were in vain, and the woman's death was recorded at 3:45 p.m. The appropriate authorities were not notified, and the room was cleaned up and the corpse was prepared for the funeral.

Later, an autopsy was ordered to assess the cause and manner of the death and was performed nine days after the death. External examination was essentially negative with no significant findings, except for some marks caused by resuscitation attempts. Green discoloration of the lower abdomen was present. Pink fluid, with pieces of material similar to the one present in the stomach, were observed in the entire respiratory tract. Smooth material, pink-violet in color, was found in the esophagus. All the viscera were congested. Sporadic subpleural petechiae could be observed. Histological investigations revealed pulmonary edema and the presence of vegetable matter in the bronchioles as well as in the alveoli. In many places, the alveoli were expanded with broken septa.

Blood and urine were collected for toxicological analysis. Quantitative determination of ethanol and systematic toxicological analysis to detect acidic, neutral, and basic drugs was performed on peripheral blood sample. They were conducted using Gas Chromatography/Mass Spectrometry (GC/MS), preceded by a solid phase extraction with mixed-mode cartridges. The analyses allowed the identification of the following drugs: fluvoxamine, clonazepam, 7-aminoclonazepam, propranolol, gabapentin, and haloperidol. Quantification of the detected drugs in the blood was performed by means of a validated Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analytical procedure and the following results were achieved: fluvoxamine (4.3mg/L), gabapentin (41mg/L), 7-aminoclonazepam (0.24mg/L), clonazepam (0.07mg/L), haloperidol (<0.01mg/L), and propranolol (0.24mg/L). Contributory causes of death, due to multiple drugs use, cannot be excluded. However, the fluvoxamine concentration in the blood exceeded approximately 20 times the upper limit of therapeutic blood levels (0.23mg/L) and was consistent with literature data about fatal poisoning.

Fluvoxamine is a Selective Serotonin Reuptake Inhibitor (SSRI) that is used in the management of depression and obsessive-compulsive disorders. Few cases of fluvoxamine intoxication are described in literature, since this drug is considered relatively safe in overdose. Nevertheless, at therapeutic and supratherapeutic concentrations, fluvoxamine might affect cardiac conduction, prolong QTc interval, cause hypotension and obtundation, and increase the risk of seizures.

In the described case, toxicological analyses were essential to determine the cause of death: poisoning with fluvoxamine, complicated by acute mechanical asphyxia due to regurgitated food. The manner of death was deliberate self-poisoning, since further investigations allowed the discovery that the woman probably stole several tablets of fluvoxamine from the clinic.

### Fluvoxamine, Overdose, Postmortem Blood Concentration

## K8 Delta-8-Tetrahydrocannabinol (Delta-8-THC): Increased Prevalence in Drug Seizure Cases and Impact on Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Analysis of Biological Specimens

Nicholas B. Tiscione, MS\*, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406; Steven J. Williams, BS\*, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406; Diana M. Lawrence, MSFS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406

**Learning Overview:** After attending this presentation, attendees will understand the increased prevalence of delta-8-THC in drug seizure cases and the potential impact on LC/MS/MS analysis of biological specimens for cannabinoids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing toxicologists of the need to evaluate LC/MS/MS cannabinoid methods for the potential of interference of delta-8-THC with delta-9-THC.

**Introduction:** Delta-8-THC is a cannabinoid that is a minor constituent found naturally in the cannabis plant. Delta-8-THC is an analog of delta-9-THC and has similar effects and receptor activity, but lower potency. Recently, drug seizure exhibits submitted in Palm Beach County, FL, have contained delta-8-THC as the primary constituent or as a mixture with delta-9-THC. The first drug seizure submission was from an incident that occurred in November of 2018. From November 2018 to June 2019, delta-8-THC has been identified in a total of 12 drug seizure cases with 4 cases from May 2019. Ten of the exhibits were vape cartridges and two were food items.

**Objective:** Evaluate the ability of a validated LC/MS/MS blood cannabinoid quantitation method employing a biphenyl LC column to discriminate between delta-8 and delta-9-THC.

**Method:** A previously described LC/MS/MS blood cannabinoid quantitation method that included delta-9-THC, delta-9-hydroxy-THC, and delta-9-carboxy-THC was employed.<sup>1</sup> Briefly, 0.5mL of whole blood was extracted by liquid-liquid extraction with hexane:ethyl acetate (80:20). Analysis was conducted on a Shimadzu® Prominence XR LC system with a SCIEX™ 3200 Qtrap® MS/MS and a Raptor™ Biphenyl column with dimensions of 50 x 2.1mm and a 2.7µm particle size. A gradient LC program was employed with LC/MS water and LC/MS methanol, each with 0.1% formic acid. The calibration range was from 1–40ng/mL for delta-9-THC and delta-9-hydroxy-THC and 5–200ng/mL for delta-9-carboxy-THC. Stable isotope internal standards were used for all three target analytes.

Three different fortified blood samples were prepared and extracted along with the routinely used calibrators and controls to evaluate the selectivity of the method through an interference study: one fortified with delta-8-THC at 40ng/mL without internal standard; one fortified with delta-8-THC at 5ng/mL with internal standard; one fortified with delta-9-THC and delta-9-hydroxy-THC at 5ng/mL, and delta-9-carboxy-THC at 25ng/mL, as well as delta-8-THC at ng/mL with internal standard.

**Results:** There was no interference from a high concentration of delta-8-THC (40ng/mL) with the internal standards. Delta-8-THC did not interfere with delta-9-OH-THC or delta-9-carboxy-THC, but did interfere with delta-9-THC. Delta-8-THC produces the same precursor/product ion transitions in the same relative abundances as delta-9-THC. The retention time for delta-8-THC (4.75) was 0.03 minutes later than the average of the calibrators (4.72), but was still within the 0.1 minute acceptance window. The Multiple Reaction Monitoring (MRM) ratios were slightly higher than the average of the calibrators (36% compared to 32%), but were also within the acceptance range of +/-20%. The 5.0ng/mL delta-8-THC control was identified by the method as containing delta-9-THC at 4.7ng/mL. The mixed control containing both delta-8-THC and delta-9-THC, each at a target concentration of 5.0ng/mL, was identified by the method to contain delta-9-THC at 9.4ng/mL. No split peak or other indication of the presence of two unique compounds was observed. Unpublished reports from laboratories employing C-18 LC columns have observed a split peak with incomplete resolution of delta-8 and delta-9-THC. Drug standards for delta-8-hydroxy-THC and delta-8-carboxy-THC were not available to evaluate potential interferences for the delta-9 counterparts targeted by the method. A polar-C18 column was evaluated and demonstrated the ability to resolve delta-8- and delta-9-THC. Further work will be conducted to develop a method employing a polar-C18 column.

**Conclusion:** The LC/MS/MS blood cannabinoid method employing a biphenyl LC column could not discriminate between delta-8- and delta-9-THC as the compounds have identical MRM transitions and were not resolved chromatographically. Delta-8-THC may also cause interference with delta-9-THC for LC/MS/MS methods that employ a C-18 column. LC/MS/MS methods for the determination of cannabinoids should be evaluated for specificity between delta-8- and delta-9-THC and the potential impact to casework examined.

### Delta-8-THC, Validation, LC/MS/MS

## K9 The Determination of the Organic Components of Newer Generation E-Cigarette Liquids

Bailey Davis, BS, BA\*, State College, PA 16801; Frank Dorman, PhD, University Park, PA 16802-4500

**Learning Overview:** After attending this presentation, attendees will learn how Gas Chromatography coupled to Mass Spectrometry (GC/MS) can be utilized to identify and quantify targeted chemical components in newer generation e-cigarette products. This will include products that contain cannabinoid compounds, such as Cannabidiol (CBD), in addition to nicotine and other materials.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing analysts with a relatively simple method to analyze e-cigarette products and informing them about the potential harms the constituents of e-cigarette liquids may pose to the public without proper product regulation and quality control measures.

In 2003, the electronic cigarette (also known as an e-cigarette, electronic nicotine delivery system or ENDS, vaporizer device, vape pen, etc.) was introduced to the global market, reaching the United States in 2007, and quickly growing into an extremely lucrative enterprise.<sup>1,2</sup> E-cigarettes differ from traditional cigarettes through the use of a heating element/atomizer to heat a cartridge composed of purified and processed nicotine, propylene glycol, vegetable glycerin, additives, and flavorings to the point of vaporization.<sup>2-7</sup> This vapor is then inhaled by the user. It is hypothesized that e-cigarettes have become such a successful product due to being heavily marketed as a smoking cessation aid and as a “healthy” alternative to traditional cigarettes.<sup>2,5,6,8,9</sup> Additionally, companies are using more modern market avenues to advertise and sell their products and are offering an extremely wide variety of nicotine concentrations and flavors that are not available for cigarettes and other nicotine alternatives.<sup>2,5,6,8,9</sup> E-cigarette vaporizers range from the first generation “cig-alike” devices to highly customizable third generation “mods” to the more recent and well known JUUL™.<sup>5</sup>

Recently, e-cigarettes have been focused on by the media with claims of lack of regulation by the Food and Drug Administration (FDA) and poor quality control.<sup>3,8-10</sup> The absence of these measures has resulted in inconsistent policies at the local, state, and federal levels and a lack of knowledge about the substances present in e-liquid and the subsequent produced vapor.<sup>6</sup> However, the largest issue addressed includes accusations that the introduction of e-cigarettes has sparked an epidemic of nicotine addiction among American youth that may act as a gateway for non-smokers to transition to traditional smoking or more illicit drug use.<sup>1,2,5,6,9,11-13</sup> The goal of this project is to further investigate and possibly identify the potentially harmful chemical components either present, or created through the use of, newer e-cigarette products common among young people in the United States.

Different types of e-cigarette liquid and devices were investigated in this project, including bulk e-liquids with a SMOK® MAG Kit third-generation device or “mod”, JUUL™ and JUUL™-compatible cartridges (this includes JUUL™, SEA100™, and Hempzilla™ pods) with a JUUL™ e-cigarette device, and thicker CBD oils and/or cannabis e-liquid cartridges with a Yocan® Evolve 2.0 Vape Pen. Samples were prepared by attaching the vaporizer devices to a smoking pump to produce vapor for each e-liquid. This vapor was pulled through a water trap in a glass impinger in order for its components to be trapped in the water and separated from the viscous propylene glycol and vegetable glycerin found in e-liquids, which are not very compatible with GC/MS systems. A liquid-liquid extraction was then performed with dichloromethane, and the samples were analyzed with an Agilent® 7890A GC and a 5975C inert MSD with Triple Axis Detector. The column utilized for separation was an Rtx-5 column (Restek®, 30m, 0.25mm ID, 0.25µm film thickness). Targeted sample components were identified using the National Institute of Standards and Technology (NIST) 2014 database and comparison to certified reference materials. Identified components were quantified via calibration standards for each target. Substances of interest included nicotine, formaldehyde, acetaldehyde, diacetyl, acetyl propionyl, CBD, THC, and others. This selection was based on previous research regarding the harmful components found in traditional cigarettes and potentially in e-cigarette products.

## K10 Driving Under the Influence of 1,1-Difluoroethane (DFE) and Marijuana

Aybike Dip, PhD, Turkish Ministry of Justice, Adana 00100, TURKEY; Ashraf Mozayani, PharmD, PhD\*, Texas Southern University, Houston, TX 77004

**Learning Overview:** After attending this presentation, attendees will better realize the intoxicating effects of DFE and marijuana on driving performance.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of DFE abuse and the importance of immediately collecting blood samples from drivers in traffic accidents. The knowledge gained will help improve investigations into vehicle accidents involving DFE and/or marijuana consumption.

DFE is a colorless, flammable hydrofluorocarbon with a slight ethereal odor. It is widely used in refrigeration, electronic cleaning products, and various aerosol propellant products that are sold in many markets.<sup>1</sup> When DFE is inhaled or huffed, it causes short but intense euphoria.<sup>2</sup> Due to its euphoric effects, it is abused by people who can easily access them, even in local supermarkets. The high from DFE inhalation can cause dizziness, euphoria, hallucinations, disorientation, loss of motor control, confusion, memory loss, pulmonary irritation, loss of consciousness, and sudden death by causing heart failure, even on the first use. Investigations of driving incidents involving DFE have shown that drivers who lost consciousness frequently have no memory of events immediately prior to the accident.

This case involved a 20-year-old man who went for a ride with his friends early in the morning. While driving around the city, he stopped the car at a local supermarket, where one of the passengers stole a can of air duster that contained compressed air used to clean computer keyboards. After leaving the market, he huffed some of the mixture from the can and passed it to the driver. A few minutes after huffing, the driver lost control of the vehicle, crashed into and snapped off a wood telephone pole, then proceeded to crash into a store. There were no fatalities; however, the driver as well as all passengers were severely injured due to the accident.

A blood sample of the driver was taken about an hour after arrival at the hospital. Blood test results were found as 0.92ng/mL of delta-9-THC (which is active ingredient of marijuana), 16ng/mL of delta-9-carboxy-THC by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), and 2µg/ml DFE by Gas Chromatography/Mass Spectrometry (GC/MS). No alcohol was detected. Per research, this appears to be the first case report of a traffic accident that involved both DFE and marijuana consumption of a living subject.

It can be concluded that the DFE level was consistent with other Driving While Intoxicated (DWI) incidents and the presence of both DFE and THC in the blood were contributing factors to the accident.

### 1,1-Difluoroethane, Marijuana, DUI

## K11 Driving Under the Influence (DUI) in the United States and Brazil

*Aline T. Bruni, University of São Paulo, Ribeirão Preto, São Paulo 14040-901, BRAZIL; Ashraf Mozayani, PharmD, PhD\*, Texas Southern University, Houston, TX 77004*

**Learning Overview:** The focus of this research is a comparative investigation of the forensic science and criminal justice aspects of DUI between the United States and Brazil.

**Impact on the Forensic Science Community:** With globalization, it is essential to know the practical realities within legal traditions and forensic science in different countries. This presentation will impact the forensic science community by increasing familiarization of similarities and differences between two countries in the application of forensic science and the law.

This study focused on comparisons of institutional structures, laws, and forensic evaluations. This study performed literature-based research from several databases: institutional information, gray literature, jurisprudence, and other enlightening sources. The comparisons were mainly overextending of forensic evidence, law definitions included the category of offenses, types, and limits of each drug, classes of tests, and other weighty information. Regarding institutional aspects, in the United States, DUI is mainly a state law offense. A federal DUI charge arises for crimes that occur on federally owned land or another location that is considered federal property. In Brazil, there is a single Code, Law 9.305/1997, which is applied to the entire country with no difference among the states.

In respect to variations in law, in the United States, some states' laws differentiate between the terms DUI and Driving While Intoxicated (DWI), but in most, the terms are interchangeable. In Brazil, there is no difference between DUI and DWI. For all states in the United States, a person is deemed to be intoxicated when the Blood Alcohol Concentration (BAC) is equal to or above 0.08% (0.08g dL<sup>-1</sup>). The penalties are also different for each state. In Brazil, there are the following situations: (1) Article 165 of the Brazilian Traffic Code considers as a misdemeanor driving under the influence of alcohol. Any amount of alcohol detected in the breathalyzer subjects the driver to the penalties foreseen in Article 165—a fine and a suspended license for 12 months, and (2) Article 306 establishes as a crime a BAC above 0.6g L<sup>-1</sup> or 0.3mg L<sup>-1</sup> exhaled air, and the punishment involves a prison sentence. In the United States, the extension of drug testing is different in each state and even in a different part of one state. Sometimes no drug gets tested if the level of alcohol at the time of driving was more than 0.08 mg L<sup>-1</sup>. In Brazil, the Nacional Transit Council (Conselho Nacional De Trânsito (CONTRAN)) states that some tests shall be performed to confirm the alteration in psychomotor ability. The influence of alcohol can be verified through a blood test or regulated breathalyzers. Other laboratory examinations will confirm the influence of other psychoactive substances. The transit agencies or the judicial police are responsible for indicating the laboratories permitted to perform the exams (Resolution 432/2013). The laws of both countries also provide punishment consequences for a refusal to take a breathalyzer test. A comparison of forensic aspects revealed that, although there are significant differences between the United States and Brazil regarding the types and amounts of substances and the relative penalties, there are also similarities such as: (1) chemical tests related to detecting the type and quantity of the substances; and (2) the police officer's testimony about the behavior of the driver is considered as evidence for DUI.

In conclusion, comparative research can be useful for disseminating the laws of other countries, which reflects differences in cultures, history, and societies between countries, in this case, between the United States and Brazil.

### Driving Under Influence, Comparative Research, United States and Brazil

## K12 Methadone-Related Deaths: A Six-Year Study in a Major Italian City

*Stefano Errico\**, Genova, ITALY; *Davide Bedocchi, MD*, Istituto Di Medicina Legale E Delle Assicurazioni, Genova 16132, ITALY; *Martina Drommi\**, Genova 16132, ITALY; *Rosario Barranco\**, University of Genova, Department of Legal Medicine, Genova 16132, ITALY; *Alessandro Bonsignore, MD, PhD\**, University of Genova, Genova, Liguria 16132, ITALY; *Francesco Ventura, MD\**, Department of Legal Medicine University of Genova, Genova 16132, ITALY

**Learning Overview:** After attending this presentation, attendees will learn about the risks of self-administration of methadone to counter heroin abuse.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the relevance of carrying out a complete autopsy examination, supported by histological and toxicological evaluations, in patients with methadone therapy, in order to identify the real cause of death and the contemporary consumption of other drugs. This presentation will also impact the forensic science community by underlying the implication of the increase in illegal sales of substances for self-administration together with methadone as a substitutive therapy and related risks in non-addicted patients.

Methadone is a synthetic opioid, a pure agonist of the  $\mu$  receptor. It has the advantages of high oral bioavailability, long half-life, absence of active metabolites, and low cost. Like other opioids, methadone causes addiction and tolerance. Side effects of methadone are pulmonary edema and respiratory depression, particularly in the chronic abuser, and ventricular arrhythmia in those subjects who consume it in high doses for illicit use. In Italy, methadone is commonly distributed by the National Health System for heroin substitutive therapy in addicted patients. Dedicated structures provide methadone for these patients. In the past years, national studies of incidence and prevalence have demonstrated an increase in illegal sales of methadone and, consequently, also an increase in deaths due to acute methadone intoxication.

This study included 31 subjects' deaths due to methadone consumption: 25 were male and 6 females. Eleven subjects (36%) were under substitutive treatment at the time of death, 3 subjects were previously monitored, and 11 subjects were unknown to the addiction therapy system. In all cases, a complete autopsy was performed and blood samples were collected for toxicological analysis using gas chromatography/mass spectrometry.

The concentration range of methadone in the blood samples was 46 to 4,058.53ng/mL, with an average of 821.46ng/mL. The range in patients under substitutive treatment was 61.8 to 4,058.53ng/mL, with an average of 1,148.86 ng/mL. The range in other subjects was 46 to 1,830ng/mL, with an average of 614.68 ng/mL. Five subjects presented a single positivity to methadone (three were followed by the National Health System, with an average concentration of 2,028.51ng/mL and the other two with an average methadone concentration of 1,166.5ng/mL). Other subjects were positive for different drugs or substances in sub-lethal concentrations: 13 subjects with alcohol, 11 with cocaine, 7 with benzodiazepines, 5 with other opioids, 2 with tetrahydrocannabinol, 3 with neuroleptics, 1 subject with serotonin re-uptake inhibitors and 1 with barbiturates; 84% of patients were positive for at least two substances.

Such results of methadone concentrations correspond to known lethal dosages. According to the literature, usual consumers of methadone develop a much higher tolerance than subjects who take it for illicit use.

The substitutive therapy with methadone is effective and works properly, but illegal sales and consumption of methadone, which has increased in recent years, can have a negative impact on self-administration of opioid addiction treatment therapies, inducing patients who enhance their own doses; moreover, it produced a rise in methadone-related deaths. Accordingly, careful monitoring of doses administered to patients is requested to make the system safer. In this context, a systematic urinary research of sucrose and lactose (disaccharides), in order to discover—with a high degree of reliability—the route of administration, could represent a medicolegal contribution to contrast and identify illegal intravenous methadone intake and related deaths.

### Methadone, Forensic Toxicology, Drug Addiction

## K13 Comparison of Ethanol Concentrations in Blood and End-Expired Breath During a Controlled Drinking Study

Sean Bortz, BS\*, Chemical Testing Section, Tomah, WI 54660; Diane Kalscheur, BS, Wisconsin State Laboratory of Hygiene, Madison, WI 53707; Lindsey K. Skaggs, BS, University of Wisconsin Platteville, Platteville, WI 53818; Heather Barkholtz, PhD, Wisconsin Department of Transportation, Madison, WI 53704

**Learning Overview:** After attending this presentation, attendees will understand how near-simultaneous Blood Alcohol Concentration (BAC) and Breath Alcohol Concentration (BrAC) quantification compares as ethanol is absorbed and metabolized during a controlled drinking study.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by comparing two popular methods of quantifying bodily ethanol concentration.

Ethanol consumption results in diverse outcomes, such as: intoxication, cognitive impairment, motor incoordination, and dependence.<sup>1</sup> These effects are likely due to ethanol's action on multiple brain proteins, specifically GABA<sub>A</sub> receptors in the central nervous system.<sup>2</sup> Although ethanol's mechanism of action in the brain has yet to be fully understood, ethanol's impairing effects are well documented and bodily alcohol concentration per se limits have been incorporated into various laws. BAC and end-expired BrAC are two popular surrogates to quantify ethanol impairment via ethanol concentration in the brain and are often cited in per se statutes. This study seeks to compare BAC (g/100ml) and end-expired BrAC (g/210L) techniques and results as performed in Wisconsin.

Measurements of ethanol concentration were determined from blood and end-expired breath during a controlled drinking study in which healthy men and women drank 0.55–1.04g ethanol per kg body weight in 60 minutes. Specimens of breath were obtained for analysis of ethanol starting at 30 minutes post-dosing, then every 15-20 minutes for two hours to obtain a curve. One of the BrAC samples in the series was accompanied by a BAC sample to determine measurement agreement throughout the curve. BAC was determined by headspace gas chromatography and BrAC was determined with an electrochemical fuel cell (Intoximeter's EC/IR II), reporting the lower of two correlating breath samples. Results of the two subject breath samples required in Wisconsin's evidential breath test sequence will be discussed as they were highly correlated ( $r=0.98$ ). Additionally, breath alcohol curves will be presented with corresponding BACs, which were also highly correlated ( $r=0.94$ ). Furthermore, comparison of measurement techniques revealed that BrAC results were generally less than the corresponding BAC by 11.8%.

When quantifying and discussing ethanol impairment, it is important to recall that both BAC and BrAC measurements are surrogates for the ethanol concentration in the brain. Results of this study demonstrate how sampling, measurement, and reporting variables impact the final ethanol concentration assessment. Both BAC and BrAC measurements are excellent proxies for ethanol concentration in the brain, and associated impairment at each concentration is well defined in other literature.<sup>3</sup> However, details of the measurement technique and any legally mandated reporting requirements should be considered and explicitly defined when describing ethanol concentration results, particularly while referencing per se limits.

## K14 Longitudinal Transdermal Fentanyl Compared With Morphine Sulfate Treatments in a Rabbit (*Oryctolagus cuniculus*) Model System: Impacts on Behavior and Health

Janna M. Andronowski, PhD\*, The University of Akron, Department of Biology, Akron, OH 44325-3908; Adam J. Schuller, BS, The University of Akron, Akron, OH 44325; Abigail R. LaMarca, The University of Akron, Akron, OH 44325; Reed A. Davis, MS, The University of Akron, Department of Biology, Akron, OH 44325-3908; Mary E. Cole, PhD, The University of Akron, Department of Biology, Akron, OH 44325; Gina R. Tubo, The University of Akron, Akron, OH 44325

**Learning Overview:** The goals of this presentation are to: (1) describe the longitudinal effects of systemic opioids, particularly fentanyl and morphine sulfate, on behavioral and physiologic parameters; and (2) demonstrate the long-term use of transdermal fentanyl patches in the management of analgesia in a rabbit model system.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing novel longitudinal data regarding the behavior and physiologic effects of prolonged opioid use in a rabbit model system. With the current trend of opioid overdoses poised to expand its impact further, forensic scientists will learn an empirical methodology for evaluating soft and hard tissue responses, behavioral changes, and physiological effects associated with prolonged opioid use in a live animal proxy.

Transdermal fentanyl patch systems have been applied to various animal species, including dogs, cats, swine, rabbits, and non-human primates.<sup>1-6</sup> However, in rabbits, the transdermal fentanyl patch literature remains sparse and its application has been investigated in a segmented manner.<sup>4,5</sup> Given the limited data available, an opportunity exists to improve understandings of the longitudinal effects of opioids on rabbit behavior and physiology. This is critical given that rabbits remain a popular laboratory animal for research activities. For example, in 2017, more than 54,000 rabbits were reportedly involved in animal research involving pain and received a pain-relieving drug as a result. Thus, the primary purpose of the current research was to develop a longitudinal model for studying the effects of prolonged opioid exposure, specifically fentanyl and morphine sulfate, in a rabbit model system.

Skeletally mature, 6-month old (2.3-3.0kg), male New Zealand White rabbits (*Oryctolagus cuniculus*;  $n=21$ ) were sourced from Covance Research Products Inc. Rabbits were individually housed in stainless steel rabbit batteries that allowed for some interaction, while keeping the animals lodged separately. The rabbits were quarantined and habituated to the testing conditions for a two-week period. Animals were randomly divided into three groups of seven animals each: morphine, fentanyl, and controls. The control group was further randomly divided into saline vehicle ( $n=3$ ) and transdermal patch groups ( $n=4$ ). Following the acclimation period, the experimental treatments for the opioid groups (morphine and fentanyl) were initiated and continued for eight weeks. The morphine sulfate group received a dose of 3mg/kg/day via subcutaneous injection. The control group was administered saline at a dose of 3mg/kg/day. A 25- $\mu$ g/h slow release transdermal fentanyl patch was placed on the interscapular region of rabbits in the fentanyl group every third day, following shaving of the hair. Patches were secured by an overlying Tegaderm™ transparent film dressing. A placebo patch (Tegaderm™) was placed on each control patch animal comparable to the experimental animals. Rabbit jackets from Lomir Biomedical were applied to all experimental patch (fentanyl) and control animals (Tegaderm™) in order to prevent the animals from chewing the dressings.

Daily observations were recorded at consistent time points. Classifications for fecal output and food consumption were assigned values of 1 (normal), 2 (moderate), and 3 (low), and compared among the treatment groups and controls using one-way Analysis of Covariance (ANCOVA) tests with jacketing as a co-variate. Fecal output was not significantly impacted by drug treatment ( $F_{(2, 17)}=0.286$ ,  $p=0.755$ ,  $\eta^2=0.033$ , power=0.095). Food consumption was significantly impacted ( $F_{(2, 17)}=5.44$ ,  $p=0.015$ ,  $\eta^2=0.390$ , power=0.841), and a Tukey's Honest Significant Difference (HSD) post-hoc test indicated that morphine rabbits were significantly depressed in food consumption compared to controls ( $p=0.012$ ).

Qualitatively, all fentanyl patch rabbits consistently displayed skin irritation and erythema, abnormal stress behaviors (e.g., acute anorexia), respiratory depression, ocular proptosis, and poor overall health compared to the morphine and control groups. While the morphine injections did not result in notable changes in outward appearance, these animals demonstrated consistently lower food consumption throughout the experiment and heavy sedation following treatments. Despite its prevalence in short-term studies in the literature, these findings suggest that long-term experimental use of transdermal fentanyl patches results in behavioral changes that may confound the effects caused solely by the narcotic in question.

This report is the first documented data characterizing longitudinal transdermal fentanyl patches as a route for administration of analgesia in rabbits. The documented adverse effects associated with such longitudinal treatments addresses an evident literature gap that will inform future forensic, biomedical, and veterinary medicine research.

## K15 Fatal Formalin Intoxication in Thailand: A Case Report

*Kamonpan Limlek, MD\**, Siriraj Hospital, Faculty of Medicine, Bangkok 10700, THAILAND; *Arthit Surawisankun, MD*, Siriraj Hospital, Department of Forensic Medicine, Bangkok 10700, THAILAND; *Peerayuht Phuangphung, PhD*, Siriraj Hospital, Forensic Medicine Department, Bangkok 10700, THAILAND

**Learning Overview:** After attending this presentation, attendees will be able to obtain practical information from a case of acute formalin poisoning in terms of clinical presentation, autopsy, and histological findings and toxicological results.

**Impact on the Forensic Science Community:** This study will impact the forensic science community by expanding knowledge of acute formalin poisoning, which is relatively rare in medicolegal cases, and by promoting safety awareness about keeping hazardous chemicals in a hospital environment.

Formalin, an aqueous solution of formaldehyde, is a common solvent used for medical purposes. It is frequently used for tissue fixation in pathology and in dead body preservation as embalming fluid. In Thailand, the embalming procedure is commonly performed by hospital personnel, for example, autopsy staff. In general, embalming fluid in Thailand frequently contains formalin, methanol, phenol, glycerin, buffers, and nitrate compounds. As embalming fluid or formalin has a pungent odor and highly irritating effects, suicidal or accidental ingestion of embalming fluid or formalin is relatively uncommon in medicolegal cases.

This study reports a case of acute and fatal formalin poisoning in a 24-year-old male who was a patient transport staff person in the hospital. The patient drank clear liquid in a water bottle placed in the hospital locker, which was later found to contain chemicals used for embalming fluid preparation. He presented with nausea and vomiting, abdominal pain, and alteration of consciousness. He was then sent to the emergency department. His laboratory results showed severe wide anion gap metabolic acidosis, hypocalcemia, and hypokalemia. His Electrocardiogram (EKG) displayed diffuse ST depression in limb leads and chest leads. He then developed hypotension, Disseminated Intravascular Coagulation (DIC), and upper gastrointestinal hemorrhage. After seven hours in the hospital, he was pronounced dead after unsuccessful cardiopulmonary resuscitation. Due to the source of water found in the bottle he drank and his clinical manifestation, his provisional diagnosis by the attending physician was acute formalin toxicity. After the postmortem inquest, his body was sent for a medicolegal autopsy at the Department of Forensic Medicine, Faculty of Medicine, Siriraj Hospital, Mahidol University for the investigation of cause of death.

Autopsy findings revealed grayish-black discoloration of both tonsils, right palatopharyngeal arch, and some areas of tracheal mucosa. In addition, lower esophageal mucosa was mildly inflamed and eroded, whereas gastric mucosa was transformed into a leathery, hardened, and grayish-black color at fundus and body of greater curvature and gastric mucosa at lesser curvature was markedly edematous. Histological findings showed necrosis of gastric mucosa and acute tubular necrosis of the kidney. Formaldehyde was detected in a postmortem femoral blood sample, gastric content, and the water bottle from which he drank. The review of previous studies in formalin or formaldehyde ingestion is also presented for comparison to this study. It is found that autopsy and toxicological findings in this case are consistent with the results from previous studies, particularly in wide anion gap metabolic acidosis and caustic injury to the stomach greater than esophagus. This result provides additional useful information for interpretation of acute formalin toxicity.

### Formalin, Intoxication, Autopsy

## K16 Determination of Chiral Cathinone in Fresh Samples of *Catha Edulis*

Abdulrhman M. Dhabbah, PhD\*, King Fahad Security College, Riyadh, SAUDI ARABIA

**Learning Overview:** The goals of this presentation are to show: (1) how using Menthyl Chloroformate (MCF) to derivatize cathinone enantiomers and yield two diastereomers; (2) the quantitative determination of *S* and *R* cathinone confirmed the presence of both enantiomers in all parts of the studied plant; (3) the screening of active constituents in different parts of the plant; and (4) the comparison of characteristic distribution between *S* and *R* cathinone in leaves and stems in Khat.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating: (1) the quantitative determination of *S* and *R* cathinone confirmed the presence of both enantiomers in all parts of the studied plant; (2) the concentration of *S*-cathinone was higher in stems while its values were lower in leaves; (3) the highest content of *S*-cathinone, which is the most psychoactive stereoisomer, was measured in the upper stems of the plant; and (4) the present study is the first quantitative investigation of the two cathinone enantiomers in different parts of fresh *Catha edulis*.

*Catha edulis* Forsk, commonly named Khat, is an evergreen wild shrub cultivated in East Africa and the Arabian Peninsula. It is traditionally consumed in these regions for its psychoactive properties. The main stimulating compound in Khat is cathinone, which consists of two enantiomers; several studies have established that *S*-(-)-cathinone is more stimulant than its *R* isomer. However, the quantitative determination of *R* and *S* cathinone in *Catha edulis* was not mentioned in previous papers. Moreover, there is still controversy about the presence of the *R* enantiomer in this plant. Thus, the present work aimed to determine the two cathinone enantiomers in different parts of fresh Khat samples.

Extraction of cathinone was carried out from different parts of fresh *Catha edulis*. The derivatization of cathinone enantiomers was done using MCF and yielded two diastereomers, which were separated by gas chromatography on a HP-5 capillary column with an excellent resolution factor (*R*s higher than 5). Figure 1 shows the chromatogram of a leaf extract after cathinone was derivatized with MCF. The three main peaks observed at 20.938, 31.857, and 33.887min. correspond to MCF, *S*-cathinone and *R*-cathinone derivatives, respectively. The structure of the two cathinone diastereomers was confirmed by mass spectrometry. Their mass spectra are shown in Figure 2; the same main fragments are observed in both spectra at *m/z* 83, 226, 105, 182, and 139, but with different abundances.

The quantitative measurements were based on a calibration curve obtained by injection of a series of standard solutions of *S*-(-)-cathinone in the concentration range from 1 to 100µg/mL. The quantitative results of *S* and *R* cathinone confirmed the presence of both enantiomers in all parts of the studied plant, while some previous studies mentioned that only *S*-cathinone was detected in this species. Also, the obtained results showed a characteristic distribution in the different parts of the plant. The concentration of *S*-cathinone was higher in stems while its values were lower in leaves. The concentrations were in the ranges 0.081-0.290mg/g and 0.087-0.211 mg/g for *S* and *R* isomers, respectively. On the other hand, the highest content of *S*-cathinone, which is the most psychoactive stereoisomer, was measured in the upper stems of the plant. The characteristic distribution of *S* and *R* cathinone was illustrated by their enantiomeric excess (ee%) in the different portions of the branch. The ee% values were positive in all stem samples of Khat, while in contrast they were negative in leaf samples. These results confirm the predominance of the most psychoactive *S*-cathinone in stems. The present study is the first quantitative investigation of the two cathinone enantiomers in different parts of fresh *Catha edulis*.

Figure 1: Chromatogram of leaf extract after derivatization with MCF

Figure 2: Mass spectra of cathinone diastereomers

The present study is the first quantitative investigation of the two cathinone enantiomers in different parts of fresh *Catha edulis*. The quantitative results of *S* and *R* cathinone confirmed the presence of both enantiomers in all parts of the studied plant, while some previous studies mentioned that only the most psychoactive stereoisomer *S*-cathinone was detected in this species. The concentration of *S*-cathinone was higher in stems while its values were lower in leaves. On the other hand, the highest content of *S*-cathinone was measured in the upper stems of the plant.

### S/R-Cathinone, Derivatization, GC/MS

## **K17 A Targeted Qualitative Screen for the Detection of Pesticides in Postmortem Specimens by Ultra High Performance Liquid Chromatography-Ion Trap-Mass Spectrometry (UHPLC-Ion Trap-MS<sup>n</sup>)**

*Marissa J. Finkelstein, MS\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; Elisa N. Shoff, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Joseph H. Kahl, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; George W. Hime, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Diane Boland, PhD, Miami-Dade Medical Examiner Department, Miami, FL 33136-1054*

**Learning Overview:** After attending this presentation, attendees will better understand the qualitative identification of 13 pesticides in postmortem samples by UHPLC-Ion Trap-MS<sup>n</sup>. Pesticide classes included in the study were common organophosphates, carbamates, triazines, and triazoles. The majority of the analytes used in this method were pesticides found at a local hardware store or used in the agricultural industry specifically for the treatment of insects, weeds, or fungi found on tropical plants or fruits.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a validated targeted screening method for the qualitative identification of pesticides in postmortem specimens and how to apply the method to several medical examiner cases in which a pesticide is suspected as a cause of death.

In Miami-Dade County, exposure to harmful pesticides is common due to its location, tropical climate, and large agricultural industry. Forms of exposure can include overspray from airplanes or tractors, occupational (farmers and landscapers), or household (improper use, storage, and application). From 2014 to 2017, Florida Poison Information Center Network ranked pesticides among the top ten exposure categories for Miami-Dade County with approximately 400 calls related to pesticide exposure reported annually. Although the number is underreported, the Miami-Dade Medical Examiner Department (MDME) reported approximately 1-2 cases per year since 2004 in which a pesticide was listed in the cause of death or in which pesticide poisoning was suspected in the cause of death. Due to the prevalence of pesticide use in the community and the potential for accidental or intentional fatalities, it is imperative that laboratories are able to identify pesticides in postmortem matrices.

The method validation plan included the evaluation of Limit Of Detection (LOD), carryover, interferences, and autosampler stability. Blank blood was utilized for the method validation studies, whereas medical examiner casework analysis included the evaluation of blood, serum, urine, and/or gastric contents obtained at autopsy. Then 500µL of specimen was fortified with a deuterated internal standard solution containing atrazine-D<sub>5</sub>. Protein precipitation was performed by the addition of 2mL of acetonitrile:methanol (95:5), followed by centrifugation at 2,800g for 10 minutes. The supernatant was analyzed using a Thermo Scientific™ UltiMate™ 3000 UHPLC coupled to a Bruker® amaZon™ SL Ion Trap Mass Spectrometer. Chromatographic separation was achieved with a Thermo Scientific™ Acclaim® RSLC 120 C18 column (2.1 x 100mm, 2.2µm) at 40°C with an aqueous mobile phase consisting of 2mM ammonium formate, 0.1% formic acid, and 1% acetonitrile in water, and an organic mobile phase consisting of 2mM ammonium formate, 0.1% formic acid, and 1% water in acetonitrile. Positive electrospray ionization was utilized with a scan range of 50-450 *m/z*. Tandem Mass Spectrometry (MS/MS) data analysis included multi-step identification using a data-dependent scheduled precursor list, which utilizes retention time and molecular ion data to trigger MS<sup>n</sup> analysis.

An in-house library containing 13 pesticides of interest and an internal standard, including retention time, parent ion spectra, and daughter ion spectra, was created based on the analysis of neat PESTANAL® standards. Chromatographic separation of all pesticides was achieved within the first ten minutes. The experimental LODs ranged from 0.10mg/L to 1.0mg/L. Carryover was not observed for any pesticide up to 10mg/L, except for diazinon, which was free from carryover up to 5mg/L. No exogenous interferences were observed. Extracts were stable on the autosampler for all pesticides up to 72 hours.

Although forensic toxicology laboratories largely deal with illicit substances, over-the-counter medications, and prescription medications, everyday household chemicals, such as pesticides, are just as fatal. With the ease of availability of pesticides to the general public, it is no surprise that they are the result of accidental or intentional poisonings and/or fatalities. Symptoms of pesticide toxicity vary depending on the pesticide, but many include nausea, vomiting, headache, dizziness, abdominal pain, and central nervous system depression; which are easy to mistake for common ailments. The development of this assay demonstrated that protein precipitation followed by UHPLC-Ion Trap-MS<sup>n</sup> analysis was a suitable method for the detection of pesticides in biological matrices. The combination of a qualitative targeted screen for pesticides, pathological findings, and clinical manifestations can be used to aid the medical examiner in determining cause and manner of death in cases where pesticide toxicity is suspected.

### **Pesticides, Postmortem Forensic Toxicology, UHPLC-Ion Trap MS/MS**

### K18 Application of Biochip Array Technology to the Simultaneous Screening of Drugs From a Single Hair Sample Using the Biochip Analyzer Evidence Investigator

Pankaj Sinha\*, Kearneysville, VA 25430

**Learning Overview:** After attending this presentation, attendees will gain an understanding about the application of biochip array technology to the simultaneous screening of drugs in hair using a semi-automated biochip analyzer. This application increases the screening capacity during the drug testing process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results from the evaluation of this new application that allows simultaneous screening of multiple drugs: amphetamine, benzodiazepines, benzoylecgonine/cocaine, cannabinoids, hydrocodone, ketamine, methamphetamine, opiates, oxycodone, and phencyclidine from a single hair sample. Simultaneous immunoassays arrayed on the biochip surface allow this multi-analytical approach, which leads to test consolidation and an increase in the screening capacity in test settings.

Biochip array technology enables the simultaneous detection of multiple analytes from a single sample. The collection of hair samples is non-invasive and the use of this matrix for drug testing provides a large window of detection as well as the history of drug exposure over time for an individual. Society of Hair Testing (SoHT) and European Workplace Drug Testing Society (EWDTs) guidelines for drug testing in hair are in place.

Competitive chemiluminescent biochip-based immunoassays were employed. Ligands were immobilized and stabilized onto the biochip surface defining an array of discrete test sites. The signal output was inversely proportional to the concentration of drug in the sample. The immunoassays were applied to the biochip analyzer Evidence Investigator. With this system, 54 biochips can be handled at a time. The extraction of the drugs from hair samples (50mg) involved water addition, centrifugation, and the addition of methanol and zircon pulverizing beads. Following spinning and pulverization, methanol was added; after decantation and drying, the reconstituted sample was added to the biochip. The total assay time including wash, extraction, and assay, was 12 hours.

The assays presented the following cut-off and Limit Of Detection (LOD) values respectively: 0.04ng/mg and 0.032ng/mg for amphetamine, 0.02ng/mg and 0.004ng/mg for benzodiazepines, 0.2ng/mg and 0.018ng/mg for benzoylecgonine/cocaine, 0.01ng/mg and 0.008ng/mg for  $\Delta^9$ -THC, 0.001ng/mg and 0.0008ng/mg for THC-COOH, 0.04ng/mg and 0.01ng/mg for hydrocodone, 0.5ng/mg and 0.354ng/mg for ketamine, 0.15ng/mg and 0.06 ng/mg for methamphetamine, 0.04ng/mg and 0.02ng/mg for opiates, 0.1ng/mg and 0.046ng/mg for oxycodone, and 0.02ng/mg and 0.01ng/mg for phencyclidine. Inter-assay precision expressed as percentage Coefficient of Variation (CV) ( $n=15$ , 50% cut-off, cut-off and +50% cut-off), was <18% for all the assays. Authentic hair samples ( $n=43$ ) were assessed with the biochip-based technology and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), the percentage agreement was 98% (amphetamine, benzoylecgonine/cocaine), 95% (cannabinoids, opiates), and 86% (methamphetamine).

In conclusion, the results indicate applicability of biochip array technology to the simultaneous screening of drugs from a single hair sample. Regarding the cut-offs, for drugs appearing in the SoHT or EWDTs guidelines, the cut-off for ketamine was the same and for amphetamine, benzodiazepines, benzoylecgonine/cocaine,  $\Delta^9$ -THC, methamphetamine, and opiates, the cut-offs were lower with the biochip platform, reflecting high sensitivity. Favorable agreement with LC/MS/MS was found for the drugs present in the authentic samples. With the Evidence Investigator, multiple samples can be assessed at a time (up to 54 biochips can be handled at the same time,) which further increases the screening capacity.

#### Biochip Array, Multi-Drug Testing, Hair Testing

## K19 Driving Under the Influence of Alcohol (DUI) and Drugs (DUID) in Southern Italy: Case Reports Showing the Necessity of a Multidisciplinary Protocol to Prove DUI and DUID

Ciro Di Nunzio, PhD\*, Magna Graecia University, Catanzaro 88100, ITALY; Aldo Di Nunzio\*, University of Naples Federico II, Naples 80100, ITALY; Michele Di Nunzio\*, Universidad de Barcelona, Barcelona 08036, SPAIN; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the need to standardize laboratory protocols for alcohol and drugs analysis on blood and urine specimens, as well as protocols for police, physicians, and first aid doctors to verify whether drivers involved in road accidents are impaired.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how only synergistic cooperation among police, physicians and first aid doctors, forensic toxicologists, and forensic engineers allows for solving the question regarding driving impairment.

Driving impairment is not easy to assess because of a variety of factors, which include prior exposure to drugs, degree of both acute and chronic tolerance, innate physical condition, and associated limitations.<sup>1</sup> Studies regarding toxicological findings among drivers hospitalized after a crash are still insufficient and not consistent either in sampling or in the analytical approach. Moreover, in Italy, toxicological analyses and impairment studies after car crashes are not routinely performed by hospital personnel but must be requested by a public prosecutor.<sup>2</sup> The most frequently used protocols in the clinical laboratory are urine immunoassay drug screenings and serum alcohol enzymatic tests. Generally, biological samples analysed are not preserved.

Reported here are three emblematic cases for discussion in which the prosecutor's office ordered the seizure of blood and urine samples taken from possibly impaired drivers and asked the court for forensic toxicological analyses.

A 20-year-old male crashed frontally with another car: only A survived. Toxicological analyses showed the presence of alcohol in blood and urine, respectively 2.01 and 2.13g/l. The biological samples were taken 51min after the car accident. The judge charged A with voluntary murder, regardless of the possible intoxication from alcohol, because the officers present at the crime scene declared A was able to understand and was not impaired.

A 37-year-old man hit a motorcycle with his car and killed the biker. The toxicological analyses showed the presence of morphine (0.23ug/l), 6-MAM (0.04µg/l), and Δ9THC (0.104 µg/l) in the blood and the presence of morphine (>1.00µg/l) and Δ9THC-COOH (>0.16 µg/l) in the urine. The biological samples were taken 1 hour and 57 minutes after the car accident. A forensic engineer showed that D had started to brake too late, with a delay of 2 seconds after the impact. The judge charged D with road murder aggravated by impairment (related to the presence of psychoactive substances in blood and to the engineer statement), even though the paramedic declared D was able to understand and was not impaired.

B, a 40-year-old man, lost control of his car and violently crashed into the car of F, who died. The toxicological analyses showed the presence of 7-aminoclonazepam (74ng/ml), methadone, and 2-Ethylidene-1,5-Dimethyl-3,3-Diphenylpyrrolidine (EDDP) (respectively 5,386ng/ml and 5,648ng/ml) in the urine. A blood sample, negative for alcohol, was thrown away. The judge charged B with road murder, but he was not declared drug impaired, even though the policeman stated he was "definitely confused."

In conclusion, only a synergistic cooperation between police, physicians and paramedics, forensic toxicologists, and forensic engineers allows solving the question of whether drivers are drug/alcohol impaired during driving.

As part of the same protocol, drivers hospitalized after a crash should be subjected to blood and urine sampling for clinical purposes and toxicological screening. Blood and urine must be preserved at -20°C for the next forensic toxicological step. The toxicological tests could highlight if alcohol and drugs—and their metabolite—are present in the blood and in what concentrations. However, we must be careful because, at the current time, specific drug concentration levels cannot reliably be equated with a specific degree of driver impairment. Moreover, as time elapses between a car crash and the medical examination/biological samples collection, the statement and the roadside tests of a law enforcement officer become crucial to help assess whether a driver is impaired. Officers and paramedics should be trained to identify signs and symptoms of drivers impaired by drugs other than alcohol. Hence, a blood test must be able to link drug presence to the observed impairment. Finally, the timing and dynamics of the impacts should always be monitored by a forensic engineer.

## K20 AH-7921 and U-47700 Series Analogs: Spectroscopic Characterization and $\mu$ -Opioid Receptor Pharmacology

John L. Krstenansky, PhD\*, Keck Graduate Institute, School of Pharmacy and Health Sciences, Claremont, CA 91711; Alexander C. Zambon, PhD, Keck Graduate Institute, Claremont, CA 91711; Thomas Hsu, PhD, Keck Graduate Institute, Claremont, CA 91711; Jayapal Reddy Mallareddy, Keck Graduate Institute, Claremont, CA 91711

**Learning Overview:** After attending this presentation, attendees will know about the pharmacological differences between the structurally related emerging synthetic opioids, AH-7921 and U-47700.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees of publicly deposited spectral information on two series of emerging synthetic opioids. This presentation will also highlight the pharmacological differences of the A-7921 analogs vs. the U-47700 analogs that may have bearing on the relative harm between the otherwise equipotent opioid series.

The published pharmacology for AH-7921 and U-47700 is more than 35 years old and was performed using non-human receptor systems.<sup>1-5</sup> This study synthesized and characterized 19 analogs of the AH-7821 and U-47700 series opioids. The spectra were deposited in publicly available databases for reference purposes and this study assessed their pharmacology using a cloned human  $\mu$ -Opioid Receptor (hMOR) in an *in vitro* stable human cell line. This was to establish the potential for abuse of these analogs and to explore differences in ligand bias in these series.

Analogs within the AH-7921 and U-47700 series were synthesized and characterized by Nuclear Magnetic Resonance (NMR), Gas Chromatography/Mass Spectrometry (GC/MS), Infrared (IR), and Raman (1,064nm). In the U-47700 series, the stereochemically pure *R,R* and *S,S* isomers were synthesized from single isomer intermediates. These spectroscopic data have been deposited in publicly accessible repositories: Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) (GC/MS data & monographs) and “Ethylenediamine synthetic opioids,” Mendeley Data, v1 <http://dx.doi.org/10.17632/tjm8x4m93k.1>.

Full concentration response curves, representing  $G_{\text{oi}}$  suppression of forskolin-stimulated adenylate cyclase, were obtained for morphine, AH-7921, and U-47700 (*R,R* stereochemistry). The  $EC_{50}$  values were 39nM, 27nM, and 9nM, respectively. These values are in agreement with the potencies reported in earlier literature. The (*S,S*) isomer of U-47700 had significantly less potency at this receptor. The literature suggests that these analogs bind to both  $\mu$ - and  $\kappa$ -opioid receptors (OPRM1 & OPRK1) but with differing affinities based on their stereochemistry.<sup>3</sup> In both AH-7921 and U-47700 series, the 3,4-dichlorobenzoyl substitution consistently demonstrated the greatest potency relative to other substitutions on the benzoyl group. Interestingly, U-47700, having the methyl group on the amide removed (Udes), retained good potency ( $EC_{50}$ =3nM), while other Udes analogs did not have a significant naloxone-reversible effect at 1 $\mu$ M.

In the AH-series, the rank order potency was as follows: 3,4-dichloro > 4-chloro > 4-trifluoromethyl > others not showing significant naloxone-reversible effect at 1 $\mu$ M. In the U-series, the rank order potency was as follows: 3,4-dichloro > 4-trifluoromethyl > 4-chloro; 4-methoxy; 4-bromo > others not showing significant naloxone-reversible effect at  $\mu$ M.

Considering that different opioid structural groups exhibit differing profiles of analgesia vs. adverse effects (respiratory depression, hyperalgesia and addictive potential, tolerance, etc.), this study explored the pharmacology of these analogs further. Receptor internalization was assessed for active analogs as a measure of  $\beta$ -arrestin recruitment.  $\beta$ -arrestin recruitment has been associated with adverse effects of opioids. Different opioid ligands display differing abilities to signal via G-proteins vs.  $\beta$ -arrestin recruitment. There is current debate whether biased ligands or ligands with balanced activities would produce the best analgesic/safety profile.<sup>6</sup> Regardless, this data show that AH-7921 leads to only modest levels of internalization similar to morphine, whereas U-47700 leads to high levels of receptor internalization, similar to the opioid peptide DAMGO.

In conclusion, these structurally similar compounds exhibit completely opposite signaling bias. These observations could indicate differences in the safety of these two emerging synthetic opioids that should be explored.

### Synthetic Opioids, AH-7921, U-47700

## K21 Screening of New Psychoactive Substances (NPS) in Human Plasma Using Magnetic Solid Phase Extraction (m-SPE) by Liquid Chromatography/Quadrupole Time-of-Flight/Mass Spectrometry (LC/qTOF/MS)

Hee-Sun Chung, PhD\*, Graduate School of Analytical Science and Technology, Daejeon 305-764, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will better understand the usefulness of m-SPE for new NPS in human plasma by LC/qTOF/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the usefulness of m-SPE for determining NPS in plasma by LC/qTOF/MS.

The numbers of NPS, including synthetic cannabinoids, phenethylamines, piperazines, and tryptamines, are continuously growing and the identification of these new drugs in biological fluids has been a big challenge in forensic toxicology. To isolate a variety of NPS in biological fluids, Protein Precipitation (PPT), Liquid-Liquid Extraction (LLE), and SPE were commonly used. To develop a new screening method, m-SPE is applied to isolate 41 NPS in this study. In m-SPE, a magnetic sorbent material is dispersed into the sample solution. The sorbent is collected from the sample solution with the application of an external magnetic field.

Forty-one NPS (13 synthetic cannabinoids: AM-1248, STS-135, AM-2233, AKB-48, 5F-AKB-48, APICA, AB-PINACA, QUPIC, 5-Fluoropentyl-3-pyridinoylindole, JWH-307, CB-13, A-836,339, and mepirapim; 12 phenethylamines: PMMA, MMDA-2, 5-APDB, 5-MAPB, 2C-NBOMe, 3-fluoromethamphetamine, 5-IT, DMMA, 25I-NBOH, 5-EAPB, 2C-C, and 2C-P; 5 Tryptamines: 5-MeO-DALT,  $\alpha$ -methyltryptamine, NMT, 5-MeO-EPT, and 4-OH-DET; 4 other substances:  $\alpha$ -PVT, Desoxy-D2PM, Ethylphenidate, and RH-34; 3 aminoindanes: MDAI, 5-IAI, and N-methyl-2-AI; 2 piperazines: NT-45 and 2,3-DCPP; and 1 phencyclidine-type substance: N-ethyl-norketamine) were spiked at 50, 100, 500, and 1,000ng/mL in plasma specimens for the development of this method. The extraction of analytes was performed by m-SPE as sorbent using COOH-functionalized multi-walled carbon nanotubes with magnetic nanoparticles (COOH-mMWCNT). The 125 $\mu$ L of sorbent was dispersed into a 200 $\mu$ L plasma by vortex to form a homogeneous suspension. The plasma was discarded after the sorbent was separated by the external magnet. Then the analytes were desorbed with 1ml elution solvent (8% formic acid in acetone: toluene (3:1, v/v)) by sonication and vortex. After that, the dispersed particles were gathered by the external magnet. The eluate was evaporated by nitrogen gas. The residue was reconstituted with 100 $\mu$ L methanol and analyzed by LC/qTOF/MS (Agilent® 1290 series LC and the Agilent® 6545 QTOF). Chromatographic conditions were as follows: mobile phase A consisted of 0.1% formic acid in water. Mobile phase B consisted of acetonitrile. Separation was achieved in 1 min. Data were acquired in full scan MS mode within the mass range m/z 50–500 at a rate of 250ms/spectrum.

In this study, m-SPE was successfully applied for the extraction of all types of NPS in the human plasma sample. This extraction method is less time-consuming and laborious than conventional cartridge SPE; also, sorbent collection does not require centrifugation. The screening method allowed the detection and identification of 41 targeted compounds by LC/qTOF/MS. Validation was performed for 41 NPS and showed acceptable limits of detection, recovery, matrix effect, and precision. The limits of detection of the 41 analytes were between 0.002 and 0.084 $\mu$ g/mL. An acceptable recovery of synthetic cannabinoids, phenethylamines, tryptamines, other substances, aminoindanes, piperazines, and phencyclidine-type substances were 57–103% (average 86), 80–96% (91), 86–89% (87), 57–98% (84), 39–88% (71), 87–92% (89), and 97%, respectively. Matrix effect ranged from 82–94% (average 88) for synthetic cannabinoids, 79–99% (94) for phenethylamines, 76–102% (92) for other substances, 90–97% (93) for tryptamines, 87–90% (88) for aminoindanes, 92–96% (94) for piperazines, and 82% phencyclidine-type substances. Both intra- and inter-day precision were < 27% (Relative Standard Deviation (RSD)%).

Based on this results, it was concluded that this method is applicable to detect many types of NPS in biological fluids with a short extraction time, low consumption of organic solvent, and easy operation. The detection of metabolites of NPS by this method will be studied in the future.

## K22 Evaluation of Sample Preparation Techniques for the Detection and Quantitation of Benzodiazepines in Human Urine and Whole Blood Using High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC-MS/MS)

Cassandra A. Swart, MS\*, Boston University School of Medicine, Boston, MA 02118; Mikayla Caldwell, MS\*, Massachusetts State Police Crime Laboratory, Maynard, MA 01754; Michael Moretto, MS, Boston University School of Medicine, Boston, MA 02118; Andrew D. Ziegler, MS, Boston University School of Medicine, Boston, MA 02118; Jenna Gardner, BA, Boston University School of Medicine, Boston, MA 02118; Nichole D. Bynum, MS, RTI International, Johnson Building, Research Triangle Park, NC 27709; Katherine Moore Bollinger, MS, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Boston, MA 02118

**Learning Overview:** After attending the presentation, attendees will be able to use the methods developed, or develop their own singular method, for urine and blood analysis of selected benzodiazepines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the analysis of selected benzodiazepines using various matrices and sample preparation methods.

**Background/Introduction:** Benzodiazepines are a class of drugs generally prescribed for treatment of anxiety, depression, and insomnia. The three most commonly encountered benzodiazepines, alprazolam, diazepam, and clonazepam, reside in the top 25 most frequently identified drugs based on the United States Drug Enforcement Administration's National Forensic Laboratory Information System 2018 Mid-Year Report and therefore remain of forensic toxicological importance.

**Objective:** The purpose of this research was to evaluate three sample preparation methods, Liquid-Liquid Extraction (LLE), Solid Phase Extraction (SPE), and Supported Liquid Extraction (SLE), for the reliable and accurate identification of six benzodiazepines in human urine and whole blood, including: alprazolam, alpha-hydroxyalprazolam, clonazepam, etizolam, diazepam, and 7-aminoclonazepam. Further, analytical methods were validated using all three of these techniques.

**Method:** A six-point calibration curve and three Quality Control (QC) samples, each in triplicate, were extracted using SLE with ISOLUTE® cartridges, SPE using Clean Screen® XCEL I cartridges, and LLE. Samples were analyzed on a High-Performance Liquid Chromatograph (HPLC) with a 4000 Q-Trap Electrospray Ionization Tandem Mass Spectrometer (ESI/MS/MS) in positive ionization mode. The method was validated in accordance to the proposed AAFS Standards Board (ASB) Standard 036, First Edition 2018, for quantitative analysis by evaluating calibration model, precision, bias, Limit Of Detection (LOD), Limit Of Quantitation (LOQ), carryover, interferences, and ionization suppression and enhancement.

**Results:** With this developed method, analysis time totaled nine minutes. A linear dynamic range of 10–1,000ng/mL was used for all analytes. Recovery of all analytes utilizing the SLE sample preparation method for urine and blood ranged from 56.44–87.73 and 26.13–82.87%, respectively; SPE sample preparation method for urine and blood ranged from 36.95–64.5 and 46.66–79.23%, respectively; and LLE sample preparation method for urine and blood ranged from 44.68–143.9 and 36.17–117.61%, respectively. The LOD utilizing SLE for urine and blood ranged from 0.5–1 and 1–5ng/mL, respectively; SPE for urine was 1ng/mL and blood ranged from 1–2ng/mL; and LLE for both urine and blood ranged from 0.5–1ng/mL.

**Conclusion/Discussion:** The development and validation of these sample preparation and analytical methods demonstrates sensitive, reliable, and reproducible results to identify and quantify six commonly encountered benzodiazepines in human urine and whole blood in rapid time. The use of LLE proved to be efficient; however, sample preparation was laborious and costly. The SLE cartridges used were approximately twice as expensive as SPE, but were the fastest method to prepare samples, whereas SPE consumed a large amount of solvent and took the most amount of time to prepare samples. Given the data discussed above, it is left up to the individual laboratories and analysts to determine which extraction method best suits their needs and current resources.

### Benzodiazepines, Sample Preparation, HPLC-MS/MS

## K23 Calculation of Potential Lactate/Lactate Dehydrogenase (LDH) Interference With Alcohol-Dehydrogenase (ADH)-Based Ethanol Assay

Amanda K. Will, BS\*, University of New Haven, West Haven, CT 06516; Sandra C. Bishop-Freeman, PhD, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27607; Julia C. Liebl, BA, Oklahoma City, OK 73103-1030; Robert H. Powers, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the potential for lactate/LDH interference in an ADH-based ethanol assay, an approach for consideration of the possibility of such interference in a particular case sample based on clinical parameters, and calculation of the magnitude of interference based on estimated, extrapolated, or determined lactate and LDH concentrations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an approach for the evaluation of potential lactate/LDH-based interference in an ADH-based ethanol assay, and for the determination of the magnitude of such interference in specific cases.

Determination of serum alcohol is a common and routine clinical test, most often performed by an enzymatic assay based on the ADH-catalyzed oxidation of ethanol to acetaldehyde with the concomitant reduction of NAD<sup>+</sup>, with the rate of NADH formation being the monitored variable (A340). Interference with an ADH-based alcohol assay by the presence of variable concentrations of lactate and LDH was demonstrated experimentally. Theoretically, the presence of adequate quantities of both lactate and LDH in a sample could result in a competitive, and interfering, reduction of NAD<sup>+</sup>, with the potential for falsely elevated or false positive alcohol results.<sup>1,2</sup> The question of the potential occurrence and magnitude of this phenomena has been the subject of a number of papers. Recently, several well-documented examples of the lactate/LDH interference with an alcohol result have demonstrated the significance such results can have with regard to forensic casework. Interference was found to be a function of variable lactate and LDH combinations, and minimum concentrations required to produce a forensically significant result (e.g., >0.0g/dL) were determined. A scaled-up version of an automated analyzer method, with volumes adjusted for manual analysis in a Ultraviolet/Visible (UV/Vis) spectrophotometer, was utilized with 0–50mM lactate (normal range ~0.5–2.2mM) and 0–10kU/L LDH (normal range ~0.12–0.22kU/L). Each lactate/LDH combination was run in triplicate, with the “Ethanol (EtOH) reading determined from a 6-point ethanol calibration curve. To generate an apparent alcohol result of 0.02g/dL at the maximal lactate concentration (50mM), an LDH of at least 4kU/L was required in the sample, and similarly, at maximal LDH concentration (10kU/L), a lactate concentration of at least 10mM was required. These results are consistent with the uncommon nature of this phenomena, suggesting that significant lactate and LDH levels are required in a sample to cause an interference. Perhaps more relevant, a clinical picture that would be expected to result in a persistently elevated lactate level, combined with significant leakage and presence in the blood of hepatic enzymes (e.g., LDH) would not be common (but can clearly occur as a consequence of disease or trauma).<sup>3</sup> The apparent EtOH readings in the lactate/LDH amended samples was linearly related to lactate concentration at specific LDH levels. Similarly, the slopes of those lines were linearly related to LDH concentration. Using these relationships (expected to be generally applicable, but assay-specific), an equation was derived that relates lactate, LDH, and expected “false-positive” ethanol readings, and describes the potential application of this approach to other assays. Finally, this equation was applied to the analysis of well-documented clinical cases, along with the consideration of relevant clinical parameters and assay results.

### Lactate, Lactate Dehydrogenase, Alcohol Dehydrogenase

## K24 Fatal Unintentional Cocaine Overdose: The Importance of a Forensic Scene Investigation

*Giuliana D'anna\**, University of Bari, Section of Legal Medicine, Bari 70124, ITALY; *Antonio De Donno*, PhD, Bari 70124, ITALY; *Giuseppe Strisciullo*, BES, University of Bari, Bari 70124, ITALY; *Francesco Introna*, MD, Dim Sezione Di Medicina Legale, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand the importance of a forensic site inspection in a case of overdose cocaine abuse. Hyperthermia is difficult to find in postmortem, as cocaine overdose deaths are not always immediately discovered, and the body remains exposed to thermal changes for a long time.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the interpretation of hyperthermia by cocaine-related deaths, which is still difficult and disputed. One of the reasons why literature offers few toxicological data about hyperthermia by cocaine involving death is data lacking about forensic scene investigations.

The correlation between mortality from cocaine and high ambient temperature is widely documented in scientific literature. Cocaine use is correlated with serious toxic effects and death. Subjects who use cocaine on a continuous basis have higher levels of circulating catecholamines. This condition manifests itself clinically as tachycardia, arterial vasoconstriction, enhanced thrombus formation, mydriasis, psychomotor agitation, seizures, coma, and even death. Cocaine modifies dopamine receptors and transporters involved in body temperature control. In fact, the substance determines cutaneous vasoconstriction at the peripheral level, while centrally interfering with the dopaminergic centers at the hypothalamic level, which are responsible for the regulation of body temperature. Hyperthermia is a well-known complication of cocaine use. However, this clinical finding is difficult to find in postmortem as cocaine overdose deaths are not always immediately discovered, and the body remains exposed to thermal changes for a long time. Therefore, the number of deaths due to hyperthermia related to cocaine abuse is quite limited. This study describes a case of cocaine-associated hyperthermia that resulted in death. A 33-year-old man was a known cocaine user. The decedent was found dead in his house by his live-in wife. The woman said the man had been using cocaine mainly by inhalation for about five years, had long been depressed, and did not leave home anymore. The wife also reported that around 8:00 p.m. she was outside with her children, and when she came back home, she discovered her husband lying on the floor of the house.

Rectal postmortem temperature (11:26 p.m.) was 41.7°C, compared to an ambient temperature of 30°C (11:30 p.m.). Hypostasis was abundant and disappeared on pressure; rigor mortis was in progression from small to large articulations. The autopsy examination showed only polyvisceral congestion; histological examinations documented myocardial fibrosis related to an initial dilated cardiomyopathy. No macroscopic abnormalities were observed in the other organs. During the forensic site inspection, three small packages containing white powder were found, later analyzed, and determined to be cocaine and lidocaine.

General drug screening conducted on a blood sample provided positive results only for residual cocaine (5.68ng/mL). Cocaine, Benzoylecgonine (BE), Ecgonine Methyl Ester (EME), and cocaethylene were measured in cardiac blood by gas chromatography and mass spectrometry (EME 1.34µg/mL, BE 4.78µg/mL, cocaethylene 0.021µg/mL), demonstrating high blood concentrations of the metabolites (6.12µg/ml), suggestive of a massive administration four to five hours before death. Considering the temperature measured during the site inspection about four hours after death, (already 41.7°C), it is hypothesized that at the time of death the victim had reached a hyperthermal peak of approximately 43–44°C.

This is a rare case in which it was possible, through the site inspection where the death body was found and the simultaneous measurement of the temperature, to identify the cause of death as hyperthermia resulting from massive cocaine intake, with no evidence of macroscopic and microscopic alterations that could justify death.

### Hyperthermia, Site Inspection, Cocaine

## K25 Presumptive Identification of Nitrite by Griess Reagent Test Strips—Applications in Suicide Investigations

Jessica Hvozdoch, MS\*, University of Florida, Gainesville, FL 32608; Meagan L. Wisniewski, PhD, University of Florida, Gainesville, FL 32608; Jennifer L. Hoyer, MS, University of Florida, Gainesville, FL 32608; Chris W. Chronister, PhD, University of Florida, Gainesville, FL 32608; Bruce A. Goldberger, PhD, University of Florida College of Medicine, Gainesville, FL 32608

**Learning Overview:** After attending this presentation, attendees will understand the utility of a simple, commercially available color test to triage potential sodium nitrite poisoning cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the use of a supplemental presumptive screening tool for an analyte that is not conventionally included in forensic toxicology panels. This knowledge may prevent expensive, undirected private laboratory testing while confirmatory methods are developed or laboratories with validated ion monitoring procedures are identified.

Nitrite poisonings have been documented for decades, with incidents including fertilizer contamination of well water, ingestion of improperly cured meats, and infant exposure to vegetables high in nitrites and nitrates. More recently, sodium nitrite and sodium azide have been advocated by online suicide forums as an effective means of fatal overdose. Three cases submitted to the University of Florida (UF) Forensic Toxicology Laboratory initially indicated suspected sodium nitrite poisoning. The fourth case underwent exhaustive toxicological testing with inconclusive test results before scene evidence implicated intentional sodium nitrite ingestion.

Spectrophotometry, ion chromatography, and Gas Chromatography/Mass Spectrometry (GC/MS) methods exist for the quantitation of nitrite and nitrate ions and are commercially available for postmortem livestock samples. However, such testing involves specialized detection equipment and/or preparation methods that are not part of standard human toxicological testing schemes, including those of the UF laboratory and its reference laboratory. Until validated methods are developed, it was hypothesized that a common Griess reagent color test (MQuant™ Nitrite Test Strips) could be used as a presumptive triage method in cases where ingestion of sodium nitrite is suspected.

Initial testing was performed on four suspected nitrite ingestion cases using available clear fluid samples. The unconfirmed presumptive test results are presented below:

Case	Sample Type	Presumptive Test Result
Negative Control	Urine	None Detected
20mg/L Standard	Aqueous (Water)	Positive
5mg/L Control	Urine	Positive
Case 1	Urine	None Detected
	Vitreous Humor	Positive
	Serum	None Detected
	Stomach Contents	Positive
	White Crystals from Water Bottle	Positive
Case 2	Urine	Positive
	Vitreous Humor	Positive
	Stomach Contents	Positive
Case 3	Urine	Positive
	Vitreous Humor	Positive
Case 4	Vitreous Humor	Positive
	Serum	None Detected
	Stomach Contents	Positive

The test strips provide a color scale for the semi-quantitative measurement of nitrite concentrations between 2 to 80mg/L, a range higher than typical urine concentrations in healthy individuals. While the test strips used in this study are intended for the monitoring of nitrite in water, the same Griess reagent color test is routinely performed in urinalysis panels indicated for the detection of urinary tract infections and endocrine disorders.

Due to the ubiquitous nature of nitrogen oxides, their association with common diseases, such as diabetes, and potential interferences (chromate, permanganate, other oxidants), test results must be interpreted with caution. Of 27 randomly selected postmortem cases of varying sample quality and exogenous content, none produced positive test results in serum, urine, vitreous humor, or stomach content samples. Therefore, in conjunction with physical indicators such as brown discoloration of the blood and cyanosis from peri-mortem methemoglobinemia (MetHb), medical history, and/or scene evidence, nitrite screening test kits can provide toxicologists with insight on suspected nitrite poisoning cases.

### Nitrite, Suicide, Presumptive Testing

## K26 The Detection and Quantification of Tianeptine in Postmortem Blood and Urine

Justin L. Poklis, BS\*, Virginia Commonwealth University, Richmond, VA 23219-0613; Janet Schultz, PhD, Oregon State Police Forensic Laboratory, Clackamas, OR 97015; Michele T. Stauffenberg, MD, Oregon State Medical Examiner, Clackamas, OR 97015-6922; Carl E. Wolf II, PhD, Virginia Commonwealth University, Health/Pathology Department, Richmond, VA 23298

**Learning Overview:** After attending this presentation, attendees will be familiar with the toxic and lethal effects of tianeptine and a method for its toxicological analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relaying information about the toxicity of tianeptine, an atypical tricyclic drug.

**Proposition Statement:** The presented postmortem concentrations of tianeptine are consistent with a fatal overdose.

**Background/Introduction:** Tianeptine is an atypical tricyclic drug approved for use in Europe, Asia, and Latin America. In the United States, tianeptine is not approved by the United States Food and Drug Administration (FDA), but is sold on websites as an unscheduled pharmaceutical agent, a nootropic or smart drug/cognitive enhancer. Tianeptine use in the United States has increased in the last several years. The National Poison Data System received a total of 11 tianeptine exposure calls between 2000 and 2013. The total number of tianeptine exposure calls increased from 5 in 2014 to 38 in 2015, 83 in 2016, and 81 in 2017. The dual activation of the mu and delta opioid receptors is believed to be responsible for causing many of the known acute and chronic effects of tianeptine, including its antidepressant and anxiety actions. The major metabolic pathway is  $\beta$ -oxidation and the principal metabolites are propanoic acid (inactive) and pentanoic acid (active) metabolites. Less than 3% of the dose is excreted unchanged in urine. There are limited published case reports of tianeptine fatal overdoses with blood concentrations ( $n=5$ ) ranging from 2–18mg/L and free tianeptine in urine ( $n=2$ ) at 2.0 and 3.2mg/L.<sup>1-4</sup>

**Case:** Presented are the femoral blood and urine results from a 31-year-old White male found at home by his girlfriend approximately four hours after he was last seen. Needles, syringes, and a glass pipe were also found at the scene. Initial screening of the blood and urine samples revealed amphetamine, methamphetamine, and tianeptine.

**Method:** A High-Performance Liquid Chromatography/Tandem Mass Spectrometry (HPLC/MS/MS) method was used for the detection and quantitation of tianeptine in blood and urine. A seven-point matched matrix calibration curve ranging from 0.001–0.100mg/L, blood and urine quality control specimens (0.001, 0.003, 0.030, and 0.075mg/L), and the samples were analyzed. Method was assessed for bias, precision, carryover, matrix effects, and dilution integrity. The linear regression coefficients of determination ( $r^2$ ) for calibration curves were 0.9996 or greater. Controls were assessed over three days in triplicate. Accuracy/bias of the quality control specimens was determined to be within  $\pm 20\%$  of the target concentrations for both blood and urine. The precision did not exceed a coefficient of variation of 15%. Validation criteria for carryover, specificity, matrix effects, and dilution integrity were also acceptable. Blood samples were deprotonated with methanol prior to extraction. To prepare the samples, 0.200mg/L protriptyline Internal Standard (ISTD) was added to 200 $\mu$ L aliquots of the calibrators, controls, and samples followed by the addition of 200 $\mu$ L of 50:50 acetonitrile: water. Samples were briefly mixed and transferred to Clean Screen FAST<sup>®</sup>SPE columns and rapidly eluted into auto-sampler vials. Analysis was performed using a Waters<sup>®</sup> ACQUITY<sup>®</sup> Xevo Tandem Quadrupole Detection (TQD) HPLC/MS/MS with ESI ionization in positive ion mode.

**Results:** The determined blood and urine concentrations were 11mg/L and 0.66mg/L, respectively.

**Conclusion:** The blood and urine tianeptine concentrations determined by the presented HPLC/MS/MS method were consistent with the limited published tianeptine fatal overdose concentrations. The blood concentration of 11mg/L was within the range of published blood tianeptine concentrations. The urine concentration of 0.66mg/L was lower than that of the two published urine postmortem tianeptine concentrations.

*This project was supported by the National Institute of Health (NIH) Center for Drug Abuse.*

## K27 Attribution Signatures for the Sourcing of Dokha and Dokha-Infused Tobacco Products

Orianna Thomas, BS\*, Cockeysville, MD 21030; Ellen Hondrogiannis, PhD, Towson University, Department of Chemistry, Towson, MD 21252

**Learning Overview:** The goal of this presentation is to educate the viewers on dokha, a new tobacco product and how to attribute that product back to its vendor.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the feasibility of using attribution and discriminant function analysis models and their impact on drug analysis. This presentation will also provide insight into an emerging drug and its elemental content.

Dokha is a tobacco product that is primarily consumed in the Middle East.<sup>1</sup> It is comprised of dried tobacco leaves, spices, flowers, and other herbs.<sup>1</sup> The tobacco for dokha is manufactured by drying fine tobacco leaves in the desert region.<sup>2</sup> This processing method tends to lead to high levels of nicotine and carbon monoxide in dokha and associated products.<sup>2</sup> Dokha is typically smoked through a pipe called a midwakh, which is capable of holding approximately 0.5 grams in a small bowl.<sup>1</sup>

Dokha belongs to a class of alternative tobacco products that includes items such as shisha, hookah, and vape pens.<sup>3</sup> There is currently a rise in alternative tobacco products as there is a reported decline in cigarette usage.<sup>3</sup> However, some of these products, like dokha, could be more harmful than cigarettes. Past research has shown that dokha tends to have significantly higher levels of nicotine when compared to certain brands of cigarettes.<sup>2</sup> There has also been research that shows dokha having potential linkages to seizure activity.<sup>4</sup> This bodes as a concern as dokha has recently made its way to the United States. In fact, certain brands can be found at various local smoke shops. Dokha itself is regulated by the Food and Drug Administration (FDA) as a tobacco product and regarding package labeling; however, it is not a scheduled drug by the Drug Enforcement Agency (DEA).

The attribution of dokha and dokha-related products could be useful in cases of overdose. The hypothesis for this study is that utilizing the elemental content, a model can be made that will allow for sourcing back to the associated vendors. It is well known that certain elements, such as chromium, lead, and cobalt, are of great concern as carcinogens.<sup>1</sup> This study also helps to provide insight into some of those elements and their concentrations in these products. A total of four vendors were evaluated for this analysis and one vendor was also evaluated for the dokha-infused hookah product that they sell. This additional dokha-infused hookah was chosen for evaluation because hookah is a particularly popular recreational drug of consumption in the United States. To retain continuity between the brands, only the unflavored type of each brand was purchased from the vendors' respective websites. Each dokha sample was digested in triplicate in an overnight digestion procedure consisting of 7N nitric acid. The Inductively Coupled Plasma/Mass Spectrometer (ICP/MS) was the instrument used to obtain the inorganic elemental data. A discriminant function analysis plot was used to establish a model for separation between each separate brand of dokha based on their respective elemental contents.

## K28 Assessment of *In Vitro* Methemoglobinemia Formation in Infant Samples

Frederick Strathmann, PhD\*, NMS Labs, Horsham, PA 19044; Cherie M. Trail, BS, NMS Labs, Horsham, PA 19022; Emily Fenton, BA, Philadelphia, PA 19125; Laura M. Labay, PhD, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will have learned the caveats of postmortem methemoglobin interpretation in adult and fetal postmortem blood and the mechanisms to circumvent these limitations for proper interpretation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a large dataset from a national reference laboratory for methemoglobin trends in adults and infants with guidance on interpretation of results.

**Hypothesis:** Interpretation of methemoglobin percentage in postmortem samples, specifically infant samples, is complicated by *in vitro* formation and susceptibility of fetal hemoglobin to oxidation in the absence of an exogenous oxidant.

**Content:** The review of historic methemoglobin results in postmortem samples collected from infants illustrated a wide distribution of results and difficulty with interpretation. Redevelopment of an existing forensic method to allow its use in clinical methemoglobinemia determination resulted in the identification of extreme elevations of methemoglobin in postmortem samples previously undetected. Suspected nitrate/nitrite ingestion was indicated for many of the elevated adult methemoglobin results and nitrate/nitrite levels via an enzymatic method were assessed in several specimens to confirm. Elevated methemoglobin results in infant samples did not routinely correlate with case histories and were proposed to be falsely increased due to a spectral interference. However, residual fetal blood samples collected from umbilical cords of otherwise healthy infants had minimal methemoglobin present, decreasing the likelihood of a broad interference due to fetal hemoglobin contributing to the high percentage of elevations observed. Oxidation studies were conducted with stored blood from adult and fetal origin, with and without an oxidizing agent present, to illustrate the relative susceptibility of fetal hemoglobin to oxidize post-collection.

**Results:** Historic data were analyzed to demonstrate the distribution of results before and after redevelopment of an existing methemoglobin method using spectrophotometry and ranged between <1% to >80%. Elevations in methemoglobin percentages in adult postmortem samples consistent with case presentation were confirmed for the presence of nitrate/nitrite using an enzymatic method. Fetal and adult samples were further assessed to evaluate the formation of methemoglobin during storage in the absence and presence of oxidizing agents with studies currently in progress.

**Conclusion:** Interpretation of postmortem methemoglobin results requires caution, specifically in infant samples. However, follow-up testing based on case presentation provides the necessary context to interpretation of the results from postmortem blood.

**Methemoglobin, Pediatric Toxicology, Nitrate/Nitrite**

## K29 Drug Trends in Korea and the Detection of Synthetic Cannabinoids in the Hair of Drug Abusers

*Byungseok Cho, PhD, National Forensic Service, Wonju 26460, SOUTH KOREA; Jeonghyun Kim, MS, National Forensic Service, Wonju 26460, SOUTH KOREA; Ilung Seol, PhD, National Forensic Service, Wonju 26460, SOUTH KOREA; Seung Kyung Baeck, PhD, National Forensic Service, Wonju, Kangwon-do 26460, SOUTH KOREA; Eunmi Kim, PhD\*, National Forensic Service, Wonju, Gangwon-do 26460, SOUTH KOREA*

**Learning Overview:** After attending this presentation, attendees will understand the drug trends in Korea and the detection of synthetic cannabinoids in the hair of drug abusers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing drug trends in Korea and data from the detection of synthetic cannabinoids in the hair of drug abusers in three recent years (2016–2018).

**Introduction:** Before the 1980s, opium and methadone were widely used in Korea. Since the 1970s, marijuana has become a public health concern, especially for entertainers. Methamphetamine has also spread remarkably in the domestic market and become the most frequently abused drug in Korea from the 1980s to the present. The first of the New Psychoactive Substances (NPS) appeared in Korea in 2009 and has increased rapidly. This study investigated the drug trends in Korea and the results from the detection of synthetic cannabinoids in the hair of drug abusers for three recent years (2016–2018).

**Methods:** The drug trends in Korea were referenced from the Drug Crime Report 2018 published by the Supreme Public Prosecutor's Office. The numbers of arrested drug criminals, arrests by drug crime type, arrests by the criminal's age, and arrested foreign drug criminals and their nationalities were investigated. The method used to analyze synthetic cannabinoids in hair samples was conducted according to the standard operation procedure of the National Forensic Service (NFS). In brief, the drugs in hair samples were extracted in ethanol and analyzed by liquid chromatography-tandem mass spectrometry. In total, 59 synthetic cannabinoids (18 synthetic cannabinoids and 41 of their metabolites) were screened.

**Results:** The number of arrested drug criminals in Korea has exceeded 10,000 since 2015 and was 12,613 in 2018. The number-one type of drug crime was "use" (making up 49% of the total), followed by "trafficking" (22%) and "possession" (8.6%). In contrast, "manufacture" was the lowest drug crime at 0.1% of the total. Criminals in their 30s and 40s made up 50% of the total. The number of foreign criminals had increased by 220%, from 295 in 2011 to 948 in 2018. Among them, nationals of China were the highest in number (making up 39% of the total), followed by nationals from Thailand (32%), the United States (9%), Taiwan (5%), Vietnam (3%), and Uzbekistan (2%). In 2018, methamphetamine was the drug that was confiscated the most (187,947g), followed by cannabis (89,145g) and cocaine (88,321g). Meanwhile, according to the NFS, the number of seized materials containing NPS at NFS has been increasing rapidly until 2014, and then decreasing gradually. In the three years (2016–2018), the most frequently detected synthetic cannabinoid in the hair of drug abusers was AB-CHMINACA, with a total of 32 cases detected. From 2016 to 2018, the number of cases with synthetic cannabinoids detected in the hair samples was 25, 24, and 4, respectively, indicating that it had decreased significantly in 2018.

**Conclusion:** Currently, although the most abused drug in Korea is still methamphetamine, the types of drugs being abused are becoming more diverse, especially with the recent emergence of NPS. The amount of cocaine confiscated in 2018 was high, which is considered unusual in Korea, where there are few cases of cocaine abuse. We need to look at the trends for the next few years. The number of synthetic cannabinoids detected in hair samples in 2018 was lower than that of previous years. It seems that newly abused NPS were not detected in the existing analysis. Because the structure of NPS changes so fast, it is difficult to reflect new changes with the existing screening methods established in the laboratory. Therefore, there is an urgent need to establish a method for detecting newly abused NPS (e.g., 5F-ADB, FUB-AMD, etc.) in biological specimens.

### Drug Trend, New Psychoactive Substances, Synthetic Cannabinoids

## K30 Electrochemical Detection of Fentanyl Using Screen-Printed Carbon Electrodes With Confirmatory Analysis of Fentanyl and Its Analogs in Oral Fluid Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

*Colby E. Ott, MS\*, Shippensburg, PA 17257; Hugo Cunha-Silva, PhD, University of Burgos, Burgos, SPAIN; Joseph A. Cox, MS, Morgantown, WV 26508; Julia Arcos-Martínez, PhD, University of Burgos, Burgos, SPAIN; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121*

**Learning Overview:** After attending this presentation, attendees will be able to explain the theory behind the use of electrochemical techniques such as Square-Wave Voltammetry (SWV) for the analysis of fentanyl and illicit substances in forensic science and will understand the importance of these techniques as screening tools.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new methods of screening illicit substances both at the crime scene and within the lab that are fast, reliable, and provide both qualitative and quasi-quantitative data. This work may aid in speeding up and improving the seized drug workflow on cases, helping to reduce backlog and increase the speed of investigations.

Due to the growing number of cases involving fentanyl and fentanyl analogs, opioid abuse poses a significant threat to the United States. Opioid-related overdose deaths have increased over the past several years leading to a public health emergency declared by the Department of Health and Human Services. New Psychoactive Substances (NPS) have compounded the issue due to having similar or increased potency. NPS are synthetic analogs to known controlled substances designed by making modifications to the core chemical structure in most cases, and include fentanyl-analogs and synthetic cannabinoids, among others. Electrochemistry can provide a rapid, sensitive, and selective screening technique to overcome the limitations faced by other methods in the field. Electrochemistry offers a versatile platform that is sensitive, portable, and low cost, which can be modified to suit a variety of needs and detection requirements.

Utilizing Screen-Printed Carbon Electrodes (SPCEs), a fast, simple, and sensitive approach toward the detection, identification, and quasi-quantitation of fentanyl, was achieved both in an electrochemical cell and as a drop on the electrode surface. Electrooxidation of fentanyl at the electrode was demonstrated using SWV between -0.5V and +1.6V with 100mM Tris-HCl buffer at pH 8.5 as supporting electrolyte. Parameter optimization was conducted. Voltammograms demonstrated the presence of two oxidation peaks at 750mV (peak I) and 880mV (peak II) versus pseudo Ag/AgCl. Fentanyl oxidation was observed at concentrations of ~76ng/mL in cell and ~300ng/mL in a 100µL drop.

Reproducibility between electrodes, assessed as the average Relative Standard Deviation (RSD), for peak I and peak II in cell was 12% and 18%, respectively. RSD in drop was 13% and 15% for peaks I and II. Accuracy of the detection method was determined in cell by analyzing single-blind samples prepared in lab and demonstrated better accuracy in lower concentrations of fentanyl versus higher concentrations. The assessment of the effects of interfering compounds, including cocaine, methamphetamine, quinine, and acetaminophen, was performed. Analysis of various ratios of fentanyl to interferent were analyzed and demonstrated the ability of the method to detect fentanyl while present in these mixtures. The mechanism of the electrooxidation of fentanyl in the system is proposed herein.

A confirmatory Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method for the analysis of fentanyl and fentanyl analogs in oral fluid using dynamic Multiple Reaction Monitoring (dMRM) was developed and validated. A total of 13 fentanyl/fentanyl analogs with 7 internal standards were analyzed. The limit of detection of the majority of drugs was determined to be 0.01ng/mL with the limit of quantitation at the lowest calibrator of 0.1ng/mL with coefficients of determination between 0.9992 and 0.9999. Solid Phase Extraction (SPE) was used in the assessment of bias, precision, matrix effects, recovery, and process efficiency, which were deemed acceptable based on validation guidelines. Selectivity was demonstrated through the analysis of 12 additional illicit substances commonly encountered in the forensic laboratory. Processed sample stability and freeze/thaw stability were also assessed.

### Electrochemistry, Fentanyl, LC/MS/MS

## K31 Frequency of Gabapentin in Postmortem Cases Screened by Enzyme Linked Immunosorbent Assay (ELISA)

*Denice M. Teem, BS\*, NMS Labs, Horsham, PA 19044; Daniel S. Isenschmid, PhD, NMS Labs, Horsham, PA 19044*

**Learning Overview:** The goal of this presentation is to summarize the prevalence of gabapentin in routine postmortem case work using ELISA screening and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) confirmation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing frequency, concentrations, and drug combination information of gabapentin in postmortem cases. This data will provide laboratories information to help make decisions as to whether or not they should include gabapentin as part of their own testing regimen.

Prior to June 2019, a large percentage of this study's laboratory's postmortem testing, which includes ELISA and high-performance Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF-MS) screens, did not routinely look for the presence of gabapentin. It was only tested for if requested by a client for direct analysis, added onto routine testing because of case history provided by a client but not ordered up front, or part of a certain testing panel that included screening by Gas Chromatography/Mass Spectrometry (GC/MS). Increased demand and prevalence of gabapentin dictated that it was necessary to include it in the scope of analysis for other testing panels. An ELISA kit became available to test for gabapentin and was incorporated into the other postmortem testing panels where the scope of analysis is more than simply drugs of abuse. The reporting limit for the screening analysis by ELISA has been established at 5.0mcg/mL and 1.0mcg/mL for confirmation analysis by high-performance LC/MS/MS, respectively.

After six weeks of collecting data, approximately 11% (681/6,224) of blood samples from cases that would not have previously been screened for gabapentin using the laboratory's previous testing platform were presumptively positive by ELISA. The confirmation rate was 82% (559/681). Observed concentrations of gabapentin during this time period ranged from (1.1-610)mcg/mL, with a mean of 17.9mcg/mL and median of 10.0mcg/mL. Decomposition is suspected to be an interferent with this ELISA kit.

Analysis of positive blood gabapentin case data near the start of the new testing platform revealed that the most frequently seen drug in combination with gabapentin was fentanyl, followed in order by ethanol, cannabinoids, oxycodone, clonazepam and 7-amino clonazepam, hydrocodone, cocaine and benzoylecgonine, amphetamine/methamphetamine, alprazolam, diphenhydramine, and heroin (defined as a case in which 6-monoacetylmorphine was detected in any matrix). Data collected over a seven-month period beginning June 2019 through January 2020, including concentration ranges of gabapentin and frequency of co-administration with other drugs, will be presented.

### Gabapentin, ELISA, Postmortem

## K32 Comparison of Data Acquisition Methods for High Resolution Mass Spectrometry (HRMS) Drug Screening

Jessica L. Ayala, MSFS\*, Sam Houston State University, Huntsville, TX 77340; Sarah Kerrigan, PhD, Sam Houston State University Department of Forensic Science, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will understand how HRMS data acquisition can be used to improve strategies for drug detection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the relative merits of quadrupole Time-Of-Flight-Mass Spectrometer (qTOF-MS) data acquisition approaches and the challenges associated with the technological shift from traditional immunoassay to HRMS-based drug screening.

According to the most recent census of publicly funded laboratories in the United States, forensic toxicology is now the most outsourced discipline in forensic science. The increased need for outsourcing can be attributed in large part to the proliferation of New Psychoactive Substances (NPS) and the expanded scope of drug testing that is required in antemortem and postmortem toxicology investigations. Over several decades, drug users have shifted from classical drugs of abuse, such as cocaine and marijuana, to new emerging synthetic drugs, including designer benzodiazepines, synthetic cannabinoids, cathinones, fentanyl analogs, and novel opioids. Traditional immunoassay-based screening techniques cannot keep pace with these developments due to the sheer number of drugs, need for adaptation, and limitations in terms of their cross-reactivity.

In order to combat this challenge, some laboratories have transitioned to MS-based screening. HRMS using qTOF-MS is of particular interest because of its sensitivity, specificity, and potential for retrospective data analysis. HRMS allows laboratories to keep abreast of the transitory drug trends and can be more readily adapted to the changing landscape of drug use than traditional immunoassay-based screening. This study focuses on the optimization of data acquisition techniques using Liquid Chromatography (LC) qTOF-MS. Three different acquisition modes were evaluated for this purpose, including TOF MS, All Ions MS, and Auto MS/MS. TOF-MS functions as a traditional time of flight instrument using a precursor ion for detection. All Ions mode MS simultaneously analyzes all precursor ions in addition to fragmenting each precursor at set collision energies, thus providing an additional layer of identification with fragment confirmation. In contrast, Auto MS/MS mode isolates one precursor ion at a time and also fragments each precursor at set collision energies. In addition, the Auto MS/MS mode utilizes an abundance threshold to dictate which precursor ions are fragmented. Using the All Ions approach, all ions that travel through the instrument are fragmented, regardless of abundance. As a consequence, there are relative merits associated with each acquisition mode. The goal of this study was to perform a side-by-side comparison of these techniques using analytes of interest in forensic toxicology. Using certified reference materials, common drugs of abuse and NPS were analyzed using optimized data acquisition methods with an Agilent® 6530 Accurate Mass qTOF-MS. A comparison was conducted for each drug's mass error, target score, and signal-to-noise ratio using each approach. The target score is a weighted value determining how well the mass, isotopic pattern, and retention time of the suspect compound coincide with the target compound.

It was hypothesized that the All Ions data acquisition mode would prove the most robust screening tool since fragmentation occurs for all precursor ions, regardless of abundance. All Ions data acquisition collects and fragments all precursor ions increasing the probability of detecting novel drugs retrospectively as a delay in identification is expected because clandestine production rate surpasses current laboratory identification capabilities. This untargeted approach to screening is highly beneficial in forensic toxicology, given the transient nature of many drug trends. Data-dependent and data-independent acquisition are explored, and the relative merits of these approaches are discussed.

### HRMS, NPS, QTOF-MS

## K33 Analysis of Cannabinoids in Vitreous Fluid

Haley Berkland, BA\*, Pittsburgh, PA 15203; Erin B. Divito, PhD, MolecularDx, LLC, Windber, PA 15963; Christopher B. Divito, PhD, MolecularDx, LLC, Windber, PA 15963; Frederick W. Fochtman, PhD, MolecularDx, LLC, Windber, PA 15963-1300; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA 15282

**Learning Overview:** The goal of this presentation is to present a Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) method development and validation study for analyzing vitreous fluid for Tetrahydrocannabinol (THC), 11-Nor-9-Carboxy- $\Delta^9$ -Tetrahydrocannabinol (THCCOOH), 11-Hydroxy- $\Delta^9$ -Tetrahydrocannabinol (11-OH-THC), and Cannabidiol (CBD). Casework examples comparing blood and vitreous cannabinoids will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the value of vitreous fluid as a toxicologically important matrix when other matrices are not available.

Cannabis is currently the most widely abused illicit drug in the world.<sup>1</sup> In the United States, recreational cannabis use is legal in 11 states and medical cannabis use is legal in 33 states. As medical and recreational uses of this substance become increasingly legal, there is a need for reliable analytical methods that can detect and analyze cannabinoids in death cases where there is a question relating to the cause and manner of death when typical matrices are not available. Vitreous humor is a gelatinous fluid located in the eyeball and is regularly drawn during autopsy and used as a matrix to test for drugs and alcohol by a postmortem toxicologist. This study utilized bovine vitreous fluid as a blank matrix for method development and validation.

THC is the primary psychoactive component in cannabis and produces the euphoric, relaxing feelings that are associated with the drug. 11-OH-THC is the primary active metabolite of THC and THCCOOH is the secondary and inactive metabolite of THC. CBD is a non-psychoactive component in cannabis that has emerged as a potential remedy for pain, anxiety, and other common health issues. Hemp-based CBD products with less than 0.3% THC content are federally legal in the United States. In this study, a method was developed and validated to quantitate THC, CBD, 11-OH-THC, and THCCOOH in bovine vitreous humor. Samples were prepared by a liquid-liquid extraction using 1 milliliter of vitreous fluid, acidified water, and organic solvents. Separations were conducted using a Phenomenex® Kinetex® C18 (2.1x100 mm, 2.6 $\mu$ m particle size) with VANQUISH™ High Pressure Liquid Chromatography System. Gradient elution was performed with 0.1% formic acid in water and acetonitrile. Identification and quantitation were performed with a TSQ Endura™ Triple quadrupole Mass Spectrometer (QqQ MS) operating in selective reaction monitoring mode. This LC/MS/MS technique combines low complexity sample preparation with the selectivity and sensitivity of LC/MS/MS.

This method was cross validated in whole blood and plasma matrices and used in routine, postmortem toxicology casework. Samples were screened using and Enzyme-Linked Immuno-Sorbent Assay (ELISA) and quantitatively confirmed using the developed LC/MS/MS cannabinoid assay. Limits Of Quantitation (LOQ) are typically 0.5ng/mL with an analytical measurement range reaching 250ng/mL. Casework samples testing positive by ELISA showed the presence of cannabinoid compounds. Blood samples testing positive for cannabinoids showed a positive correlation for trace levels of THCCOOH in vitreous.

This method allows for detection of CBD that can clarify the reported use of federally legal food supplements and/or products used for their reported medicinal benefit. Driving under the influence of marijuana is a major concern in society and postmortem cases involving motor vehicle fatalities need to have forensically valid testing for interpretation of marijuana usage. Furthermore, it is important to differentiate detection of CBD and metabolites versus THC and metabolites in these cases.

## K34 Chiral Separation of Methylphenidate, Ethylphenidate, and Ritalinic Acid in Blood

*Christina Smith, BS\*, Red Oak, TX 75154; Madeleine J. Swortwood, PhD, Sam Houston State University, Huntsville, TX 77341*

**Learning Overview:** After attending this presentation, attendees will understand chiral separation of cognitive stimulants and how to effectively isolate and extract them from biological samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the attendees with a unique approach to extraction of cognitive stimulants from blood. With this, a novel approach to chiral separation will be presented to the forensic community.

There has been a recent trend of abusing cognitive stimulants. Drugs such as Methylphenidate (MPH) are commonly prescribed for Attention-Deficit/Hyperactivity Disorder. MPH exists as two enantiomers, though the Dextro (D) configuration is more potent. Analytically, separation of the isomers is essential. However, chiral analysis poses challenges to researchers. Currently, there are no methods available to detect multiple chiral stimulants, and their metabolites in a single analysis. While Ritalinic Acid (RA) is the primary metabolite, Ethylphenidate (EPH) is also produced when alcohol is co-administered. Due to limited assays, this study sought to develop a method that separates the enantiomers of MPH and its metabolites following isolation and extraction from blood samples. Methods such as this are critical to understanding the pharmacokinetics of such cognitive stimulants.

Blood (0.25mL) was fortified with deuterated internal standards (0.025mL). The samples were diluted with phosphate buffer (pH 6) and allowed to stand for five minutes before centrifugation. Following conditioning with methanol and phosphate buffer, samples were loaded onto DAU clean screen extract Solid-Phase Extraction (SPE) cartridges. Cartridges were washed with 0.1M acetic acid and methanol. Analytes were eluted with 2% ammonium hydroxide in methanol, dried, and reconstituted in mobile phase. An Agilent® Technologies 1290 Infinity Liquid Chromatograph coupled to an Agilent® 6470 Triple Quadrupole spectrometer was used for detection of the analytes. Chiral separation was achieved using an Agilent® Poroshell Chiral-V column (2.1 x 100mm, 2.7u) with a flow rate of 0.6mL/min. Mobile phase consisted of deionized water (A) and trifluoroacetic acid (0.0125%, v/v) and ammonium acetate (0.025%, w/v) in methanol (B) at a ratio of 2:98 (A:B) with an isocratic elution. The run time was four minutes.

When developing this method, various parameters were assessed in order to optimize chiral separation. Different gradient elution systems with different buffers and mobile phase composition were investigated in hopes of achieving full baseline separation of the enantiomers. With the final mobile phase and column selections (discussed above), full baseline resolution between the D- and L-MPH enantiomers and the D- and L-EPH enantiomers was achieved. In the same injection, this study was also able to detect and separate RA. Various sample preparation techniques such as protein precipitation, liquid-liquid, supported liquid, and other SPE chemistries were investigated. Optimal isolation and extraction of the analytes in blood was achieved in the extraction discussed above. Recoveries were >90% and matrix effects were <±22% with the exception of RA (80%). All matrix effects and extraction recoveries were compensated by matched deuterated internal standards.

This is the first known method that chromatographically separates the enantiomers of MPH and EPH, in addition to RA. This method also utilized simple SPE to isolate the drug and metabolites from a single sample of blood (0.25mL).

*This research was funded by Sam Houston State University Office of Research and Sponsored Programs Internal Grant Program.*

### Chiral Separation, Methylphenidate, Blood

## K35 Scientific and Careful Setting Up of a Lethal Oleander Leaves Infusion

Giulia Gubinelli\*, Bari 70124, ITALY; Francesca Donno, MD, University of Bari, Bari 70121, ITALY; Gianni De Giorgio, Section of Legal Medicine, Bari 70124, ITALY; Ilaria Lacavalla, MD, Policlinico di Bari, Bari 70124, ITALY; Alessandro Dell'Erba, PhD, Risk Management Unit, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will know more about determining suicidal death by poisoning through the autonomous preparation and drinking of a *Nerium oleander* leaves infusion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a complete evaluation of the forensic aspects of *Nerium oleander* self-poisoning, analyzing scene investigation, external body examination, autopsy findings, and toxicological and histological analysis.

Suicidal oleander poisoning is uncommon, although some cases are described in the literature.<sup>1</sup>

The uniqueness of this case lies specifically in what the scene investigation findings suggested, namely the scientificity of the act implemented by the man, a laboratory technician, who arranged everything in great detail and in a manner that shows the fully lucid and conscious intention of killing himself. The additional unique element, further supporting full awareness and thorough planning of the act, was the presence on the scene of warnings for “Poison,” showing concern for people approaching the scene after his death. Per research, this is the first report of suicide using an infusion of *Nerium oleander* leaves and the first time toxicological analyses have investigated the ratio of oleandrin concentrations in the vitreous humor versus the cardiac/peripheral blood and other biological samples.

*Nerium oleander* is an indoor and ornamental plant of an evergreen shrub, widespread in Mediterranean countries and one of the most poisonous plants known to humans. All parts are toxic. The effect is primarily due to the cardiac glycosides (oleandrin, nerin, digitoxigenin, and olinerin). Oleandrin is the principal toxin. Clinical manifestations of poisoning appear a few hours after intake and include gastrointestinal, central nervous system, and cardiovascular effects, characterized by nausea, vomiting, salivation, colic, diarrhea, ataxia, drowsiness, muscular tremor, ventricular tachycardia, dysrhythmia, and heart blockage. *Nerium oleander* poisoning can be accidental, homicidal, or suicidal.<sup>2</sup>

Reported here is the case of a suicidal poisoning of a 71-year-old man, which occurred in Castellana Grotte (BA) in March 2019. The scene investigation (the man's house) revealed the presence of a steel pan, with its cover on, sealed with packing tape.

A small piece of white Scotch<sup>®</sup> tape was on the cover, with a note in pen on it: *Poison. Wash pan and funnel carefully or throw everything away.* Inside the pan, elongated dark green leaves, small trunks, and a plastic funnel were found. A smaller pan and a bottle were also present on the scene, both containing a golden yellow fluid. A piece of white Scotch<sup>®</sup> tape was also present on the bottle, with the following note: *Poison.* An empty glass was also located at the scene.

The external examination performed on the man's body revealed blood percolation from respiratory orifices. No other significant findings were encountered.

The autopsy findings showed multi-organ congestion, as is common in cases of oleander poisoning.<sup>3</sup> Moderate congestion was present in the kidneys, liver, brain, and lungs. The lungs also showed some indications of hemorrhagic suffusion. Stomach content showed the presence of a brown liquid (0.5cc). The bowel was resected with absence of the distal portion of the small intestine and the right part of the large one, as the man had been previously operated for cecum carcinoma.

The histological examination of the tissues corroborated edema of the kidneys, liver, brain, and lungs with some indications of hemorrhagic infiltration in the latter, as macroscopically observed. No other abnormalities were revealed.

Toxicological investigations performed by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) on the samples collected during the autopsy (blood, urine, gastric content, vitreous humor, liver) confirmed the presence of toxic levels of oleandrin in all specimens.<sup>4</sup> In detail, the results of oleandrin quantification were: blood 37.5ng/ml; vitreous humor 12.6ng/ml; urine 83.8ng/ml; liver 205ng/mg; and gastric content 31.2µg/ml. Oleandrin was also present into the yellow liquid found at the scene, in a concentration of 38.5µg/ml. Hence, the diagnosis of self-poisoning through the ingestion of an infusion of oleander leaves.

This case is a good illustration of the overall set of forensic aspects relating to self poisoning by means of an infusion of the oleander leaves, with the added detail of the meticulous planning of the suicide.

### Toxicology, Oleander Leaves Infusion, Fatal Intoxication

## K36 Comparison of Manual Protein Precipitation and Automated Protein Precipitation Using DPX Low Porosity Tips in Blood, Urine, and Tissues

Danielle C. Mata, MS\*, Santa Ana, CA 92703

**Learning Overview:** After attending this presentation, attendees will understand the benefits of automating their extractions using low porosity tips in place of traditional protein precipitation methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a novel automated option for protein precipitation of various common toxicological matrices.

Historically, protein precipitation is a commonly used manual clean-up process in many toxicological drug assays for blood and tissue samples. Often referred to as “protein crash,” this initial step rapidly removes numerous biological interferences prior to a more thorough downstream sample clean up. Traditionally, an organic solvent, most commonly acetonitrile or methanol, is added to denature the sample and initiate protein precipitation. This is followed by a quick vortex step and centrifugation prior to decanting the supernatant for further extraction, if needed.

The widespread use and robustness of protein precipitation makes it an ideal process to automate, especially in laboratories with large case loads. Recently, DPX Technologies has presented an automated method for the quantitation of testosterone in serum using Low Porosity Filtration Tips (LPFT). This tip-based method uses a quick (less than two minutes) and effective, patent-pending, Tip-on-Tip (ToT) technology that automates protein precipitation and filtration to isolate the supernatant. Using the DPX tips, one can eliminate the need for manual vortex mixing, centrifugation, and supernatant transfer.

This study is a comparison of the DPX ToT method on an INTEGRA Biosciences VIAFLO using LPFT to the Orange County Crime Lab’s Scientific Working Group for Forensic Toxicology (SWGTOX) -validated method that uses a traditional protein precipitation process. The validated method analyzes for 23 drugs, including benzodiazepines, antihistamines, and sedative hypnotics, in antemortem blood, postmortem blood, urine, brain homogenate, liver homogenate, and stomach content homogenates. Brain and liver homogenates were diluted anywhere from 2x to 12x with water, and stomach content homogenates were diluted between 10x and 500x with water prior to treatment.

After completing protein precipitation, both techniques followed the validated extraction procedure. Both precipitation methods, which included standards, controls, and case samples, were injected on a Waters® ACQUITY® UPLC with a Waters® BEH C18 column (1.7µm, 2.1 x 100mm) and Xevo TQ-S to compare the results.

Various concentrations and matrices were analyzed using both techniques to determine if the ToT method using the LPFT correlated to the SWGTOX-validated method. Same-day studies between the two techniques indicated that the LPFT works just as well as the more traditional protein crash method. For antemortem and postmortem blood specimens, the percent difference between the two methods ranged between 5.8% and 8.5%. Significantly, the ToT method was able to handle not only blood and urine but also tissue homogenate samples at various pre-extraction dilutions. Varying diluted brain, liver, and stomach content specimens had % differences for the two methods of 8.3%, 4.0%, and 4.7%, respectively. Importantly, precision studies were successful using the ToT method on a concentrated liver homogenate with percent differences of 2.5% and 7.9% for alprazolam and hydroxyzine, respectively. These initial investigative results demonstrate that protein precipitation can be automated for SWGTOX-validated forensic applications for Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis. Significantly, adaptation of an automated crash method for forensic laboratories offers several unique advantages, including reducing the hands-on time requirement for the analyst, minimizing potential human errors, and further negating the long-term health effects of repeated pipetting.

### Protein Precipitation, Sample Preparation, Benzodiazepines

## K37 Variability in Direct Analysis in Real Time-High Resolution Mass Spectrometry (DART®-HRMS) Instrument Parameter Optimization Due to Molecular Identity

Jessica L. Sprague, MS\*, Winter Park, FL 32792; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816

**Learning Overview:** This presentation will introduce attendees to the importance of the identity of targeted molecules when optimizing DART®-HRMS instrument parameters. This presentation will show attendees that when developing protocols for DART®-HRMS targeted screening, the identity of the target molecule will drastically impact the performance of the instrument. Therefore, it is necessary to optimize DART®-HRMS parameters for specific compounds, rather than whole classes of molecules or evidence samples that other screening methods may target.

**Impact on the Forensic Science Community:** For DART®-HRMS instrumentation to be operationalized in a crime laboratory, instrumental methods for analysis must be optimized by the crime laboratory facility. This presentation will impact the forensic science community by emphasizing the importance of optimizing DART®-HRMS to specific compounds, which in turn improves the sensitivity of the instrument as a screening tool.

DART®-HRMS instrumentation is rising in popularity in forensic research, due to its vast applications in all forensic disciplines as a robust evidence screening tool. Recent research has shown DART®-HRMS applications in drug chemistry, toxicology, and trace evidence subdisciplines, including sexual assaults, explosives, and fire debris investigations. DART®-HRMS can be used as a faster, more specific, and more sensitive alternative to traditional forensic screening methods (i.e., Enzyme-Linked Immuno-Sorbent Assay (ELISA) and canine detection).

DART®-HRMS analysis is a highly sensitive and specific instrumental technique. Evidence samples can be introduced to the DART® ionization source in any phase of matter. Analyte molecules desorb from the surface of the sample after exposure to a heated metastable gas stream (i.e., excited-state helium). The excited metastables interact with atmospheric air molecules (i.e., water and oxygen), forming atmospheric ions. These ions cause the analyte to undergo soft ionization, resulting in the creation of molecular ions and adducts. Analyte ions are then carried through an HRMS, and the masses of the ions can be reported to four decimal places. Relative isotope abundances can then be used to preliminarily identify unknown analytes.

The instrumental parameters used in DART®-HRMS can affect the sensitivity of analysis for semi-quantitative work. Variable instrument parameters include the voltage at the exit grid, desorption temperature, and width of the sample gap, among others. Such instrument parameters can affect the ionization mechanisms at the ionization source by varying the availability and thermochemical energy of both the metastable and analyte species. Molecules that ionize most readily in DART® atmospheric conditions can dominate the resulting mass spectra, reducing the sensitivity in the analysis of other molecules in mixtures.

Optimization of DART®-HRMS parameters will be necessary for any forensic lab attempting to adopt DART®-HRMS instrumentation for casework. The preliminary data in this study notably show that the instrument parameters *must* be optimized for each compound of interest in forensic screening. Five compounds of evidentiary value were analyzed at varied exit grid voltages (50–550V, in positive or negative mode as appropriate). Each compound exhibited different functional groups and thermochemical properties, but were prepared at the same concentrations (ppm). There were no definable trends in the resulting analytical sensitivity as measured by relative standard deviations of the slope of the generated calibration curve. The results lead to the recommendation that any optimization of DART®-HRMS analyses must be performed for each specific molecule of analytical interest, rather than general molecular classes utilized by alternative screening methods.

### DART®-HRMS, Forensic Screening, Instrument Optimization

## K38 High-Throughput Screening of Drugs of Abuse in Biofluids via 96-Solid-Phase Microextraction and Transmission Mode Direct Analysis in Real Time-Mass Spectrometry (TM-DART<sup>®</sup>-MS)

Frederick Li, MS\*, IonSense, Inc, Saugus, MA 01906; Paul Liang, BS, IonSense, Inc, Saugus, MA 01906; Brittany Laramee, BS, IonSense, Inc, Saugus, MA 01906; Brian Musselman, PhD, IonSense, Inc, Saugus, MA 01906

**Learning Overview:** After attending this presentation, attendees will gain insight into how DART<sup>®</sup>-MS can be automated for high-throughput screening of drugs from toxicological specimens, such as urine and plasma. Attendees will also understand how Solid-Phase Microextraction (SPME) can be automated and used to extract and concentrate the drugs of abuse from the sample matrix and reduce matrix suppression for DART<sup>®</sup>-MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing and discussing the potential value of employing SPME DART<sup>®</sup>-MS for high-throughput screening of drugs of abuse from urine and plasma. SPME provides a simple and automatable clean-up method to preconcentrate the drugs prior to analysis by DART<sup>®</sup>-MS, improving both sensitivity and selectivity. DART<sup>®</sup>-MS is an ambient ionization MS technique that has tremendous potential for high-throughput implementation due to its easy operation, speedy analysis, and high sensitivity. By coupling SPME with DART<sup>®</sup>-MS, this approach provides the forensic examiner the capability of rapidly generating high-fidelity data for the identification of drugs of abuse from urine and plasma.

Protocols for urine specimen drug tests typically involve a multi-step analysis process. First, a screening method, such as an Immunoassay (IA), is used to quickly identify specific or classes of drugs present in the urine. Next, a confirmatory method, such as Gas Chromatography/Mass Spectrometry or Liquid Chromatography/Mass Spectrometry (GC/MS or LC/MS), is used to confirm a positive or, in some instances, negative result. Although immunoassays are rapid and inexpensive, specificity varies based on the assay and can result in high rates of false positives and false negatives. Chromatography-based MS techniques can also be used as a screening tool and are very specific, but they have run times that are often lengthy, requiring up to 30 minutes per sample, which limits throughput.

To increase sample throughput while maintaining a high level of sensitivity and specificity for drug screening, liquid handling robotics was employed with SPME TM-DART<sup>®</sup>-MS to automate the SPME extraction and elution, as well as sample deposition and presentation to the DART<sup>®</sup>-MS. This coupling takes advantage of the speed and sensitivity of DART<sup>®</sup>-MS while reducing user input required for SPME and further increasing the speed of the DART<sup>®</sup>-MS analysis. Using a liquid handling robot, the manual transfer of the SPME fibers between the conditioning, extraction, and elution steps and the deposition of the eluent onto the wire mesh sample substrates for TM-DART<sup>®</sup>-MS were eliminated. With this approach, 96 samples can be analyzed in as little as 20 minutes. This approach demonstrated reduced matrix suppression and sensitivity in the parts per billion range. Bovine blood was fortified with fentanyl and detected at concentrations as low as 100ng/mL. Bovine blood was also fortified with a mixture of eight compounds, which includes fentanyl, norfentanyl, acetyl fentanyl, cis-3-methyl fentanyl, furanyl fentanyl, FIBF, 4-ANPP, and cyclopropyl fentanyl. All eight compounds were detected at concentrations as low as 100ng/mL. In addition to SPME, the liquid handling robot was also used to deposit nanoliter volumes of sample to reduce matrix suppression for TM-DART<sup>®</sup>-MS, and the resulting data showed improved sensitivity. Signal response for both methadone and codeine were significantly greater with 200nL than with 1 $\mu$ L. Furthermore, the limit of detection for methadone was improved twofold, from 100ng/mL to 50ng/mL. This approach of using SPME in combination with TM-DART<sup>®</sup>-MS and liquid handling robotics demonstrated a unique approach for high-throughput screening of drugs of abuse with good sensitivity and selectivity.

### DART<sup>®</sup>-MS, Solid-Phase Microextraction, Drugs of Abuse

## **K39 Comprehensive Analysis of 34 Fentanyl Analogs Including Carfentanil From Liver Tissue Using Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Analysis**

*Kylea M. Mathison\*, West Virginia University, Morgantown, WV 26506; Joseph A. Cox, MS\*, Morgantown, WV 26508; Colby E. Ott, MS, Shippensburg, PA 17257; Joseph A. DelTondo, DO, Allegheny General Hospital, Pathology, Pittsburgh, PA 15212; James C. Kraner, PhD, Office of the Chief Medical Examiner, Charleston, WV 25302; Kristen M. Bailey, MS, Office of the Chief Medical Examiner, Charleston, WV 25302; Myron A. Gebhardt, MS, Office of the Chief Medical Examiner, Charleston, WV 25302; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121*

**Learning Overview:** After attending this presentation, attendees will better understand a QuEChERS extraction protocol utilized for the quantitative analysis of 34 different fentanyl analogs from liver tissue and detection using an LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a comprehensive procedure for the analysis of emerging fentanyl analogs extracted from postmortem liver tissue through the use of a safe method that reduces potential contamination while maintaining sensitivity.

Opioid overdoses have increased in recent years, and according to the National Institute on Drug Abuse currently more than 130 people die from an opioid overdose each day within the United States. The analysis of these analogs from biological specimens pose an analytical challenge to practitioners due to the acute lethal intoxication concentrations, continuous variations of analogs, and wide variations in chemical structure. Additionally, Postmortem Redistribution (PMR) of concentrations of drugs such as fentanyl within a deceased individual can occur with time and has the potential to change the concentration in the peripheral blood, while studies have shown that PMR is not as frequently occurring in the liver. Therefore, based on the PMR tendencies of fentanyl, liver or other organ tissues are needed to provide the medical examiner the proper data to make an informed decision on the manner or cause of death when fentanyl is present and may provide a more adequate indication of antemortem concentrations compared to blood.

Liver specimens are often homogenized with bladed devices that can require costly disposable parts or require cleaning to avoid contamination. Here, this study is proposing to use a disposable single tube with steel beads for homogenization. Presented in this study is a QuEChERS method to extract fentanyl and fentanyl analogs from human liver samples.

This method used prepackaged extraction powder containing magnesium sulfate and sodium acetate, 0.1g of liver tissue, three stainless steel balls, and 2mL dispersive-Solid Phase Extraction (SPE) tubes, containing 25mg of Primary Secondary Amine (PSA), 25mg end-capped octadecylsilane (C18<sub>EC</sub>), and 150mg magnesium sulfate. Homogenization was achieved using a high-speed mixer mill with homemade attachments for 1.7mL centrifuge tubes and 4.5mm stainless steel balls for pulverization, reducing the risk of cross contamination by producing a homogenized sample in a single disposable tube. The quantitation method was performed on an Agilent® 6470 LC/MS/MS system coupled with a 1290 Infinity® II LC system. Chromatographic separation was achieved on a Zorbax® Eclipse Plus™ C18 RRHD 3.0x100mm, 1.8µm column with 0.1% formic acid and 5mM ammonium formate in water (mobile phase A), and 0.1% formic acid in methanol (mobile phase B).

An evaluation of a QuEChERS extraction procedure is presented in this study as an alternative analytical method for efficient extraction and detection of fentanyl and fentanyl analogs. The evaluated parameters include selectivity, matrix effects, linearity, bias, precision, and proof of applicability using authentic fentanyl case samples. Average recoveries for the 34 fentanyl analogs were 101.1% and 104.4% for low (1µg/kg) and high (50µg/kg), respectively. Average matrix effects for the 34 fentanyl analogs were 99.3% and 98.4% for low and high, respectively.

The comprehensive extraction and LC/MS/MS method developed for analysis of liver tissue for fentanyl and fentanyl analogs is precise, sensitive, and reproducible for complex forensic matrices such as liver tissue.

### **Fentanyl Analogs, QuEChERS, Postmortem Liver**

## K40 Validation and Comparison of Three Sample Preparation Techniques for Quantitation of Amobarbital, Butalbital, and Phenobarbital in Blood and Urine Using Ultra-Fast Liquid Chromatograph/Tandem Mass Spectrometry (UFLC/MS/MS)

Chi Hin Marco Chan\*, Oklahoma City, OK 73104; Monique Oles, Maynard, MA 01754; Nichole D. Bynum, MS, RTI International, Johnson Building, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Boston, MA 02118

**Learning Overview:** After attending this presentation, attendees will be able to choose among the methods developed for the analysis of selected barbiturates in blood and urine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on sample preparation methods for the analysis of select barbiturates in various matrices.

**Background/Introduction:** Barbiturates are a class of drugs that act as Central Nervous System (CNS) depressants. They were vastly used as sedative, hypnotic, anticonvulsant/antiepileptic, and anesthetic agents in the 20<sup>th</sup> century. Today, only 12 types of barbiturates are still in use for therapeutic purposes. The rest have been greatly replaced by benzodiazepines due to narrow margins of safety. However, barbiturates are still a prevalent choice of abuse among the public and, therefore, are of forensic toxicological importance.

**Objective:** The objectives of this research study were to validate three different sample preparation methods (Liquid-Liquid Extraction (LLE), Supported-Liquid Extraction (SLE), and Solid-Phase Extractions (SPE)) for the quantitation of three barbiturates (amobarbital, butalbital, and phenobarbital) in blood and urine using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS); and to compare the efficiency and effectiveness between methods for extraction of barbiturates under the laboratory setting at Boston University School of Medicine.

**Method:** Six-point calibration curve with three quality control samples were extracted using LLE, SLE with Biotage® ISOLUTE® SLE+ cartridge, and SPE with Waters® Oasis™ PRiME Hydrophilic-Lipophilic Balanced (HLB) cartridges. All analyses were conducted using a Waters® XBridge™ C18 LC column (3.5µm particle size; 50mm length; 2.1mm internal diameter) on a Shimadzu® UFLC coupled to a SCIEX™ 4000 QTRAP MS/MS with negative Electrospray Ionization (ESI) mode. Method validation was performed according to the American Academy of Forensic Sciences Standards Board (ASB) standard 036, First Edition 2017. Calibration model, carryover, Limit Of Detection (LOD), Limit Of Quantitation (LOQ), bias and precision, stability, dilution integrity, interferences, ion suppression/enhancement, and recovery were evaluated for quantitative analysis.

**Results:** A six-point linear calibration model (20-2,000ng/mL) with 1/x weighting was reproducible in all three sample preparation methods for quantifying amobarbital, butalbital, and phenobarbital in blood and urine with  $r^2$  greater than or equal to 0.994. Bias and precision evaluated from three controls throughout the range of the curve were within  $\pm 20\%$  and  $\pm 20\% CV$ , respectively. Neither carryover nor interferences were observed. Detection limits were evaluated down to 5ng/mL depending on the extraction procedure. Samples were able to be diluted up to 50 times prior to instrumental analysis. Samples were stable on autosampler at room temperature up to 72 hours after their initial analysis. Recovery of barbiturates from blood and urine all ranged from 45% to 86%. The effect of ionization suppression or enhancement demonstrated only minimal impact on the validation.

**Conclusion/Discussion:** This study has successfully validated three sample preparation methods (LLE, SLE, and SPE) for the quantitation of three barbiturates (amobarbital, butalbital, and phenobarbital) in blood and urine using LC/MS/MS. By comparing each method's efficiency and effectiveness, LLE was the best at quantifying barbiturates in blood and SLE was the most suitable method for extracting barbiturates from urine. These findings can be used further for examining the overall reliability and reproducibility of the validated methods in different laboratories. Results obtained can also be used to explore the possibility for streamlining sample preparation in the forensic laboratory.

### Barbiturates, Sample Preparation, LC/MS/MS

## **K41 Determination of Synthetic Cannabinoids AB Pinaca and AB-Fubinaca With Disposable Screen Printed Carbon Electrodes (SPCE) Modified With Nanoparticles and Enzymes**

*Miriam Barquero Quirós, PhD, University of Costa Rica, San Pedro, San Jose 11504, COSTA RICA; Luis E. Arroyo, PhD\*, West Virginia University, Morgantown, WV 26506-6121; Julian Portuguese, University of Costa Rica, San Jose 11501, COSTA RICA*

**Learning Overview:** After attending this presentation, attendees will be able to explain the theory and use of amperometric electrochemical techniques with disposable modified electrodes as screening tools in forensic science and to understand their implications in the fast quantification of novel synthetic cannabinoids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a novel analytical approach that provides both qualitative and quantitative information. The proposed methodology allows the on-site testing and quantification of synthetic cannabinoids at low concentration without sample destruction and as a miniaturized detection system.

Characteristics linked to electrochemical analysis include the speed of analysis, low cost, sensitivity, miniaturization, and low volume of testing material, with all of them being quickly adapted to forensic sciences practice. Screen-Printed Carbon Electrodes (SPCEs) are optimal testing devices due to low cost and disposable character, small sample volume, and the possibility of hosting modification on its surface via nanomaterials or enzymes to act as biosensors. The electrochemical process taking place can provide qualitative and quantitative information about an analyte under scrutiny. Most known SPCEs are carbon-based ink, with the additional advantage of having a significant potential window for analyte detection and possible surface modifications. The development of nanostructures at the electrode surface increases the current process and facilitates the incorporation of enzymes via functionalization. Enzyme Nanoparticles (E/NPs/SPCEs) have been shown their electrochemical performance due to selectivity and sensitivity.

Four amperometric biosensors based in the inhibitory activity of synthetic cannabinoids on enzymes were developed. AB-Pinaca and AB-Fubinaca on Acetylcholinesterase (AChE) using Acetylthiocholine Iodide (ATI) and glucuronyl transferase enzyme Uridine Diphosphate (UDP) with serotonin as substrates showed their inhibitory effect on amperometric substrates current. SPCEs were modified with gold NPs (AuNPs) for AChE and Multi-Wall Carbon Nanotubes MWCNT) for UDP. Enzymes were immobilized with carbodiimide and glutaraldehyde, respectively, and experimental optimization conditions were assessed. Michaelis-Menten apparent constants (KMapps) of biosensors were estimated in the presence and absence of inhibitors. Increasing slopes of calibration curves and values of KMapps indicate inhibitory effect at low concentration. Biosensors showed Limit of Detection (LOD)  $(8.4-13.0) \times 10^{-5}$  M; Limit of Quantitation (LOQ)  $(2.9-4.3) \times 10^{-4}$  M; Relative Standard Deviation (RSD) repeatability slopes (3.4–8.2%); RSD reproducibility slopes (3.6–9.7)%, and recovery (96.8–99.6)%. This is the first time that biosensors based on the inhibitory effect of synthetic cannabinoids on these enzymes have been applied to quantitative determination.

**AB Pinaca Fubinaca, Disposable Electrodes, Enzymes Nanoparticles**

## K42 A Fatal Case of Body Stuffer Syndrome

Francesca Iannaccone\*, Pisa 56123, ITALY; Costanza Filomena, Florence 50036, ITALY; Alice Chiara Manetti, MD, University of Pisa, Forensic Pathology, Toscana, Pisa 56126, ITALY; Sara Turco, MD, Pisa, ITALY

**Learning Overview:** This case of a fatal cocaine overdose in a body stuffer not only confirms the limits of instrumental diagnostics in the recognition of corporal drug users, but also helps to better define the pathological characteristics of this peculiar syndrome. This case also demonstrates that cocaine body stuffers, contrary to general belief, can develop toxic symptoms beyond 24 hours after ingestion, and that delayed toxicity can occasionally lead to death.

**Impact on the Forensic Science Community:** This case will impact the forensic science community by better defining histopathological and toxicological findings of the unique type of cocaine overdose known as “body stuffer syndrome.”

**Introduction:** Intracorporeal drug concealment is a frequent illicit practice in drug trafficking, since it is impossible to identify drug carriers if no medical complications occur.<sup>1,2</sup> Sometimes, drug concealment is the impulsive act of consumers or small traffickers (the so-called mini packers or body stuffers) attempting to evade control by law enforcement. In this case, the risk of acute intoxication is higher, because poor drug packaging, due to the extemporaneousness of the gesture, results in an increased probability of rupture or leakage.<sup>3,4</sup> The clinical picture, known as “body stuffer syndrome,” varies according to the type of drug and the amount of substance absorbed, and can prove lethal, as exemplified in this case.<sup>5-8</sup>

**Case Report:** A 29 year-old female drug pusher, while in custody, reported general malaise with abdominal pain. Physical examination, conducted at the local hospital’s emergency department, revealed: hypothermia, tachycardia, hypotension, mydriasis, areflexia in the lower limbs and hyporeflexia in the upper limbs, right supra-orbital hematoma, and right shoulder hematoma. Electrocardiogram (ECG) only confirmed tachycardia, while echocardiogram did not show abnormalities. A total body Computed Tomography (CT) scan revealed: peri-ponto-mesencephalic subarachnoid hemorrhage, ischemic brain lesions, and hepatic injury with perihepatic and perisplenic fluid effusion (without splenic lesions). Blood analysis showed hyperglycemia, leucocytosis, high transaminase levels, and hypercapnic acidosis. Toxicological tests revealed high levels of cocaine and its metabolite benzoylecgonine in serum (over 50.00g/L and 5.26 /L, respectively) and urine (22.5g/L and 76.9g/L, respectively). The patient rapidly went into a coma; she was admitted to the Intensive Care Unit (ICU) and placed under mechanical ventilation and colloid infusion for hypotension. She died three days after admission. At autopsy, a single, open plastic bag, undetected by the previous CT scan, was found in the gastric lumen, which presented several deep, necrotic ulcers. Hemorrhagic areas in the lungs, kidneys, and liver, and a (modest) peri-ponto-mesencephalic leptomenigeal hemorrhage were also observed. The heart showed mild concentric myocardial hypertrophy (ventricular wall maximum thickness =2.2cm), and a small hemorrhagic area in the anterior papillary muscle. Histological examination confirmed the polyvisceral bleeding pattern; particularly relevant were the plentiful hepatic hemorrhagic foci, communicating with dilated sinusoids, in complete absence of inflammatory reaction. Heart samples showed microarterial damage and foci of contraction bands; deep ulcerations, bounded by parietal necrosis, and intense hemorrhagic phenomena were detected in the gastric samples. Postmortem toxicological analysis documented very high levels of cocaine and benzoylecgonine in all biological samples (5.74g/L and 43.23g/L in urine, 1.72g/L and 4.3 g/L in blood, respectively) and cocaine in the plastic bag content (381.20g/L).

**Discussion:** Cocaine is the drug most commonly involved in severe intoxications associated with body concealment, although fatal cases in body stuffers are rare, according to literature, in comparison with heroin, cannabis, and ecstasy toxicosis.<sup>9,10</sup> This case of fatal cocaine overdose in a body stuffer not only confirms the limits of instrumental diagnostics in the recognition of corporal drug users, but also helps to better define the pathological characteristics of this peculiar syndrome. In fact, to date, conventional radiology—normally used to search for drug packages within the gastrointestinal system—have limited diagnostic value, as exemplified by this case in which the radiological images conducted have been thoroughly revised, with a negative outcome. The case presented here also demonstrates that cocaine body stuffers can develop toxic symptoms beyond 24 hours after ingestion, and that delayed toxicity can, occasionally, lead to death.<sup>11,12</sup> It appears that the integrity of the packaging has a significant predictive value in determining the time and likelihood of toxicity, although in some fatal cases the autopsy showed intact packages.<sup>13</sup> In this case, sustained leakage from the package into the gastric lumen probably led to a massive absorption of cocaine into systemic circulation, causing a dramatic clinical picture and the lesions observed at autopsy and at histological examinations, of which the “peliotic-like” liver alterations (dilation of the hepatic sinusoids, communicating with cystic blood cavities, delimited by endothelium, and surrounded by a band of connective tissue) were the most atypical, for liver damage is not usually reported in cocaine intoxications.<sup>14-18</sup>

## K43 A Different Approach in the Estimation of the Time Since Death: Concurrence of Thanatochronological and Toxicological Data in a Case of Cocaine Assumption-Related Death

Luigi Papi, University of Pisa, Institute of Legal Medicine, Pisa 56100, ITALY; Fabio Stefanelli, University of Pisa, Pisa, ITALY; Silvio Chericoni, University of Pisa, Pisa, ITALY; Alice Chiara Manetti, MD\*, University of Pisa, Forensic Pathology, Toscana, Pisa 56126, ITALY; Costanza Filomena, Florence 50036, ITALY; Francesca Iannaccone, Pisa 56123, ITALY

**Learning Overview:** The goal of this presentation is to provide a different approach in the evaluation of the Postmortem Interval (PMI).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by giving an example of how toxicology and thanatochronology could be integrated in the estimation of the time since death.

**Introduction:** The estimation of the time since death has been a longstanding issue for forensic pathologists. Its usefulness is mostly evident in cases of violent death, in which a precise evaluation of the PMI may help direct investigation enquiries to a potential suspect of homicide. Furthermore, it can sometimes be relevant in case of other crimes, such as failure to provide assistance.

As is widely known, the parameters obtained through the evaluation of supravital reactions, which are usually used to establish the PMI, are modified by variation of numerous factors related to the environment and to the body itself.<sup>1,2</sup> Because of this variability, it is not always easy to obtain a precise chronological reference of death, despite the technologic progress and the introduction of new methods, such as the biochemical analysis of vitreous humor and the study of electrical excitability of skeletal muscle; furthermore, often only a wide time window is obtained.<sup>3-5</sup> However, the estimation of the decrease of body temperature is still the most reliable method used, supplemented by the others thanatochronological criteria.<sup>6</sup>

In some cases, toxicology can help pathologists to better define the PMI; in fact, when the time of consumption is known, it is possible to estimate the time elapsed since the consumption of a substance by its concentration in blood and tissues.<sup>7</sup>

This work is about a case of cocaine-related-death, in which the definition of a precise PMI, obtained by the concurrence of thanatochronological and toxicological data, had a fundamental role in substantiating the failure-to-provide-assistance hypothesis.

**The Case:** A 47-year-old man was found dead at 6:30 p.m. in a hotel room, where he arrived with his girlfriend around 3:30 a.m.–4:00 a.m. of the same day. The woman reported the man took intravenous cocaine first around 1:00 a.m. when they were in another place, and then a second time in the hotel room, approximately between 4:00 a.m.–5:30 a.m. During the first interrogation performed by the police, she said she left the room at 5:30 a.m. while the man was sleeping; then she said she went back to the hotel around 12.00 a.m. to bring him home, but he preferred to stay, so she left again and never came back. This reconstruction of the facts was denied by the hotel keeper's witness, who reported that the woman definitely left the room around 12:00 a.m. At this point, the woman gave another version of the story; she said she left the hotel at 1:00 p.m. and her boyfriend was still alive.

The judicial authority supposed the man had died in a timeframe incompatible with the woman's story, so the hypothesis of failure-to-provide assistance took place. The thanatochronological data (obtained during the inspection at 8:30 p.m.: body temperature 31.0°C/87.8°F, room temperature 19.3°C/66.74°F) placed the time of death around 9:30 a.m.; the Henssge nomogram (corrective factor: 1) was used. The autopsy didn't reveal any concomitant disease or traumatic lesions able to justify the death, except for a sign of needle puncture at the right groin.

To assess the cause of death, toxicological analyses were performed and the cocaine and benzoylecgonine levels in the blood (446ng/ml and 8,427ng/ml, respectively), brain (0.51ng/mg and 1.56ng/mg, respectively), and liver (0.05ng/mg and 3.48ng/mg, respectively) confirmed cocaine overdose as the cause of death. The toxicological data were also used to estimate the PMI. The blood, brain, and liver cocaine/benzoylecgonine ratio (0.05, 0.33 and 0.014, respectively) and the brain/blood cocaine ratio (1.14) placed the death around 4–6 hours after cocaine injection. This chronological reference perfectly matched with thanatochronological information.

This case represents an example of how the classic thanatochronological data could be integrated with toxicological analysis to estimate the time since death, if the time since the last intake of the substance of interest is known. This could be a different approach for solving the historical issue of the evaluation of PMI.

## K44 Determination of Nicotine and Cotinine in Saliva

Sultan M. Büyüker\*, Uskudar University, Istanbul 34662, TURKEY; Kaan Yilancioglu, PhD\*, Üsküdar University, Istanbul 34662, TURKEY; Rabia Aydin, BS\*, Uskudar University, Istanbul 34662, TURKEY; Sevil Atasoy, PhD\*, Uskudar Üniversitesi Adli Bilimler Enstitüsü, Istanbul, TURKEY

**Learning Overview:** It is important to determine the amount of nicotine and cotinine in oral fluids by instrumental methods in body fluids. It is crucial to have confirmation of the declarations of the employees that they are not smokers. Thus, the goal of this study was to determine the fast and accurate chromatographic methods for the determination of nicotine and cotinine in oral fluids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that there are several methods for determining nicotine and cotinine in saliva.

The level of nicotine and cotinine increases in the body depending on the frequency and amount of smoking. With increased use of cigarettes, an increase of these substances is observed in the saliva, which is an important sample in forensic sciences. Regardless of the use of harmful products, it is important to determine compounds in the body fluids. Measurement in a short time will, of course, shorten the time for instant determination, but it is necessary to use instrumental analyses to make quantitative determinations and to detect very small concentrations in the body. A few of these are High-Performance Liquid Chromatography (HPLC), Gas Chromatography/Mass Spectrometry (GC/MS), and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). An ideal marker for assessing the smoking status of individuals should have a reasonable half-life, be specific, and be obtained at concentrations that can be measured using available analytical methods.<sup>1</sup> Nicotine has an important place for tobacco addiction among cigarette smoke components. The half-life of nicotine is approximately two hours, and the duration of analysis in saliva should be adjusted accordingly.<sup>1</sup> Cotinine is the main metabolite of nicotine and it is specific. The half-life of cotinine is approximately 18–20 hours. It is a preferred analyte because it meets the necessary conditions and can be detected in all matrices.<sup>1</sup>

Samples were taken from 50 smoking and 50 non-smoking volunteers from a dental clinic in Istanbul for analysis. For example, saliva samples that are held in the mouth for five minutes were used (at this stage, the main purpose is avoiding foaming). Three different methods were determined for saliva intake. In the first method, a paper pad (1mL holding capacity) saturated with sodium chloride (3.5%), citric acid (0.3%), potassium sorbate, sodium benzoate, and gelatin (0.1% each) was used.

The pH was adjusted to 7.2 by addition of sodium hydroxide. The treated pad was dried, placed in the mouth for about two minutes, and gently moved back and forth to ensure it was moistened. Samples were centrifuged twice for 10 to 15 minutes at 10,000rpm to prevent residues or non-food particulate matter from mixing in the recovered saliva. The clear saliva sample thus obtained was frozen at 20°C for analysis.<sup>1</sup> The other method was to collect the sample with the help of Salivette® tube.

The volunteer was asked to chew the cotton taken from the inner tube for two minutes until it was saturated with saliva. The cotton was taken back to the inner tube, centrifuged, and the saliva sample was passed to the outer tube. Another method was to collect saliva passively and keep the samples immediately between 2°C–8°C, then store it at -80°C until analysis.<sup>2</sup> The most important goal is to achieve fast, reliable reporting in forensic cases with various techniques to measure nicotine and cotinine levels in the oral matrix, including colorimetric experiments, immunological tests, saliva tests, GC, and HPLC.<sup>3</sup> The methodology of this study is based on GC/MS.

### Instrumental Analysis, Cotinine, Nicotine

## K45 The Detection and Quantification of Fentanyl in *Phormia Regina* (Calliphoridae) and Its Effects on Growth and Developmental Rate

Brianna L. Robinson\*, Conklin, NY 13748; Ian Dadour, PhD, Murdoch University/TSW Analytical, Perth, Western Australia 6151, AUSTRALIA; Karen S. Scott, PhD, Arcadia University, Glenside, PA 19038; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Boston, MA 02118

**Learning Overview:** After attending the presentation, attendees will understand the detection of fentanyl in black blow fly (*Phormia regina*) (Meigen) larvae using Supported Liquid Extraction (SLE) and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Attendees will also learn how the presence of fentanyl in the food substrate of larvae affects their growth and development throughout larval stages.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing entomological data on *Phormia regina* to increase accuracy of minimum Postmortem Interval (mPMI) determinations as well as provide a quick method of extraction and detection for fentanyl in blow fly larvae.

As a primary colonizer of carrion, *Phormia regina* plays a vital role in both nutrient recycling and ecosystems via carrion decomposition. They are currently used by forensic scientists in establishing mPMI estimation during criminal cases, but recent research has that larvae can be further used for the detection of drugs and toxins when traditional matrices are unavailable.<sup>1,2</sup>

Fentanyl is a rapid-onset synthetic opioid with extremely high potency.<sup>3</sup> Illegally, fentanyl has been increasingly used as an adulterant mainly due to the ease of manufacturing and availability of its precursors to be shipped internationally.<sup>4</sup> Due to the increase in accidental deaths by overdose, fentanyl is now routinely screened for in toxicological analysis. Death from fentanyl can be rapid, and by the time a body is discovered, significant time may have passed. When sampling traditional body fluids becomes difficult due to their absence, external factors, or the presence of skeletonization, insects may serve as reliable alternative specimens for toxicological analyses.<sup>1</sup>

There have been several studies that have confirmed the reliability of entomological specimens for qualitative analysis; however, quantitative extracts remain questionable and unreliable. In addition, the presence of toxins has been shown to increase or delay development of entomological specimens, which can be critical in a criminal investigation. It has become critical to understand the detection and effects of fentanyl on different matrices due to its increased use and high contribution to overdosing.

The purpose of this study was to further analyze the question currently poised for forensic entomologists/toxicologists: is there is any correlation between concentrations of toxins in human postmortem tissue to those concentrations detected in blow fly larvae and can they be used reliably as samples for toxicological investigations? Using *Phormia regina*, this study evaluated LC/MS/MS to quantify and qualify fentanyl accurately as well as obtain some preliminary information pertaining to the effects of fentanyl on larvae development.

A maximum of 100 individual pupae received from the University of New Haven in West Haven, CT, and University College of St. Mary in Omaha, NE, were placed inside a mesh enclosure with an ambient temperature of 26–28°C. Chunks of beef liver were provided to the adults to facilitate oviposition. Eggs were collected and placed on homogenized ground liver pre-dosed with fentanyl. The doses were a high-end therapeutic level (50ng/mL), a toxic level (125ng/mL), a lethal level (250ng/mL), and beyond lethal level (500ng/mL).

The larvae were monitored, and sample larvae were taken every day to confirm the lifecycle stage. Triplicate larvae samples were collected at the 2<sup>nd</sup> instar, 3<sup>rd</sup> instar, and post-feeding life stages. The larvae were homogenized, extracted, and analyzed using LC/MS/MS. Fifteen random specimens were selected and used as a representative set every day for each dose to monitor life stage duration. These larvae were also measured to obtain a growth curve.

During the trial, fentanyl was detected in 2<sup>nd</sup> and 3<sup>rd</sup> instar larvae fed on toxic and lethal level dosed meat while detection remained minimal or nonexistent in the post-feeding larvae of any dose. There was no correlation found between the feeding substrate and the larvae samples of any stage of the life cycle. The development rate to 2<sup>nd</sup> instar was delayed and correlated with the increase of fentanyl, thus prolonging the total time for development from two to four days.

With the increase of fentanyl throughout the Eastern coast of the United States and the prominent presence of *Phormia regina* in decomposition, this study aimed to find results that will lead to the use of larvae as alternative matrices. This study demonstrated that fentanyl was detectable in 2<sup>nd</sup> and 3<sup>rd</sup> instar larvae in toxic and lethal doses. Further, it demonstrated that fentanyl delayed development in *Phormia regina* by up to four days when exposed to high levels of lethal dosing, effecting accurate PMI. It was also concluded that there is no correlation between spiked food substrates and the concentration found in the analyzed insect.

## K46 Emergence of Delta-8 Tetrahydrocannabinol (THC) in Driving Under the Influence of Drugs (DUID) Investigation Casework

Ayako Chan-Hosokawa, MS\*, NMS Labs, Horsham, PA 19090; Loan Nguyen, BS, NMS Labs, Willow Grove, PA 19090; Renee L. LaFord, MS, NMS Labs, Horsham, PA 19044; Wendy R. Adams, PhD, NMS Labs, Horsham, PA 19044-2208

**Learning Overview:** After attending this presentation, attendees will be able to identify delta-8 THC and its appearance in various marijuana-containing products. Additionally, this presentation will illustrate an important analytical challenge related to constantly changing drug trends and how it was addressed in a high-throughput laboratory setting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the recent increase in prevalence of THC isomers in DUID cases. Furthermore, an example method is described, along with its validation and application, showing how it effectively reduced both repeat testing and cancellations due to unresolved peaks.

Cannabinoids are the most frequently reported illicit drug class in DUID investigation casework, with a consistent positivity rate over 50%. Since September of last year, the cancellation rate for the cannabinoids confirmation performed using a 2D High-Performance Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) demonstrated a steady increase (from 1.3% to 3.8%) due to the presence of unresolved interfering substances. The observed interference demonstrates a distinctive pattern affecting identifications and quantification of both delta-9 THC and delta-9 Carboxy THC (THCCOOH).

As a part of an investigation, an e-cigarette device containing an amber-colored viscous solution was submitted to the laboratory. The oily substance was diluted 100-fold for analysis. Two peaks with equally high response were identified as delta-9 THC and delta-8 THC, in addition to a presence of Cannabidiol (CBD) and four other unidentified components in the e-cigarette cartridge. Ultimately, additional work revealed delta-8 THC ( $RT=5.01\text{min}$ ) and delta-8 THCCOOH ( $RT=3.05\text{min}$ ) to be responsible for the observed interferences with delta-9 THC ( $RT=4.92\text{min}$ ) and delta-9 THCCOOH ( $RT=3.14\text{min}$ ), respectively.

Delta-9 THC and delta-8 THC are constitutional isomers ( $C_{21}H_{30}O_2$ ; MW 314.46), as are their carboxy metabolites ( $C_{21}H_{28}O_4$ ; MW 344.44). The similarity between the two isomers was not previously a challenge due to the relatively small concentrations of delta-8 THC encountered after traditional marijuana consumption. Delta-8 THC is a naturally occurring cannabinoid found in most cannabis plants. It is typically present at low concentrations (less than 1% of dried cannabis flowers). It is psychoactive, but has a lower potency as compared to delta-9 THC. Recently, delta-8 THC has been marketed as an alternative to marijuana. Delta-8 THC has been identified in botanicals, e-liquids intended for vaping, and edibles. The increase in cancellations due to delta-8 compounds required modification of the existing method that had been successfully employed for the past three-and-a-half years.

To separate the delta-8 and delta-9 isomers, a new analytical method was developed and validated. Cannabinoids were extracted from whole blood using liquid-liquid extraction, separated in a 2D LC system with a Phenomenex® SecurityGuard™ Cartridge (C6-Phenyl, 4 X 2mm) as a trap column and a Phenomenex® Kinetex® C18 (100 x 3mm; 2.6micron) as an analytical column, over a runtime of 11.5min and detected by an AB SCIEX™ API 4500 system equipped with an Electrospray Ionization (ESI) source operating in positive ionization mode with scheduled multiple reaction mass spectrometric monitoring. The method validation protocol was based on the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines, including linearity, limit of detection, lower limit of quantitation, precision and accuracy, interfering substances, matrix effect, dilution of samples, and carryover. The calibration for THC and THCCOOH was linear from 0.5 to 50ng/mL and 5.0 to 500ng/mL, respectively. The minimum total precision (described as %CV) and accuracy (shown in %difference) were 3.4% and -3.4% for THC and 3.1% and -3.9% for THCCOOH, respectively. The method met validation criteria for all studies. Most importantly, each set of isomers were fully resolved: delta-8 THCCOOH ( $RT=5.69\text{min}$ ); delta-9 THCCOOH ( $RT=5.74\text{min}$ ), delta-9 THC ( $RT=8.21\text{min}$ ); and delta-8 THC ( $RT=8.65\text{min}$ ).

For efficiency, routine DUID cases continue to reflex to the pre-existing 2D LC/MS/MS cannabinoids confirmatory analysis with a 6min runtime. However, if the presence of delta-8 isomers is indicated, the blood specimen is re-analyzed to separate the cannabinoid isomers using the new method. With this new strategy, the cancellation rate decreased from 3.8% to 0.6%, providing forensically defensible results in more than 100 cases.

### Delta-8 THC, Isomers, Vaping

## K47 A Seven-Year Review of Vehicular Crash Toxicology Data at the West Tennessee Regional Forensic Center

Elizabeth C. Conner, MPH, CHES\*, Sevierville, TN 37864; Erica Curry, MD, Collierville, TN 38017

**Learning Overview:** The goals of this presentation are to: (1) describe trends of alcohol and drug use in vehicular fatalities at the West Tennessee Regional Forensic Center from 2011 to 2017; and (2) identify variables that may be related to vehicular substance use, such as age, gender, race, and crash type.

**Impact on the Forensic Science Community:** Drug-related vehicular fatalities remain an important public safety issue. This research provides a preliminary assessment of toxicology data for vehicular fatalities in Shelby County, TN. The hope is to provide direction for future research on postmortem toxicology.

According to 2016 data from the Governors Highway Safety Association, 43.6% of nationwide motor vehicle fatalities tested positive for at least one drug.<sup>1</sup> The Centers for Disease Control (CDC) show that alcohol was involved in 28% of motor vehicle fatalities in 2016, while other illicit drugs were implicated in 16% of fatalities.<sup>2</sup> Recent data indicate that drug-related motor vehicle crashes remain an important public safety issue.<sup>1,2</sup> The purpose of this work is to describe the trends of alcohol and drug use in motor vehicle fatalities at the West Tennessee Regional Forensic Center (WTRFC) from 2011 to 2017.

Information was extracted from the Forensic Death Investigation and Decedent Information (ForensicDIDI) database for all fatal vehicular crashes in Shelby County, TN, from 2011 to 2017. A total of 1,150 fatal vehicle crashes were reported. Of these, 717 (62%) decedents had toxicology data available. For the 717 decedents with toxicology data, 412 (57.5%) tested positive for at least one substance, while 305 (42.5%) tested negative for any substance. Drugs were consolidated into six classes and analyzed for trends of use from 2011 to 2017.

Analysis revealed that 78% of decedents with positive toxicology results were male. Decedents were 46% White, 49% Black, and 5% other races. Close to half of decedents (48%) were between the ages of 18 and 34 years. Polysubstance use was noted among 44% of decedents, with the remaining 56% of decedents testing positive for a single substance. A majority of decedents (74%) were drivers, while 26% were passengers, pedestrians, or unknown. Single vehicle crashes (54%) were slightly more common than multiple vehicle crashes (45%). Alcohol (38%) was the most commonly detected drug, followed by marijuana (28%) and opioids (13%). Cocaine (8%) and benzodiazepines (7%) were detected in a similar number of decedents, while amphetamines (3%) and methamphetamine (3%) were found in the lowest numbers. Overall, drug use remained steady with a slight increase in substance use during the 2015–2017 period. The most notable increase was marijuana, particularly in the years 2016–2017. Amphetamine use has shown a decline, while methamphetamine use has slightly increased. Seventy-five percent of decedents who tested positive for alcohol were at or above the legal limit Blood Alcohol Concentration (BAC) of 0.08. Furthermore, 67% of decedents had a BAC between 0.1 and 0.3. In terms of polysubstance use, 44% of decedents tested positive for two or more drugs. Polysubstance use increased during 2015–2017, with the years 2016 and 2017 showing an increase in polysubstance use that closely parallels the number of single-substance users. For the two most common drugs, alcohol and marijuana, 76 decedents tested positive for both substances, which equates to 43% of marijuana users and 31% of alcohol users.

This review of toxicology data at the WTRFC serves as an initial look at the prevalence of drug- and alcohol-related motor vehicle fatalities in Shelby County. Decedents who tested positive for one or more drugs were overwhelmingly male and nearly half of decedents were in the 18-to-34-year-old age range. Alcohol, marijuana, and opioids were the most common drugs implicated in fatalities, with alcohol being the most prevalent. Marijuana use showed a notable increase and was consistently the second most common substance detected. A sizeable percentage (44%) of decedents were found to be positive for two or more substances, pointing to polysubstance use while driving as a common issue. Future research in this area could work to better characterize postmortem drug levels that indicate intoxication.

### Vehicular Fatalities, Toxicology, Forensic Pathology

## K48 Toxicological Findings and Demographics of Phencyclidine (PCP) Use in Houston From 2013 to 2018

Dayong Lee, PhD\*, Houston Forensic Science Center, Houston, TX 77002; Peter R. Stout, PhD, Houston Forensic Science Center, Houston, TX 77002

**Learning Overview:** After attending this presentation, attendees will have learned about the prevalence, blood toxicological profile, and demographic distributions of PCP-positive Houstonian drivers involved in a traffic accident or suspected of impaired driving. Attendees will also learn about common signs and symptoms observed during Drug Recognition Expert (DRE) evaluation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing valuable regional information to better understand the demographic patterns of PCP-impaired or suspected impaired drivers in Houston, TX, over six years. The long-term objective is to help design and implement regulations and prevention systems that will lead to a reduction in PCP-impaired driving.

The first reported illicit use of PCP occurred in San Francisco, CA, in the 1960s. Shortly thereafter, PCP use was found in other metropolises, including Chicago, IL, Miami, FL, New York, NY, and Philadelphia, PA. While abuse of PCP subsequently declined at the national level, it continues in Houston. In 2010, the Drug Enforcement Administration (DEA) reported the arrest of nine Houston residents and the seizure of 57 gallons of PCP, the largest PCP seizure in DEA history.

This research evaluates PCP-positive cases of driving while intoxicated or driving under the influence of drugs, occurring from 2013 to 2018. The blood samples were collected from drivers and submitted by the Houston Police Department (HPD). They were then analyzed for alcohol and drugs by the HPD Crime Laboratory, Reference Laboratories, or Houston Forensic Science Center (HFSC). Toxicological findings and demographic information, including age, sex, and race/ethnicity, were evaluated for the impaired driving cases that tested positive for PCP in blood. Additionally, the Drug Influence Evaluation findings completed by DRE officers for selected cases in 2018 were examined when the officers deemed the individuals to be under the influence of a dissociative anesthetic. IBM® SPSS Statistics version 24 and Microsoft® Excel® 2016 were used for statistical evaluation.

A total of 610 Driving While Intoxicated (DWI) cases positive for PCP in blood were identified in which the traffic offense occurred between August 2013 and December 2018; they represented approximately 16% of all DWI cases from 2013 to 2018 (estimated  $n=3,929$ ). The mean (median, range) PCP concentration was 47 (43, 7-180) ng/mL. Twenty-two percent of those cases were female and 78% were male; 85% were Black, 10% were White, and 5% were other races/ethnicities as identified by the arresting officer. No significant differences in median and distribution of PCP concentrations ( $P's > 0.05$ ) were observed between females (median 43ng/mL) and males (43ng/mL); among Blacks (44ng/mL), Whites (39ng/mL), and others (37ng/mL); and among offense years, 2013–2018 (36-58ng/mL). Forty three percent of the cases were positive for PCP only. Among the remaining 57% in which one or more other drugs/metabolites were identified, cannabinoids were the most frequently detected analytes (35%), followed by ethanol (13%) and cocaine/metabolite (13%). When the study population was examined by age ( $\leq 30$ , 31–40, and  $\geq 41$  years), the proportions of male and Black PCP-positive drivers decreased with younger age groups. For 12 cases from 2018, signs and symptoms of PCP-positive drivers observed by DRE officers were examined. Common indications included slurred speech, chemical breath odor, watery and/or bloodshot eyes, vertical/horizontal gaze nystagmus, impaired coordination/balance, and impaired divided attention.

Median PCP concentrations among demographic cohorts were remarkably similar, which indicates a possible concentration range desired by PCP users. The PCP concentration range found in the present study were comparable to other reports (7–240ng/mL), albeit the mean value in the present study was slightly lower.<sup>1-3</sup> The number of PCP-positive DWI cases has been rising in Houston in recent years (166% increase from 2016 to 2018), making risk assessment of PCP-impaired driving for evaluation efforts increasingly important.

## K50 The Effects of Synthetic Cannabinoids and Poly-Drug Use on Drug Recognition Expert Evaluations

*Amanda L.A. Mohr, MSFS\*, Center for Forensic Science, Willow Grove, PA 19090; Judith Rodriguez Salas, MS, Wyncote, PA 19095; Alex J. Krotulski, MS, Center for Forensic Science Research & Education, Willow Grove, PA 19090; David Andrascik, BS, Pennsylvania DUI Association, Harrisburg, PA 17110; Barry K. Logan, PhD, NMS Labs, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will be able to describe the effects of synthetic cannabinoids, both unaccompanied and in combination with other drugs of abuse, such as fentanyl, cocaine, or methamphetamine, on evaluations performed by Drug Recognition Experts (DREs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data related to the physiological signs and symptoms associated with the ingestion of synthetic cannabinoids, both on their own and in combination with other commonly encountered drugs in oral fluid collected concurrently with evaluations performed by DRE officers.

The DRE program was developed to establish a systematic procedure for identifying and documenting signs of impairment in subjects suspected of being under the influence of drugs. The DRE program is currently the best tool for evaluating a subject's drug-related impairment at the roadside. Several studies have demonstrated the reliability of the DRE program for traditional drugs of abuse; however, there are limited reports related to the constellation of symptoms associated with use of synthetic cannabinoids alone or in combination with traditional drugs of abuse. The purpose of this evaluation was to compile DRE evaluation data and relate it to the analytical findings obtained from comprehensive oral fluid testing.

Participation in the evaluation was strictly voluntary and performed as part of the DRE certification process. A total of 25 subjects were assessed using the standardized evaluation protocol for drug influence. Parameters of evaluation included presence or absence of nystagmus, pulse rate, Lack Of Convergence (LOC), One Leg Stand (OLS), Walk And Turn (WAT), modified Romberg balance, pupil size in three different lighting conditions, blood pressure, and body temperature, among others. At the conclusion of the evaluation, an oral fluid sample was collected using the Immunalysis™ Quantisal® device for laboratory-based analysis. Samples were analyzed using a SCIEX™ TripleTOF® 5600+ quadrupole time-of-flight mass spectrometer coupled to a Shimadzu® Nexera® ultra high-performance liquid chromatograph.

Five subjects tested positive for 5F-MDMB-PICA, a popular synthetic cannabinoid, in the absence of any other drugs. In all five cases, no nystagmus was noted, and only one had slight indications of LOC. All subjects had difficulty with the WAT test (e.g., missing all heel-to-toe steps, inability to keep balance, and stepping off the line) and OLS test (e.g., swaying while balancing, using their arms, hopping, and putting their foot down). Only one of five of the DRE opinions included cannabis.

Fifteen subjects tested positive for fentanyl in combination with 5F-MDMB-PICA, with 4 of the 15 also testing positive for 4F-MDMB-BINACA. Horizontal Gaze Nystagmus (HGN) and a lack of smooth pursuit were noted in only one individual. LOC was present in ten of the subjects (66%) and most exhibited flaccid muscle tone. All 15 DRE opinions correctly noted a narcotic analgesic, but only 2 also indicated cannabis.

Three subjects tested positive for cocaine and 5F-MDMB-PICA, and two subjects tested positive for methamphetamine and 5F-MDMB-PICA. One individual displayed HGN and a lack of smooth pursuit. All five subjects demonstrated difficulty on the WAT and OLS tests; four subjects had LOC. Only one subject had dilated pupils. The DRE opinion in all five cases was a Central Nervous System (CNS) stimulant.

The opinion of a DRE is based on physiological and behavioral indicators consistent with specific drug categories. The ever-changing drug market, which now includes combinations of Novel Psychoactive Substances (NPS) -like synthetic cannabinoids as well as an increase in the frequency of poly-drug use encompassing NPS and traditional drugs of abuse, adds to the complexity of the DRE evaluation. In cases in which fentanyl is present, physiological signs and symptoms of other drugs used could be masked. Therefore, comprehensive toxicology testing, including NPS, is imperative to ensure all substances contributing to the impairment are identified.

### Synthetic Cannabinoids, Fentanyl, DRE

## **K51 The National Forensic Laboratory Information System (NFLIS) Survey Findings: Toxicology Testing Practices by Toxicology Laboratories and Medical Examiner and Coroner Offices**

*DeMia P. Pressley, MS\*, Drug Enforcement Administration, Springfield, VA 22152; Liqun Wong, MS, Springfield, VA 22152; Terrence Boos, PhD, Drug Enforcement Administration, Springfield, VA 22152; BeLinda J. Weimer, MA, Research Triangle Park, NC 27709; Hope Smiley-McDonald, PhD, RTI International, Research Triangle Park, NC 27709; Katherine Moore Bollinger, MS, Research Triangle Park, NC 27709; Megan Grabenauer, PhD, RTI International, Research Triangle Park, NC 27709-2194; Jeffrey M. Ancheta, BS, Research Triangle Park, NC 27709; Neelima Kunta, BS, RTI International, Research Triangle Park, NC 27709; David Heller, BS, RTI International, Research Triangle Park, NC 27709; Jeri D. Roper-Miller, PhD, RTI International, Research Triangle Park, NC 27709*

**Learning Overview:** After attending this presentation, attendees will understand the findings from the Drug Enforcement Administration's (DEA's) 2017 NFLIS Survey that were not previously published.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing toxicology laboratories and medical examiner, and coroner offices information regarding toxicology testing practices for opiates, opioids, amphetamines, cocaine, marijuana/Tetrahydrocannabinol (THC), phencyclidine, phenethylamines, piperazines, synthetic cannabinoids, and synthetic cathinones. This presentation will also report on respondents' use of toxicology reference laboratories.

The NFLIS is a program of the Drug Enforcement Administration (DEA), Diversion Control Division. DEA conducted a 2017 NFLIS Medical Examiner and Coroner (MEC) Office Survey and a Toxicology Laboratory (TL) Survey between June and October of 2017. These results were published on the NFLIS website. Survey results highlighted findings related to operation, caseloads, turnaround times, toxicology testing practices, accreditation, and information management systems. The purpose of this presentation is to provide the community with information on toxicology testing practices that were not reported in these publications. This information can benefit laboratory management decisions as well as aid interpretation of national statistics.

MEC and TL respondents were asked to report their testing frequency as always, sometimes, or never for specific drugs and drug classes. Further, they were asked to report their frequency of quantifying these drugs and drug classes using the same measures. Data from TLs are reported by laboratory ownership (public or private) and by caseload size of the responding laboratory. Data from MECs are reported by type of office and jurisdiction size if reported by the responding MEC.

TLs reported "always" conducting toxicology testing for the following drugs or drug classes more than 75% of the time: alcohol, amphetamines, barbiturates, benzodiazepines, carisoprodol, cocaine, heroin, marijuana, opiates and opioids, phencyclidine, and Z-drugs (e.g., zolpidem). TLs reported opiates or opioids other than heroin or fentanyl as the least likely drug class to never be quantified (11%), whereas fentanyl-related substances were most likely to never be quantified (52%). Higher percentages of small and public TLs (both greater than 30%) than medium, large, and private TLs (each less than 25%) reported never quantifying fentanyl.

MECs reported "always" conducting toxicology testing for the following drugs or drug classes more than 75% of the time: alcohol, amphetamines, cocaine, and opiates or opioids other than heroin and fentanyl. Overall, less than 13% of MECs reported never quantifying buprenorphine, fentanyl, fentanyl-related substances, heroin, and opiates or opioids other than heroin or fentanyl.

NFLIS publicly shares data through various reports throughout the year, including midyear and annual reports. As NFLIS expands into other data collections such as toxicology laboratory data, additional reports such as on the toxicology laboratory survey will be provided to the community.

---

### **NFLIS, DEA, Toxicology**

## K52 Data-Supported Poly-Drug Use Among Fentanyl Users: A Toxicology Perspective

Alex J. Krotulski, MS\*, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Susan Varnum, PhD, Temple University, Philadelphia, PA ; Barry K. Logan, PhD, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will be able to discuss the extent to which fentanyl drug users are consuming other substances, including legacy drugs of abuse and Novel Psychoactive Substances (NPS), and the drug classes that are most commonly found in combination with fentanyl.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing comprehensive data regarding patterns and practice of poly-drug use that, in turn, have an impact on policies relating to death investigation and forensic toxicology testing practices, as well as public health and public safety preparedness and response.

The opioid epidemic continues to contribute to morbidity and mortality in the United States, growing and evolving since the increase in prevalence of fentanyl in the heroin supply began around 2014. Following the identification of mixtures of fentanyl and heroin in seized material, laboratories began identifying new variants of fentanyl, often referred to as analogs or derivatives. The number of new fentanyl analogs in the drug supply increased and diversified until the temporary federal “core structure” scheduling of fentanyl-related substances by the Drug Enforcement Administration in February 2018. Now, post fentanyl analog scheduling, the illicit synthetic opioid market has transitioned back to primarily fentanyl, but with evidence of poly-drug use. Based on this observation, this study sought to document patterns of poly-drug use in forensic toxicology casework to determine what substances were most frequently found in conjunction with fentanyl.

Analytical testing was performed via Liquid Chromatography quadrupole Time-Of-Flight Mass Spectrometry (LC/qTOF/MS) using a SCIEX™ TripleTOF™ 5600+ coupled with a Shimadzu® Nexera® XR UHPLC. This represents a non-targeted drug testing approach that differs from traditional forensic toxicology testing protocols. Discarded sample vial extracts, primarily collected from testing procedures for the directed analysis of synthetic opioids, were acquired from a large forensic toxicology laboratory (NMS Labs). All sample extracts were deidentified prior to inclusion in this study. In total, 3,543 sample extracts were analyzed and processed against an extensive, and continuously updated, in-house library database containing more than 700 drugs, including fentanyl, fentanyl metabolites, fentanyl analogs, other synthetic opioids and drugs of abuse, as well as an extensive number of NPS.

The results from comprehensive data processing included the identification of a wide variety of substances covering all classes and included parent drugs (e.g., fentanyl), metabolites (e.g., norfentanyl), and synthesis precursors (e.g., 4-ANPP) or byproducts (e.g., acetyl fentanyl). For a more accurate determination of drug use, individual identifications were categorized under explicit parent drug groups prior to complex data analysis to determine positivity and combinations. For example, results of fentanyl, norfentanyl, and/or beta-hydroxy fentanyl were all categorized as “fentanyl positive:” 4-ANPP and acetyl fentanyl were not considered for inclusion based on undistinguishable source. Drug classes evaluated included stimulants (e.g., cocaine, methamphetamine, MDMA), opiates/opioids (e.g., heroin, tramadol, buprenorphine), hallucinogens (e.g., ketamine, phencyclidine), and benzodiazepines (e.g., diazepam, alprazolam), as well as these same classes for NPS.

Overall, 1,301 (36.7%) sample extracts were deemed fentanyl positive. The majority (79.8%) of fentanyl positivity was accompanied by poly-drug use, including the presence of one or more drugs of abuse and/or NPS. Fentanyl was found in combination with as many as seven drugs and/or NPS (excluding therapeutics, adulterants, etc.). With respect to drugs of abuse, fentanyl was most commonly found in combination with stimulants (46.0%) and other opiates/opioids (42.8%). Fentanyl was more commonly found in combination with cocaine (26.4%) than methamphetamine (13.1%). Fentanyl combinations with opiates included heroin (28.3%), tramadol (11.1%), and methadone (9.4%). With respect to NPS, fentanyl was most commonly found in combination with synthetic opioids (27.3%) and more rarely found in combination with synthetic stimulants (4.2%), designer benzodiazepines (3.9%), and novel hallucinogens (1.3%).

These results demonstrate the great extent to which fentanyl users are using other substances, either concurrently with or in proximity to their fentanyl use. Fentanyl poly-drug use is significant from forensic toxicology and public health perspectives, as combined drug use creates drug-drug interactions and more complex adverse effect profiles. To better understand poly-drug use, laboratories should consider developing all-inclusive, non-targeted assays for more comprehensive determination of all substances on board at the time of impairment or death.

### Fentanyl, Poly-Drug, Toxicology

## K53 New Trends in Lysergic Acid Diethylamide (LSD) Use and Recommendations for Analysis

*Ryanne Brown, MSFS\*, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; Jeff Walterscheid, PhD, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; Jessica L. Knittel, MS, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902*

**Learning Overview:** After attending this presentation, attendees will be better informed regarding the prevalence of LSD in postmortem and human performance casework. The expansion of novel LSD analogs will also be discussed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of increasing LSD trends and the importance of having methods in place for sensitive screening and confirmation analyses.

The 1960s were the time of hippies, tie-dye, and LSD. Arguably, this drug defined mainstream recreational drug use of the era with its hallucinogenic effects. While new legal restrictions diminished its popularity in the 1970s, an apparent comeback appears to be on the horizon with more analogs and higher potencies. Over the past five years, the Armed Forces Medical Examiner System–Division of Forensic Toxicology (AFMES-DFT) has observed an upward trend in the detection of LSD in blood and urine specimens. In 2018, 46 cases were confirmed positive for LSD and/or the primary metabolite 2-oxo-3-hydroxy-LSD, as compared to 32 cases from 2015 to 2017. As of July 2019, 34 have already been reported positive, putting this year on track to set a new high if this trend continues.

For screening large batches of casework, it is efficient to use a sensitive LSD immunoassay kit. An immunoassay kit is used at AFMES-DFT that has a Limit Of Detection (LOD) of 0.5ng/mL. Using a 1ng/mL LSD concentration for 100% activity at the decision point, the primary metabolite 2-oxo-3-hydroxy-LSD was calculated to retain only 9% cross-reactivity at the same concentration. This could lead to false negative screens if only the metabolite is present without parent LSD. However, the metabolite is often ten-fold more concentrated than the parent, so the screen may still be successful even with low concentrations of LSD.

With new analogs coming on the market, immunoassays become even more useful to a toxicology lab. LSD analogs all share a similar structure to LSD, with modifications at the N-1 or N-6 positions or substitutions for diethylamide. These analogs can cross-react on an immunoassay and elicit a positive response if at a high enough concentration. Several commercially available reference standards for these analogs were purchased and characterized with the following cross-reactivities: AL-LAD (12%), ETH-LAD (16%), LSZ (18%), 1B-LSD (57%), 1P-LSD (60%), and ALD-52 (83%). This level of cross-reactivity could lead to a number of unconfirmed positive cases if these analogs are not included in the confirmatory testing panel.

A proposed recommendation to prevent this discrepancy is to have a hallucinogenic screening panel targeting LSD, 2-oxo-3-hydroxy-LSD, and their analogs as an escalated testing option when there are clear signs of intoxication without any positive result from routine panels. This can be implemented by using immunoassays, Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), or LC/Time Of Flight/Mass Spectrometry (LC/TOF/MS) analysis. At minimum, one form of analysis should be used on suspected cases.

Case histories may prove especially useful when indicating which cases should proceed to this testing. Examples of indicative histories from casework include those who were running naked through traffic or jumping off buildings with the belief they had the ability to fly. This makes it extremely important for requesting agencies to provide more detailed descriptions about patient behavior in the histories to aid in targeted laboratory testing. It is even more important for labs to test for not only LSD, but also its analogs as their popularity will only continue to increase. Failure to implement appropriate testing for LSD will result in missing confirmations, reporting numerous cases as falsely negative, and underestimating the prevalence of LSD in the community.

### LSD, NPS, Screening

## K54 Xylazine Alone and in Combination With Opioid Drugs in Forensic Toxicology Casework

Sherri L. Kacinko, PhD\*, Willow Grove, PA 19090; Edward J. Barbieri, PhD, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will understand the frequency of xylazine detection in forensic toxicology casework, the potential effects of the drug alone, and the combined effects with opioids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the pharmacology of xylazine and its detection in forensic toxicology casework.

Illicit drugs are often “cut” prior to being sold to the end user. Diluents such as lactose are used to dilute the drug and add bulk to the preparation, but have no pharmacological impact. Adulterants such as procaine may ease the pain of injection and diphenhydramine may enhance the sedative effects of heroin while helping with side effects such as itching. The purpose of this study was to evaluate the frequency of xylazine, a veterinary anesthetic/analgesic, detected alone or in combination with heroin, fentanyl, or fentalogs in blood samples submitted to a large reference laboratory.

Data from cases received between May 1, 2013, and June 30, 2019, and screened by liquid chromatography/time-of-flight/mass spectrometry were extracted from the NMS Labs Laboratory Information Management System. Xylazine was included in the scope of this assay, but routine confirmation and quantification of xylazine did not begin until January 2019. Based on the confirmation rate (approximately 90%) of presumptive positive cases after the availability of the confirmation test, the entire data set was used to evaluate the frequency of xylazine in casework.

One thousand twenty-five cases had a presumptive positive finding for xylazine. Seven cases had no opioids detected and two contained xylazine and methadone. The remaining cases contained one or more of the following opioid drugs: fentanyl (796), heroin (461), morphine (139), 2-furanylfentanyl (26), fluoroisobutyryl/para-fluorobutyrylfentanyl (23), carfentanil (25), 3-methylfentanyl (7), methoxyacetylfentanyl (6), valerylfentanyl (6), cyclopropylfentanyl (5), butyryl/isobutyrylfentanyl (5), U-47700 (3), acrylfentanyl (2), and fluorofentanyl (1). Quantitative data for xylazine were available for 236 cases that had comprehensive screening performed. The mean (range) xylazine concentrations in postmortem ( $N=226$ ) and driving under the influence of drugs ( $N=10$ ) cases were 73 (5–9,100) and 25 (5.3–53) ng/mL, respectively. Fentanyl concentrations were 0.84–420ng/mL in 228 of these cases. Ninety-five cases contained morphine and 40 of these also had 6-Monoacetylmorphine (6-MAM) reported in blood. Mean concentrations for morphine and 6-MAM were 130 and 20ng/mL, respectively. Three postmortem cases that underwent comprehensive screening at NMS Labs and had quantitative confirmation of xylazine contained xylazine in the absence of fentanyl, morphine, or 6-MAM. The information available about these cases is summarized below.

Xylazine (ng/mL)	Other Drugs	History
16	Cis-3-methylfentanyl=0.12ng/mL Bupropion=14ng/mL Hydroxybupropion=360ng/mL Diphenhydramine=150ng/mL Citalopram/Escitalopram=76ng/mL Citalopram/Escitalopram=85ng/mL	Suspected overdose.
9,100		Found in truck with bottle of xylazine and suicide note.
6.6	Metaxlone=0.15µg/mL Citalopram/Escitalopram=390ng/mL	Found having seizures. History of opioid use.

Blood/plasma xylazine concentrations in individuals known to be exposed to xylazine and survived ranged from 570–4,600ng/mL and a postmortem blood xylazine concentration of 16,000ng/mL was reported in a case of intentional intravenous administration. In this study, the xylazine concentrations in cases where opioids were detected are low compared to the reported concentrations in fatal cases, but the potential combined effects cannot be ignored. Reported adverse effects of xylazine include obtundedness, bradycardia, cardiac arrhythmias, and respiratory depression. Therefore, when combined with other central nervous system depressants such as fentanyl or heroin, xylazine may increase risk of overdose in otherwise opioid-tolerant individuals.

### Xylazine, Opioids, Fentalogs

## K55 The Persistence of 3-Methylfentanyl (3-MF) in Pennsylvania

Donna M. Papsun, MS\*, NMS Labs, Willow Grove, PA 19090-2910; Melissa Fogarty, MSFS, The Center for Forensic Science Research & Education, Willow Grove, PA 19090; Sherri L. Kacinko, PhD, Willow Grove, PA 19090; Barry K. Logan, PhD, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will be able to describe the resurgence of 3-MF in forensic casework between 2016 and 2019, after a nearly 30-year hiatus in Pennsylvania.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by detailing trends regarding the reappearance of 3-MF, including change in positivity over time, demographics, and quantitative data from casework, which will all highlight the unique regional reach of this compound as well as the challenges related to the toxicological confirmation of 3-MF.

In recent years, novel analogs of fentanyl primarily shipped from China have flooded the recreational drug market, but not all emerging substances are newly encountered variants. 3-MF, one of the most potent opioids detected to date, was first encountered in 1979 when it was tied to 100 overdose deaths in California; it was colloquially referred to as “China White.” Two separate incidents of Pennsylvania production were noted in the 1980s. In 1985, the Drug Enforcement Administration (DEA) arrested a chemist for producing and selling 3-MF in Delaware, and in 1988, a second chemist from western Pennsylvania was identified as the source of the drug, which was a factor in 18 fatal overdoses in Allegheny County. Following a nearly 30-year hiatus, in early 2016, 3-MF was reported in seized drug exhibits and drug-related overdose death toxicology tests results from Allegheny and Philadelphia Counties. By 2017, nine total states (Delaware, Maryland, Michigan, New Jersey, New York, Ohio, Pennsylvania, Virginia, and West Virginia) reported 3-MF seizures to NFLIS, with Ohio and Pennsylvania reporting the greatest amounts.

With the reappearance of 3-MF in drug seizures, a toxicological assay was required to confirm its presence in biological specimens. Toxicological analysis of 3-MF has presented significant challenges to toxicology laboratories, due to its potency and presence of its enantiomeric pairs, ( $\pm$ )*cis* and ( $\pm$ )*trans*-3MF. Confirmatory testing has improved over time with ultimately separation and quantitation of *cis* and *trans*-3MF becoming available late 2017 with a reporting limit of 0.05ng/mL using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

Between 2016 and the first half of 2019, 206 blood samples have confirmed positive for the presence of 3-MF. In 2016, 35 cases were reported, which increased to 93 in 2017, dropping to 64 in 2018, and finally to 14 cases during the first half of 2019. These blood samples originated from eight different states (Delaware, Michigan, New Jersey, New York, Ohio, Pennsylvania, Vermont, and West Virginia), with Pennsylvania accounting for 89% of the positives. Within Pennsylvania, 25 different counties reported 3-MF in forensic casework; Montgomery County alone reported 34% of the positives. The toxicology positivity data largely correlates with the geographical distribution of the drug seizure data. Of the 200 cases reporting gender, 70% of the cases involved males while 30% involved females. Age was reported in 184 cases; the average age of an individual involved in a 3-MF case was 35±11 years old, with a reported age range of 1–62 years old.

3-MF has been confirmed in both Driving Under the Influence (DUID) and Postmortem (PM) investigation casework. It has been reported in 29 DUID cases; 10 cases reported 3-MF qualitatively or as a sum of the enantiomers, while 19 cases include isomeric quantitation. Ninety death investigation cases have reported 3-MF isomeric quantitation. A comparison of concentrations for DUID and PM casework is shown in Table 1.

Blood Cases		<i>Cis</i> -3MF (ng/mL)	<i>Trans</i> -3MF (ng/mL)
DUID	N	19	14
	Average ( $\pm$ SD)	0.35±0.24	0.15±0.066
	Range	0.080-1.1	0.05-0.29
PM	N	89	76
	Average( $\pm$ SD)	0.87±1.1	0.36±0.40
	Range	0.060-7.2	0.051-2.2

**Table 1: *Cis* and *trans*-3MF blood concentrations in DUID and PM casework**

3-MF is a highly potent fentanyl analog that is analytically challenging, since it presents itself in two enantiomeric pairs. ( $\pm$ )*Cis*-3-MF is 16 times more potent than fentanyl, and is typically present in higher concentrations than the ( $\pm$ ) *trans*-3MF isomer. It has reappeared in the limited geographical area of Pennsylvania and neighboring states. The limited geographical distribution raises the possibility of local production, reminiscent of the 1980s, as opposed to importation from China.

### 3-Methylfentanyl, NPS, Fentalog

## K56 The Quantitation of *N*-Ethylpentylone (Ephylone) in Blood Samples From Victims of Suspected Drug-Facilitated Sexual Assault

Lisa J. Reidy, PhD\*, University of Miami Toxicology Laboratory, Miami, FL 33136; Kristin W. Kahl, MS, University of Miami Toxicology Laboratory, Miami, FL 33136; Alex Giachetti, BS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Diane Boland, PhD, Miami-Dade Medical Examiner Department, Miami, FL 33136-1054

**Learning Overview:** The goal of this presentation is for attendees to learn about the prevalence and blood concentrations of *N*-ethylpentylone in drug-facilitated sexual assault casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by disseminating information regarding the prevalence of *N*-ethylpentylone, and that it is a concentration in blood specimens from victims of suspected drug-facilitated sexual assaults. This presentation also seeks to describe the associated findings and self-reports from the victims to document voluntary consumption and to ascertain any side effects experienced.

**Background:** The classification of a Drug-Facilitated Crime (DFC) includes Drug-Facilitated Sexual Assaults (DFSA), which can be defined as a sexual activity occurring whereby the victim is incapacitated by drugs and/or alcohol and thereby unable to consent. According to the media, drugs commonly implicated in cases of sexual assault are flunitrazepam (“roofies”), Gamma-Hydroxybutyrate (GHB) and ketamine. Conversely, according to published literature, when examining toxicological results from DFSA victims, ethanol is the most frequently encountered drug, and voluntary drug consumption identified as the highest risk factors for DFSA. While Central Nervous System (CNS) depressants are typically associated with DFSA crimes, any substance that can cause incapacitation through cognitive or psychomotor effects can render someone a victim of non-consensual sexual contact. *N*-1-(1, 3-benzodioxol-5-yl)-2-(ethylamino)-1-pentanone, also known as *N*-ethylpentylone or ephylone, is a synthetic cathinone belonging to the phenethylamine class. *N*-ethylpentylone can cause a state of mental confusion, and when used in combination with other drugs can have a synergistic or additive effect. Side effects from *N*-ethylpentylone use include euphoria, dizziness, vertigo, confusion, tachycardia, and agitation, which is similar to “molly” or “ecstasy,” substances commonly considered to be Methylenedioxymethamphetamine (MDMA), which has been implicated in DFSA cases.

**Method:** All DFSA cases that were submitted to the University of Miami Toxicology Laboratory (UMTL) in 2018 were examined for the presence of *N*-ethylpentylone. Urine specimens were screened and confirmed using a basic liquid-liquid extraction analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Time Of Flight (LC/TOF) instrumentation.

Urine samples were analyzed for ethanol using Headspace/Gas Chromatography/Flame Ionization Detector (HS/GC/FID) instrumentation. *N*-ethylpentylone was confirmed in 11 urine specimens. The associated blood specimens were then sent for quantitation of *N*-ethylpentylone at a reference laboratory (Miami-Dade Medical Examiner, Miami, FL). The case summaries and histories were evaluated in all 11 cases.

**Results:** In 2018, 8% of DFSA cases submitted to the UMTL were positive for *N*-ethylpentylone in the urine specimens. The time from the alleged incident to the time of blood collection ranged from 5 to 56 hours. Five of the 11 cases confirmed *N*-ethylpentylone in the blood specimens at less than the lower limit of quantitation (10ng/mL). Two cases had no detectable *N*-ethylpentylone in the blood specimen. Of the 4 cases where quantitative values were within the linear range, the concentrations ranged from 10–46ng/mL. None of the 11 cases had detectable alcohol in the urine or blood specimens, and 7 cases had other drugs present, some of which were reported as ingested by the subjects. Other drugs identified include benzodiazepines (alprazolam and clonazepam), cocaine, antidepressants (citalopram, quetiapine, and fluoxetine), and cannabis.

Information obtained from the toxicology questionnaire for sexual assault cases documented that 7 out of the 11 victims reported using cannabis recently. One of the victims reported using recreational “molly,” another reported that she had been forced to ingest “ecstasy” before the incident occurred. Common side effects reported include: drowsiness (73%), sedation (73%), confusion (45%), memory loss (45%), blackout (45%), and hallucinations (27%).

**Conclusion:** Despite the literature documenting the prevalence of alcohol in DFSA cases, alcohol was not detected in the blood or urine specimens in any of the cases in which *N*-ethylpentylone was identified. From the results presented, testing for designer drugs, including the synthetic cathinones, should be incorporated into routine DFSA casework, even if not indicated by the victim. The side-effect profile of *N*-ethylpentylone could lead a victim to be vulnerable and more susceptible as a victim of non-consensual sexual contact.

### *N*-Ethylpentylone, Sexual Assault, Side Effects

## K57 Buprenorphine-Related Deaths in North Carolina From 2010 to 2018

*Sandra C. Bishop-Freeman, PhD\**, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27607; *Laura Friederich, Durham, NC 27701-2821*; *Marc Feaster, BS\**, Durham, NC 27713; *Christopher T. Garrell, BS*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27607; *Michelle B. Aurelius, MD*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27699-3025; *Jason S. Hudson, PhD*, North Carolina Office of the Chief Medical Examiner, Raleigh, NC 27607

**Learning Overview:** After attending this presentation, attendees will understand the epidemiology and the increase in buprenorphine deaths in North Carolina and will gain an appreciation of the pharmacology of buprenorphine in combination with other Central Nervous System Depressant (CNSD) substances, including therapeutic prescription medication. In addition, attendees will understand how analytic, autopsy, and investigation information may be critical to determine cause of death in challenging buprenorphine toxicity cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the complex mechanism of action of buprenorphine and norbuprenorphine. The additive effects of CNSDs, especially those drugs that interact with P-glycoprotein (P-gp), will be discussed. This will improve the understanding and interpretation of postmortem buprenorphine cases and emphasize the need for correlation with death investigation information.

Between 2010 and 2018, there were more than 100 cases in which buprenorphine was detected in the peripheral blood and considered the cause of death with *no other opioids* or substances found in the supratherapeutic range. Of these cases, 65% were male. The ages of decedents varied widely, with a range of 14–63 years. The mean/median peripheral blood concentrations for parent and metabolite were 4.5/2.3ng/mL and 8.2/3.5ng/mL, respectively. These concentrations overlap those reported in the literature for opioid-dependent subjects receiving sublingual maintenance therapy. The route of administration, if available, scene findings, and decedent behavior prior to death were strongly considered by the pathologist for each case to provide context to the drug cause of death. For these data, a query was performed in the North Carolina Controlled Substances Reporting System for each decedent. For this particular set of buprenorphine cases, the decedents would have presumably survived the ingestion of other CNSDs, or therapeutic medications, if not for the presence of buprenorphine and its metabolite.

A majority of the buprenorphine deaths involve decedents with underlying cardiovascular disease. This raises the possibility that individuals with underlying cardiovascular disease may be more susceptible to the toxic effects of buprenorphine. While safer than other opioid alternatives, buprenorphine may not be void of effects on the heart, especially when not used as prescribed, and thus predispose individuals with heart conditions to an untimely death.

Determining cause of death in buprenorphine-related cases can be difficult. Deaths from buprenorphine may be underestimated in epidemiological data because of the lack of a defined toxic or lethal range involving a drug with a good safety profile, especially when compared to other opioids used for medication-assisted treatment. As the treatment of opioid-use disorder becomes a priority, more awareness of the challenges of postmortem interpretation is needed in the forensic community as increased use and diversion of buprenorphine are inevitable.

### **Buprenorphine, Postmortem, Opioid**

## K58 Evaluation of the Long-Term Stability of Select Phenylacetylindole, Cycloalkylindole, Quinoliny, and Carboxamide Synthetic Cannabinoids in Human Whole Blood Using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Erika Phung, BS\*, Boston University School of Medicine, Boston, MA 02118; Katherine Moore Bollinger, MS, Research Triangle Park, NC 27709; Sabra R. Botch-Jones, MS, Boston University School of Medicine, Boston, MA 02118; Daniel Lee, MS, Boston University School of Medicine, Boston, MA 02118; Cassandra A. Swart, MS, Boston University School of Medicine, Boston, MA 02118; Megan Grabenauer, PhD, RTI International, Research Triangle Park, NC 27709-2194; Nichole D. Bynum, MS, RTI International, Johnson Building, Research Triangle Park, NC 27709

**Learning Overview:** After attending this presentation, attendees will learn to assess the stability of synthetic cannabinoids in human whole blood using LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing long-term stability results of synthetic cannabinoids under various storage conditions.

**Background/Introduction:** Despite efforts to control synthetic cannabinoids, clandestine manufacturers continue to modify their structures to avoid legal consequences, creating an ever-changing analytical target for forensic laboratories. Forensic toxicology laboratories often lack the needed resources or do not have the capabilities to test for these compounds and metabolites, requiring specimens to be submitted to reference laboratories. Drug stability can be affected by long storage times, temperature, and preservatives. Although these factors can be controlled, systematic research is necessary to identify their impacts on the stability of these new synthetic cannabinoids that are continually emerging.

**Objective:** The purpose of this research was to assess the stability of 17 synthetic cannabinoids in human whole blood using LC/MS/MS over a 35-week period. The method was validated in accordance to the Academy Standards Board method validation guidelines for quantitative analysis and stability evaluation of the following analytes: phenylacetylindoles JWH-250 and RCS-8; cycloalkylindoles UR144 and XLR11; quinoliny PB-22 and NM2201; and carboxamides 4-cyano CUMYL-BUTINACA, 5-fluoro-3,5-ABPFUPPYCA, 5-fluoro ADB-PINACA, 5-fluoro PY-PINACA, ADB-PINACA, APP-PICA, CUMYL-THPINACA, EMB-FUBINACA, MDMB-FUBICA, MEP-CHMICA, and MO-CHMINACA.

**Methods:** Stability under room temperature (20°C), refrigerator temperature (4°C), and freezer temperature (-20°C) at high (10ng/mL) and low (1.5ng/mL) concentrations each in triplicate were evaluated at ten selected time points: 0-hour, 24 hours, 72 hours, 1 week, 3 weeks, 5 weeks, 9 weeks, 17 weeks, 21 weeks, and 35 weeks. Blood was preserved with sodium fluoride prior to the stability study. Extraction of analytes was conducted using Supported Liquid Extraction (SLE+) ISOLUTE® cartridges. The extracts were analyzed using a Waters® Xbridge™ reverse-phase C18 column (3.5µM, 2.1 x 50mm) by Shimadzu® HPLC with a SCIEX™ 4000 Q-Trap Electropray Ionization/Tandem Mass Spectrometry (ESI+/MS/MS) in positive ionization mode. The total run time was eight minutes with a 0.6mL/min flow rate and 10µL injection volume.

**Results:** Linear calibration curves for each analyte had acceptable R<sup>2</sup> values >0.99 using a weighting factor of 1/x. A linear dynamic range of 0.5ng/mL to 25ng/mL was used for all analytes within acceptable ±20% calculated bias and imprecision, except NM2201 and APP-PICA had a Limit Of Quantitation (LOQ) of 0.1ng/mL and MO-CHINACA had a working range of 0.5–15ng/mL. No signs of carryover were observed. Analytes were considered stable if the average area ratio at the time point examined was within ±20% of the average area ratio response at time point zero. Phenylacetylindole, cycloalkylindole, and carboxamide analytes were stable up to 35 weeks under all temperatures, such as JWH-250, 5-fluoro PY-PINACA, and UR144, with core structures of a carbonyl substituent on a pyrazole or pyrrole with surrounding non-polar groups of hydrocarbons and heterocyclic rings. Compounds with two polar carbonyl functional groups present, such as EMB-FUBINACA, 5-fluoro ADB-PINACA, APP-PICA, and MEP-CHMICA, were found to experience degradation earlier at one week or less in room temperature and refrigerated storage conditions. 5-fluoropentyl analogs, such as XLR11 and 5-fluoro ADB-PINACA, in comparison to their counterpart analytes, UR144 and ADB-PINACA, were unstable at earlier time points of less than one week under room temperature and/or refrigeration.

**Conclusion:** The validated method demonstrates a sensitive and reliable way to positively identify 17 different synthetic cannabinoids in human whole blood in rapid time for stability analysis. Further, the use of SLE improved sample preparation efficiency by decreasing the extraction time from 1 hour to 30 minutes compared to traditional extraction methods, such as solid-phase extraction and liquid-liquid extraction. The select 17 synthetic cannabinoids generally degraded in the order of room temperature, refrigerator, then freezer temperature. Long-term stability results revealed that the overwhelming majority of synthetic cannabinoids were stable up to 35 weeks when kept frozen.

### Synthetic Cannabinoids, Supported Liquid Extraction, Stability

## K59 The Quantitative Analysis of Fentanyl and Fentanyl Analogs in Hair

Ryan B. Paulsen, PhD\*, *Psychemedics Corporation, Culver City, CA 90230*; Michael I. Schaffer, PhD, *Psychemedics Corporation, Culver City, CA 90230*; Virginia Hill, BS, *Psychemedics Corporation, Culver City, CA 90230*; Neil Stowe, PhD, *Psychemedics Corporation, Culver City, CA 90230*; Judy Guan, BS, *Psychemedics Corporation, Culver City, CA 90230*

**Learning Overview:** After attending this presentation, attendees will know how to detect fentanyl use through hair analysis. Attendees will also know how to identify the presence of fentanyl analogs and their metabolites in hair.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a method for the detection and quantitation of fentanyl, fentanyl analogs, and their metabolites in hair. Data on the prevalence of fentanyl analogs that are also appearing in fentanyl users' hair will also be presented.

**Hypothesis:** Fentanyl, fentanyl analogues, and their metabolites are detectable in the hair of fentanyl users. The fentanyl can be extracted and analyzed via microwave extraction, solid phase preparation, and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) analysis.

An LC/MS/MS method for the analysis of fentanyl and fentanyl analogues in hair was developed. The assay was validated for fentanyl, norfentanyl, acetyl fentanyl, acetyl norfentanyl, furanyl fentanyl, furanyl norfentanyl, carfentanil, norcarfentanil, butyryl fentanyl, butyryl norfentanyl, valeryl fentanyl, and para-fluoro-butyryl fentanyl. The method was validated for precision, accuracy, linearity, carryover, interference, matrix suppression, recovery, and dilution integrity.

The fentanyl was extracted from the hair via microwave extraction in 9:1 methanol:trifluoroacetic acid. The solid phase clean-up was performed with DPX-CX tips on a Hamilton® STARlet liquid handler. The samples were sequentially washed with 0.1M acetate buffer pH 4.0, methanol/0.1 M HCl (4:6), and methanol, and eluted with 80:20:3 methylene chloride:isopropanol:ammonium hydroxide. The eluent was dried and reconstituted in mobile phase. The analysis was performed on a QTRAP® 6500+ LC/MS/MS with a Shimadzu® LC30-AD binary pump system and PAL-HTCxt with a DLW wash system. A Phenomenex® Kinetex® C18 150 x 2.1 mm, 1.7 µm particle size, 100 Å pore size Ultra Performance Liquid Chromatography (UPLC) column using a gradient elution with 0.1% formic acid in water and 0.1% formic acid in methanol was employed for chromatographic separation.

The presence of fentanyl was confirmed in 110 samples that had previously been screened by enzyme immunoassay for fentanyl. The sample pool utilized for the screening consisted predominantly of samples that had previously identified as positive for heroin metabolite (6-monoacetylmorphine, morphine). Many of the samples were also positive for other street drugs, mostly cocaine and methamphetamine.

The median concentration for the fentanyl was 132.5pg/mg. The median concentration for norfentanyl was 10.4pg/mg. The average ratio of fentanyl to norfentanyl was 20:1.

Many of the 110 positive samples contained other fentanyl derivatives. Furanyl fentanyl was detected in 55% of the samples; and butyryl fentanyl, carfentanil, and acetyl fentanyl were detected in a smaller fraction of the samples. No valeryl fentanyl or para-fluoro butyryl fentanyl was detected in any of these samples. The normetabolites of the fentanyl derivatives were also detected in samples with high concentrations (typically >100pg/mg) of the parent drug.

No samples were identified that had fentanyl analogs to the exclusion of fentanyl. This is somewhat due to poor cross-reactivity of some of the fentanyl analogs in the immune-assay, although butyryl fentanyl, valeryl fentanyl, furanyl fentanyl, and acetyl fentanyl have 100% or better cross-reactivity.

This method was used to successfully extract and analyze fentanyl, fentanyl analogs, and their metabolites in hair. Samples were identified containing fentanyl, furanyl fentanyl, carfentanil, butyryl fentanyl, and acetyl fentanyl.

### Fentanyl, Analogs, Hair

## K60 Physicochemical Characterization of 19 Fentalogs: Lipophilicity

Madison R. Schackmuth, BS\*, Huntsville, TX 77320; Sarah Kerrigan, PhD, Sam Houston State University, Department of Forensic Science, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will have increased understanding regarding the physicochemical properties of fentanyl analogs (fentalogs) and their importance in forensic science.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing additional information concerning the lipophilicity of fentalogs and their overall impact in terms of analytical separations and the interpretation of results.

Forensic toxicologists are tasked with the identification of New Psychoactive Substances (NPS) in biological matrices and may be required to interpret their findings. Yet, the physicochemical properties of these new and emerging drugs are not always known. Although fentanyl and a small number of derivatives used for medical or veterinary procedures are well characterized, physicochemical properties have not been determined for many emerging fentanyl analogs. Lipophilicity plays an important role in terms of separation and analytical determination, as well as the overall pharmacology of the drug (i.e., absorption, distribution, metabolism, and excretion). It is described by parameters such as partition coefficients ( $\log P/\log D$ ) and Volume of distribution ( $V_d$ ).

Partition coefficients were determined for 19 fentalogs. Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) was used to experimentally determine partition coefficients (octanol/water) for (+)-cis-3-methylfentanyl, 4-ANPP, acetylfentanyl, butyrylfentanyl, isobutyrylfentanyl, furanylfentanyl, valerylfentanyl, norfentanyl, norcarfentanyl, alfentanil, remifentanil, sufentanil, carfentanil, p-fluoroisobutyrylfentanyl, p-fluorobutyrylfentanyl, p-fluorofentanyl, o-fluorofentanyl, and  $\beta$ -hydroxythiofentanyl. An Agilent® 1290 Infinity LC coupled to an Agilent® 6470 triple quadrupole mass spectrometer was employed in positive Electrospray Ionization (ESI) mode. Fentalogs were separated using gradient elution using a mobile phase consisting of deionized water/acetonitrile containing 0.1% formic acid. Data were acquired using Multiple Reaction Monitoring (MRM) and data analysis was performed using Agilent® MassHunter™ software. Source conditions were optimized for all analytes and chromatographic resolution was achieved for all 19 fentalogs.

Experimentally determined partition coefficients were compared with specialized software-generated data from three independent sources (ACD, ALogPS, and LogKOW).  $\log D$  values for the 19 fentalogs were measured over a wide range (<0.1 to 2.7) in octanol/water. Partition coefficients were also evaluated over a range of pH values in aqueous buffer systems. The results highlight important differences in the lipophilicity of fentalogs with phenethyl, piperidine, aniline, or *N*-propionyl substitutions. Although numerically determined partition coefficients can be of value for forensic chemistry and toxicology applications, the comparison of experimental and software-generated data can provide important insight regarding future fentalogs that have yet to emerge. Per research, this study may be the largest characterization of fentanyl lipophilicity to date. The observed differences in lipophilicity can have important implications in terms of the pharmacology and toxicology of these synthetic opioids.

### Fentalogs, Partition Coefficients, $\log P/\log D$

## K61 Identification of Mitragyna Alkaloids and Metabolites as Biomarkers of Kratom Use in Postmortem Urine Samples

Stephanie Basiliere, BS\*, Huntsville, TX 77340-2593; Sarah Kerrigan, PhD, Sam Houston State University, Department of Forensic Science, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will be familiar with the identification of mitragyna alkaloids in biological samples using Liquid Chromatography/quadrupole/Time Of Flight/Mass Spectrometry (LC/qTOF/MS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying additional alkaloids of *Mitragyna speciosa* as biomarkers of kratom use. In addition, the merits of enzymatic and chemical hydrolysis of phase II metabolites will be discussed.

*Mitragyna speciosa* (kratom) is a tree native to Southeast Asia that has been utilized as both a medicine and cultural tradition by the local populace. The plant is known to have dose-dependent effects—in low doses it produces a stimulant effect, and in high doses an opiate effect. Although not federally regulated, kratom's unique effects and unregulated status make it an ideal target for recreational drug use. The plant is known to contain more than 20 corynanthe-type indole alkaloids, of which the primary psychoactive components are Mitragynine (MG) and 7-Hydroxymitragynine (MG-OH). Other prominent compounds of kratom include two diastereoisomers of mitragynine (Speciogynine (SG) and Speciociliatine (SC)) and another structurally similar alkaloid, Paynantheine (PY). These three alkaloids are not reported to be psychoactive. In addition, MG's metabolism has been studied and several prominent phase I metabolites have been identified including 16-Carboxymitragynine (16-COOH-MG), 9-O-Demethylmitragynine (9-O-DM-MG), and most notably, MG-OH. Following the administration of kratom, biological samples may contain a mixture of these structurally similar mitragyna alkaloids in addition to their metabolites. This can present a significant challenge in terms of analytical detection.

A previously validated LC/qTOF/MS assay was used for the quantitative and qualitative identification of four kratom alkaloids (MG, MG-OH, SG, and SC) in postmortem urine. A modified LC/qTOF/MS assay was also used to further investigate phase I and phase II metabolites of MG among these kratom users. Chemical and enzymatic hydrolysis of glucuronides and sulfates were evaluated. In the absence of reference standards, phase I metabolites were identified using high-resolution mass spectra and retention time matching. Recombinant cytochrome P450 enzymes were used to generate phase I metabolites *in vitro* for this purpose.

Using unhydrolyzed specimens, parent drug (MG) was identified in all samples tested over a concentration range of 26–1,987ng/mL. Other kratom alkaloids were also detectable in all 16 samples with concentrations ranging from 2–317ng/mL (PY), 59–1,684ng/mL (SG), and 23–3,309ng/mL (SC). Notably, among 12 of the 16 samples, concentrations of speciociliatine, speciogynine (or both alkaloids) exceeded that of MG. MG-OH, which is known to be unstable, was detected in nine samples. 9-O-DM-MG was identified in 12 of the 16 samples, but 16-COOH-MG was identified in only one specimen.

Deconjugation using recombinant enzymes proved more effective than either chemical hydrolysis or enzymatic hydrolysis using traditional glucuronidase and sulfatase preparations. Detectability of the carboxylated metabolite (16-COOH-MG) significantly increased following hydrolysis. However, the abundance of 9-O-DM-MG and MG-OH were only marginally improved by the additional sample preparation step, and stability issues were identified. Overall, deconjugation of phase II metabolites in urine proved to be of little benefit.

Given the increase of kratom usage in the United States and its reported use for the non-medically supervised treatment of opioid abstinence syndrome, identification strategies are needed. In addition to MG and MG-OH, several other alkaloids (SC, PY, SG) can be used to identify kratom use. In addition to these potential biomarkers, 9-O-DM-MG was the most abundant metabolite and was readily detected without deconjugation. However, until an analytical reference standard is available, it is unlikely to be incorporated into routine testing.

### Kratom, Urine, Biomarkers

## K62 Rapid Detection and Separation of Isomeric Fentanyl Analogs Using Gas Chromatography-Atmospheric Pressure Chemical Ionization-Trapped Ion Mobility-Time of Flight/Mass Spectrometry (GC-APCI-TIMS-TOF/MS)

Elisa N. Shoff, MS\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; Cesar E. Ramirez, PhD, Florida International University, Miami, FL 33199; Juergen Kempf, PhD, Institute of Forensic Medicine, Freiburg 79104, GERMANY; Francisco A. Fernandez-Lima, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will better understand a novel instrumentation technique for the separation and identification of isomeric fentanyl analogs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing an alternative high-resolution instrumentation technique for toxicological analysis that is complementary to traditional chromatography/mass spectrometry workflows.

The emergence of Novel Psychoactive Substances (NPS) in the United States, especially fentanyl analogs, has led to the need for alternative screening and quantitative techniques capable of achieving both high sensitivity and specificity. Due to the clandestine nature of these compounds, the potential for the development of isomeric sets is high, thus increasing the need for method development of a complementary separation technique for the detection and quantification of isomeric substances. With relatively unknown potencies among structural isomeric and isobaric sets, being able to distinguish between these compounds is paramount when properly certifying the cause and manner of death. In the present work, the use of complementary gas-phase separation was evaluated for the analysis of fentanyl analogs, specifically GC-APCI coupled to TIMS-TOF/MS.

Sixteen fentanyl analogs, as shown in Table 1, including six sets of isomers, were prepared in methanol using certified reference standards provided by the Miami-Dade Medical Examiner Department (MDME). All standards were fortified into whole blood and extracted via protein precipitation with acetonitrile. In addition, previously analyzed postmortem case samples, provided by the Institute of Forensic Medicine, Medical Center at the University of Freiburg, Germany, were also extracted and sampled to confirm the application of the method developed. Chromatographic separation was achieved using a GC equipped with a DB-5 non-polar capillary column, coupled to an APCI source in positive ionization mode. A 15min thermal ramping method was used, with compound elution between 6-10 minutes of the total run time. Using the standards provided, the GC-TIMS-MS method was optimized, and detection of analogs was achieved using a commercial TIMS-TOF with an internal mobility and accurate mass calibration.

**Table 1. Analytes**

Despropionyl ortho-fluoro fentanyl (298 Da)	Cyclopropyl fentanyl (348 Da)	Benzyl fentanyl (322 Da)	3-methyl fentanyl (350 Da)	Para-fluorobutyryl fentanyl (368 Da)	Meta-fluoro fentanyl (354 Da)	Fentanyl (336 Da)
Despropionyl para-fluoro fentanyl (298 Da)	Crotonyl fentanyl (348 Da)	Acetyl fentanyl (322 Da)	Butyryl fentanyl (350 Da)	Para-fluoroisobutyryl fentanyl (368 Da)	Ortho-fluoro fentanyl (354 Da)	Furanyl fentanyl (374 Da)
					Para-fluoro fentanyl (354 Da)	Methoxyacetyl fentanyl (352 Da)

All fentanyl analogs were positively identified using high resolution mass accuracy, with experimental  $m/z$  values within 1ppm of calculated theoretical  $m/z$  value. All analytes were linear from 1ng/mL to 500ng/mL post-extraction and no endogenous or exogenous interferences were observed. An increase in signal to noise was noted when signals were filtered in the GC, IM, and MS domains, allowing for increased sensitivity. A Collision Cross Section (CCS) value, which is a term that represents the interaction between the target ion and the drift gas ( $N_2$ ) in the TIMS cell, is used to characterize the measured IM of a compound. CCS was measured for all fentanyl analogs (<1% error) and mobility separation was classified as a difference in CCS value larger than  $0.6 \text{ \AA}^2$ ; this separation was achieved for four out of the six sets of structural isomers. All analytes were also observed as having a characteristically high mobility resolving power ( $R > 100$ ). In addition, five out of the six sets of isomers were chromatographically resolved ( $r > 1$ ). Successful separation was achieved for each set of isomers either by IM, chromatography, or both. The analytes detected in the previously analyzed postmortem case samples, including furanyl fentanyl, and methoxyacetyl fentanyl, were confirmed positive on the present method, with quantitative values within 20% of the previously measured concentrations. The use of GC-IM spectrometry for the detection of fentanyl analogs in the field of toxicology demonstrates the advantage of orthogonal separation techniques and multi-dimensional identification (retention time, CCS value, and accurate mass). Ongoing experiments will assess the use of liquid chromatography, as well as the addition of more analytes to the method.

## K63 Determination of Novel and Non-Routine Benzodiazepines and Suvorexant in Whole Blood by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)

Luke Garcia\*, Marshall University, Huntington, WV 25701; Nicholas B. Tiscione, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406; Dustin Tate Yeatman, MS, West Palm Beach, FL 33406; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701

**Learning Overview:** After attending this presentation, attendees will understand the benefits and limitations of an efficient analytical method for the determination of select benzodiazepines and suvorexant in whole blood by LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a validated method for the detection of select benzodiazepines and suvorexant in whole blood.

**Introduction:** Benzodiazepines are frequently encountered in human performance forensic toxicology cases, such as drug-facilitated assaults and impaired driving, due to their effect on the central nervous system. The growing trend of Novel Psychoactive Substance (NPS) -benzodiazepines has increased the need to expand the scope of targeted assays. In the past 19 months, the Palm Beach County Sheriff's Office Crime Lab has received drug seizure submissions containing clonazepam, etizolam, flualprazolam, and flubromazolam.

**Objective:** Develop and validate an efficient method for quantitative determination and/or qualitative identification of select novel and non-routine benzodiazepines and suvorexant in whole blood by LC/MS/MS.

**Method:** Two hundred microliters of whole blood was prepared by protein precipitation using LC/MS-grade acetonitrile. Analysis of the samples was performed on a Shimadzu® Prominence XR LC system with a SCIEX® 3200 QTRAP® MS/MS and a Raptor™ Biphenyl column with dimensions of 50 x 2.1mm and a 2.7µm particle size. A gradient LC program with a flow rate of 0.6mL/minute was used with LC/MS-grade water and acetonitrile, both with 0.1% formic acid. The total run time was eight minutes. Stable isotopically labeled internal standards of bromazepam, clonazepam, clobazepam, diclazepam, estazolam, etizolam, suvorexant, and triazolam were used. The method was validated by evaluating the calibration model, sensitivity, carryover, selectivity/specificity, repeatability, bias, robustness, a case sample evaluation, ionization suppression/ enhancement, and extract stability.

**Results:** Two different quantitative ranges were employed based on anticipated concentrations of each analyte in whole blood. The range for Group 1 (clonazepam, diclazepam, flualprazolam, flubromazepam, flubromazolam, loprazepam, lormetazepam, and triazolam) was 5–100ng/mL. The range for Group 2 (bromazepam, clobazepam, clonazepam, estazolam, etizolam, phenazepam, prazepam, suvorexant, and tetrazepam) was 25–500ng/mL. Flubromazepam and prazepam were validated for qualitative identification only. The Limit Of Detection (LOD) was 1ng/mL for Group 1 (except clonazepam, flubromazolam, and triazolam, which was 5ng/mL) and 5ng/mL for Group 2. The Limit Of Quantitation (LOQ) was administratively set to the lowest calibrator. The calibration model for all analytes used a quadratic curve fit with 1/x weighting. Within-run ( $n=3$ ) and between-run ( $n=15$ ) precision for the quantitative analytes did not exceed 14% for controls prepared at the LOQ (in five different matrix sources), a midpoint concentration, and a concentration within 20% of the highest calibrator. Bias did not exceed  $\pm 14\%$ . An evaluation with previously characterized case samples ( $n=19$ ) demonstrated interference for one of the ion transitions for triazolam in one case that may interfere with its identification. There was no interference with other common analytes from drug classes, such as stimulants, tetrahydrocannabinols, opioids, and other benzodiazepines. Ionization suppression/enhancement of the target response relative to the internal standard was not greater than  $\pm 25\%$  for all analytes, except prazepam at the LOQ and loprazepam at both the LOQ and a concentration within 20% of the highest calibrator. Extract stability of flubromazepam did not exceed 24 hours (peak area varied by  $\geq 20\%$ ). Tetrazepam and triazolam demonstrated stability up to 48 hours. Clonazepam, lormetazepam, and phenazepam demonstrated stability up to 72 hours. All other compounds demonstrated stability up to 96 hours. A certified reference material for suvorexant was not available and therefore will be reported qualitatively even though all validation requirements were met. Flubromazepam and prazepam demonstrated bias  $> \pm 20\%$  with control replicates prepared in alternate matrix sources at the LOQ. Stable isotope-labeled internal standards may be required for quantitation of those analytes by this method.

**Conclusion:** The presented method requires a small volume of sample, minimal sample preparation, and demonstrated acceptable performance for the quantitative analysis of 15 of the 17 compounds evaluated. This method allows for the quantitative determination and/or the qualitative identification of 16 novel and non-routine benzodiazepines and suvorexant in whole blood by LC/MS/MS.

### Benzodiazepines, Validation, LC/MS/MS

### **K64 Fentanyl Epidemic on the West Coast: Accidental Overdose Death Trends in San Francisco From 2008 to 2019**

*Kelsa L. West, MS\*, Aptos, CA 95003-9792; Luke N. Rodda, PhD, San Francisco Office of the Chief Medical Examiner, San Francisco, CA 94124*

**Learning Overview:** After attending this presentation, attendees will understand how fentanyl has become an alarming epidemic on the West Coast, as well as what the trends within the drug use and deaths are. Additionally, this presentation will highlight how the fentanyl epidemic impacts local communities, medical examiner offices, and public health as a whole.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering insight to trends among sole fentanyl consumption, as well as co-consumption with other drugs, such as medicinal opioids, heroin, methamphetamine, and cocaine. These trends may shed light onto how agencies can better address the epidemic in local communities, including the implementation of preventative strategies. Importantly, this data highlights how forensic laboratories can better observe the issue through an efficient and systematic toxicological approach. Furthermore, this presentation may highlight the need for more uniformity across and within forensic labs in terms of medical death definitions (both cause and manner of death classifications) and methods and regime of toxicological analyses.

Fentanyl is most widely known for its medical uses, but there has been a trend, both locally and nationwide, that illicit drugs are being laced with fentanyl, and agencies are more often detecting fentanyl with other illicit drugs. The addition of fentanyl and fentanyl analogs into, or consumed with, other drug products can produce potentially dangerous consequences, even to opioid-tolerant individuals who may be unaware of such additions.

It was the goal of this research to uncover the trend of fentanyl-related deaths in the City and County of San Francisco from 2008 to 2019. Since 2014, there has been a sharp increase in fatal overdoses involving fentanyl in San Francisco, which surpassed fatal overdoses involving heroin and/or opioids by 2016. In 2015, 2016, 2017, and 2018, there were approximately 18, 23, 43, and 104 deaths involving fentanyl, respectively, with almost all of those deaths being classified as accidental overdoses.

Opioid-like overdose symptoms in stimulant users led to the discovery of fentanyl-laced cocaine and methamphetamine, where many users were hospitalized and/or died as a consequence. From 2016 onward, the presence of fentanyl in methamphetamine- and cocaine-related deaths has also increased significantly.

Outbreaks of fentanyl analogs have also been observed since late 2015 when the ingestion of furanyl fentanyl by a young male in 2017 led to his death. Fentanyl analog inclusion was typically seen in counterfeit medication or recreational pills. Like methamphetamine and cocaine users, victims seemingly had no indication of previous fentanyl or fentanyl analog use, highlighting that tolerance to such potent fentanyl and fentanyl analogs plays a factor in opioid-naïve users.

The results have shown that there indeed is an upward trend of the detection of fentanyl in death cases, both in accidental overdoses and non-accidental overdoses. These trends must first be detected, then considered, and continually captured for the interests of law enforcement agencies, forensic laboratories, and, importantly, given to public health agencies for drug harm reeducation measures.

---

#### **Fentanyl Epidemic, Forensic Toxicology, Opioids**

## K65 Accidental Acute Combined Drug Toxicity Involving Heroin and Fentanyl in a 10-Year-Old Child

Joseph H. Kahl, MS\*, Miami-Dade Medical Examiner Department, Miami, FL 33136; Benjamin Mathis, MD, Miami-Dade County Medical Examiner Department, Miami, FL 33136; George W. Hime, MS, Miami-Dade Medical Examiner Department, Miami, FL 33136; Diane Boland, PhD, Miami-Dade Medical Examiner Department, Miami, FL 33136-1054

**Learning Overview:** The goal of this presentation is to describe the circumstances and postmortem toxicological findings of a case involving an accidental acute heroin and fentanyl overdose in a 10-year-old child.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of the severity of the national opioid epidemic.

A 10-year-old Black male was found unresponsive at home by his mother, lying facedown on a couch in cardiac arrest. Emergency medical services responded to the scene and initiated Cardiopulmonary Resuscitation (CPR). The decedent exhibited trismus, resulting in the administration of 10mg of midazolam in order to secure an airway. He was transported via ambulance to the emergency room but was pronounced dead shortly after arrival. Naloxone was never administered, most likely due to the decedent's age and lack of circumstantial evidence at the scene to suggest opioid abuse. According to the decedent's uncle, he had spent the day swimming with his family at the community pool and was observed awake and alert an hour before being discovered unresponsive by his mother. He had eaten a snack, vomited, and sat down on the couch to watch television.

At autopsy, the medical examiner noted that the decedent had aspirated his gastric contents and exhibited pulmonary congestion and cerebral edema with no other remarkable findings. Central and peripheral blood, vitreous humor, and total gastric content were collected and submitted for toxicological analysis. Comprehensive toxicology testing was performed, including a volatiles screen, a 5-assay Enzyme-Linked Immuno-Sorbent Assay (ELISA) screen, and a blood drug screen by both Gas Chromatography/Mass Spectrometry (GC/MS) and Liquid Chromatography/Ion Trap/Mass Spectrometry (LC/Ion Trap/MS<sup>n</sup>). Morphine, 6-acetylmorphine, codeine, fentanyl, and midazolam were identified in the decedent's peripheral blood and were quantified by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). 6-acetylmorphine and fentanyl were confirmed in the decedent's vitreous humor and were also quantified in the decedent's gastric content. Postmortem concentrations of detected analytes were as follows:

**Table 1:** Postmortem Concentrations of Detected Analytes

Analyte	Specimen	Concentration
Morphine	Blood – Iliac Vein	0.015mg/L
6-Acetylmorphine	Blood – Iliac Vein	<1.0ng/mL
	Gastric Content	<1.0ng/mL
Codeine	Blood – Iliac Vein	<0.010mg/L
Fentanyl	Blood – Iliac Vein	15.5ng/mL
	Gastric Content	6.5ng total
Midazolam	Blood – Iliac Vein	0.100mg/L

Based upon the autopsy results and the toxicology findings, the medical examiner determined the cause of death to be an acute combined drug toxicity involving heroin and fentanyl. The manner of death was ruled an accident. Although the media speculated that the decedent found the drugs either at the pool facility, on his way home, or in his home, video footage was obtained showing the decedent acting normally while walking to his house from the pool facility, and law enforcement concluded that there was no reason to believe the drugs were in the house. Despite the extensive investigation, little to no additional information was revealed regarding how and where the decedent came in contact with heroin and fentanyl. This case demonstrates the reach of the national opioid epidemic and that victims can come from all different demographics.

### Fentanyl, Heroin, Postmortem

## K66 A Fatal Mono-Intoxication With 4-Fluoroisobutyrylfentanyl

Roelof Oosting, PharmD, Netherlands Forensic Institute, The Hague, NETHERLANDS; Lauriane Drouin, Netherlands Forensic Institute, The Hague, NETHERLANDS; Rogier van der Hulst, PharmD, laan van Ypenburg 6, The Hague, NETHERLANDS; Ingrid Bosman, PhD\*, The Hague 2497 GB, NETHERLANDS

**Learning Overview:** After attending this presentation, attendees will understand the need to share and publish postmortem toxicological data on new psychoactive substances such as fentanyl analogs for toxicological interpretation in new casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing toxicological data on the presence and concentration of 4-fluoroisobutyrylfentanyl, a new psychoactive substance, in various biological samples.

During the past decades, there has been an increase in the appearance of fentanyl analogs as new psychoactive substances. Fentanyl is a synthetic narcotic opiate with strong analgesic properties and is about 100 times more potent than morphine. Because of its high potency, fentanyl and fentanyl derivatives are misused and abused and may cause death. Limited toxicological data are available on these new fentanyl derivatives. In this presentation, new toxicological data of a fentanyl derivative in a postmortem case are presented. The goal was to explain the cause of death of a 35-year-old man who was encountered in need of resuscitation in his bathroom. He died shortly afterward. Drug paraphernalia (including a base pipe) and a small amount of rough material were found near the victim.

At the Drugs Department, the rough material was investigated using Gas Chromatography/Mass Spectrometry (GC/MS), Infrared (IR) spectroscopy, and Nuclear Magnetic Resonance (NMR). At the Toxicology Department, the body material obtained from autopsy was investigated for toxic substances following the standard screening protocol on ethanol, drugs, medicines, and pesticides using Headspace/Gas Chromatography/Flame Ionization Detection (HS/GC/FID), Liquid Chromatography/Time-Of-Flight/Mass Spectrometry (LC/TOF/MS), GC/MS, and Ultra-Performance Liquid Chromatography/Diode-Array Detection (UPLC/DAD). Furthermore, 4-Fluoroisobutyrylfentanyl (4-FIBF) was subsequently identified and quantified using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

Toxicological analysis on the body material showed the presence of 4-FIBF. With the chromatographic method, the separation of the 2, 3, and 4-fluorobutyrylfentanyl and 2, 3, and 4-fluoroisobutyrylfentanyl isomers could not be confirmed. However, the fentanyl derivative was identified in the rough material as almost pure 4-FIBF. Therefore, it is very likely that the derivative found in the body material was 4-FIBF. Concentrations of 4-FIBF were measured in various biological samples, including femoral blood, heart blood, vitreous humor, brain tissue, liver tissue, and urine. The measured concentrations were respectively 0.030mg/L; 0.12mg/L; 0.067mg/L; more than 0.081mg/kg; 0.44mg/kg, and between 0.0010 and 0.025mg/L. No other compounds were found.

In literature, only two cases were found with toxicological data on 4-FIBF. In a publication by M. Rojkiewicz et al. in 2017, the concentrations of 4-FIBF measured were higher compared to this case although it was not clear whether the analyzed blood was peripheral blood or heart blood.<sup>1</sup> Based on the toxicological results, it was concluded that the measured concentrations of 4-FIBF could have contributed to or possibly explain the cause of death if no other plausible cause was found. The additional role of heart muscle inflammation seen at autopsy could not be completely excluded.

In conclusion, this case showed a fatal intoxication of 4-FIBF. The presence and concentration of 4-FIBF was measured in various biological samples. Because only two other cases with data on 4-FIBF were published, these additional postmortem toxicological data on this new psychoactive substance are very useful for the toxicological interpretation.

### 4-Fluoroisobutyrylfentanyl, Fatal Intoxication, Postmortem

## K67 Circumstances, Postmortem Findings, and Toxicology in a Series of Methoxyacetylfentanyl-Related Deaths

Robert Kronstrand, PhD\*, National Board of Forensic Medicine, Linköping, Ostergotland SE 587 58, SWEDEN; Svante Vikingsson, PhD, National Board of Forensic Medicine, Linköping 58758, SWEDEN

**Learning Overview:** The goal of this presentation is to increase the knowledge of the toxicology of Methoxyacetylfentanyl (MAF) by providing quantitative data in postmortem cases and discuss cases of fatal intoxications.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the awareness of new non-routine drugs, the toxicology of MAF, and provide an insight into the postmortem findings.

MAF is a fentanyl analog, with replacement of the propionamide group by a 2-methoxyacetamide group. MAF is also closely structurally related to fentanyl (having an additional fluorine in the 2-position on the aniline ring structure). In Europe, MAF became available in late 2016. The first death in Sweden occurred on December 3, 2016. MAF was scheduled as a hazardous product prohibited for sale in Sweden on January 25, 2017, and later that year, on October 19, scheduled as a narcotic drug. This study reports the circumstances, postmortem findings, and toxicological findings in 11 deaths related to the intake of MAF.

Quantification of MAF in femoral blood was performed on an LC-30AD liquid chromatography system equipped with a Triple Quad 4500 mass spectrometer. Mobile phases A (0.05% formic acid in 10mM ammonium formate) and B (0.05% formic acid in methanol) were used at a flow rate of 0.8mL/min; the linear gradient was from 2% B to 100% B in 3.0min. An Acquity® BEH Phenyl column (60°C) was used. Electrospray in positive mode was used for ionization. Data acquisition with two transitions for MAF with  $m/z$  353.20/188.10 as quantifier and  $m/z$  353.20/105.10 as qualifier was used with D5-fentanyl as the internal standard ( $m/z$  342.0/188.0). A 0.5g aliquot of blood was fortified with internal standard and precipitated with 0.75mL of acetonitrile:ethanol (90:10) with the addition of 0.075% formic acid.

The 11 decedents were aged 27 to 41 years (mean 32.5), with one female and ten males. The manner of death was accidental in seven cases, natural disease in one case, and undetermined in three cases. The cause of death was intoxication by MAF alone ( $N=7$ ) or in combination with other drugs in all but one case, where death was attributed to acute complications of an underlying heart disease but with possible contribution from MAF. Significant postmortem findings that pointed toward opiate toxicity were lung congestion and lung and brain edema with a mean combined lung weight of 1,469 grams. Three subjects also presented with froth in the airways. There were few other significant findings, but pneumonia, hepatitis, and atherosclerosis of varying degrees were pathologies found. At least eight of the decedents had a history of drug abuse, and all but two were found dead indoors. One subject was found alive but in respiratory and cardiac arrest. At the hospital, the patient presented with RLS8 and an MAF concentration of 41ng/g. During hospitalization, the patient never regained consciousness and also developed acute kidney injury. The MAF concentrations in femoral blood ranged between 18–140ng/g with a mean of 47ng/g and a median of 34ng/g. In the literature, there are ten cases reported from the United States and three cases from Denmark where MAF was quantified in femoral blood. Concentrations were 22, 23, and 56 (ng/g) in the Danish cases and ranged between 0.21–39.9 (ng/mL) in those reported from the United States (mean 17.7ng/mL). Polydrug use was confirmed from toxicological analyses in all cases, but no other non-prescription opioids were present. Benzodiazepines (alprazolam, clonazepam, and diazepam) as well as the non-prescription norfludiazepam and etizolam were present, together with numerous other prescription drugs and the scheduled drugs amphetamine and tetrahydrocannabinol. At least three different routes of administration were suggested from the death scene findings: injection, oral administration of tablets, and snorting. The deaths occurred between December 2016 and May 2018, both prior to and after scheduling of MAF in Sweden.

The concentrations of MAF were in the upper concentration range compared to those previously reported in femoral blood and contribute to previous knowledge of fatal concentrations. Polydrug use was common but not necessarily an acute contributing factor. Since most deaths were accidental and unwitnessed, a possible risk factor is the use of MAF alone. The scheduling of MAF did not preclude its use.

### Methoxyacetylfentanyl (MAF), New Psychoactive Drugs, Fatal Intoxication

## K68 Homicidal Paraquat-Induced Respiratory Failure: A Case Report and Overview of Paraquat Testing in the Forensic Setting

Elaine J. Oldford, BS\*, Western Michigan University, Kalamazoo, MI 49006; Theodore T. Brown, MD, Kalamazoo, MI 49008; Prentiss Jones, Jr., PhD, Western Michigan University Homer Stryker MD School of Medicine, Kalamazoo, MI 49007; Kenneth D. Hutchins, MD, Miami-Dade County, Miami, FL 33136

**Learning Overview:** After attending this presentation, attendees will recognize clinical findings, classic autopsy gross and histologic abnormalities, and the potential need for expanded toxicology testing in deaths due to paraquat toxicity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of performing a complete autopsy and obtaining additional, non-routine specimens for toxicology testing during medicolegal autopsy examinations when the circumstances of death include suspected poisoning.

Paraquat is a water-soluble, highly toxic agent used in pesticides worldwide. Due to easy accessibility, it is commonly seen within the context of suicide in developing nations.<sup>1</sup> Complications of paraquat toxicity can mimic many respiratory diseases and be difficult to diagnose and treat, and subsequent mortality often ensues. Postmortem, pulmonary congestion, fibrosis, and glomerulosclerosis may be observed.<sup>2</sup> A combination of clinical history and findings at autopsy may suggest paraquat poisoning. However, both antemortem and postmortem testing of blood and urine can be negative. Preferential accumulation of paraquat in the lungs should be kept in mind, as paraquat testing of lung tissue can reveal the cause of death. Presented here is a medicolegal autopsy case of respiratory failure by homicidal paraquat poisoning after additional toxicology testing was performed on lung tissue.

A 69-year-old female who lived in Jamaica reported increased asthma-like attacks and generalized pain soon after she informed her husband that she wanted a divorce. Despite medical treatment, her symptoms persisted. One week later, she presented to the emergency room for worsening dyspnea and evidence of kidney and liver malfunction. Despite treatment for possible viral pneumonia with a superimposed bacterial infection, she ultimately died in the hospital due to respiratory failure, approximately one month after her initial symptoms. After death, the decedent's family was concerned that her husband might have poisoned her with paraquat (sold as Gramoxone® in Jamaica), given his increasingly abusive behavior. The decedent also messaged friends that her husband had made her food at the time she became sick, something that he had not done in years. Due to the allegations and clinical circumstances of respiratory failure over a relatively short period, a medicolegal autopsy was performed.

The autopsy was most significant for diffuse pulmonary fibrosis, a finding consistent with generalized lung injury that can be due to multiple etiologies. Review of the medical records included negative H1N1, influenza A, and influenza B testing. Paraquat testing on both antemortem blood and postmortem urine were negative. However, paraquat testing performed on lung tissue was confirmed at a concentration of 44ng/g by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). Given these findings and the circumstances provided, the cause of death was attributed to complications of paraquat toxicity, and the manner of death was homicide.

Paraquat toxicity can manifest in a number of ways according to paraquat's accumulation within tissues. Depending on the dose, initial symptoms may be vague and easily confused with infectious diagnoses. Due to the small amounts ingested over time, this case displayed progressive dyspnea and persistent non-specific symptoms. Both negative findings and the lack of improvement with antibiotics and antivirals may guide the clinician toward other diagnoses. Furthermore, contextual information is essential. In this case, the decedent lived in Jamaica, where paraquat is more widely available than in the United States.

Knowledge of factors that can influence the pharmacokinetics of paraquat and other potential toxins such as solubility are critical in suspected poison-related deaths. Toxicology testing for paraquat performed on blood and urine may come back negative due to rapid uptake into highly perfused tissues, such as the lungs and kidneys.<sup>3</sup> Therefore, a negative result does not rule out paraquat toxicity. In this case, tissue samples were necessary to confirm paraquat as the causal agent. Furthermore, the use of a highly selective and sensitive analytical technique such as LC/MS/MS is required for a definitive determination of paraquat. LC/MS/MS is a preferred technique routinely used in the quantitative assessment of the severity of suspected poison-related intoxication. Though not routine, LC/MS/MS testing of lung tissue for paraquat is recommended if there is a strong suspicion of paraquat poisoning and diffuse lung injury is documented at autopsy.

### K69 Caught Looking: A High-Profile Vessel-Related Fatality in Miami, Florida

*Diane Boland, PhD\**, Miami-Dade Medical Examiner Department, Miami, FL 33136-1054; *Joseph H. Kahl, MS*, Miami-Dade Medical Examiner Department, Miami, FL 33136; *Jennifer Gonyea*, Miami-Dade Medical Examiner Department, Miami, FL 33136; *George W. Hime, MS*, Miami-Dade Medical Examiner Department, Miami, FL 33136; *Kenneth D. Hutchins, MD*, Miami-Dade County, Miami, FL 33136

**Learning Overview:** After attending this presentation, attendees will understand the role and importance of toxicology testing in the investigation of vessel-related fatalities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of the toxicological investigation and the role of drug impairment in vessel-related fatalities.

According to the Boating Accidents Statistical Report issued by the Florida Fish and Wildlife Conservation and Commission, the State of Florida has averaged 56 vessel-related fatalities per year since 2009. Miami-Dade County, located in the southeastern part of the state, ranks high among the top ten Florida counties in which boating incidences occur. Miami is a city defined by water with boating and salt life very much a part of its culture. Whether fishing, snorkeling, scuba diving, or sunbathing, enjoying time on a boat is an everyday, year-round pastime that requires very little experience but offers an atmosphere conducive for “partying” and drinking alcoholic beverages. Unfortunately, this combination resulted in a high-profile fatality in Miami involving a Major League baseball player and two additional passengers.

The three men were known to be socializing and having drinks at a popular bar on South Beach. They left the establishment and boarded a 32-foot SeaVee® center console. The vessel began traveling from the Atlantic Ocean when it collided into a jetty as it attempted to enter the channel at a very high rate of speed. Autopsies completed determined blunt force trauma and drowning as the cause of death for all three occupants. The captain of the vessel had an iliac blood ethanol concentration of 0.147% and a cocaine and benzoylecgonine concentration of 0.126mg/L and 0.282mg/L, respectively. The second passenger had an iliac blood ethanol concentration of 0.065% and cocaine and benzoylecgonine of 0.077mg/L and 0.482mg/L, respectively. Both decedents with cocaine identified also had cocaethylene present at a level below the limit of quantitation (0.050mg/L) for the method. The third passenger had an iliac blood ethanol of 0.044% with only citalopram detected. The toxicology findings determined that ethanol and drugs were a factor in this boating accident. Overall, it was concluded that the vessel captain operated with his normal faculties impaired, in a reckless manner, at an extremely high rate of speed. The combination of ethanol and cocaine, at night, in an area with known navigational hazards such as the rock jetties and channel markers contributed to the fatal accident.

Toxicology testing is important in vessel-related fatalities for determining the presence or absence of impairing substances and can help in understanding the circumstances surrounding boating accidents. In this particular case, multiple factors were at play, including speed, darkness, navigational hazards, and impairment due to alcohol and drugs.

#### Boating, Vessel Fatality, Toxicology

## K70 Urinary Metabolites in Fatal Intoxications With Methoxyacetylfentanyl Could Indicate Time Until Death

Syvante Vikingsson, PhD\*, National Board of Forensic Medicine, Linköping 58758, SWEDEN; Robert Kronstrand, PhD, National Board of Forensic Medicine, Linköping, Östergötland SE 587 58, SWEDEN

**Learning Overview:** The goal of this presentation is to increase attendees' knowledge of methoxyacetylfentanyl toxicology by providing urinary data in postmortem cases and discussing the potential value of such data in case interpretation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing knowledge of methoxyacetylfentanyl toxicology and providing data to facilitate interpretation of urinary findings in fentanyl analog intoxications.

Methoxyacetylfentanyl is a fentanyl analog in which the propionamide group is replaced by a 2-methoxyacetamide group. It contributed to 11 intoxications in Sweden between 2016 and 2018. In this study, urinary metabolites in eight fatal cases involving methoxyacetylfentanyl (all male, age 27–41) were analyzed. Femoral blood concentrations ranged from 17–140ng/g and the Cause Of Death (COD) was intoxication, except for one case listing COD as acute complications of an underlying heart disease but with possible contribution from methoxyacetylfentanyl. The hypothesis was that urinary metabolite profiles might correlate to the time between intake and death, potentially indicating a short period of abstinence before the last dose.

Urinary metabolites were analyzed by Liquid Chromatography/quadrupole Time-Of-Flight/Mass Spectrometry LC/qTOF/MS (Agilent® 1290/6550) with and without hydrolysis with  $\beta$ -glucuronidase/arylsulfatase. Samples were diluted 1:4 in 1M sodium acetate buffer pH 5 and a negative urine sample was included as a control. The metabolites were separated on an Acquity® HSS T3 column (150 × 2.1mm, 1.8 $\mu$ m, Waters®) using a 13min gradient from 1%–40% acetonitrile with 0.1% formic acid in both solvents (60°C, 0.5mL/min). The method was not quantitative; but for individual analytes, peak areas generally correlate well with concentration. For confirmation of identified metabolites, methoxyacetylfentanyl was incubated with hepatocytes (5 $\mu$ M, 1 million cells/mL). Duplicate incubations for zero, one, three, and five hours were analyzed with the same method as the urine samples.

In total, 25 urinary metabolites were found, including eight glucuronides. Major biotransformations were O-demethylation, dealkylation to form the nor-metabolite, mono- and dihydroxylations of the phenethyl moiety (the latter with subsequent methylation), as well as combinations thereof. Methoxyacetylfentanyl was detected as the parent compound in all cases, and the most abundant metabolites in hydrolyzed urine samples included O-desmethyl-, O-desmethyl, phenethyl-hydroxy-, phenethyl-hydroxymethoxy-, and normethoxyacetylfentanyl.

When looking at the abundances of the parent compound methoxyacetylfentanyl, M21 (O-desmethyl) and M18 (glucuronide of M21) in urine, three distinct groups were observed. In three cases, the abundances of methoxyacetylfentanyl, M18 and M21 were all low (<380k, <21k, and <270k counts, respectively), which in combination with a substantial concentration in femoral blood (21–140ng/g) may indicate an acute intake while abstinent and a “rapid” death. In two of those cases, a syringe was found at the scene, suggesting intravenous administration and a rapid onset.

In two other cases, the abundances of methoxyacetylfentanyl (>2,400k) and M21 (>1,200k) were high while the abundance of M18 was low (<280k). This could indicate an acute intake while abstinent but a more delayed death where phase I metabolite M21 was formed and at least some phase II metabolite M18 was produced. Femoral blood concentrations were 17 and 31ng/g. In hepatocytes, M21 reached a plateau after 1h while M18 was still increasing at 5h of incubation.

In the remaining three cases, the abundances of methoxyacetylfentanyl (>3,000k) as well as both M18 (>2,300k) and M21 (>9,300k) were high, which could be indicative of an acute intoxication in a chronic user. (This group includes the case in which methoxyacetylfentanyl was a possible contribution to complications of heart disease.) Femoral blood concentrations were 18–51ng/g.

Based on eight cases, the major urinary metabolites of methoxyacetylfentanyl were identified. Differences in the abundance of methoxyacetylfentanyl and its major metabolites could be interpreted to indicate fatal intoxications in abstinent or chronic users. It is postulated that urinary concentrations of methoxyacetylfentanyl and two metabolites, in combination with the methoxyacetylfentanyl concentration in femoral blood, might be good indicators of the time between administration and death as well as prior use. However, to verify this, further (preferably quantitative) measurements of urinary methoxyacetylfentanyl, M18, and M21 in cases with well-established case histories are needed.

### Methoxyacetylfentanyl, Fatal Intoxication, Metabolites

## K71 Identification and Quantification of Classic, Prescription, and Synthetic Opioids in Hair by Liquid Chromatography Tandem Mass Spectrometry (LC/MS/MS)

Natalia A. Platosz, BS\*, John Jay College of Criminal Justice, New York, NY 10019; Marta Concheiro-Guisan, PhD, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** After attending this presentation, attendees will better understand how hair can be used as a matrix to identify and quantify different types of opioids, including fentanyl and derivatives, using Solid Phase Extraction (SPE) and LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a validated method for the confirmation of a comprehensive panel of opioids, including classic, prescription, and synthetic opioids, in hair. The current widespread misuse of both prescription and non-prescription opioids in the United States has reached an epidemic status. According to the United States Department of Health and Human Services, every day more than 130 people in the United States die after overdosing on opioids, and 2.1 million had an opioid use disorder in 2016. Drug testing tools to monitor opioid use and abuse habits in both the living and postmortem are necessary to understand the opioid use pattern, identify risk groups, and cause of death. Hair is becoming an alternative matrix of increasing interest in forensic toxicology to investigate drug use and abuse patterns due to its long window of detection. Hair growth rate is about 1cm/month; therefore, segmental hair analysis provides information of drug exposure from at least one to several months before samples collection.

**Hypothesis:** Highly sensitive and specific identification and quantification of a comprehensive panel of opioids in hair samples can be achieved utilizing SPE as a sample preparation and LC/MS/MS as an instrumental technique.

**Method:** This procedure allows for the confirmation of 27 opioids (8 classic and prescription opioids and 19 synthetic opioids) in 25mg of hair. After hair decontamination, the sample was pulverized using a beadmill. To 25mg of this powder, 15 internal standards (morphine-d3, codeine-d3, 6-acetylmorphine-d3, hydrocodone-d6, hydromorphone-d3, oxycodone-d3, fentanyl-d5, norfentanyl-d5, EDDP-d3, methadone-d3, oxymorphone-d3, tramadol-13C-d3, sufentanyl-d5, isobutyryl fentanyl-d5, and valeryl fentanyl-d5) and 2mL of digestion solution (0.01% formic acid + 2.5mM ammonium formate in water and methanol, 95:5, v/v) was added. The hair sample was digested overnight at 37°C in a heating block. The digestion was cleaned of interferences using a Phenomenex® Strata™-XC Strong Cation SPE cartridge. The elutants were dried under nitrogen and reconstituted using the initial mobile phase concentration (A:B, 95:5, v/v) containing 0.01% formic acid + 2.5mM ammonium formate (A) and acetonitrile (B) prior to LC/MS/MS analysis.

The chromatographic separation was performed in gradient mode employing a 100 x 2.1mm Kintex® C-18 analytical column with a 1.7µm particle size and mobile phases A and B. The gradient was programmed to run from 5% to 20% acetonitrile for 3min, 20% to 28% for 11min, 28% to 95% for 10min, then back to 5% for 1min, along with a 5min equilibration for a total run time of 30min. These chromatographic conditions were capable of resolving closely eluting isomers, such as 3-methylfentanyl, butyryl fentanyl, and isobutyryl fentanyl. The Shimadzu® mass spectrometer triple quadrupole LC/MS-8050 was employed in electron spray ionization positive mode, and two multiple reaction monitoring transitions were acquired per analyte.

The Limit Of Quantification (LOQ) was established to be 1pg/mg (3-methyl-fentanyl, 4-anpp, 4-methoxy-butyryl-fentanyl, acetyl fentanyl, acryl-fentanyl, alfentanil, butyryl fentanyl, carfentanil, EDDP, fentanyl, furanyl-fentanyl, isobutyryl fentanyl, MT-45, para-fluorobutyryl fentanyl, sufentanil, U-47700, and valeryl fentanyl), 10pg/mg (6-acetylmorphine, hydrocodone, methadone, morphine, norfentanyl, oxycodone, oxymorphone, and tramadol), or 100pg/mg (codeine and hydromorphone). The method was fully validated following the Scientific Working Group for Forensic Toxicology (SWGTOX) guidelines. The parameters evaluated were linearity, limit of detection and LOQ, imprecision, accuracy, carryover, matrix effects, extraction efficiency, process efficiency, interferences, and autosampler stability.

**Conclusion:** A sensitive and specific method was developed for the identification and quantification of 27 classic, prescription, and synthetic opioids in hair by LC/MS/MS.

### Opioids, Hair, LC/MS/MS

## K72 Assessment of Postmortem Liver Samples Using a Validated Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) Extraction for Fentanyl and Metabolites With Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Analysis

Joseph A. Cox, MS\*, Morgantown, WV 26508; Colby E. Ott, MS, Shippensburg, PA 17257; Joseph A. DelTondo, DO, Allegheny General Hospital, Pathology, Pittsburgh, PA 15212; James C. Kraner, PhD, Office of the Chief Medical Examiner, Charleston, WV 25302; Kristen M. Bailey, MS, Office of the Chief Medical Examiner, Charleston, WV 25302; Myron A. Gebhardt, MS, Office of the Chief Medical Examiner, Charleston, WV 25302; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will better understand a modified QuEChERS extraction combined with a sensitive method for determining concentrations for fentanyl and two known metabolites, norfentanyl and despropionyl fentanyl (4-ANPP), in postmortem liver specimens using LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relaying a procedure that utilizes the unique properties of a QuEChERS extraction with modifications to allow for the extraction of fentanyl and metabolites from challenging postmortem matrices.

The opioid crisis in the United States has a serious impact on society. According to the National Institute on Drug Abuse (NIDA), more than 100 people die every day of opioid overdose. Even more concerning is the increase of overdose deaths involving synthetic opioids (e.g., fentanyl and fentanyl analogs), with increases from 3,105 deaths in 2013 to 28,466 deaths in 2017 (a 915% increase). In a forensic postmortem toxicological workflow, various specimens are often submitted for testing, including urine, blood, liver, kidney, and other tissues. For medicolegal death investigations, the interpretation of toxicological findings is a key component to establish the cause of death of an individual.

Common practices for tissue extractions involve Solid Phase Extraction (SPE) or Liquid-Liquid Extraction (LLE), but the process for these techniques can be time consuming and often involve tissue homogenization using blenders that could allow cross-contamination. In recent years, a QuEChERS extraction protocol was introduced in the market to deal with samples with a high content of fatty materials. By its nature, the liver contains many lipids that can contribute to matrix effects and be problematic for instrumentation. QuEChERS is ideal for tissue extractions due to its two-part process that allows for a direct extraction with organic solvent in the first stage, followed by a dispersive-solid phase extraction step. QuEChERS embraces the advantages of LLE, direct extraction from tissue with an organic solvent and cost effectiveness, combined with the advantages of SPE, reduction of matrix effects and impurities, without sacrificing selectivity or robustness.

In this study, the use of a modified QuEChERS extraction was demonstrated for testing a 0.2g liver sample. Homogenization was achieved using a Retsch® MM 200 high-speed mixer mill with homemade attachments for 1.7mL centrifuge tubes and 4.5mm stainless steel balls for pulverization, reducing the risk of cross-contamination by producing a homogenized sample in a single disposable tube. The quantification method was performed on an Agilent® 6470 Triple Quad Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) system. Chromatographic separation was achieved on a Zorbax® Eclipse Plus™ C18 RRHD 3.0x100mm, 1.8µm column with 0.1% formic acid and 5mM ammonium formate in water (mobile phase A) and 0.1% formic acid in methanol (mobile phase B).

The validation of a QuEChERS extraction protocol is presented in this study as an alternative analytical method for efficient extraction and detection of fentanyl and its primary metabolites, norfentanyl and 4-ANPP. The LC/MS/MS analysis was validated following the American Academy of Forensic Sciences Standards Board (ASB) standard 036 guidelines. The evaluated parameters include selectivity, matrix effects, linearity, bias, precision, processed sample stability, and proof of applicability using authentic fentanyl case samples.

The validation of the quantitative method for fentanyl, norfentanyl, and 4-ANPP was performed with a Limit Of Detection (LOD) of 0.1µg/kg and an Analytical Measurement Range (AMR) of 0.5 to 100µg/kg. Overall, the QuEChERS technique met all the acceptable criteria set by Matuszewski et al. with recoveries higher than 90.2%, matrix effects greater than 80.4%, and process efficiencies greater than 76.7% with %CV values below 12.8% for all target analytes.<sup>1</sup> The authentic case samples ranged in fentanyl concentrations from 56.6 to 462.3µg/kg with a mean of 149.2µg/kg ( $n=10$ ). The range of norfentanyl concentrations was 1.9 to 50.0µg/kg with a mean of 14.1µg/kg ( $n=10$ ). The range of 4-ANPP concentrations was 3.2 to 23.7µg/kg with a mean of 7.5µg/kg ( $n=7$ ).

The method was validated and the calibration curves reconcile well with forensic toxicology criteria. The extraction and LC/MS/MS method developed for the analysis of liver tissue for fentanyl, norfentanyl, and 4-ANPP is precise, sensitive, and reproducible at forensically relevant concentrations.

### **K73 A Food and Drug Administration (FDA) -Cleared Immunoassay Screen and Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) Confirmation for Benzodiazepines in Hair**

*Neil Stowe, PhD\*, Psychomedics Corporation, Culver City, CA 90230; Ryan B. Paulsen, PhD, Psychomedics Corporation, Culver City, CA 90230; Virginia Hill, BS, Psychomedics Corporation, Culver City, CA 90230; Michael I. Schaffer, PhD, Psychomedics Corporation, Culver City, CA 90230*

**Learning Overview:** After attending this presentation, attendees will have learned the performance characteristics of an FDA-cleared immunoassay for benzodiazepines in hair, and the concentrations of selected benzodiazepines in hair samples after an extended aqueous wash. The concentrations are determined via LC/MS/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing knowledge regarding methods useful for determining the concentrations of selected benzodiazepines in hair samples.

**Hypothesis:** Benzodiazepines could be detected in hair samples using a patented digestion method to remove the drug from hair, followed by a qualitative enzyme immunoassay screen. The benzodiazepine concentrations could then be determined quantitatively in hair using LC/MS/MS.

Hair samples were screened by: (1) drug extraction from hair using a patented method (United States Patent 8,084,215), and (2) performing an in-house developed microplate immunoassay using a selected monoclonal antibody with an oxazepam cutoff at 1ng/10mg hair and controls at -50/+100% of the cutoff. The immunoassay is designed for qualitative use and has been cleared by the FDA (k163590). Cross-reactivity of the immunoassay with selected benzodiazepines using oxazepam calibrator was alprazolam (277%), lorazepam (13%), diazepam (550%), nordiazepam (220%), oxazepam (100%), and temazepam (312%). The effects of cosmetic treatments (permanent wave, dye and bleach, relaxer, and shampoo) using benzodiazepine negative and positive samples in the immunoassay were determined. In this study, all negative hair samples remained negative after treatment, with all positive samples remaining positive after treatment. A comparison study ( $n=392$ ) of the immunoassay with LC/MS/MS results after an extended aqueous wash was conducted with stored samples previously received for workplace drug testing by the Psychomedics laboratory. All samples identified as negative by the immunoassay were confirmed as negative by LC/MS/MS ( $n=234$ ). One hundred thirty-four samples identified as positive by the immunoassay were confirmed positive by LC/MS/MS. Twenty-four samples identified as positive by the immunoassay were confirmed below the cutoff but containing drug above Lower Limit of Quantification (LLOQ) by LC/MS/MS after an extended aqueous wash.

The confirmation process consisted of a new hair aliquot that was first washed using an extended aqueous method followed by solid phase extraction and quantitation using an AB SCIEX™ API 3200 for LC/MS/MS confirmation using primary and secondary ions for each analyte in positive multiple reaction mode. The benzodiazepines confirmed were alprazolam, lorazepam, diazepam, nordiazepam, oxazepam, and temazepam. The cutoff for the confirmation was set at 0.2ng benzodiazepine/10mg hair. The LC/MS/MS method was linear from 0.05 to 20ng/10 mg with LLOQ of 0.05ng/10mg hair for all analytes. The LC/MS/MS method was reviewed and cleared by the FDA as a part of the benzodiazepine 510k process (k163590).

**Conclusion:** The first-of-its-kind, FDA-cleared, immunoassay screen and LC/MS/MS confirmation for benzodiazepines in hair has been presented. This study has provided the hair concentrations of six benzodiazepines analyzed by the assay.

#### **Benzodiazepines, Immunoassay, Hair**

## K74 Developing a Raman Microspectrophotometric Method to Quantitate Carboxyhemoglobin (COHb) in CO-Exposed Blood Samples

Haley Melbourn, MS\*, Raritan, NJ 08869; Marianne E. Staretz, PhD, Cedar Crest College, Allentown, PA 18104; Heather Maldonado, MS, Wilmington, DE 19801; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** After attending this presentation, attendees will understand how Raman microspectrophotometry may be used to quantitate the COHb concentration of blood samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a novel method for COHb quantitation using Raman microspectrophotometry that is comparable with established spectrophotometric methods while eliminating the need for time-consuming sample preparation and limiting the use of consumables and the generation of waste.

COHb quantitation is a routine toxicological analysis performed in cases of acute carbon monoxide poisoning. Quick and easy-to-use methods of COHb quantitation include spectrophotometry and CO-oximetry, although these methods can be inaccurate and imprecise both at low concentrations and in putrefied postmortem specimens. More reliable gas chromatographic quantitation methods are available as well, but these require extensive sample preparation and, therefore, require elevated use of consumables and increased analysis time. The goal of this study was to develop a Raman microspectrophotometric COHb quantitation method and assess its precision and accuracy in estimating the COHb concentration of ten experimental unknown samples that were subsequently analyzed using an Ultraviolet (UV)-visible spectrophotometric method.

A Thermo Scientific™ DXR2 Raman microscope equipped with a 785nm laser was used to determine the COHb concentration of the samples analyzed for this study. Stock solutions of 0% and 100% COHb were prepared by bubbling ultra-zero air and carbon monoxide, respectively, through whole human blood (healthy living donor, gender not specified) containing K<sub>2</sub>EDTA anticoagulant for 30 minutes. A total of eight calibrator sets ranging from 0%–100% COHb at 10% increments were prepared via appropriate dilution of the stock solutions. These calibrators were deposited in 20- $\mu$ L aliquots onto aluminum foil-covered microscope slides, which were then subsequently dried in a fume hood for at least one hour prior to analysis. Spectra were acquired at ten separate locations on each sample, and these spectra were then averaged to provide a representative Raman spectrum of each sample. All spectra acquired were preprocessed in the OMNIC™ for Dispersive Raman software (version 9.8.372) using a sixth-order polynomial fluorescence correction prior to data analysis.

A strong linear correlation (*Average*  $R^2=0.98$ ) was found to exist between COHb concentration and the ratio of the peak intensities at approximately 1,552 $\text{cm}^{-1}$  and 1,580 $\text{cm}^{-1}$ . From the eight calibration curves analyzed, the limits of detection and quantitation were found to be 4.4% and 13.2% COHb, respectively. Intra- and inter-day studies of three calibrators (10%, 30%, and 50% COHb) indicated high precision, with the coefficient of variation ranging from 0.85%–4.26%. The accuracy of this method was evaluated through the quantitation of ten experimental unknowns, each analyzed in triplicate. Using the proposed Raman microspectrophotometric method, the true concentrations of seven of the unknowns were within the 95% confidence limits of the predicted COHb concentrations, with the percent error ranging from 2.00%–54.00%. The highest error was associated with unknowns having a COHb concentration at or below 10% COHb, below the limit of quantitation. The unknowns were subsequently analyzed using a Cary 3500 UV-Visible spectrophotometer, resulting in only six of the unknowns' true concentrations being within the 95% confidence limits of the predicted COHb concentrations, with the percent error ranging from 6.86%–77.20%. In this case, the highest error was associated with an unknown that had been correctly quantitated via the Raman microspectrophotometric method with a percent error of 3.60%.

This study demonstrates that Raman microspectrophotometry may be used to quantitate the COHb concentration of blood samples. Furthermore, this method is comparable with established spectrophotometric methods while eliminating the need for time-consuming sample preparation and limiting the use of consumables and the generation of waste.

### Carbon Monoxide, Carboxyhemoglobin (COHb), Raman Microspectrophotometry

## K75 EtG/EtS in Ethanol Negative Urine Specimens From Sexual Assault Victims

*Kristin W. Kahl, MS\*, University of Miami Toxicology Laboratory, Miami, FL 33136; Lisa J. Reidy, PhD, University of Miami Forensic Toxicology Laboratory, Miami, FL 33136*

**Learning Overview:** After attending this presentation, attendees will understand the significance of urine Ethyl Glucuronide/Ethyl Sulfate (EtG/EtS) testing in sexual assault cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data demonstrating the usefulness of EtG/EtS urine quantitation from victims of sexual assault where alcohol is indicated but ethanol is not detected.

EtG and EtS are minor metabolites of ethanol that have traditionally been used as biomarkers of ethanol use in abstinence programs due to their longer half-lives relative to ethanol. The longer half-lives of these metabolites may also be useful for crimes where reporting and sample collection times may vary, such as Drug-Facilitated Crimes (DFC). The classification of a DFC includes Drug-Facilitated Sexual Assaults (DFSA). According to literature, ethanol is the most frequent drug detected in DFSA victims; however, due to the variation in reporting and sample collection times, some victims may not have blood or urine collected until hours or days after the alleged incident. Delays in sample collection can result in specimens being negative for ethanol, even if the victim was intoxicated at the time of the incident. This study investigates whether EtG and EtS are useful markers of ethanol use in DFSA cases where urine specimens are negative for ethanol.

Urine specimens utilized in this study were from suspected DFSA victims submitted to the University of Miami Toxicology Laboratory (UMTL) from June 2018 to July 2019. Specimens were first analyzed for ethanol using Headspace/Gas Chromatography/Flame Ionization Detector/Mass Spectrometry (HS/GC/FID-HS/GC/MS/FID) with a Limit Of Detection (LOD) of 0.01g/100mL. If ethanol was not detected in a urine specimen and alcohol was indicated from case histories, the specimens were analyzed for EtG and EtS by Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS). The quantitative EtG/EtS method was validated according to the Scientific Working Group for Forensic Toxicology (SWGTOX) validation guidelines.

The quantitation range for EtG was 200–10,000ng/mL (LOD 100ng/mL) and 50–2,500ng/mL for EtS (LOD of 25ng/mL) with a 1/x linear model. No significant matrix effects or carryover were observed. A dilution study was also performed during validation and case specimens were diluted, when necessary. Due to EtG being produced without the ingestion of ethanol, EtG is only reported if EtS is also present in the urine specimen. Case information and history were taken from sexual assault cases forms. The quantitative results, ratio of EtG:EtS, and case information were reviewed for each case.

Between June 2018 and July 2019, 167 urine DFC cases were submitted to the UMTL, of which 70 specimens were tested for EtG/EtS. Neither EtG nor EtS was detected in 12 of the specimens. Sixty-four cases directly stated, or indicated, that alcohol may have been involved in the incident, but no ethanol was detected. Of the cases in which alcohol was indicated, EtG and/or EtS was reported in 57 (89%) of the cases. The concentration of EtG ranged from 212ng/mL–467,650ng/mL and 60–117,650ng/mL for EtS. In seven cases, both EtG and EtS or only EtS were detected but were less than the lower limit of quantitation. The ratio of EtG:EtS ranged from 0.84–12.96 (mean: 3.85, median: 2.67). The range of time elapsed from the time of the incident to sample collection was 7–137h. Seven specimens were collected within 0–12h, 24 specimens were collected within 13–24 h, 16 specimens were collected within 24–48 h, and 23 specimens had unknown collection times or were collected more than 48 hours after the alleged incident.

Although testing for EtG/EtS in DFSA cases is not considered routine, the results presented show a high level of consistency between self-reported alcohol use and the detection of EtG/EtS in urine specimens when ethanol is not detected. The results also show that although sample collection times after the alleged incident can vary, EtG/EtS are still able to be detected for multiple days after ethanol ingestion, thereby corroborating the victim's statement of alcohol use.

### Sexual Assault, Ethyl Glucuronide, Ethyl Sulfate

## K76 Postmortem Pediatric Forensic Toxicology

Robert A. Middleberg, PhD\*, NMS Labs, Willow Grove, PA 19090; Nikolas P. Lemos, PhD, Lemos Toxicology Services, San Francisco, CA 94114; Andrew M. Baker, MD\*, Hennepin County Medical Examiner's Office, Minneapolis, MN 55415; Loralie Langman, PhD\*, Mayo Clinic, Rochester, MN 55905; Chris Milroy, MD, LLB\*, Ottawa Hospital, Ottawa, ON K1H 8L6, CANADA

**Learning Overview:** After attending this presentation, attendees will have gained an appreciation for the challenges unique to toxicological findings in postmortem pediatric cases. Attendees will learn interpretive guidelines for pediatric cases involving forensic toxicology in both a general and case-specific sense.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by further delineating the interpretive aspects of toxicological findings in the pediatric population.

In this 20<sup>th</sup> Annual Special Session within the Toxicology section, pediatric cases involving toxicological findings are discussed. As a relative dearth of interpretive information involving toxicological findings in the pediatric population exists, this session is a forum to help elucidate and clarify such issues. The format is a short case presentation or issue-specific concern, including pharmaco- toxicokinetic data and other relevant ancillary information, followed by audience participation to provide interpretive clarity around case-specific impacts of the toxicological findings. This session, attended by various sections of the Academy, allows for various perspectives of case issues that lead to integrative consensus, or differing opinions, as to cause of death in children.

Four cases will be presented that highlight the difficulty in assessing the role of toxicants in each case or the lengths one must go to in some cases to reach some interpretive value. Chris Milroy, MD, LLB, Andrew Baker, MD, Loralie Langman, PhD, and Robert A. Middleberg, PhD will be reviewing cases from their experience as forensic pathologists and toxicologists that highlight the issues and confounders in the pediatric population.

Dr. Milroy will be discussing a case involving diphenhydramine with an interesting twist. While cases involving diphenhydramine in young children have been reported and summarized in postmortem literature, each case presents challenges due to the pharmacological nature of the substance and other potential co-morbidities.

Dr. Baker will focus on an unresolved case involving an elevated sodium finding in vitreous humor in a 6-year-old. He will explore possible explanations given the case history and seek audience input to further case closure.

Dr. Langman will introduce a case of *in utero* death. As these cases are particularly challenging in respect to toxicological findings, continued discussions on this subject matter will hopefully bring some clarity to case findings in these deaths.

Dr. Middleberg will present a case of a 14-year-old female who was tortured and killed by her mother and mother's boyfriend. The dismembered body was found to contain what appeared to be high concentrations of diphenhydramine. Questions surrounding the findings were significant in respect to manner and cause of death and the ultimate outcome of the case.

### Pediatric, Toxicology, Postmortem

### LW1 The Murder of Matt Warren: Father of Former Alameda County Prosecutor, Three-Time California Governor, and Supreme Court of the United States (SCOTUS) Chief Justice Earl Warren

Gregory E. Laskowski, MPA\*, *Criminalistics Services International, LLC, Bakersfield, CA 93308*; Chris Livingston, MLIS\*, *California State University Bakersfield, Bakersfield, CA 93311*

---

**Learning Overview:** After attending this presentation, attendees will learn about the investigation of an unsolved murder from 1938. Attendees will learn about the investigative techniques of a high-profile murder case of the time and will also learn how modern investigative methods can be applied to a crime scene from more than 80 years ago.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing knowledge when reviewing historical evidence in the form of documents and crime scene photographs. Attendees may catch a glimpse into the thinking of a famous political figure and how the death of his father may have influenced his decisions as Chief Justice of the Supreme Court.

On May 14, 1938, Methias Warren, father of former United States Supreme Court Justice Earl Warren (*Brown v. Board of Education*), presidential candidate, three-time Governor of California, and chair of the infamous commission investigating the assassination of John F. Kennedy (JFK) that bears his name, was found bludgeoned to death in his home at 707 Niles Street in Bakersfield, CA. Many theories regarding the identity of the killer and the motive were asserted. Many argued that the assailant was most likely a transient. However, the evidence points to other plausible motives. There were many other “whodunit” theories, and, to this day, the case remains an unsolved mystery.

Eighty years later, the Historical Research Center on the campus of California State University, Bakersfield accessioned the records of the Kern County Superior Court. Buried within this body of records is information that sheds light on this cold case. Records include police reports, crime scene photographs, interviews, autopsy photographs, coroner’s inquest, and newspaper articles of the day. A “dream team” of investigators was assembled representing multiple law enforcement agencies across the state of California. These were the “crack” investigators of the day. Newspapers of the day published detailed descriptions of the crime scene. Readers even had glimpses into the published photographs of the crime scene. Yet, the case remains unsolved, even when the “third degree” was employed while questioning suspects. Tensions developed between the local law enforcement officials charged with investigating the crime and the handpicked investigators brought in by Warren.

While limited forensic science applications were applied in this case, the evidence recorded at the time was such that those techniques could have been employed. Techniques such as latent fingerprint development, footwear examination and comparison, and bloodstain pattern analysis are but a few that might have been employed at that time. This begs the question: What effect did not knowing who committed the murder of his father have on the chief justice? Could a case decision that resulted in the issuance of the Miranda warning or his desire to determine what happened in the assassination of JFK been a result of his anxiety? What could have turned a staunch Republican into the overseer of what was considered a liberal Supreme Court? This presentation will discuss this evidence, reflecting upon the investigative techniques of the time, the political implications, and brief bloodstain pattern analysis of the crime scene based upon evidence photographs.

---

#### Warren, SCOTUS, Murder

### LW2 Old Shaky: The C-124 Globemaster

*James McGivney, DMD\*, Saint Louis, MO 63119*

---

**Learning Overview:** After attending this presentation, attendees will understand the role of the C-124 Globemaster in the aviation history of the United States military and its involvement in a number of mass disasters.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by detailing the history of the C-124 Globemaster.

Back in the day, the C-124 Globemaster was the largest military transport ever manufactured. The plane had two decks and could carry 200 fully equipped soldiers or serve as a hospital transport for 124 patients on litters along with their attending staff. As a cargo hauler, it could carry tanks, guns, trucks, and other heavy equipment. It was the only aircraft of its time capable of transporting heavy equipment, such as tanks and bulldozers, without disassembling the equipment.

The plane did not see any service in World War II but was developed from a prototype of the World War II-era Douglas C-74 Globemaster and from lessons learned during the Berlin Airlift. The C-124's design featured two large clamshell doors and a hydraulically actuated ramp in the nose, as well as a cargo elevator under the aft fuselage.

The first deliveries of the Globemaster began in May 1950 and continued until 1955 with a total of 448 aircraft. The C-124 was operational during the Korean War and was also used to assist supply operations for Operation Deep Freeze in Antarctica. The aircraft performed heavy lift cargo operations for the United States military worldwide, including flights to Southeast Asia, Africa, and elsewhere. From 1959 to 1961, they transported Thor missiles across the Atlantic to England. The C-124 was also used extensively during the Vietnam War transporting materiel from the United States to Vietnam. Until the C-5A became operational, the C-124, and its sister, the turboprop C-133 Cargomaster, were the only aircraft available that could transport very large loads.

The plane was powered by four Pratt & Whitney piston engines-rated at 3,800hp that could push it through the air at a speed of 320mph, at a range of almost 2,200 miles. It could carry 216,000lbs., maximum.

“Old Shaky’s” name derived from the large Pratt & Whitney piston engines, which had cylinders the size of coffee cans. The noisy conglomeration of connecting rods, push rods, and pistons made for a deafening roar and a shaky plane ride.

The Pratt & Whitney R-4360 Wasp Major was the largest mass-produced aircraft piston engine ever made. It was a 28-cylinder, 71-liter, 56 sparkplug, air-cooled radial monster. It was initially supercharged. The final evolution of the Wasp Major incorporated a turbocharger as well.

The plane was involved in several noteworthy accidents. In 1951, a Globemaster ditched in the Atlantic Ocean off of Ireland due to a cargo fire. Initially, a search plane spotted men in life rafts, but when rescue vessels arrived on scene, no survivors or rafts were found.

In November 1952, a C-124A that left McChord Air Force Base in Washington state crashed into the Colony Glacier on Mount Garrett, some 40 miles east of Anchorage, AK. All 41 passengers and 11 crew members were lost. Sixty years later, debris from the plane and remains of some of the victims were found by the Alaska National Guard on June 10, 2012, having apparently been uncovered due to the receding of the glacier. By 2014, remains of 17 victims had been recovered and identified by the Defense POW/MIA Accounting Agency (DPAA).

On June 18, 1953, a Globemaster took off from Tachikawa Air Base in Japan. Shortly after takeoff, one of the engines failed, forcing the pilot to make an emergency landing. Due to a loss of airspeed, the pilot lost control and crashed into a melon patch, killing all 7 crew members and 122 passengers. At the time, these 129 fatalities constituted the worst accident in aviation history and would not be exceeded until a midair crash over New York City in 1960.

### Aviation, Globemaster, Mass Disaster

### LW3 Murder of the Schoolmarm: The First School Shooting

*Alexander Jason, BA\*, ANITE Group, Pinole, CA 94564*

---

**Learning Overview:** The goal of this presentation is for attendees to become familiar with techniques of shooting incident reconstruction and evidence collection used in a historic 1850 shooting incident.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how firearms evidence was utilized in an early (1850) shooting reconstruction and how the same techniques can be currently utilized to perform a shooting reconstruction.

This incident was an early documented shooting reconstruction and from historical research it appears to be the first school shooting in the United States.

In 1850, the local schoolmarm was fatally shot as she attempted to unlock the one-room schoolhouse early one morning. The weapon was a shotgun. The fatal wounds were in the left side of her head where pellets had penetrated. There were also pellet strikes on the schoolhouse door, which was behind her. There were no witnesses, but one key piece of evidence was a shotgun wadding found between a nearby tree and the schoolhouse. The wadding was a small section of paper that, after an investigation by the local sheriff, incriminated a young man who was charged with murder. A basic shooting reconstruction was performed by placing a broom straw into one of the perforating holes in the schoolhouse door. This straw pointed back toward a location near a tree where footprints were found in the dirt, which also implicated the suspect. Although the suspect denied involvement in the shooting, key evidence was recovered from his clothing that proved to be of high probative value. The suspect was charged with the murder and a trial was held.

The historical official records of the trial were obtained and the details of this incident made possible a review of the investigation and the trial testimony, which was hand-recorded in the courtroom. The trial resulted in the defendant being found guilty and sentenced to death by hanging.

A key element in the trial was examined in this study's experiment utilizing a similar black powder shotgun and newspaper. High-speed videography was used to show several aspects of the projectiles and wadding dynamics. The purpose of the experiment was to determine the possibility that paper used as wadding would not be burnt or destroyed during the black powder ignition. This presentation will show how the trajectory reconstruction was performed and how the paper wadding was used to convict the suspect. A video demonstration and re-enactment will be utilized to demonstrate the operation of the double-barrel black powder shotgun used in the incident and how the paper wadding was identified to the suspect.

---

### Shooting Reconstruction, Shotgun, School Shooting

### LW4 To Infinity and Beyond: E.T. at the Crime Scene and the Forensic Challenges of the Current Era

Matteo Borrini, PhD\*, Liverpool John Moores University, Liverpool, AE L3 3AF, UNITED KINGDOM

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how modern multicultural society represents a challenge for forensic investigators.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing examples of the problems offered to the investigators by the current multicultural environment and movements of populations.

The history of the American Academy of Forensic Sciences (AAFS), established in 1948, and that of the so-called modern ufology that begins with the Kenneth Arnold “flying saucer” sighting on June 1947, are almost contemporary. However, they are two completely different worlds: the first based on the rigorous application of scientific principles for legal purposes, the other on the use of a (pseudo)scientific method to search evidence of contacts with intelligent entities from other planets.

But what would happen if we cross borders and combine these two worlds? What would happen, in a hypothetical scenario, if E.T. crossed the boundaries of the galaxy and interacted with the human world?

In previous AAFS scientific meetings, it has been demonstrated how topics apparently far from the forensic world may instead represent food for thought in the investigation of ancient beliefs, of historical murders, or ritual practices.<sup>1-4</sup> In addition, these unusual topics can provide a springboard for teaching and dissemination of forensic sciences.<sup>5</sup>

The approach to the ufological world is aligned with the intention of the previous presentations, but also offers a further opportunity of analysis on the theme of “other” populations. Currently, millions of people interact and cross borders, creating multiethnic nations. This scenario represents a new and greater challenge for forensic practitioners, especially for those (e.g., anthropologists) involved in the identifications of unknown individuals.

The examination of the supposed alien abduction cases and the related testimonies under regressive hypnosis is an excellent example of the dangerous use of some interview techniques. These reports are also a fertile ground for the evaluation of eyewitness statements, offering the possibility to study the mechanisms of (false) memories. It is known how testimonial evidence can create difficulties in the reconstruction and interpretation of criminal events if recorded without well-established protocols.

In addition, the critical analysis of the so-called “alien autopsy video” related to the supposed Roswell Unidentified Flying Object (UFO) crash is useful for both teaching and scientific purposes. The examination of the film allows not only the debunking of this video, but also the opportunity to analyze and discuss the evolution of autopsy techniques, particularly in contexts of Disaster Victim Identification (DVI) and mass disasters.

Finally, the cute alien E.T. and all the creatures from other planets depicted in science-fiction movies are metaphors of the problems related to foreign individuals that cross the borders without documents. If people travel without leaving a trace of their movements in the country of origin and arrival, they become vulnerable subjects who may be involved in crimes as victims or offenders. The lack of data makes their identification and protection difficult and sometimes impossible.

Although aliens have never crossed the galaxy’s borders to reach our planet, their fictional stories can inspire the forensic community to cross the boundaries of science to develop new strategies to guarantee protection and safety for everyone in new, multicultural societies.

The goal of this presentation is to provide an opportunity to discuss some of the forensic aspects related to a new reality, where individuals increasingly move between countries, and the forensic community is called upon to guarantee the safety and security of everyone.

### LW5 Leonhard Euler's Mysterious Blindness and Fever

*John David Bullock, MD, MPH\*, Winchester, MA 01890; Harrison B. Hawley, MD, Miami Valley Hospital, Dayton, OH 45409-2902; Ronald E. Warwar, MD, Warwar Eye Group, Dayton, OH 45409*

---

**Learning Overview:** The goals of this presentation are for the attendee to: (1) learn how to analyze historical data in order to make a retrospective diagnosis; and (2) learn about brucellosis

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how to analyze historical/biographical data in order to diagnose distant events/conditions.

The renowned Swiss polymath Leonhard Euler (1707-1783; spent the vast majority of his adult life at the St. Petersburg Academy of Sciences in Russia) is often grouped along with Archimedes, Newton, Gauss, and Riemann as one of the five most famous mathematicians of all time and the most prolific. He produced 886 papers and books and is honored by 96 eponymous mathematical terms. He introduced the concept of a function,  $f(x)$ , the modern notations in trigonometry, and the mathematical symbols:  $e$ , for the base of the natural logarithm;  $\sigma$ , for summation; and  $i$ , the imaginary number representing the square root of minus 1. He popularized  $\pi$ . He derived "Euler's identity,"  $1 + e + i + e^i = 0$ , which has been called the "most remarkable formula in mathematics" by Nobel Laureate Richard Feynman, and he was the first to present Newtonian dynamics in mathematical form. He has been honored by stamps, currency, a Paris street, and a lunar crater.

In 1735, at age 28, he developed an inexplicable and near-fatal febrile disease that spontaneously remitted. A mezzotint copy by Vassili Sokolow of a (now lost) portrait of Euler in 1737 by Johann Georg Brucker shows a normal physiognomy and appearance of both eyes. The following year, Euler suffered a relapse of his febrile illness and began to lose the sight of his right eye associated with what was described as an "abscess" (most likely, septicemia causing a septic cavernous sinus thrombosis with ischemic optic neuropathy). His fevers continued. A 1753 portrait by the celebrated Swiss painter Jakob Emanuel Handmann shows a ptotic right upper eyelid with slight right miosis (consistent with a right Horner's syndrome), a right hypertropia (consistent with a right fourth cranial nerve palsy), and normally appearing anterior ocular segments. In 1766, Euler developed a cataract in the left eye, the unsuccessful 1771 extraction of which left him virtually completely blind, but still able to perform highly complex mathematical calculations in his head. He then continued his prodigious output of mathematical discoveries to an even greater extent. In 1783, Euler suddenly developed a fatal brain hemorrhage, most likely the result of a ruptured intracranial aneurysm.

Today, common causes of recurrent fever include immunizations, viral infections, heat exhaustion, chronic inflammation, malignant tumors, antibiotic, hypertensive or seizure medications, and certain bacterial infections, including, but not limited to, tuberculosis, typhoid fever, epidemic typhus, or tertiary syphilis, all of which are either incorrect or extremely unlikely.

For centuries, an essential part of the Russian diet has been raw milk, the consumption of which is a significant risk factor for brucellosis, the chronic debilitating febrile illness attributed to the pioneer nurse Florence Nightingale after her return to the United Kingdom from the Crimean War in 1856. Brucellosis, also known as undulant or Malta fever, is a highly contagious, and the most common, zoonosis, is caused by the ingestion of unpasteurized milk, cheese, and other dairy products or undercooked meat from animals (usually sheep or goats) infected with a small, gram-negative, non-motile, non-spore-forming, non-encapsulated, rod-shaped coccobacillary bacteria that functions as a facultative intracellular parasite, causing a chronic disease, usually persisting for life. This organism, eponymously designated *Brucella spp.*, was first noted in a splenic autopsy specimen by the Scottish pathologist and microbiologist Sir David Bruce. The Mediterranean Fever Commission of 1904–1906, chaired by Bruce, traced its transmission to the unpasteurized milk of Maltese goats.

An exhaustive literature review strongly suggests that, given the history of an acute, febrile illness that progresses to a chronic disease with ophthalmic and neurological complications (CN IV palsy, Horner's syndrome, and optic neuropathy), and having the possible terminal event being rupture of a mycotic intracranial aneurysm, the most likely diagnosis to explain this complex set of circumstances regarding the blindness and death of Leonhard Euler is undulant fever, progressing to neuro- and ocular-brucellosis, and death by rupture of a *Brucella*-infected cerebral aneurysm.

---

### Euler, Brucellosis, Fever

### LW6 Forensic Photo Analysis: Who, What, When, Where, Why?

Colleen M. Fitzpatrick, PhD\*, Fountain Valley, CA 92708

**Learning Overview:** By attending this presentation, attendees will learn how multidisciplinary analysis can be applied to solve a mystery, based on the example of this picture of an old barroom, taken in the late 19<sup>th</sup> or early 20<sup>th</sup> century.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the value of a multidisciplinary approach for extracting an assortment of details that can nevertheless be used in a coherent manner to solve a mystery based on the questions who, what, when, and why.

There was no *a priori* information about the photo except for an address on the back—805 Baronne Street, apparently a location in the New Orleans, LA, business district. Yet through careful observation, it has been possible to determine the Global Positioning System (GPS) coordinates of the photographer, the date the picture was snapped to within a few weeks, and the likely occasion for which it was taken.

Historically, the date of the picture must be prior to October 1919 or after April 1933—either before or after Prohibition. There are many items in the photograph, both obvious and not so obvious, that could assist in narrowing the date further. The Falstaff® beer sign, the Coors® beer pennant, the cash register, even the pictures on the wall behind the bar (actually advertisements for alcoholic drinks) are useful in indicating a date of about 1910 when all of those products were simultaneously on the market.

However, the most valuable items for dating the picture are not in the bar, but are seen outside the bar, specifically the car that is visible through the open door, parked under a sign on a shop across the side street. The car can be compared to vintage catalogs to identify it as a 1911–1912 Ford® Roadster®, which provides an earliest date as October 1, 1910, the date the first Roadster® rolled off the production line.

The sign is more difficult to analyze, as only parts of the lettering are visible. However, using old city directories, the mystery of the sign and the identity of the bar's owner can be solved. Beginning in 1912, the bar belonged to Paul Dimaggio, the great-grandfather of the picture's owner. He is listed at that address until 1919, when he probably closed the bar because of the ban on alcohol sales. With the assistance of modern image processing, the writing on the sign can be deciphered to read "Goreau Plumbing."

The only problem with this is that, according to the city directories, the Goreau Plumbing Company moved from that location in 1909—at least that is the last year it is listed at that address. In 1910, the address is absent from the directory, and in the 1911 directory, the building across the street was occupied by the Southern Packing Manufacturing Co. So how is it possible that the Goreau sign appears in the background of a photograph of Paul Dimaggio, even though he does not appear in the directory on Baronne Street until 1912, long after the Goreau's were gone?

Using city directories and maps, it has been possible to determine eight events that had to happen in a specific order to create the scene in the picture with Paul DiMaggio standing in his bar with the sign for the Goreau Plumbing Company visible across the side street. There is only one place the photographer could have been standing, and there is likely only one occasion for the picture.

## Young Forensic Scientists Forum—2020

### Y1 Exploring Variation in the Human Nasal Bones Using Elliptical Fourier Analysis (EFA)

*Leann G. Rizor, BS\*, Ypsilanti, MI 48197; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN 46227-3697*

**Learning Overview:** After attending this presentation, attendees will better understand the complex morphology of human nasal bone shape and the effects of ancestry, sex, and age at death on the observable variation in this skeletal region. The learning objectives include demonstrating the usefulness of EFA to describe complex skeletal shapes prior to constructing predictive models for use in a forensic setting.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to a growing body of knowledge regarding the range of normal variation present in the upper face.

Forensic anthropologists study skeletal variation in order to make predictions regarding the ancestry, sex, and age at death of unidentified remains for the medicolegal system. Ancestry determination is an important aspect of biological profile construction as this information is often included in missing persons reports. Ancestry is determined from the skeleton by utilizing both quantitative and qualitative trait assessments. While qualitative trait definitions allow for the inclusion of nuances in shape variation not easily captured through quantitative approaches, qualitative traits are inherently problematic because of their reliance on observer experience and extreme trait depictions. This pilot study uses EFA to more precisely capture the complex shape variation in the upper facial skeleton. EFA reduces the subjectivity in assessing qualitative traits, allows for the recognition of small nuances in shape, and allows for a precise determination of the influence of relevant independent variables, such as sex and ancestry, on that shape variation.

This study utilizes a sample of 97 Euro-American and 42 Afro-American individuals from the Bass Collection at the University of Tennessee, Knoxville. The nasal bones were photographed with a Nikon® D3200 DSLR camera and an 18–55mm lens following a strict alignment protocol. The digital images were then uploaded into Photoshop® v.17.1 and edited so that only the outlines of the isolated nasal bones remained. These nasal bone renderings were then uploaded into SHAPE™ v.1.3 and subjected to elliptical Fourier and Principal Component (PC) analysis. The following null hypotheses were tested with Analysis of Covariance (ANCOVA) using the principal component scores as dependent variables: (1) nasal bone shape is not influenced by ancestry, (2) nasal bone shape is not influenced by sex, (3) nasal bone shape is not influenced by age at death, and (4) nasal bone shape is not influenced by the interaction between sex and ancestry.

The first four effective PCs (PC1 to PC4) account for ~95% of the total variation in nasal bone shape and were subsequently examined in detail. These PCs describe, respectively: nasal bone height relative to breadth, frontonasal suture breadth relative to nasal tip breadth, nasal bone symmetry, and overall nasal bone breadth. The vast majority of the systematic variance in shape (~80%) is described by PC1, with only a small amount (~15%) being accounted for by the other three PCs combined. In the ANCOVAs, relative nasal bone height is significantly influenced by sex, ancestry, and the interaction between these two variables, with the interaction being the most important: on average, Afro-American females exhibit taller nasal bones relative to width than their male and Euro-American counterparts. Frontonasal suture breadth relative to tip breadth (PC2) is affected by sex and especially the interaction: Afro-American males exhibit relatively broader nasal tips than the other groups. Nasal asymmetry (PC3) seems to vary randomly, not being affected by any of the independent variables in the ANCOVAs. Finally, overall breadth (PC4) is affected by ancestry and age when controlling for nasal bone length: Afro-Americans and older individuals tend to display broader nasals than Euro-Americans and younger individuals.

This study illustrates the complex nature of nasal bone variation, as ancestry, sex, their interaction, and age all significantly influence nasal bone shape in specific circumstances. While nasal bone shape is often used in a forensic context to determine ancestry, this study demonstrates that the interaction between ancestry and sex contributes more to that variation than either ancestry or sex alone. Furthermore, the percentage of variation in shape explained by all PCs amounts to less than 2%, indicating that over 98% of the variation observed in nasal bone shape cannot be explained by sex, ancestry, age, and/or the interaction. Therefore, more sophisticated research is needed before accurate predictive models can be created utilizing this anatomical region.

#### Elliptical Fourier Analysis, Human Variation, Nasal Bones

### **Y2 The Efficiency of a DNA Database for Sexual Crimes by Its Victim-Offender Relationship: A Portrayal From Central Brazil**

*Nigela Rodrigues Carvalho, MS\*, Polícia Científica do Estado de Goiás, Goiânia, Goiás 74.840-170, BRAZIL; Thais C.V. Gogonzac, Lagene-Secretaria de Estado de Saúde de Goiás, Goiânia 74605-010, BRAZIL; Mariana F. Mota, Polícia Científica de Goiás, Goiânia 74425-030, BRAZIL; Grasielly D.O. Araújo, Polícia Científica de Goiás, Goiânia 74425-030, BRAZIL; Yanna A.R. Lima, Hospital da Universidade Federal de Goiás, Goiânia 74605-020, BRAZIL; Neide M.O. Godinho, Polícia Científica de Goiás, Goiânia 74425-030, BRAZIL*

---

**Learning Overview:** After attending this presentation, attendees will understand how DNA databases are extremely useful in investigating sexual crimes and will see their efficiency in the victim-offender relationship.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing, through the results obtained in this research, that the hypothesis of the “no need to use DNA databases to investigate sexual crimes” is totally refuted. In addition, the results show greater elucidation of sexual offenses of unknown perpetrators.

Despite the technological advances, there is a growing accumulation of sex crimes evidences stored without being tested for DNA for many reasons. One of these reasons is the idea that most of these crimes are committed by known offenders, thus the law enforcement agencies did not view DNA evidence as helpful or necessary to the task of investigating a reported crime; with the consequence being there was no indication of suspects for confrontation. However, with the advent of DNA databases, this evidence has been seen as valuable sources of information for investigations. International studies indicate that DNA typing can be useful for both known and unknown assault cases. In Brazil, there is no study with this approach, and its implantation of DNA databases is recent. Thus, the objective of this study was to evaluate the potential of the DNA Database of the Estate of Goiás (Brazil) in the elucidation of sex crimes by its victim-offender relationship.

The samples were submitted to DNA extraction by differential lysis with the PrepFiler® Express™ Forensic DNA Extraction kit and the AutoMate Express™ system, followed by amplification of Short Tandem Repeat (STR) autosomal genetic markers with GlobalFiler®, capillary electrophoresis in the ABI® 3500 genetic analyzer, and by the insertion in the DNA Database of State of Goiás using the Combined DNA Index System (CODIS) 7 software. The sample's rate was evaluated with profiles eligible for insertion and coincidence rates according to the victim-offender relationship and for the statistical approaches the program EpiInfo™ v. 7 was used.

A total of 2,165 cases were reviewed, of which 286 had information regarding victim-offender relationships. After DNA typing, 192 were inserted in the DNA Database of State of Goiás, of which 71 were related to known aggressors, 121 to stranger aggressors, and genetic coincidences were detected only with cases of unknown aggressors, involving 41 cases. Thus, the hypothesis of the “no need to use DNA databases to investigate sexual crimes” is totally refuted. In addition, the results indicated greater elucidation of sexual offenses of unknown perpetrators. Due to the limited body of studies with this approach in Brazil, the Brazilian DNA Databases have only been used for a few years and with its characteristics of legal basis, it can be stated that the greater elucidation of sexual offenses of unknown perpetrators is a current picture that can be modified according to the evolution of the Brazilian DNA database's growth. Thus, future research should be performed for a reliable view. Currently, it is understood that this tool cannot be ruled out for crimes of non-stranger aggressors.

---

#### **DNA Database, Sexual Crimes, Victim-Offender Relationship**

### Y3 The Effect of Human Decomposition on Fired Bullets and the Implications for Identification

Shelby Szymoniak\*, Michigan State Police, Detroit, MI 48226; Rachel E. Smith, BS, Marquette, MI 49855; Jane Wankmiller Harris, PhD, Northern Michigan University, Marquette, MI 49855

---

**Learning Overview:** After attending this presentation, attendees will understand the effects of human decomposition on individual characteristics in land impressions on bullets and how the deterioration over time affects an examiner's ability to analyze the bullets.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel analysis of an examiner's ability to identify the source weapon in cases involving bullets found in decomposed human remains.

For the purpose of this study, copper full metal jacketed bullets were placed in various regions of the body in two donors (Donor 1 and Donor 2) at the Northern Michigan University Forensic Research Outdoor Station (FROST) during the summer of 2019. Two bullets were placed in each of the selected regions so one could be left *in situ* during the entire data collection period and one could be repeatedly removed and replaced to assess the effects of decomposing soft tissue at shorter time intervals. All bullets were test fired from the same firearm into a standard tank at the Michigan State Police Detroit Laboratory and one control bullet was retained for comparison against the study bullets.

The condition of the donors and the other research in which they were participating affected the researchers' decisions regarding bullet placement. Prior to bullet placement, Donor 1 was in an advanced state of decomposition, meaning decomposition in some areas of the body was too far advanced for them to be viable placement locations. Donor 1 bullets were placed in the eye sockets, abdominal cavity, resting on the left femur, and in the soil near the body. Prior to bullet placement, Donor 2 was in an early stage of decomposition, but was part of an ongoing study focusing on gut bacteria, which precluded placement of bullets in the abdomen. Donor 2 bullets were placed in the right and left arms and resting on the left femur.

When the study bullets were removed for examination, they were analyzed for physical changes, cleaned, and compared to a control bullet using a comparison microscope according to standard agency protocols. After the examination, the bullets were replaced in the same locations. Three possible conclusions could be reached during the examination: identification, similarities (inconclusive), or unsuitable. The examination of the bullets involved examining each land impression independently and reaching a conclusion, then analyzing the bullet as a whole to determine if could be identified, despite damage to some land impressions.

Analysis showed that within only a few days of exposure to decomposing tissue, the copper displayed areas of discoloration, which appeared as a marbling effect. The areas of the bullets that were in direct contact with the bone (femur) were consistently lighter in color than the rest of the bullet(s). The copper also underwent oxidation, and patina formed around the exterior of the bullet. During the examinations, the patina was removed to observe the individual marks. The bullets that remained untouched until the conclusion of the study displayed a thicker layer of patina.

Results demonstrate that the number and quality of land impressions still visible after exposure to decomposing human tissue differed according to location, length of exposure time, and contact with bone. The bullets left *in situ* until the end of the data collection period were more heavily corroded than those that were removed and cleaned over time. Over time, the individual characteristics in the land impressions became dulled and less distinct, and pitting became apparent in the copper jackets. Additionally, maggot activity appears to have accelerated the rate of change observed on the bullets, as the bullets placed in Donor 1 (after most of the maggots had left the body to pupate) were identifiable longer than those placed in Donor 2, which progressed through all stages of entomological activity following bullet placement.

This research demonstrates the need to be aware of the potential effects of decomposing tissue on the ability to identify the source weapon that may have fired bullets related to the cause and manner of death of decedents. Additional research is needed to ascertain the effects of different time intervals and possibly those related to the seasons and other climatic factors.

#### Decomposition, Bullet, Comparison

## Young Forensic Scientists Forum—2020

---

### Y4 Recovering Latent Fingerprints From Duct Tape After Removal From Various Surfaces Using Dry Ice

Vivian Hoang\*, *University of Northern Colorado, Greeley, CO 80639*

---

**Learning Overview:** The goal of this presentation is to provide criminal insight on the most advantageous method for recovering latent fingerprints from duct tape.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing latent print examiners an alternative method of removing duct tape and will assist in determining which latent fingerprint development method works best after applying the dry ice/acetone slush.

Duct tape is a common item of physical evidence found at many crime scenes. Duct tape has been used to facilitate different crimes, and the criminal population utilizes duct tape in a variety of ways. Some victims of violent crime are restrained or bound with duct tape, and duct tape is used to package items related to criminal activity. While there has been research in the area of preserving and recovering latent fingerprints from duct tape, very few studies have examined the use of dry ice for separation from various surfaces. The purpose of this study was to examine how dry ice reduces the adhesive properties of tape, specifically duct tape, and how the removal affects the quality of recovered latent fingerprints.

The researcher in this study examined the quality of recovered fingerprints separated from various surfaces using a dry ice/acetone slush. Initially, a series of preliminary experiments were conducted to observe how specific physical states of dry ice successfully separated tape from wood, metal, and glass. Dry ice was applied in blocks, crushed, powdered, and in an acetone slush. The following brands of duct tape used on each surface included Gorilla® Tape, 3M® Super Tough Duct Tape, 3M® All-Weather Duct Tape, Shurtape®, and 3M® Tough Duct Tape. All of the forenamed duct tapes were separated from wood, metal, and glass. A dry ice/acetone slush (-78.5°C) provided the most successful method for separation.

A latent print development method was used on each of the duct tapes after removal from the surfaces. The various developing methods that were used to recover latent fingerprints included cyanoacrylate fuming followed by Ardrox™ dye, ninhydrin, 1,8-Diaza-Fluorenone (DFO), Wetwop™, and crystal violet. The quality of recovered latent fingerprints was determined by using a grading system based on ridge detail and minutiae points. Preliminary results have shown that cyanoacrylate fuming followed by Ardrox™ dye, Wetwop™, and crystal violet yielded identifiable fingerprints. Additionally, it was observed that the texture of duct tape could interfere with the quality of developed prints, making the ridge detail difficult to see.

The final results of this study will assist latent print examiners by providing an alternative method of removing duct tape and will assist in determining which latent fingerprint development method works best after applying the dry ice/acetone slush.

### Y5 Enhanced Collection and Recovery of Cellular Material, Coupled With Direct Polymerase Chain Reaction (PCR), From Rough Surfaces for Forensic “Touch DNA”

*Joseph M. Rahm, BS\*, International Forensics Research Institute, Florida International University, Miami, FL 33199; DeEtta Mills, PhD, Florida International University, Miami, FL 33199*

---

**Learning Overview:** After attending this presentation, attendees will understand that comparing a novel method of collection of trace DNA samples from smooth to rough surfaces and objects with a novel vacuum device, the optimization and testing of different filter matrices (e.g., polyvinylacrylate vs. polycarbonate), and new high-fidelity polymerases to provide more robust and complete DNA profiles, along with comparing and eventually eliminating DNA extraction methods, serve to train the student in the entirety of the traditional DNA workflow. Ultimately, enhancing collection with a vacuum device and forgoing DNA extraction for direct PCR will create a new workflow for adequately processing trace DNA samples.

**Impact on the Forensic Science Community:** The implementation of the Venturi Vacuum Device (VVD), a simple vacuum technology, into the front-end processes of forensic DNA typing could lead to a reevaluation of standard collection techniques of trace evidence. The VVD and direct PCR will have a positive synergistic effect on downstream processes, providing improved genetic profiles. This device could revolutionize the conventional approach to the collection of challenging forensic samples and the subsequent evaluation of DNA profiles generated and used in criminal casework.

The inclusion of DNA evidence in criminal cases is the gold standard of the contemporary courtroom. Of late, collection of low quantities of cellular material is becoming more common throughout federal and state crime labs that use touch DNA, a class of biological trace evidence that is recovered from the epithelial cells in the sweat and oils on the hands of individuals. However, the challenge remains on how to efficiently collect touch DNA evidence associated with casework ranging from property crimes to sexual assault and murder. The downstream analytical success of such valuable evidence continues to be hampered by inadequacies involved in its collection. The inability of traditional collection matrices—cotton swabs—to adequately pick up, then release cellular material once it has been collected has a direct impact on the success of a useable or full DNA profile. This is especially prevalent with touch DNA of unknown quality and found on rough surfaces where a swab falls apart or cannot easily access a surface to even obtain a sample. Therefore, there is a strong need to enhance the collection of cellular trace evidence from rough surfaces commonly encountered at crime scenes.

This research addresses these inherent collection shortcomings by improving cellular collection and subsequent recovery of DNA, especially from rough surfaces, using a field-portable VVD (patent pending). A VVD creates a vortex of negative pressure by passing compressed air (CO<sub>2</sub>) through a narrow section of piping, generating a powerful suction. Attaching a Polycarbonate Filter (PCF) to the VVD apparatus allows for the use of the vacuum and suction processes to collect the cellular material. The VVD will first be tested on mock touch samples placed on stainless steel bars (smooth surface), then rope and brick (rough surfaces) using a known quantity (100 cells) of epithelial cells placed on the surfaces. Second, true touch samples from 100 individuals handling rough objects will be sampled with the optimized protocol. This will be compared to samples collected with traditional cotton swabs, where cotton swabs tend to rip and tear when used on porous and textured surfaces. Once collection issues have been addressed, the next step is to eliminate loss of DNA in downstream processes due to DNA extraction. The DNA loss resulting from multiple extraction steps and tube changes adversely affect the success of recovering enough DNA to generate a robust profile. With that said, the combination of VVD collection and direct PCR, forgoing extraction and quantitation steps, will significantly increase the probability of obtaining probative DNA profiles.

### Y6 DNA Contamination From Handled Sharpie® Markers Used to Outline Bodily Fluids in a Forensic Laboratory

*Danielle Guckin\*, Pittsburgh, PA 15219-5920; Lisa R. Ludvico, PhD, Duquesne University, Pittsburgh, PA 15282; Pamela L. Marshall, PhD, Duquesne University, Pittsburgh, PA 15282; Sara E. Bitner, MS, Pittsburgh, PA 15222; Betsy Wisbon, MS, Allegheny County Office of the Medical Examiner, Pittsburgh, PA 15222*

---

**Learning Overview:** After attending this presentation, attendees will better understand contamination via DNA transfer caused in the laboratory and the impact this contamination has on interpreting data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying a method of introducing DNA contamination into the laboratory through common practice and how this can be prevented in order to reduce the likelihood of contamination as much as possible while processing evidence.

With the ever-increasing sensitivity of DNA technology, DNA transfer is more readily detected and observed in fragment analysis data. In a crime laboratory, forensic biologists are handling tools that can instigate this DNA transfer event, leaving traces behind on evidence. This research will determine whether forensic biologists transfer DNA from evidence to evidence using Sharpie® markers that outlined bodily fluids prior to DNA extraction.

Forensic biologists outline bodily fluids with markers before swabbing for further DNA analysis to visualize where the samples are located. This is especially important when the biological material is not visible to the naked eye, such as semen, and an Alternative Light Source (ALS) is required. The marker is used multiple times on separate pieces of evidence, which may or may not be from the same case. This transferring of DNA could contaminate evidence with DNA from separate individuals and from unrelated cases, creating more noise and mixture data interpretation in the fragment analysis results.

A preliminary study was employed to confirm DNA can be extracted from the tips of Sharpie® markers. To do this, human whole blood and human semen were deposited on blue denim and black T-shirt swatches. After the bodily fluid dried for at least one week, the Sharpie® markers were purposely drawn over the bodily fluids, using either a black Sharpie®, metallic silver Sharpie®, or white China Sharpie® marker, depending on the substrate color. The tip of the Sharpie® marker was then swabbed using a Puritan® cotton swab and the double-swab technique. Both a 5% Chelex extraction and a QIAGEN® DNA Investigator Kit were used to determine which extraction method was more efficient. Each sample combination was repeated in quintuplicate with a positive, negative, and substrate control for a total sample size of 128. The samples were quantified using the QuantStudio™ 5 Real-Time Polymerase Chain Reaction (PCR) instrument and the Quantifiler® Human DNA Quantification Kit. The GeneAmp® PCR System 9700 and GlobalFiler® PCR Amplification Kit were used to amplify all samples and a 3130 Genetic Analyzer was used to genotype the samples.

The results obtained from the preliminary study showed DNA can be extracted from Sharpie® markers. This study also showed the QIAGEN® DNA Investigator Kit yielded more efficient results, which were then utilized for further research. After the preliminary experiment, the mock scenario was implemented to re-enact a practical situation in a laboratory. This employed the same techniques; however, the clothing was donated to better simulate a practical situation. Additionally, reference samples were collected via buccal swabs from the individuals who donated the bodily fluid and clothing. The Sharpie® markers were used to outline the bodily fluids on up to three swatches containing biological material from a different source. The samples were extracted, and the data was compared to the reference samples to identify if the Sharpie® markers were transferring DNA in detectable quantities.

Identifying contributing factors to DNA contamination in a crime laboratory is imperative so that measures can be taken to prevent further contamination. This is especially critical for low copy number samples or samples that do not contain enough material for conservation. Recognizing and understanding all possible avenues of contamination will create a more sterile and safer environment for the processing of evidence.

#### DNA Transfer, Contamination, Fragment Analysis

## Young Forensic Scientists Forum—2020

### Y7 Ultraviolet (UV) Absorption Properties of Synthetic Cathinones

Jane Berger, BS\*, Cedar Crest College, Allentown, PA 18104; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104; Matthew R. Wood, PhD, Ocean County Sheriff's Department, Toms River, NJ 08753; Marianne E. Staretz, PhD, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** After attending this presentation, attendees will understand how UV/Visible (UV/Vis) spectrophotometry can be used to determine the wavelength maxima and molar absorptivity of synthetic cathinones.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reporting the UV/Vis spectrophotometric properties of synthetic cathinones, including the wavelength maxima and molar absorptivity in methanol, and how this information can be used to screen seized drugs for these compounds.

Seized drug analyses are routinely performed and are a major part of the workload in crime laboratories across the country. Typically, color or spot tests are used to presumptively identify a controlled substance with subsequent confirmation by Gas Chromatography/Mass Spectrometry (GC/MS). While most traditional drugs of abuse, such as heroin and cocaine, can be presumptively identified by common color tests, this is not the case with synthetic cathinones. The Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) has published recommendations for the minimum requirements for the forensic identification of seized drugs.<sup>1</sup> In these recommendations, SWGDRUG has classified analytical techniques incorporated within an analysis scheme into three categories based upon the level of selectivity they achieve. UV/Vis is listed as a category B technique since it is not very selective, particularly when compounds have similar structural properties. For this reason, it has not been a commonly used technique for screening seized drugs. There is very little data reported in the peer-reviewed literature about the UV/Vis spectral properties of synthetic cathinones. For this reason, and the fact that there is limited presumptive test options for these compounds, the UV/Vis spectral properties were investigated. The determination of wavelength maxima and molar absorptivities in methanol were determined for more than 20 synthetic cathinones. Hopefully, this information will be useful to practitioners analyzing seized drugs.

A Beckman Coulter® DU-800 UV/Vis spectrophotometer, Mettler Toledo LabX™ UV/Vis spectrophotometer, and a Cary 3500 UV/Vis spectrophotometer were used to create calibration curves based on dilutions sets prepared using Cerilliant® and Cayman Chemical certified reference standards. Nine working solutions were created from a 10- $\mu\text{g}/\text{mL}$  stock solution of each synthetic cathinone by diluting with American Chemical Society (ACS) -grade spectrophotometric methanol. The concentrations ranged from  $5 \times 10^{-5}\text{M}$  (stock) to  $5 \times 10^{-6}\text{M}$ . A set of stock and working solutions for each synthetic cathinone was prepared in duplicate from separate certified standards with different lot numbers. Spectra were acquired on all three aforementioned instruments for each synthetic cathinone for each dilution set. All spectral data acquired were processed using Microsoft® Excel® for MAC® (version 16.30) to determine molar absorptivity, standard deviation, and Coefficient of Variation percentage (CV%).

Data obtained on all three UV/Vis spectrophotometers were in excellent agreement (CV% < 4%). Wavelength maxima varied slightly for all cathinones depending on the functional group substitution. Methyleneoxy-ring substitution resulted in multiple wavelength maxima. For all cathinones analyzed in methanol, the wavelength maxima were in the range of 230.6nm (methylone) to 279.4nm (methedrone). Regression analysis of plotted data (absorption vs. concentration) resulted in good linear correlation (all above  $R^2=0.99$ ) for every synthetic cathinone analyzed on all three instruments. Molar absorptivity values in methanol ranged from  $1.18 \times 10^5\text{L}\cdot\text{cm}^{-1}\cdot\text{mol}^{-1}$  (methcathinone) to  $1.97 \times 10^5\text{L}\cdot\text{cm}^{-1}\cdot\text{mol}^{-1}$  (methylone).

This presentation reports spectral data for more than 20 synthetic cathinones that have not been reported previously. This includes wavelength maxima and molar absorptivity data recorded from cathinones in methanol. Although UV/Vis spectrophotometry is not highly selective, the information reported here can be used with other analytical data to identify and quantify synthetic cathinones. Sample preparation is simple and the analysis is not time consuming. This study demonstrates that UV/Vis spectrometry has the potential to be used as a screening tool in crime laboratories for the analysis of synthetic cathinones in drug seizures.

### **Y8 The Possibility of Personal Identification By Measurement of Scapular Volume and Bone Conformation: A Preliminary Assessment With Postmortem Full-Body Computed Tomography (CT)**

*Alissa M. Shida, MS\*, Osaka City University Medical School, Osaka 545-8585, JAPAN; Aoki Yayoi, BA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Kei Ikeda, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Naoto Tani, MA, Osaka City University Medical School, Osaka 545-8585, JAPAN; Tomoya Ikeda, PhD, MD, Osaka City University Medical School, Osaka 545-8585, JAPAN; Takaki Ishikawa, MD, PhD, Osaka City University Medical School, Osaka 545-8585, JAPAN*

---

**Learning Overview:** After attending this presentation, attendees will learn the value of postmortem imaging for personal identification using scapula morphometric values from postmortem CT.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that with scapular morphometrics, CT data can be used to obtain objective indicators for personal identification.

The value of postmortem imaging for personal identification has clearly emerged in recent years, and applications of postmortem bone imaging to the determinations of sex, height, weight, and other characteristics have been investigated. This study reports on a preliminary investigation into the relationship of scapula morphometric values from postmortem CT to sex, age, height, weight, and other physical properties.

An analysis was performed for 570 adult autopsies (359 men, 211 women; mean age 60 years; range 18–98 years) with no observable injury, damage, or other effects on anatomical structure. CT was performed using a Hitachi Medical Multislice ECLOS-16 system and scapular 3D structure reproduction images were analyzed on a Fujifilm SYNAPSE VINCENT volume analyzer.

Among the various scapular measurement points, this study measured straight-line distance from the most superior point (D) on the superior angle to the most inferior point (C) on the inferior angle and from the most posterior point (I) on the crest of the glenoid fossa border to the spine base center point on the medial border (B), and left-right scapular volume and mean CT values. Sex determination by Receiver Operating Characteristic (ROC) curves of inter-D-C distances in the left and right scapulae showed sensitivity of 0.88–0.91 and specificity of 0.88–0.92, and that by scapular inter-IB distance showed sensitivity of 0.89–0.91 and specificity of 0.89–0.91, indicating high determination capability. Sex determination capability by volume was even higher, at 0.97–0.98 sensitivity and 0.95–0.96 specificity. No strong correlations (no correlation  $\sim r=0.56$ ,  $p<0.001$ ) of scapular measurement values to height or weight were observed. Taken together, the results indicate that with scapular morphometrics, CT data can be used to obtain objective indicators for personal identification.

### Y9 Testing of a Probe Capture Next-Generation Sequencing Assay for the Analysis of Nuclear Short Tandem Repeat (STR) and Single Nucleotide Polymorphism (SNP) Markers

Tanya Tannous\*, Sacramento, CA 95835; Shelly Y. Shih, MS, Children's Hospital Oakland Research Institute, Oakland, CA 94609; Henry A. Erlich, PhD, Children's Hospital Oakland Research Institute, Oakland, CA 94609; Cassandra Calloway, PhD, Children's Hospital Oakland Research Institute, Oakland, CA 94609

---

**Learning Overview:** The goal of this presentation is for attendees to recognize the value of probe capture enrichment Next Generation Sequencing (NGS) assays in the analysis of genetic markers from single DNA shotgun libraries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees an alternative method to Polymerase Chain Reaction (PCR) amplification for analyzing challenging samples, including highly degraded samples and mixtures.

DNA from biological samples in forensic casework may be mixed or in degraded condition. In samples with highly degraded DNA, both PCR primer binding sites may not be present on the template DNA fragments, and conventional PCR amplification and Capillary Electrophoresis (CE) analysis of STR may fail. Probe capture enrichment utilizes overlapping biotinylated probes to capture fragmented DNA. Since STR regions cannot directly be targeted for capture, DNA regions flanking the STRs were targeted using probe capture enrichment.

Previously, it was demonstrated that the SNP probe capture/NGS system can capture and sequence DNA fragments as short as 35 base pairs with input as low as 0.5ng while yielding 99%–100% reportable SNP genotypes.<sup>1</sup> Reportability is determined by meeting the minimum threshold requirement for read depth of >500 reads per base. This study tested the performance of SNP (v3.0) and STR (v1.0) probe capture panels with the same shotgun libraries. Three commercial control DNA samples, Promega's® 2800 M, the National Institute of Standards and Technology's SRM2391-c, and Coriell Cell Repositories' NA24149, and 12 blood-derived DNA population samples were prepared using a "shotgun" approach and given unique dual-indexed barcode sequences. DNA shotgun libraries were pooled for probe capture enrichment. The enriched products were sequenced on Illumina® MiSeq®. SNP and STR sequence data were analyzed using NextGENe® and GeneMarker® HTS Software.

Ninety-six percent of SNPs ( $n=496$ ) were reportable using this custom SNP (v3.0) probe capture panel in samples with input amounts of DNA at 25ng. Some of the STR loci could be analyzed by inspection of the sequence read "pile-ups" with reads that spanned the STR corresponding to the known length variants. This "proof of concept" study with this STR (v1.0) panel identified sequence polymorphisms that would be undetectable by conventional CE analysis. The successful development of probe capture NGS for both STR and SNP assays would provide practitioners an alternative method to PCR amplification for analyzing challenging samples, including highly degraded samples and mixtures.

### Y10 A Profile of Fatal Poisoning Cases Brought for Postmortem Examination at a Tertiary Care Institute in India—A Retrospective Study of 21 Years of Autopsy Cases

*Rajesh Kumar, MBBS, MD\*, Ranchi, Jharkhand 834001, INDIA; Jay N. Pandit, MBBS, MD, All India Institute of Medical Sciences Campus, New Delhi 110049, INDIA*

---

**Learning Overview:** After attending this presentation, attendees will understand some principles on trends, magnitude, and profiles of fatal poisoning cases in the national capital region of India.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by sensitizing attendees regarding the poisoning problem in India.

Trends of poisoning have been constantly changing throughout the world with the advent of new agents. The high incidence of suicide by poisoning among young adults can be checked by frequent psychological counseling and by tackling their problems sympathetically. Education of the community with regard to proper storage and use will reduce the incidence of poisoning. This presentation will highlight analyzed data with relevant tables and figures.

Poisoning is a significant global public health problem. According to World Health Organization (WHO) data, in 2012, an estimated 193,460 people died worldwide from unintentional poisoning. In 2017, the 55 United States poison control centers provided telephonic guidance for nearly 2.12 million human poison exposures. In India, the National Poisons Information Centre (NPIC) at All India Institute of Medical Sciences (AIIMS) received 16,420 telephone calls for guidance regarding poison exposure between April 2006 and March 2016. Globally, much is known and documented regarding poisoning. Contrarily, in India, less is known regarding poisoning due to the unavailability of published data, access to databases, and very few established national poison surveillance centers for the collection of reliable data.

The incidence of morbidity and mortality due to poisoning in India is among the highest in the world. It is estimated that more than 50,000 people die every year from toxic exposure. Despite the vast number, evidence on prevalence pattern in India is still limited. The goal of this present study was to retrospectively analyze various aspects of poisoning cases conducted at AIIMS, New Delhi, during the period of January 1998 to December 2018. Autopsy reports were studied and data analyzed to discover classes of poisonous agents that have been used in fatal poisoning cases. The data has been analyzed as to the manner of death and frequency of intoxications as well as age and sex of the deceased. A total of 31,848 autopsies were conducted at AIIMS during the past 21 years (1998–2018) with the cause of death as intoxication in 1,118 cases. The spectrum of substances that are abused, taken deliberately, or accidentally is continuously changing, reflecting scientific progress in the pharmaceutical and chemical industry. The present study shows the highest mortality due to agrochemicals poisoning (497). This study clearly demonstrates the uniformity of male preponderance over female in a ratio of 2:1. The most common cause of death in this study was suicidal death (1,016) followed by accidental death (92), and the least were cases due to homicidal death (10). This study shows an overall decrease in the trend of poisoning cases, but control is still needed since the poisons are easily available and less regulated.

### Y11 The Detection and Quantification of Trace Fentanyl in Mixtures With a Portable Raman Instrument and Chemometrics

Ling Wang, PhD\*, Florida International University, Miami, FL 33139; Mario O. Vendrell-Dones, BS, Florida International University, Miami, FL 33199; Sevde Dogruer, Bogazici University, Istanbul 34893, TURKEY; Bruce R. McCord, PhD, Florida International University, Miami, FL 33199

---

**Learning Overview:** The goal of this presentation is to describe a detection method based on Surface-Enhanced Raman Spectroscopy (SERS) with a portable Raman instrument and a chemometric model to distinguish mixtures of fentanyl/heroin, fentanyl/cocaine, and fentanyl/heroin/cocaine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a SERS-based chemometric method for the presumptive screening of opioids. This new method is fast and can rapidly distinguish fentanyl analogs from other drugs.

The abuse of opioids has become a critical issue in the United States over the past five years. New synthetic fentanyl analogs continue to appear in street drugs, resulting in increased threats to the public health. Since the appearance of these new fentanyls, prior screening methods, such as immunoassay, have had difficulty in the detection and analysis of the multiplicity of opioid analogs in the market. This study has been working on an alternative screening method using SERS coupled with metal nanoparticles and aggregating agents. SERS is a rapid screening method that provides molecular fingerprint signals at toxicological concentrations. The procedure is simple and fast, and it is convenient for use in both point-of-care analysis and laboratories. The new method can detect fentanyl analogs, cocaine, and heroin at low to sub ng/mL concentrations, as well as distinguish fentanyls in mixtures with cocaine or heroin, even at levels as low 0.01% fentanyl in the mixture.

The SERS method utilizes gold/silver nanostars in colloidal form that are mixed with magnesium chloride and aggregated. Next, drug samples are added to aggregated silver/gold nanostars and allowed to incubate for five minutes. On the surface of the aggregated nanostars, the creation of hot spots produces localized surface plasmon field effects resulting in an improvement in SERS enhancement. The SERS spectrum provides molecular vibration information that can identify individual compounds. Chemometrics, such as linear discriminant analysis and principle components analysis, were then used to create a model to cluster classes of drug samples, as well as distinguish single drugs and their mixtures. The resultant data assist in the calculation of the percentage of fentanyl in the mixture based on the composite spectra.

The SERS method permits a rapid, easily operated presumptive test for opioids. It is orthogonal to mass spectrometry and sufficiently sensitive to detect compounds at toxicological levels. As a result, it should be particularly useful for the screening of fentanyl analogs, mixtures with heroin and/or cocaine, as well as other novel psychoactive substances and mixtures.

---

**Fentanyl Mixtures, SERS, Portable Raman**

### Y12 Visualizing and Detecting Explosives Through the Use of High-Performance Thin-Layer Chromatography (HPTLC)

*Julia Pietrangelo, BS\*, Cedar Crest College, Allentown, PA 18104; Marianne E. Staretz, PhD, Cedar Crest College, Allentown, PA 18104; Vincent J. Desiderio, Jr., MS, United States Postal Inspection Service, Washington, DC 20260; Thomas A. Brettell, PhD, Cedar Crest College, Allentown, PA 18104*

---

**Learning Overview:** After attending this presentation, attendees will have gained a basic understanding of how to use an HPTLC system to detect explosives.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel way to detect explosives in any criminal instance, such as acts of terrorism. This method allows for explosives to be detected and differentiated with the hope of one day being able to trace the components back to an initial source and identify a potential suspect.

As terrorist attacks involving the use of explosives persist around the globe, the development of novel methods for the detection and identification of explosive residues continues to be an important pursuit. Thin Layer Chromatography (TLC) is one of the many analytical methods commonly used to detect explosives. As an extension of the capabilities of TLC, it is proposed that HPTLC in conjunction with chemical development can provide valuable information when attempting to detect explosives.

The goal of this project was to evaluate different mobile phase systems in an attempt to identify which system would provide the best HPTLC separation of explosives. Many different solutions were employed to visualize the explosive solutions such as: a horseradish peroxidase solution, N,N-dimethyl-1,4-phenylenediamine dihydrochloride solution, potassium iodine-starch solution, ammonium thiocyanate-ferrous sulfate solution, ferrous hydroxide solution, modified Griess reagent, 1% diphenylamine solution, 0.02% diphenylbenzidine solution, and 0.2% diphenylbenzidine solution. Out of these nine solutions, 1% diphenylamine in hexane provided the most promising results. The plates were spotted using an automatic sampler. After spotting, the samples were developed in a developing chamber. During development, appropriate solvent phases were investigated to ensure proper separation. To this end, two mobile phases were compared. The first mobile phase tested was an 8:4:3 ratio of toluene, hexanes, and acetone. The second mobile phase explored was an 8:4:3 ratio of toluene, hexanes, and ethyl acetate. After comparison of these two mobile phases, it was determined that a mixture of toluene, hexanes, and ethyl acetate provided the best separation.

Due to the fact that nitroaromatics and nitramine compounds can be detected after irradiating with 254nm Ultraviolet (UV) light; pictures of the plate were taken under white light, 254nm, and 366nm light using a visualizer. The plates were then treated with 1% diphenylamine in hexane by vertically dipping the plates into the solution and allowing them to dry before photographing again under the same conditions. Treating the plates with the 1% diphenylamine solution allows for the identification of nitrite esters. Last, measurements were taken using a scanner, and an overall report of the measurements was generated. At this point in the project; 1,2-dinitrobenzene, 3,4-dinitrotoluene, Ethylene Glycol Dinitrate (EGDN), nitroglycerin, nitroguanidine, Pentaerythritol Tetranitrate (PETN), and picric acid have been examined using this procedure. All the explosives tested, with the exception of nitroguanidine and picric acid, were separated using this method. In the future, this method could be used to detect single-component explosives or explosive mixtures.

### Y13 The Effects of Storage Conditions and Time on Extracted Ignitable Liquids Using Gas Chromatography/ Mass Spectrometry (GC/MS)

Sierra Strnisa\*, Canonsburg, PA 15317; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA 15282

---

**Learning Overview:** After attending this presentation, attendees will understand how variables such as temperature and storage containers affect the ability to identify petroleum distillates through GC/MS analysis over several months.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by aiding in the establishment of optimal storage procedures, designed for ignitable liquid extracts, for the preservation of accurate analytical results.

In arson investigations, recovery of an ignitable liquid can be the determining factor in whether a fire is ruled accidental or intentional. In some cases, fire debris recovered from the scene must be archived in the event that a sample must be analyzed at a later time, though little is known about how to properly store extracted samples in order to maintain the integrity of analytical results over time. Up to this point, there has been research conducted comparing analytical results using different storage containers, extraction techniques, and analysis methods over longer periods of time; however, temperature has not yet been considered in conjunction with these other factors. To address this gap in research, the conjoined effect that storage temperature and container have on analytical results over time were tested by storing in two different containers at two different temperatures across a nine-month period.

Ignitable liquids can be classified into eight basic categories and three sub-categories; this study focused on petroleum distillates, just one of these eight classifications, due to their accessibility and low cost. Three petroleum distillates (Crown<sup>®</sup> White Gas Camp Fuel, Crown<sup>®</sup> Paint Thinner, and Crown<sup>®</sup> 1-K Kerosene) classified into different sub-categories (light, medium, and heavy) were selected as samples. Samples were extracted onto activated charcoal strips using a passive headspace method. The charcoal strips were then transferred to a Sirchie<sup>®</sup> Nylon Fire Debris Bag or PTFE-lined glass vial. Once contained, samples were stored under room temperature conditions or refrigerated at 4°C. After storing for intervals of three months, six months, and nine months, extracted samples were subsequently analyzed using GC/MS to visualize peak profiles. The protocol mentioned previously was followed for preparation of “time 0” samples (samples that were extracted and immediately run on the GC/MS with no storage) in order to provide a baseline for comparison purposes. Analysis of sample data was performed through identification of target compounds according to the American Society for Testing and Materials protocol by utilizing the National Institute of Standards and Technology Mass Spectral database.<sup>1</sup> Comparisons were made between all variables (storage time, container, temperature, and among the distillates chosen), noting any loss of target compounds or signal strength. This research may indicate a modification to standard protocol for the storage of extracted ignitable liquids in the future, ensuring accurate results.

### Y14 Testing Kinship Via Mitochondrial DNA on Colony vs. Non-Colony Cats

Ashley Ruddy\*, Scranton, PA 18505; Lisa R. Ludvico, PhD, Duquesne University, Pittsburgh, PA 15282

**Learning Overview:** The goal of this presentation is to draw attention to a portion of wildlife forensics and examine the social structure of colony and non-colony feral cats (*Felis catus*). Attendees will gain an understanding of Trap-Neuter-Return (TNR) and its role in this study via mitochondrial DNA (mtDNA), the mating structure of feral cat colonies showing degree of relatedness, and the impact of the *Felis catus* population on wildlife forensics.

**Impact on the Forensic Science Community:** This presentation will impact the forensics science community by examining the social structure of feral cats. In addition, *Felis catus* Short Tandem Repeats (STRs) were the first non-human STR evidence used in a court of law.

Populations of feral cats (*Felis catus*) have drawn public attention due to a variety of reasons, including the increasing population size, caterwauling, destruction of property, and decreasing rodent and bird populations. Although controversial, several communities have implemented the TNR method, developed in Rome, Italy.<sup>1</sup> TNR has been praised for population management, but cats are often demonized in wildlife forensics for their tendencies of property destruction and preying on rodent and bird populations. TNR clinics have provided the cat ear tips used in this study, which examined whether colony cats are more likely to be related than cats of the general population (non-colony cats). Colony feral cats are cats that were once domesticated and now returned to the wild, living in a specific environment with other cats. Non-colony feral cats are the same, but do not live in these groupings. Past research shows the importance of mtDNA in examining lineages. The degree of relatedness was to be determined separately for these two groups. The alternative hypothesis for this study is that colony cats are more related than non-colony cats.

Frankie's Friends, a non-profit spay and neuter clinic, was the ear tip provider for this research. The sample size is  $n=40$  colony cat ear tips and  $n=40$  non-colony cat ear tips. The method of extraction employed was the QIAGEN® QIAamp® DNA Mini Tissue Kit. This was followed by a quantitation step using the NanoDrop™ Lite Spectrophotometer by Thermo Scientific™. The average concentration for colony cats was about 11.7ng/uL after extraction. Two primer sequences, Lf15926 and Hf3, were used to amplify the HV1 region of mtDNA and followed up by sequencing with the ABI® BigDye® Kit, 3130 Genetic Analyzer, and Chromas software. The population statistics based on mtDNA testing will be presented.

### Y15 The Effects of the Evidence Preservation System (EPS) on the Storage of DNA Samples

*Devin J. Doyle, BS\*, Duquesne University, Pittsburgh, PA 15282; Pamela L. Marshall, PhD, Duquesne University, Pittsburgh, PA 15282; Lisa R. Ludvico, PhD, Duquesne University, Pittsburgh, PA 15282*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the investigation into the usage of the EPS as a potential viable storage unit in comparison to common laboratory storage practices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by testing a new technology in sample storage that could be utilized in most laboratory settings. This new technology could potentially prove to be the ideal storage environment to help improve and maintain the quality and quantity of DNA.

This research hypothesizes that the EPS unit will have higher quality and quantity DNA samples compared to room temperature, with similar results to 4°C and -20°C storage environments.

Storage of collected samples is a concern for all disciplines of forensic science. Without proper storage, especially DNA samples, the DNA will become unusable as it could become degraded, cross contaminated with other samples, etc. Much of the preliminary research revealed that there were very few studies on the storage of forensic samples regarding ideal protocols, let alone those that involved combining many controlled storage aspects, such as temperature, humidity, and Ultraviolet (UV) exposure. This research focuses on the EPS by Forensic Solutions, Inc., which is a controlled environment able to be programmed to control temperature and humidity while also preventing UV radiation exposure and bacterial growth on samples.

The purpose of this research was to perform comparative studies between normal laboratory storage conditions of -20°C, 4°C, and room temperature environments, and the EPS unit storage by examining their effects on the quantity and quality of degraded DNA samples as well as the drying weight of samples. For the drying weight comparisons, T-shirts were obtained with no specific material preference and were washed to mimic actual use by an individual rather than ideal conditions. One hundred forty-four 2"x2" swatches were then cut from one shirt and weighed before having blood deposited on them. One hundred twenty samples received a blood deposit of 50µL while 24 swatches were left unaltered for negative controls and 24 0.5mL tubes were filled with 50µL of blood to serve as the positive controls. Once dried, these samples were re-weighed, then placed and sealed inside labeled coin packages. These packages were separated into groups of 42 for each of the four environments (30 samples, 6 positive controls, 6 negative controls) and stored in their respective environments for a six-month period.

For the degraded sample comparisons, preliminary testing was done to determine the medium the blood was to be deposited on and the amount of blood that was to be deposited. It was decided that clothing swatches with 50µL of blood would be an adequate medium for this experiment. One hundred sixty-eight 2"x2" clothing swatches were cut from another washed shirt. One hundred forty-four of these samples received a 50µL deposit of blood while the remaining 24 were left unaltered to serve as negative controls. Once dried, 120 of the swatches were then exposed to UV radiation for ten minutes to irradiate the non-deposit side of the swatch for degradation. The samples were then placed and sealed in labeled coin packages. These packages were separated into groups of 42 for each of the four environments (30 samples, 6 positive controls, 6 negative controls) and stored in their respective environments for a six-month period.

Every month, five samples, one positive control, and one negative control were removed from each storage environment from both the degradation study and the drying weight study experiment groups. The degradation samples would undergo extraction, quantitation, amplification, and detection to determine any changes in quality and quantity of the DNA between storage environments. The drying weight samples would have their weights recorded and compared for any weight changes between the storage environments. Due to the importance of the storage of forensic samples across all disciplines, the EPS unit could be a very useful resource that could change and potentially improve the way various forensic samples are stored.

### Y16 Generating Artificially Degraded Human DNA in an Environmental Chamber

*Natalie Rivera Cardenas, BSc\*, Arizona State University West Campus, Glendale, AZ 85306; Natalie Damaso, PhD, Oak Ridge Institute for Science and Education, FBI Laboratory, Woodbridge, VA 22191; Patrick Rydzak, PhD, Stafford, VA 22554; James M. Robertson, PhD, Reserve Support Unit, Quantico, VA 22135*

**Learning Overview:** After attending this presentation, attendees will better understand the mechanisms of DNA degradation on various substrates when exposed to environmental conditions, such as Ultraviolet (UV), humidity, and temperature over time and their effect on obtaining a full Short Tandem Repeat (STR) profile.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing experimental methods that can be used in preparing artificially degraded DNA over time.

Environmentally damaged samples contain either degraded DNA fragments or contain somewhat intact DNA with single-stranded nicks and DNA lesions that can hinder acquisition of a complete DNA profile. As a result of this, there is a need in forensic research to generate artificial degraded DNA samples that can be used to improve and test STR typing protocols.

Within the field of forensic science, the testing and analysis of DNA has become notably important and contributed in solving crimes over the years. However, the issue on whether or not it is possible to retrieve an accurate DNA profile from degraded blood left behind at a scene is a recurring concern in the criminal justice system. Often, DNA left at crime scenes is scarce and highly degraded due to various environmental exposure conditions, such as heat, humidity, and UV irradiation. Environmentally damaged DNA may result in failure of amplification, and samples may not have a sufficient number of loci, which are needed for match comparisons. Thus, the purpose of this project was to optimize a method to artificially degrade control DNA and blood stains on different substrates (i.e., jeans and cotton shirt) using controlled environmental conditions (i.e., temperature, humidity, UV). This was done to mimic a “casework type” degraded sample that can be later used to: (1) test novel, enhanced methods (e.g., extraction kits, enhanced polymerase or STR kits) for obtaining a complete STR profile; and (2) better understand the mechanisms of degradation on various substrates and conditions.

To accomplish this, either control DNA (e.g., 9947A) or blood was applied to 1" x 1" squares of cotton and jeans fabrics. Next, the fabric squares were placed in the Environmental Chamber (Q-Sun Xe-3 Test Chamber) under conditions to imitate an outdoor environment (i.e., 15 hours of 71% RH, 0.21–0.25 W/m<sup>2</sup>, 35°C, followed by 9 hours of 60% RH, no UV, 35°C) and fabrics were recovered at various time points across 8 days. DNA extraction was performed for the blood samples using the QIAamp<sup>®</sup> DNA Investigator Kit and the EZ1<sup>™</sup> Advanced XL instrument and all samples were quantified using Quantifiler<sup>®</sup> Trio for all of the time points to obtain the DNA concentration (ng/ul) and level of Degradation (DI). STR profiles were obtained using the Identifiler<sup>®</sup> Plus and the THERMO FISHER<sup>™</sup> CE 3130XL to determine the level of degradation (e.g., ski slope effect, locus drop out, and decrease in Relative Fluorescent Units [RFU]) at the various time points.

Analysis Of Variance (ANOVA) and Tukey’s post-hoc statistical analysis revealed evidence of the ski-slope effect (i.e., a decrease in the RFU of larger loci targets compared to smaller ones;  $p=0.001$ ) and a significant decrease ( $p<0.001$ ) in the concentration of DNA recovered from pant samples (avg 5.96±1.70) when compared to shirt samples (avg=8.71±1.95). Furthermore, significantly higher DNA concentrations were recovered from samples at the 72hr time point than samples at 192hr time point ( $p=0.003$ ). However, no significant difference in the degradation index was found for any sample at any time. Overall, results illustrated a promising method that decreased DNA recovery and illustrated a ski-slope effect indicative of typical degraded DNA STR results.

### Y17 Geospatial Analysis of Canadian Drowning Locations

Vienna C. Lam, MA\*, Simon Fraser University, Burnaby, BC V5A 1S6, CANADA; Barbara Byers, HBA, Lifesaving Society, North York, ON M2J 1P8, CANADA; Gail S. Anderson, PhD, Simon Fraser University, Burnaby, BC V5A 1S6, CANADA

---

**Learning Overview:** After attending this presentation, attendees will better understand how geospatial tools can be applied to identify environmental risk factors associated with fatal incident locations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how new geospatial techniques can be used to enhance current practices in risk mitigation of aquatic landscapes.

This presentation will assess coroner and medical examiner data of fatal drowning accident propensity and Emergency Medical Services (EMS) access in Canadian waters from January 2006–December 2016 (an 11-year period). The Response Time (RT) between when a call is made to EMS and EMS arrival is known to be a strong indicator of patient survivability. Studies have shown that when the initial call cannot be made or there are lengthy delays that result in an RT past four to six minutes, chances of favorable neurological outcomes diminish dramatically.<sup>1</sup> It is for this reason that stable cellular reception plays an important role in fatal drowning risk reduction and for the purpose of contacting EMS when accidents near and within water take place. In Canada, there are many attractive, pristine lakes without commuter road networks that can be readily accessed, yet many of these areas do not have cellular coverage. The aim of this study was to identify the strength and type of cellular network available at Canadian drowning locations using geospatial analysis tools as a means of identifying areas of heightened risk due to unstable or limited cellular reception.

In this study, the geospatial coordinates of drowning locations were collected by the Lifesaving Society and based on coroner and medical examiner files from across Canada. Case demographics were assessed to identify risk factors associated with individual characteristics and environmental, geographic features. The spatial perimeters of lake systems and ocean fronts were then identified in this study using the Abacus Dataverse Network in the form of Canadian maps produced by DMTI Spatial. Cell towers were then identified for all locations, along with information on the number of cells per tower and the approximate range and strength of the signal based on ideal weather conditions through Statistics Canada. The network type and generation of broadband cellular network technology, such as Global System for Mobile Communications (GSM), Code Division Multiple Access (CDMA), Universal Mobile Telecommunications System (UMTS), and Long Term Evolution (LTE), was also used to analyze the type of coverage available. Results show that a hierarchical processing of identified fatal drowning locations can successfully be categorized through an assessment of EMS access of these locations. There are certain lakes that pose a higher risk because of limited cell reception, and their risk can be categorized based on the number of reported incidents, as well as the type and amount of reception that exists at each site.

### Y18 A Modern Trail of Tears: The Missing and Murdered Indigenous Women (MMIW) Crisis in the United States

A. Skylar Joseph, MS\*, Elbow Lake, MN 56531

**Learning Overview:** After attending this presentation, attendees will understand the history leading up to the current MMIW crisis; top risk factors for MMIW; why this crisis needs to be addressed at both the local and national levels; and preliminary actions that can be taken by local law enforcement agencies and forensic science divisions to help mitigate this national crisis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by raising awareness of the ongoing crisis of MMIW that is currently being experienced in cities across the United States and Canada and will offer some preliminary actions that forensic science practitioners can implement in order to facilitate positive change regarding this issue.

In the United States, American Indian and Alaskan Native people experience higher rates of violence than all other ethnicities. On some reservations, indigenous people experience murder at a rate of ten times the national average.<sup>1</sup> Additionally, homicide is the third-leading cause of death for indigenous women and girls between the ages of 10–24 years and the fifth-leading cause of death for indigenous women between 25–34 years of age.<sup>1</sup> The purpose of the present research has been to investigate the MMIW crisis, determine the cities with the highest rates of MMIW, and to offer suggestions to help fix the root causes for this national crisis.

In the present study, missing persons data was analyzed from the National Missing and Unidentified Persons System (NamUs), the National Crime Information Center (NCIC), and from data collected and published in a report produced by the Urban Indian Health Institute (UIHI).<sup>2</sup> Additionally, unidentified persons data was analyzed from NamUs, and data regarding murder cases of indigenous women was analyzed from the UIHI report.<sup>2</sup> Locations with the highest rates of MMIW cases in the country were identified as potential “hot spots.” Additional analysis of these locations took into account demographic data from the United States census, fracking locations in the United States, and other socio-political factors that could be affecting the MMIW case prevalence in these areas.

Following the analysis, a total of 23 locations were determined to be “hot spots” for MMIW cases. Of these 23 locations, five were identified as being of the highest priority for intervention due to their disproportionately high rates of MMIW cases. These locations are Albuquerque, NM; Anchorage, AK; Gallup/McKinley County, NM; Seattle/King County, WA; and Tacoma/Pierce County, WA. Furthermore, hydraulic fracking across the United States seems likely to be a contributing factor in the rate of MMIW cases in 9 to 16 of the identified “hot spots.”

Currently in the United States, despite a national movement to raise awareness to the MMIW crisis, there has yet to be any actions taken by the federal government to address this issue. The present study has served to identify the primary “hot spots” for MMIW cases and has isolated some of the key contributing factors to this national problem. With this information, a more direct, community-based action plan can be developed in each of these “hot spots” to provide more immediate help to these communities. In order to most holistically address this issue, actions need to be taken at both the local and federal levels, and this study aims to highlight what those initial actions should be.

### Y19 A Longitudinal Study of the Effects of Storage Conditions on DNA Recovery From Condoms

*Claire J. Loretta\**, Pittsburgh, PA 15203; *Lisa R. Ludvico, PhD*, Duquesne University, Pittsburgh, PA 15282; *Pamela L. Marshall, PhD*, Duquesne University, Pittsburgh, PA 15282; *Stephanie J. Wetzel, PhD*, Duquesne University, Pittsburgh, PA 15282

---

**Learning Overview:** After attending this presentation, attendees will understand the relationship between storage duration, storage temperature, and condom brand on the quantity and quality of male DNA recovered from condoms.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a simple, yet essential, proof-of-concept that has yet to be investigated—the impact of condoms on DNA degradation. This presentation will serve as the framework for future studies so that the individual variables in question can be studied in greater detail.

With increased public awareness of the value of DNA in criminal investigations, the number of sexual assaults involving condom use has also increased. Maximizing the utility of evidence—both biologically and chemically—has presented a variety of challenges to an assortment of forensic professionals, such as crime scene investigators, detectives, and laboratory technicians.

Typically, the most crucial evidence in a sexual assault investigation is collected from the survivor during a medical forensic examination in the form of a Sexual Assault Kit (SAK). Unfortunately, the backlog of untested SAKs in the United States is immense. However, condoms are not collected with SAKs and therefore are separately submitted for forensic testing. Because condoms circumvent the SAK backlog, they are often processed much more rapidly, creating a huge advantage for investigators that may allow them to identify a perpetrator without SAK evidence.

While the consequences of DNA degradation are well established across a wide variety of conditions, literature pertaining to the influence of condoms on DNA degradation is practically non-existent. Of the literature concerning condoms, research is primarily focused on the detection and identification of chemical compounds found within condom lubricants. The majority of these efforts contribute to a broader objective—to establish a universal classification scheme and to construct a database of sexual lubricant profiles. Though sexual lubricant analysis is an important and rapidly growing field of trace evidence, it does not exhibit the same discriminatory power and identification capacity that DNA does.

The objective of this study was to investigate the effects of condoms on DNA degradation; it established a fundamental understanding of the relationship between DNA, condoms, and storage conditions.

Both DNA quantity and quality were measured across three variables: (1) time, (2) temperature, and (3) condom brand. Neat semen from one male was aliquoted into condoms from three manufacturers (Trojan<sup>®</sup>, Durex<sup>®</sup>, and Sustain<sup>®</sup>), followed by sample storage at three different temperatures (25°C, 4°C, and -20°C). The total storage duration was one year (52 weeks) with sample analysis at four separate intervals:  $t_0=0$  weeks,  $t_1=16$  weeks,  $t_2=32$  weeks, and  $t_3=52$  weeks.

All samples were extracted using the DNA IQ<sup>™</sup> System and quantified via a QuantStudio<sup>™</sup> 5 Real-Time PCR System using the Quantifiler<sup>®</sup> Human DNA Quantification Kit. The sample extracts were then amplified with the GlobalFiler<sup>™</sup> PCR Amplification Kit via a GeneAmp<sup>®</sup> PCR System 9700; all samples underwent capillary electrophoresis in a 3130 Genetic Analyzer and were analyzed with GeneMarker<sup>®</sup> HID software. In addition to DNA analysis, microscope slide smears were prepared and stained with Christmas Tree stain to evaluate sperm morphology. Finally, the primary chemical compounds of each condom lubricant were identified using quadrupole Time-Of-Flight Liquid Chromatography/Mass Spectrometry (qTOF-LC/MS) performed on an Agilent<sup>®</sup> 6530 qTOF-LC/MS.

The quantities of DNA at  $t_1$  and  $t_2$  were relatively consistent. All samples stored at 25°C had DNA concentrations of 0.01ng/μL or less, while samples stored at 4°C and -20°C had concentrations between 2.35–3.78ng/μL at  $t_1$  and 2.25–8.56ng/μL at  $t_2$ . No significant differences in DNA concentrations were observed between the three condom brands or between the storage temperatures of 4°C and -20°C.

By investigating the progression of DNA degradation within condoms, consistent methods for optimal condom preservation can be employed. Furthermore, supplementing a database of the chemical profiles of sexual lubricants with biological counterparts would considerably increase the value and versatility of such a database.

---

#### Condoms, DNA Degradation, Storage

## Young Forensic Scientists Forum—2020

### Y20 The Benefits of Automation in Forensic Toxicology: A Lean Six Sigma and Cost-Analysis Approach

*Sarah J. Guertin, BS\*, Birmingham, AL 35205; Elizabeth A. Gardner, PhD, University of Alabama Department of Criminal Justice, Birmingham, AL 35294-4562; Hui Liu Yong, BS, Alabama Department of Forensic Sciences, Hoover, AL 35244; Curt E. Harper, PhD, Alabama Department of Forensic Sciences, Hoover, AL 35244*

**Learning Overview:** After attending this presentation, attendees will be proficient in Lean Six Sigma and cost-analysis techniques used to identify inefficient methods and processes in the laboratory.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the advantages of automating extraction and preparation methods for toxicological analysis.

**Background:** Reducing backlogs, improving turnaround times, and streamlining methodology are major focus points for forensic toxicology laboratories. A factory-minded approach in which cases are considered widgets will allow a laboratory to identify areas for improvement. Lean Six Sigma is a process that relies on a collaborative team effort to improve performance by systematically removing waste and reducing variation. By applying this approach combined with a detailed cost-analysis, inefficient or costly processes in the laboratory can be identified. Analytical methods identified in this exercise are excellent candidates for automation transition. Fully automated instruments and equipment, such as the Randox<sup>®</sup> Evidence Analyzer and Hamilton<sup>®</sup> Starlet, are excellent options for automation.

**Method:** Each standard operating procedure used by the Alabama Department of Forensic Sciences was reviewed and observed. An itemized list of consumables was created, and the cost of each item was obtained from previous purchase orders. The average analyst time, salary, and hourly wage were calculated and used to determine the cost of analyst time dedicated to each assay. An MS<sup>®</sup> Excel<sup>®</sup> template for cost compilation (with and without personnel cost) was created in order to determine the cost of each individual method. The cost per maximum-sized batch and cost per case of each assay was calculated. Cost comparison between assays are listed as follows: (1) blood drug screening methods using the Tecan Evo<sup>®</sup> 75 (semi-automated) versus Randox<sup>®</sup> Evidence Analyzer (fully automated), (2) oral fluid drug confirmation methods using Dispersive Pipette Extraction (DPX) on the INTEGRA VIAFLO 96 (semi-automated) versus Hamilton<sup>®</sup> Starlet (fully automated), and (3) opioid quantitation methods using traditional Solid Phase Extractions (SPE) (manual) versus Thermo Scientific<sup>™</sup> SOLA $\mu$ <sup>™</sup> SPE well plate on Hamilton<sup>®</sup> Starlet (fully automated).

**Results:** The most costly and inefficient method identified was the opioid blood quantitation method by traditional SPE. When transitioned to the fully automated Hamilton<sup>®</sup> Starlet, the cost per case and extraction time were reduced by 59% and 50%, respectively. In addition, the sample capacity (batch size) was doubled compared to traditional SPE. Similarly, the oral fluid drug confirmation method using the Hamilton<sup>®</sup> Starlet reduced the cost per case and extraction time by 29% and 38%, respectively. The sample capacity was doubled compared to the semi-automated confirmation method with the INTEGRA VIAFLO 96. The cost per case of a blood drug screen with the fully automated Randox<sup>®</sup> costs 10% more than a blood drug screen with the semi-automated Tecan. However, Randox<sup>®</sup> requires 64% less analyst time per batch.

**Conclusion:** Lean Six Sigma entails removing waste, increasing speed, and reducing variation. A major component of time is the sample preparation and extraction prior to instrumental analysis. If this can be automated, a scientist can focus on other aspects of their duties, such as reporting, reviewing, or providing expert witness testimony. This study provides a better understanding of cost per case, cost per batch, and major contributors to cost, including personnel time. Suggested strategies to reduce inefficiencies and costs include maximizing batch size and reducing analyst time by converting methods to full automation. Future studies will involve evaluating instrument and data analysis cost and time.

#### Cost Analysis, Automation, Lean Six Sigma

### Y21 Further Development of Scoring Rules for Sample Comparisons Using Automated Particle Micromorphometry of Aluminum (Al) Powders

Kayla M. Moquin\*, Quantico, VA 22135; Cami Fuglsby, MS\*, South Dakota State University, Brookings, SD 57007; JenaMarie Baldaino, MS, Quantico, VA 22135; Danica Ommen, PhD, Iowa State University, Statistics, Ames, IA 50011; Christopher P. Saunders, PhD, Brookings, SD 57006; Jack Hietpas, PhD, Penn State University, University Park, PA 16802; JoAnn Buscaglia, PhD, FBI Laboratory, Counterterrorism & Forensic Science Research Unit, Quantico, VA 22135

**Learning Overview:** After attending this presentation, attendees will better understand various strategies currently being researched for the interpretation and discrimination of forensic explosive evidence associated with Al powders. Attendees will also gain an understanding of how automated microscopical imaging, in combination with various statistical methods, may aid in forensic investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the application of Al particle micromorphometry as a quantitative method for the characterization and comparison of explosive evidence, which may also provide valuable lead information for forensic investigations.

**Hypothesis Statement:** The use of automated microscopy in combination with various processing and statistical techniques will provide further source discrimination and investigative leads in source identification involving the use of Al powders in Improvised Explosive Devices (IEDs).

IEDs are often composed of commercial or readily available materials. One such material that can be obtained from multiple sources is Al powder; a common metallic fuel, it has many legitimate uses and applications, making it an easily accessible material. Although many of these sources are marketed in powder form, sources not already in powder form can be easily and inexpensively produced via simple methods found online. This circulation of amateur methodologies for the production and usage of Al powder has put dangerous and destructive tools in the hands of homemade bomb makers, creating the need for new and quantitative identification and analysis methods. For this reason, it has become increasingly important to evaluate not only the composition of such devices, but also to analyze and distinguish between various forms of Al powder for additional investigative and intelligence value.

Previous work done on this research project has displayed the ability to differentiate between methods of Al powder manufacturing (i.e., industrial vs. homemade) through the use of various microscopy techniques: automated particle micromorphometric analysis as well as Scanning Electron Microscopy/Energy Dispersive X-Ray Spectroscopy (SEM/EDS). These techniques have shown differentiation in morphology and surface characteristics among these powders. Further, the comparison of similarities and dissimilarities has been statistically scored and evaluated to determine the viability of the method to distinguish between two samples/sources based on 17 characteristics. This presentation aims to build upon previously presented work: the analysis of more Al powder samples has allowed for a more robust data set, and additional statistical approaches have been developed and tested on these high-dimensional, large data sets.

In this work, slides intended for automated imaging were prepped using ~1,000 $\mu$ g of bulk Al powder placed into a microtube containing Permout<sup>®</sup> mounting medium, then mixed thoroughly to avoid uneven dispersion before a set aliquot (via pipet) was placed dropwise onto a slide with a coverslip firmly set over it. This process was conducted such that for each sample, there were a total of seven subsamples (microtubes) and three aliquots (taken from the same microtube), for a total of 21 coverslips per sample. Once mounted, the Al samples were imaged using a transmitted light microscope fitted with an automated stage and automated z-focus. For each coverslip, 200 images were taken at random Fields Of View (FOV) to statistically characterize the distribution of particles in a subsample. Once imaging was complete for each subsample, the resulting data was batch processed using a commercial image analysis software with customized code to fit the parameters to be measured; the image was converted to a binary image, and particles were then measured and counted for each field of view. Seventeen parameters were measured, accounting for various size and shape characteristics of the particles.

Using various statistical means (various machine learning methods applied to summary statistics of subsamples and score-based methods for measuring the dissimilarity of distributions of particles), empirical tests have thus far shown that the ability of the proposed method to correctly characterize the type of powder based upon the 17 parameters is significant. Further, it has displayed that in most instances of incorrect or misidentification for data attribution to a certain sample, the sample has been misidentified with another sample of the same type (e.g., foil sample A misattributed to foil sample C). Both within-source and between-source score distributions were analyzed statistically to further determine how to improve upon the method; various trials utilizing different portions of data were implemented to determine which factors affected results and how those findings may allow for improvement of the analytical and interpretative methods.

### Y22 Gas Chromatography With Dual Cold Electron Ionization Mass Spectrometric and Vacuum Ultraviolet Detection (GC/MS-VUV) for the Analysis of Phenylethylamine Analogs

Jordan L. Tanen\*, Rutland, VT 05701; Ioan Marginean, PhD, The George Washington University, Washington, DC 20007; Ira S. Lurie, PhD, The George Washington University, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will understand the advantage of GC/MS-VUV in improving confidence in the analysis of Phenylethylamine (PEA) analogs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a rapid method for the identification of PEA analogs involving no liquid-liquid extraction and/or derivatization. This study provides a novel set of tools for the reliable identification of emerging drugs.

PEAs belong to a class of psychoactive drugs that have become more prevalent during the past several years. Certain PEAs were popularized by Alexander Shulgin in his book *PIHKAL*.<sup>1</sup> Many of these drugs are currently being synthesized to circumnavigate drug laws. Online availability results in easy access to many emerging drugs. There have been several deaths attributed to 2C PEAs in both the United States and Europe. Several case studies have shown the adverse effects of PEAs in humans. Because of these reasons, drugs like synthetic PEAs are controlled substances scheduled by the Drug Enforcement Administration.

The majority of drug analyses are commonly performed by GC with Flame Ionization Detection (FID) or MS detection. MS detection is preferable due to its ability to identify compounds based on mass-to-charge ratios and fragmentation patterns, whereas identification by FID relies heavily on the retention time of analytes. The analysis of PEA analogs, including positional isomers, with classical detection methods such as MS poses a few challenges for the forensic chemist. Classical electron ionization of certain compounds, such as phenethylamine analogs results in mass spectra with little to no molecular ions. The mass spectra are also insufficient for discrimination of certain positional isomers. This study demonstrates that the use of GC/MS-VUV can improve the analysis of PEAs. Cold electron ionization can increase the relative intensity of the molecular ions in mass spectra, as well as providing major fragments, while VUV can discriminate between most positional isomers.

Excellent chromatographic performance was obtained for PEA analogs by adding sodium bicarbonate to methanolic solutions of standard compounds. From a mixture of 40 PEA compounds, 21 were resolved with a resolution greater than 1 using VUV detection. However, all solutes could be resolved using a combination of MS detection (single ion monitoring) and/or VUV detection (deconvolution). The relative intensity of the molecular ion was increased for all 2C compounds, while molecules in the NBOMe class showed lower or no increase in molecular ion relative intensity. VUV spectra can be added to a library database as an aid for the identification of PEAs, including positional isomers. The VUV software is also capable of deconvoluting coeluting analytes. PCA was performed on both VUV and MS data of 5 dimethoxymamphetamine positional isomers to demonstrate the improved capability for discrimination of VUV detection.

### Y23 Improved Methods for the Genetic Identification of Burned Skeletal Remains

Kadir Dastan, PhD\*, Istanbul Yeni Yuzyil University, Istanbul 34010, TURKEY; Emel Hulya Yukseloglu, PhD, Istanbul University-Cerrahpasa, Istanbul 34010, TURKEY

**Learning Overview:** The goal of this presentation is to offer best-practice procedures for the extraction of DNA from human cremated remains and to recover DNA useful for identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a predictive model to determine which cremated human remains are likely to produce the best results for the extraction of DNA.

The cremation process consists of burning the corpse at temperatures of up to 1,000°C, reducing it to bone remains or bone fragments, which are often ground to a consistency similar to that of sand. In the identification of forensic cases, it is critical to obtain information on the victim's identity from burned bone and teeth remains.<sup>1</sup> When bone and teeth are burned, both their physical and chemical properties change significantly, which prevents anthropological evaluations and successful DNA profiling. Heat causes difficulties in the identification techniques in which bones and teeth are used, depending on the degree of temperature exposure. Therefore, it is necessary to evaluate the results of observation and analysis, and the information obtained in a certain order, with the changes occurring in bone and teeth during the burning period. The identification of burned or buried bones and teeth has always been a difficult process due to the diminished quality and quantity of DNA, and it is still a challenge.<sup>2</sup> Due to heterogeneity in DNA due to the heterogeneity within the bone, unfortunately, the only reliable method for obtaining DNA from cremated samples such as burned bones and teeth is still not available in the literature.<sup>3</sup>

Previous research on DNA analysis of cremated remains has shown limited success.<sup>4</sup> This study examines adjustments or improvements throughout the DNA analysis workflow to improve methods of identifying human cremated remains. DNA was extracted from bone fragments using a commercial silica-based method or an enhanced extraction method that modifies the commercial kit to determine which process resulted in maximum DNA recovery. Several extracts from a single bone fragment were combined, then concentrated with an Eppendorf® Vacufuge. All extracts were quantified using the real-time Polymerase Chain Reaction (PCR) to evaluate the recovery of nuclear or mitochondrial DNA. Concentrated extracts were amplified using the GlobalFiler® PCR amplification kit with an increased PCR cycle protocol and analyzed using capillary electrophoresis or a complete mitochondrial DNA genome multiplex developed internally for sequencing in the Illumina® MiSeq®. Multiple samples from individual sets of remnants were examined to assess the consistency of the results. The results indicate that low levels of nuclear DNA can be recovered from the cremated bone with partial STR profiles obtained from combined and concentrated extracts; however, exaggerated stochastic effects, such as increased stuttering, allele fall, and peak height imbalance, were observed in some profiles due to the low amount of initial template and the use of an increased cycle PCR, thus complicating the interpretation of the profile.

### Y24 The Efficiency of DNA Isolation and Profiling From Burned Human Teeth Remains

Kadir Dastan, PhD\*, Istanbul Yeni Yuzyil University, Istanbul 34010, TURKEY; Emel Hulya Yukseloglu, PhD, Istanbul University-Cerrahpasa, Istanbul 34010, TURKEY

**Learning Overview:** The goal of this presentation is to offer best-practice procedures for the isolation of DNA from burned human teeth remains and to recover DNA useful for identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a predictive model to determine which incinerated human teeth remains are likely to produce the best results for Short Tandem Repeat (STR) analysis.

Because teeth are the hardest tissue in the human body and one of the most abundant types of biological remains available in forensic cases, this study focused on evaluating the effectiveness of DNA isolation from burned teeth and obtaining a DNA profile under different conditions of exposure to temperature and time.<sup>1,2</sup>

Twenty-five healthy erupted third molars, aged 18 to 71 years, were collected. The teeth were divided into seven groups and treated at different temperatures: 100°C, 200°C, 300°C, 400°C, 500°C, 600°C, and 700°C. The teeth of each group were treated at the assigned temperature for 1 minute, 5 minutes, 10 minutes, and 15 minutes, extracting one tooth after each period of time. The control and burned teeth were mechanically ground and subjected to DNA extraction and amplification. Based on the amplification data, it was not possible to obtain DNA from the teeth subjected to 400°C for 10 and 15 minutes, 500°C for 15 minutes, 600°C for 5 minutes, and 700°C for 5, 10, and 15 minutes. In the first temperatures and times, 100°C and 200°C, 1 and 5 minutes, it was possible to obtain an amplification similar to that of the controls; however, in most STRs, the amplification was very low from 300°C for 1 or 5 minutes onward.

This indicates that even in teeth burned and subjected to high temperatures, it is possible to amplify the DNA, at least the domestic DNA; however, the data also show that it would be difficult to obtain an STR profile, probably due to the size of these regions that makes them more prone to degradation.<sup>3</sup> The results of this research provide a quantitative study for obtaining a DNA profile of burned teeth.<sup>4</sup> Future research could extend these results by analyzing other potential regions of DNA for identification under the same conditions.

### Y26 Cost-Effective Robust Authentication and Environmental Monitoring of Forensic Evidence

*Peter Gompper\*, San Francisco, CA*

---

**Learning Overview:** After attending this presentation, attendees will have learned about the weaknesses of existing forensic evidence containers as they relate to the detection of lost, counterfeit, or degraded material. Attendees will also have learned about the utility of the “last mile” problem when developing solutions to these problems, and why custody-chain tracking is unable to support solutions to such events. Finally, attendees will have learned about recent innovations in packaging and how they support reliability and efficient evidence processing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing and elaborating on the necessity of secure unit-level evidence packaging as the optimal means of meeting guidelines. This presentation will also propose performance actions, including how best to: (1) detect an incursion across the surface boundary of an evidence package; (2) authenticate evidence using encryption; (3) register the environmental status of biological evidence; (4) support custody chain requirements (i.e., data regarding location, date, responsible contact, etc.); and (5) support inspection readiness efforts and performance initiatives for agencies unequipped with advanced evidence management systems.

From crime scene to presentation at court, forensic material evidence is at risk of careless handling, theft, counterfeiting, tampering, and environmental degradation. Such “triggering events” can become liability issues for law enforcement agencies, crime labs, courts, and communities dependent upon the credibility of criminal justice systems. Property and evidence managers attempt to mitigate against a wide variety of events by manual and semi-automated processes that focus on custody chain monitoring, tracking in-transit evidence, and controlling access to evidence rooms. The weakness of both manual and semi-automated systems is the lack of unit-level detection of an event. For instance, containers with unique identifiers—such as signature lines, barcodes, or adhered Radio Frequency Identification Devices (RFID) tags—can easily be broken, copied, replaced, or decrypted to thwart systems-level security. Without robust unit-level security, systems-level weaknesses leave evidence at risk, at any point along the custody chain.

To reliably and conveniently authenticate evidence without additional cost or burden to evidence handlers, an electronic Tamper-Evident Packaging (eTEP) was developed. The packaging acts as a one-time irreversible surface monitor capable of communicating to smart phones, electronic devices, and evidence management systems in the submission, handling, presentation, and disposition of items of evidence. Additionally, to support best practice in the maintenance and integrity of biological evidence, the eTEP laminate was designed to detect environmental changes (as outlined by the National Institute of Justice/National Institute of Standards and Technology (NIJ/NIST) Technical Working Group on Biological Evidence, NIST Interagency/Internal Report (NISTIR) 7928).

As a part of the National Science Foundation’s I-Corps program, this presentation will outline the innovation to conference attendees and request feedback and insight regarding potential usability within varying agencies.

**Evidence, Monitoring, Theft**

## Young Forensic Scientists Forum—2020

### Y27 The Evaluation of DNA Extraction Methods for Chewing Gum Samples

Chelsea Jones\*, Sharpsburg, GA 30277; Ashton B. Jones\*, Fuquay-Varina, NC 27526; Britannia J. Bintz, MSc, Cullowhee, NC 28723; Frankie L. West, PhD, Cullowhee, NC 28723

**Learning Overview:** After attending this presentation, attendees will better understand three different DNA extraction methods, including the PrepFiler® BTA™ method, Phenol-Chloroform-Isoamyl Alcohol (PCIA) purification, and a combined protocol. A comparison of the extraction yields, degree of DNA degradation, sample purity, and the advantages and disadvantages of each method will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by ultimately enabling analysts to make informed decisions regarding the selection of the most appropriate DNA extraction method for chewing gum samples.

Chewing gum samples are potential sources of DNA in forensic casework. Historically, several different methods have been used to extract DNA from chewing gum samples, however, few systematic studies have been conducted to show whether one method is superior to others. In this work, two commonly used methods were tested, including the Applied Biosystems® PrepFiler® BTA™ kit and the PCIA purification method. The PrepFiler® BTA™ kit is often employed in crime laboratories because it is efficient and designed for problematic sample matrices, including bones, teeth, and adhesives. The PCIA method, however, is not as commonly used today because it is labor intensive and requires the use of toxic organic solvents. Per research, no study has been conducted to show that the PrepFiler® BTA™ method results in higher DNA yields than PCIA purification for chewing gum samples. In addition, an optimized protocol was also tested, which included sample lysis using the PrepFiler® BTA™ buffer followed by DNA purification with PCIA and PrepFiler® BTA™ magnetic beads.

It was initially hypothesized that the optimized protocol would be superior because: (1) it would lead to a high yield given that peer-reviewed literature suggested that the use of PCIA results in complete digestion of the chewing gum sample, leading to the release of all DNA present within the gum; and (2) that the extract would be free of inhibitors and other contaminants since multiple purification steps were included. Each method was tested independently by extracting DNA from forensically relevant chewing gum samples. To create these mock samples, gum was chewed for a period of five minutes by a male donor and was then buried outdoors in soil for one week. During this time, environmental humidity and temperature were monitored. DNA was then extracted from the samples, using one of the three protocols described above. The extracts were then assessed for yield, degree of degradation, and presence of inhibitors using quantitative Polymerase Chain Reaction (qPCR) and the Applied Biosystems® Quantifiler® Trio kit. Results were then compared to determine which method, if any, was most efficient at producing large quantities of high-purity, high-molecular weight DNA. DNA yields obtained from qPCR were normalized, then statistically compared using Analysis of Variance (ANOVA). This analysis showed that PCIA purification alone produced statistically significantly higher yields of DNA than the other two extraction protocols tested.

After these results were obtained, the experiment was conducted again, using more controlled variables, including flavor of the gum, extraction incubation times, environmental exposure times, and time intervals between sample chewing and burial. The extraction methods described above were also used for this additional set of samples.

Based on the results obtained from both rounds of experiments, it was determined that the most effective method for DNA extraction from a forensically relevant chewing gum sample was the PCIA extraction method, rather than the PrepFiler® BTA™ or custom extraction methods also tested.

#### PrepFiler® BTA™, DNA Extraction, Chewing Gum

### Y28 Using Loop-Mediated Isothermal Amplification (LAMP) to Identify At-Risk Species in the Field

Brooke Driscoll\*, Orchard Park, NY 14127; Nickolas P. Walker, BS, East Amherst, NY 14051; Jan E. Janecka, PhD, Duquesne University, Pittsburgh, PA 15282

---

**Learning Overview:** After attending this presentation, attendees will better understand LAMP and its use as a field method for identifying species of interest for wildlife forensics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a species identification technique for trafficked animal samples that can be performed directly in the field.

Species identification through DNA analysis is relevant to population genetics, species conservation, and wildlife forensics. Unfortunately, many species of interest are endemic to areas with little access to advanced scientific technology. This means that DNA testing must be outsourced to other areas or testing must wait until the researchers are in a different location. Additionally, the biological substrate for the species of interest may contain limited amounts of DNA. This pertains mainly to highly elusive species that can only be readily studied using scat and to trafficked samples such as teeth, claws, and scales. All of these substrates pose greater DNA processing difficulties when compared to the more traditional blood samples. To better aid in the research of endangered and at-risk species, a method is needed that can accurately identify species through unconventional biological substrates with minimal laboratory instrumentation.

A promising solution to this issue is LAMP. This amplification method has similar sensitivities to traditional Polymerase Chain Reaction (PCR) but can be done at isothermal temperatures. This eliminates the need for a thermocycler during the reaction. LAMP has also been studied with fluorescent, in-tube visualization methods that reduce the need for agarose gel. The entire process is relatively fast, requiring only a 30-minute incubation. Using these methods, it is possible that species could be identified in a field environment.

The main question to be answered by this research is: can a field-accessible kit be developed for non-invasive species identification using the LAMP method? Previous research has shown that isothermal amplification can be performed with minimal laboratory equipment, but a functioning kit has not been assembled that can accurately identify species in the field. The species of interest in this study is the snow leopard, which is highly elusive and difficult to study. A non-invasive sampling source for DNA is often scat, which poses difficulties for DNA analysis due to inhibitors. Creating a method based off of this substrate will allow the method to be more adaptable to other low-level DNA substrates.

The method is conducted primarily using a heat block, a fluorescent dye, components of the Lucigen® LavaLAMP™ kit, and an animal sample. The suspected snow leopard scat is collected in Mongolia and China, dried with a desiccant material, and shipped to the United States for testing. Approximately 100 of these scat samples will be rehydrated for testing. The DNA is tested by dipping Whatman® No. 1 filter paper into the scat, then into a lysis buffer, and then placed directly into the LavaLAMP™ amplification mix. Prior to incubation, calcein and manganese (II) chloride are added as fluorescent indicators. The samples are heated on a heat block to 70° Celsius for 30 minutes. Following amplification, the samples are immediately visualized under Ultraviolet (UV) light, with fluorescence being indicative of amplification. The expected results of this study are that the scat samples can be identified with high accuracy and reliability without the use of a thermocycler or agarose gel. Initial results have shown that the method is reliable with scat samples and can be visualized using the calcein fluorescence. Once further optimized, the method will be applied in China so that samples will not need to be sent to the United States for analysis. This kit will allow wildlife forensics and species conservation efforts to be conducted in resource-poor areas to accurately identify endangered and trafficked species.

### Y29 FARO® Laser Scanner as a Tool for Bloodstain Pattern Analysts: Documentation of Bloodstains Enhanced by Luminol and BlueStar®

Tiffany Hogberg, BA\*, Syracuse University, Syracuse, NY 13210

**Learning Overview:** The goal of this presentation is to test the FARO® laser scanner's ability to capture chemiluminescence created by the application of luminol and BlueStar® to a dilution series of bloodstains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by beginning to define the capabilities of a 3D crime scene documentation system and testing if it can be advantageous for analysis as well as documentation.

**Hypothesis:** Due to the limitations of the FARO® Laser Scanner's equipment, it is predicted that the current methodology used to document luminol and BlueStar® reactions, photography, will be more accurate in documenting the chemiluminescence of the two reagents.

Luminol and BlueStar® have commonly been used at crime scenes to locate potential bloodstains.<sup>1</sup> Luminol is known to have a shorter chemiluminescence than BlueStar®, while BlueStar® is known to enhance potential bloodstains in locations that have more light exposure, such as outdoors scenes. Photography is the documentation for these methods of stain enhancement, with photographs being taken within seconds of luminol and BlueStar® application. There have been new developments in crime scene documentation due to the desire to capture the scene "as-is" for litigation; however, experimentation has not been done to test the capabilities of these new systems in documenting crime scenes that have been enhanced using reagents such as luminol and BlueStar®. This research will use the FARO® laser scanner to document bloodstain patterns enhanced with these reagents.

**Experimental Design/Materials and Methods:** This experiment is set up as four trials repeated three times. Two sets of bloodstains made from blood diluted at 1:1, 1:10, 1:50, 1:100, 1:500, and 1:1000 and will be created on two different surfaces, carpet and concrete, using 5mL of sheep's blood. The stains will be created and allowed to dry for two hours prior to their washing. The stains will be washed away using dish soap and water. The carpet and concrete will be allowed to dry for 24 hours prior to application of the reagents. One set of diluted bloodstains on the carpet will be enhanced using luminol and the other set using BlueStar®. The same procedure will be followed for the bloodstains on the concrete. Both the FARO® laser scanner and a Nikon® D7200 will be set up to record the reactions of each bloodstain. The documentation will be completed in a mostly dark environment.

The results for each stain will be evaluated to determine the sensitivity of the reagents, as well as the effectiveness of both means of documentation. The FARO® laser scanner is predicted to document the BlueStar® reactions better than the luminol reactions, as BlueStar® is known to have a longer chemiluminescence. The FARO® laser scanner takes longer to document the room because of the amount of data it is collecting. Scans roughly take five minutes to complete. However, because of the time required to scan a room using the FARO® laser scanner, it is predicted the documentation from the Nikon® D7200 will be the most effective in capturing the reactions. As for the sensitivity of each reagent, it is predicted that the BlueStar® will be more sensitive than the luminol to highly diluted bloodstains. This belief is based on known prior experiments in forensic literature of BlueStar® and luminol sensitivity.

### Y30 Methamphetamine Confirmation Analysis After Controlled Vicks® VapoInhaler™ Injection Into Oral Fluid

Julia N. Canello\*, Pittsburgh, PA 15220; Stephanie J. Wetzel, PhD, Duquesne University, Pittsburgh, PA 15282; Frederick W. Fochtman, PhD, MolecularDx, LLC, Windber, PA 15963-1300

**Learning Overview:** The goal of this presentation is to further investigate false-positive assay testing for methamphetamine after a common nasal decongestant has been applied to neat oral fluid samples using Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring enantiomer concentrations of methamphetamine after positive assay results using oral fluid, a matrix not commonly used for routine assay testing. This study will also allow attendees to understand the relationship between enantiomeric compounds, such as methamphetamine, and how their effects can be used for very different outcomes.

Methamphetamine, a Schedule II stimulant of the Amphetamine family, is currently the second most widely abused illicit drug in the country.<sup>1</sup> Methamphetamine is sought for its extensive psychoactive stimulant effects that include instant subtle psychosis, attention deficit, and decreased motor skill ability.<sup>2</sup> Two isomers of the drug, dextro- (D-) and levo- (L-), form its composition; however, each produce very different effects when active. For example, many over-the-counter nasal decongestants contain both isomers but only produce the vasoconstriction qualities of L-methamphetamine (L-MAMP). As a result, false positive assays for methamphetamine have consistently been an issue in the forensic community for years. Specifically, drug assay screenings have been known to read positive for methamphetamine use after Vicks® VapoInhaler™ (and other nasal decongestants) intake using various matrices, resulting in a false positive for the illegal substance D-Methamphetamine (D-MAMP). The unfortunate results propose an increased need for confirmatory methods after such occurrences. This research aims to identify false positive assay results for methamphetamine associated with Vicks® VapoInhaler™ injection into neat oral fluid samples.

Previous research has been conducted in order to recover D-MAMP after Vicks® intake using matrices such as urine and blood, but has only scarcely been investigated using oral fluid. Current research used a Molecular Devices SpectraMax® i3x Plate Reader to measure absorbances of oral fluid samples that were spiked with varying concentrations of Vicks® products. An Immunalysis™ Methamphetamine Assay Kit was used to test the amount of D-MAMP present in such samples at a range of 0-100ng/mL. The Limit Of Quantification (LOD) cutoff of this test was found to be 50ng/mL, a concentration that can prove comparable to workplace assay kits. Solid Phase Extraction (SPE) was used for samples that provided a positive assay to prepare for LC/MS/MS using a positive pressure manifold and Strata™-X strong cation Phenomenex® SPE cartridges. The quantity of D-MAMP was detected and confirmed using the Agilent® Technologies 6460 LC/Triple Quadrupole/MS operating in positive mode.

It has been hypothesized that the oral fluid samples that have been injected with higher concentrations of Vicks® products will produce false positive assay results for the illegal substance D-MAMP. Method validation for the SPE and LC/MS/MS parameters for extracting methamphetamine from varying oral fluid samples has proven to work successfully. Proof of concept using the SpectraMax® i3x has been completed using both positive control samples and spiked oral fluid samples with D-MAMP, L-MAMP, and D/L-MAMP standards, showing a subtle yet consistent decrease of absorbances in increasing D-MAMP concentrated samples.

Detecting exact concentrations of both D-MAMP and L-MAMP isomers in these Vicks® products can eventually lead to more specific immunoassays that will produce fewer false positives. The use of oral fluid can provide law enforcement and workplace testing facilities an easier collection method for drug screening. Nasal decongestants such as Vicks® VapoInhaler™ are used in many people's everyday lives across the nation, so it is vital that the forensic science community understand the process and work toward a solution to reduce false positive results.

## Program Committee Financial Disclosure—2020

---

As a sponsor of continuing education, the American Academy of Forensic Sciences (AAFS) must ensure balance, independence, objectivity, and scientific rigor in all its educational activities. All faculty participating in a sponsoring activity are expected to disclose any significant financial interest or other relationship: (1) with the manufacturer(s) of any commercial product(s) and/or provider(s) of commercial services discussed in an educational presentation; and (2) with any commercial supporters of the activity. (Significant financial interest or other relationships can include such things as grants or research support, employee, consultant, major stockholder, member of speaker's bureaus, etc.) AAFS has an established policy regarding conflicts of interest that includes decisions the Program Committee members may make in selecting content for the Annual Scientific Meeting Program. By serving on the committee, regardless of the role, each member has agreed to comply with Section 1.4.7. of the AAFS *Policy and Procedure Manual*.

To serve on the 2019-20 Program Committees, it is required that relevant AAFS staff members, program committee members, and/or reviewers complete a Financial Disclosure Form before being provided access to review submissions for the program. For continuing education accreditation purposes, the disclosed relationships are published below so learners are aware of the nature of any relationships that may impact the selection of presentations for the program. If a committee member failed to provide complete disclosure of a relevant financial interest or relationship, the committee member or reviewer was not allowed to serve. The executed Faculty Disclosure Forms are on file in the AAFS Office.

## Presenting Author Financial Disclosure – 2020

As an accredited provider of Continuing Medical Education, the American Academy of Forensic Sciences requires speakers to disclose any real or apparent conflict of interest they may have related to the content of their presentation(s). The existence of commercial or financial interest of authors related to the subject matter of their presentation(s) should not be construed as implying bias or decreasing the value of their presentation(s). However, disclosure should help participants form their own judgments. AAFS and the Program Committee review the submissions to ensure that the content is educational and not a commercial presentation for companies and their products. Participants may notify AAFS by email (abstracts@aaafs.org) should any presentation be considered solely a commercial endorsement presentation. Notification should include presentation number/ID (e.g., BS10, E100, W30) and speaker name.

If an author failed to provide complete disclosure of the discussion of commercial products, a relationship with the manufacturer including employee/employer relationship, sources of support for the research project, and/or the discussion of unlabeled or unapproved uses of pharmaceuticals/medical devices, the presentation was not accepted. Authors are required to disclose at the beginning of each presentation any information disclosed and listed below. Copies of the executed disclosure forms are kept on file in the AAFS Office.

*The following presenting authors have disclosed financial relationships with commercial entities.*

### A

Jose R. Almirall, PhD - W26  
Agilent®, Analytical Solutions and Providers (ASAP Analytical)  
(Discussion of Commercial Products or Services).

### B

Jane Berger, BS - Y7  
Beckman Coulter, Mettler Toledo, Cary, Cayman Chemical,  
Cerilliant (Discussion of Commercial Products or Services).  
Catherine O. Brown, MSFS –  
Discloses no financial relationships with commercial entities. – S2  
Agilent®, Waters® (Discussion of Commercial Products or  
Services) – B9.  
Bruce Budowle, PhD – B32  
COPAN® (Discussion of Commercial Products or Services).

### C

Kelsey Cagle – F18  
Agilent® (Discussion of Commercial Products or Services).  
Brady Carter, PhD – C29  
Multi-Spectral Imaging System (Discussion of Unlabeled/  
Investigational Use of Product/Device).  
Claire M. Cartozzo, MS – A132, E46, H159  
Applied Biosystems®, Illumina®, Life Technologies™, Onset,  
QIAGEN®, THERMO FISHER™ YSI (Discussion of Commercial  
Products or Services).  
Eoghan Casey, PhD –  
Discloses no financial relationships with commercial entities. –  
C34, C41, S1  
Cellebrite®, IBM® (Discussion of Unlabeled/Investigational Use of  
Product/Device). – C32  
Carole E. Chaski, PhD –  
ALIAS: Automated Linguistic Identification & Assessment  
System. (Discussion of Unlabeled/Investigational Use of Product/  
Device). – D18, D22  
SynAID (Discussion of Unlabeled/Investigational Use of Product/  
Device). – D29  
Mollie S. Comella – B85  
Applied Biosystems®, COPAN®, SoftGenetics®, THERMO  
FISHER™ (Discussion of Commercial Products or Services).

Billy S. Cox, Jr. –  
Discloses no financial relationships with commercial entities. – D28  
Bosch (Discussion of Unlabeled/Investigational Use of Product/  
Device). – D31  
Nicole S. Cusack, BS – B109  
Invitrogen™, QIAGEN® (Discussion of Commercial Products or  
Services).  
Natalia Czado, MS – B44  
Applied Biosystems®, COPAN®, Thermo Fisher Scientific™  
(Discussion of Commercial Products or Services).

### D

Alyssa Daniels – B40  
Beckman Coulter®, Illumina®, QIAGEN®, THERMO FISHER™  
(Discussion of Commercial Products or Services).  
Bailey Davis, BS, BA – K9  
Agilent® (Discussion of Commercial Products or Services).  
Jon Davoren, MS – B108  
Illumina® (Discussion of Commercial Products or Services).  
Haylea Debolt – B177  
Agilent®, LECO® (Discussion of Commercial Products or Services).  
Catia P. Dombaxe – E1  
Bluestar® (Discussion of Unlabeled/Investigational Use of  
Product/Device).

### F

Allie Flores, BS – B136  
Bode Technology™, Promega®, Qiagen®, THERMO FISHER®  
(Discussion of Commercial Products or Services).

### G

Ryan Greaney – E2  
Fuji, Sirchie® (Discussion of Unlabeled/Investigational Use of  
Product/Device).  
Ellen M. Greytak, PhD –  
GEDmatch, Parabon® Nanolabs, (Discussion of Commercial  
Products or Services). – W20  
Parabon® Snapshot (Discussion of Unlabeled/Investigational Use  
of Product/Device). – W20

## Presenting Author Financial Disclosure – 2020

### H

Brittany C. Hudson, MS – B154

Biotech Support Group, Invitrogen™, Millipore®, Procter & Gamble®, Puritan®, Sigma Aldrich, THERMO FISHER® (Discussion of Commercial Products or Services).

### I

Samiah Ibrahim, BSc –

Discloses no financial relationships with commercial entities. –

J17, J18, J29

Faxitron® Bioptics, LLC (Discussion of Commercial Products or Services). – J15

Donna M. Iula, PhD – W21

Cayman Chemical (Discussion of Commercial Products or Services).

### J

Kristin Jones, BS – B37

GE Healthcare, Millipore®, Thermo Fisher Scientific™ (Discussion of Commercial Products or Services).

### K

Joseph H. Kahl, MS – K65

Emergent BioSolutions®, Inc. (Discussion of Commercial Products or Services).

Roger Kahn, PhD – B151

Institute of Environmental Science and Research (ESR) (Discussion of Commercial Products or Services).

Lisa B.B. Kasamba – E1

Bluestar® (Discussion of Unlabeled/Investigational Use of Product/Device).

### L

Amy Laabs, MFS – B23

KIWICARE®, Safariland® Group, Speedball, WD-40® (Discussion of Unlabeled/Investigational Use of Product/Device).

Steven B. Lee, PhD –

THERMO FISHER® (Discussion of Commercial Products or Services). – B47

THERMO FISHER® (Discussion of Unlabeled/Investigational Use of Product/Device). – B47

James W. Liang, BS – B83

Applied Biosystems®, Invitrogen™, Thermo Fisher Scientific™, Zyagen (Discussion of Commercial Products or Services).

### M

Daniel Madrzykowski, PhD –

UL® FSRI Fire Investigation Web Portal (Discussion of Unlabeled/Investigational Use of Product/Device). – D8

Discloses no financial relationships with commercial entities. – W3

Kathleen M. Maguire, BS – B34

Bio-Rad™, COPAN®, Promega®, Puritan®, QIAGEN® (Discussion of Commercial Products or Services).

Laksh Malik – B109

Invitrogen™, QIAGEN® (Discussion of Commercial Products or Services).

Tyler L. McDermott, MS – B113

Thermo Fisher Scientific™, Verogen (Discussion of Commercial Products or Services).

Judy Melinek, MD –

Discloses no financial relationships with commercial entities. – BS2

Alumilite, Polyform, Ultronic (Discussion of Unlabeled/Investigational Use of Product/Device). – B127

Kevin W.P. Miller, PhD –

Discloses no financial relationships with commercial entities. – B138

Hamilton (Discussion of Unlabeled/Investigational Use of Product/Device). – W19

Linda L. Mitchell, BS –

PracticePanther®, com (Discussion of Unlabeled/Investigational Use of Product/Device). – J16

Discloses no financial relationships with commercial entities. – W23

CeCe Moore –

Parabon® Nanolabs (Discussion of Commercial Products or Services). – W20

Parabon® Snapshot (Discussion of Unlabeled/Investigational Use of Product/Device). – W20

Sarah V. Morello – E2

Fuji, Sirchie® (Discussion of Unlabeled/Investigational Use of Product/Device).

Ashley Morgan, MS – B110

Applied Biosystems® (Discussion of Commercial Products or Services).

### N

John Nixon, MBA – D4

TriggerScan™ (Discussion of Unlabeled/Investigational Use of Product/Device).

Maher Nouredine, PhD –

COPAN® Italia, Thermo Fisher Scientific™ (Discussion of Commercial Products or Services). – E4

Discloses no financial relationships with commercial entities. – E77

### P

Morgan S. Peters – B66

QIAGEN® (Discussion of Commercial Products or Services).

Pierre-Antoine Peyron, MD – H181

Abbott™ (Discussion of Commercial Products or Services).

### R

Martina Reif, MS – C32

Cellebrite® (Discussion of Unlabeled/Investigational Use of Product/Device).

Ciara Rhodes – B38

Life Technologies™, Illumina®, QIAGEN®, Quanta Biosciences, (Discussion of Commercial Products or Services).

## Presenting Author Financial Disclosure – 2020

James M. Robertson, PhD – B6

Illumina®, InnoGenomics®, Promega®, ThermoFisher Scientific™, Verogen, (Discussion of Commercial Products or Services).

### S

Gert Saayman, FCPath – H91

University of Pretoria (Discussion of Unlabeled/Investigational Use of Product/Device).

Matteo A. Sacco, MD –

Discloses no financial relationships with commercial entities. – D2, E96, E97, H33, H34, H35, H73, H74, H129, I27

OptiTrack™, Supermicro® Systems (Discussion of Unlabeled/Investigational Use of Product/Device). – E83

Sarah J. Seashols Williams, PhD – B33

Bode Technology™, Life Technologies™, Promega®, QIAGEN® (Discussion of Commercial Products or Services).

Ismail M. Sebetan, MD, PhD –

Discloses no financial relationships with commercial entities. – E15, E47, I3

KIWICARE®, Safariland® Group, Speedball, WD-40® (Discussion of Unlabeled/Investigational Use of Product/Device). – B23

Jagmahender Singh Sehrawat, PhD –

Image J software (Discussion of Unlabeled/Investigational Use of Product/Device). – G17

Discloses no financial relationships with commercial entities. – G38  
Arizona State University Dental Anthropology System (Discussion of Unlabeled/Investigational Use of Product/Device). – G43

Richard Selden, MD – A38

ANDE® Corporation (Discussion of Commercial Products or Services).

Iris L. Shields, DDS – G13

CT scan (Discussion of Unlabeled/Investigational Use of Product/Device).

Pankaj Sinha – K18

Randex® Toxicology Ltd. (Discussion of Unlabeled/Investigational Use of Product/Device).

Patricia M. Speck, DNSc –

Thermo Fisher Scientific™ (Discussion of Commercial Products or Services). – E42

Discloses no financial relationships with commercial entities. – W9

Paul Stein, PhD –

Discloses no financial relationships with commercial entities. – E15, E47, I3

KIWICARE®, Safariland® Group, Speedball, WD-40® (Discussion of Unlabeled/Investigational Use of Product/Device). – B23

Jonah W.P. Stone, BS – A29

Applied Biosystems®, Life Technologies™, QIAGEN® (Discussion of Commercial Products or Services).

### V

Mark Vecellio, MFS –

Bluestar®, Fuji, Sirchie® (Discussion of Unlabeled/Investigational Use of Product/Device). – E1, E2

Discloses no financial relationships with commercial entities. – E114

### W

Mark A. Walch, MArch, MPH – C21

Software product based on the Federal Bureau of Investigation's Project GRAFF (Discussion of Unlabeled/Investigational Use of Product/Device).

Devin Walker – E1

Bluestar® (Discussion of Unlabeled/Investigational Use of Product/Device).

Denise Wohlfahrt, BS –

Applied Biosystems®, Illumina®, Invitrogen™, QIAGEN®, Zymo Research (Discussion of Commercial Products or Services). – B87

Applied Biosystems®, Illumina®, Invitrogen™ (Discussion of Commercial Products or Services). – H161

*The following presenting authors disclose no financial relationships with commercial entities.*

### A

Maurice Aalders – B92

Christoffer K. Abrahamsson, PhD – B196

Adriano Acella – K5

Alexander Acosta – B143

Donovan M. Adams, MS – A178

## Presenting Author Index—2020

The presenting author index can provide a quick reference to find when and in what section presenting authors are scheduled to present at the 2020 Annual Scientific Meeting. The reference table below assists you in finding the section in which the presentation will be given. Letters correspond to the scientific discipline/section in which the presentation is being made while the number corresponds to the numerical sequence of the presentation within the section.

A	Anthropology	J	Questioned Documents
B	Criminalistics	K	Toxicology
C	Digital & Multimedia Sciences	LW	Last Word Society
D	Engineering & Applied Sciences	BS	Breakfast Seminar
E	General	ES	Evening Session
F	Jurisprudence	L	Luncheon
G	Odontology	S	Special Session
H	Pathology/Biology	W	Workshop
I	Psychiatry & Behavioral Science	Y	Young Forensic Scientists Forum

### A

Aalders, Maurice - B92  
Abrahamsson, Christoffer K. - B196  
Acella, Adriano - K5  
Acosta, Alexander - B143  
Adams, Donovan M. - A178  
Adams, Dwight E. - W6  
Adams, Joshua L. - W8  
Ademaj, Xhemajl - B51  
Admire, Lindsey - B2  
Adolph, Natalie L. - W24  
Adserias-Garriga, Joe - A5, W7  
Afra, Kamar - A176  
Afsin, Huseyin - G3, G44  
Agnew, Amanda M. - A122, W18  
Ainger, Timothy J. - E35, W25  
Aitkenhead-Peterson, Jacqueline A. - A95  
Akhtar, Shahnaz - B74  
Akiyama, Cliff - E70  
Akmeemana, Anuradha G. - B126  
Alberink, Ivo - W19  
Alexander, Abigail L. - H110  
Algee-Hewitt, Bridget F.B. - A174  
Ali, Amina - I35  
Allred, Brent M. - B161, E80  
Almela, Ángela - D23  
Almirall, Jose R. - W26  
Alongi, Alberto - B71  
AlQahtani, Sakher J. - BS1, G19, G28, G31  
Alsalamah, Shada - C30, G19  
Altalie, Salem - G40  
Amadasi, Alberto - H16  
Amaral, Maria Eduarda A. - F1  
Amico, Francesco - H17  
Ammer, Saskia - A115  
Amoresano, Elaine R. - H150  
Anderson, Bruce E. - W11  
Anderson, Gail S. - H158  
Anderson, Robert D. - D39  
Andrello, Luisa - H112  
Andrews, Sally E. - G36  
Andrews, Zachary B. - B73  
Andronowski, Janna M. - A59, K14  
Angel, Miriam - J7

Angrisani, Carmelinda - A3  
Annas, George D. - ES1, I29  
Antoniak, Sandra - F7  
Antoun, Vanessa - S1  
Appleford, Colin - K6  
Aquila, Isabella - D2, E83, E96, E97, H18, H33, H34, H35, H73, H74, H129, I27  
Ardell, Christopher L. - B18  
Argo, Antonina - H167  
Armelli, Kerianne - A69, H87  
Armstrong, Adam C. - W8  
Armstrong, Bonnie - W13  
Armstrong Hoskowitz, Natalie - I34  
Arroyo, Luis E. - B123, K41  
Aschheim, Kenneth W. - G19, G31, W14  
Ashiq, Muhammad Irfan - B74  
Ashraf, Zuhra - H166  
Atasoy, Sevil - J11, K44  
Austin, Dana - A60, A108  
Ayala, Jessica L. - K32  
Aydin, Rabia - K44

### B

Babcock, Kailey - H128  
Babcock, Russell S. - W20  
Bäckström, Björn - H8  
Baden, Michael M. - F2  
Baigent, Christiane I. - A143  
Bailey, Christine - A142  
Bailey Van Houten, Lora - B45, B135  
Baker, Andrew M. - H99, K76  
Baldari, Benedetta - H113  
Baldino, Gennaro - B71, H29  
Barbaric, Lucija - B104  
Barie, Wyatt - B118  
Barišic-Jaman, Berislav - D25  
Barranco, Rosario - H23, H57, H135, K12  
Barrett, Morgan - B43  
Bartelink, Eric J. - A35, A115  
Basiliere, Stephanie - K61  
Batterman, Steven C. - S2  
Battiato, Sebastiano - C14  
Bauer, Corey A. - F31  
Baumann, Michael H. - W21  
Baumgarten, Brooke R. - B155  
Beach, Jocenel J. - B103  
Beasley, Melanie M. - A110  
Beaty, Kristine G. - B76  
Bell, Kathy - E21  
Bell, Michelle L. - B88, L1  
Beltempo, Pasquale - E18, E120, I31  
Bennett, Jennifer - F5  
Berger, Jane-Y7  
Berkland, Haley - K33  
Bertozzi, Giuseppe - E10, E11, E12, E13, E40, E41, E87, H2, H136, H137, H138  
Bertram, Dean J. - W6  
Bertrand, Benoit - A160  
Bertsch, Ingrid - I18  
Bethard, Jonathan D. - A113, A177, W25  
Bever, Robert A. - B106  
Beyer, Brittany N. - S2  
Bhaloo, Zain - S2  
Bieber, Frederick R. - W20  
Biehler - Gomez, Lucie - A163  
Bird, Cate E. - A85  
Bishop, Brett - W23  
Bishop-Freeman, Sandra C. - K57  
Blackwell, Thomas M. - B156  
Blair, Nathan - A73  
Blake, Brooke H. - H148  
Blevins, Brittney L. - A24  
Boileau, Michelle - B192  
Boland, Diane - K69  
Bolhofner, Katelyn L. - W22  
Bolte, John H. - D37, W18  
Bonaccorso, Luana - A25, E9, H116  
Bonato, Omar - E90, H13  
Bonetti, Jennifer - B185, W21  
Bonsignore, Alessandro - H19, H57, H135, K12  
Boone, Alice B. - B70  
Borrini, Matteo - B3, LW4  
Bortz, Sean - K13  
Bosch, David R. - D9, D26, D33  
Bosco, Caterina - E9, H116  
Bosman, Ingrid - K66  
Bowen, April - D13  
Boyd, Donna C. - A45

## Presenting Author Index—2020

Bozenko, Joe - B24, B196  
Bracewell, Tammy - A134  
Bradley, Kimberly - C33  
Braun, Tim - W10  
Brenner, Charles H. - F10, F11  
Briones, Alice - H103  
Brits, Desiré - A155  
Brodeur, Amy N. - W6  
Brooks, Evie K. - B215  
Brosz, Helmut G. - D30, D32  
Brown, Catherine O. - B9, S2  
Brown, Ryanne - K53  
Bruno, Katelyn E. - W23  
Bryant, Erick P. - E114  
Bucht, Rebecca E. - B36  
Budowle, Bruce - B32  
Bugajski, Kristi - E109  
Bugelli, Valentina - H76  
Bullock, John David - LW5  
Buresh, Michael - F29, F30  
Buscaglia, JoAnn - B164  
Butler, Daniel C. - H120  
Butler, John M. - F9  
Butler-Derose, Kimberly - E15  
Büyüker, Sultan M. - K44  
Buzzini, Patrick - S2  
Byrd, Jason H. - W14

### C

Cagle, Kelsey - F18  
Caldwell, Mikayla - K22  
Callahan, Michael - D41  
Campbell, Jessica L. - A27  
Campbell, Jorien - L2  
Campobasso, Carlo P. - H76, W5  
Campos, Jesus A. - E82  
Candelario Gorbea, Mariel - A107  
Canello, Julia N. - Y30  
Cao, Yijian - B5  
Capistran, Briana A - B180  
Capitaneanu, Cezar - G10  
Caputo, Fiorella - H23, H135  
Carabellese, Felice F. - I15, I16, W5  
Carew, Rachael M. - A58, E19, W24  
Carnes, Julie A. - C4  
Carney, Amy Y. - W9  
Carpenter, Douglas J. - W3  
Carpenter, Morgan N. - B55  
Carriquiry, Alicia L. - B173, W2  
Carter, Brady - C29  
Carter, Helen R. - H132  
Carter, Joye M. - S1  
Carter, Melinda L. - A170  
Cartozzo, Claire M. - A132, E46, H159  
Carvalho, Nigela Rodrigues - Y2  
Casey, Eoghan - C32, C34, C41, S1

Castellanos, Daniel - A113  
Caten, Reilly - E103  
Cawley, William D. - A137  
Cecchetto, Giovanni - A48  
Celentano, Jennifer - A34  
Cena, Greta - A25, C15  
Cerreta, Michelle - B200  
Chaimowitz, Gary A. - I7  
Chambers, Megan I. - B130  
Champod, Christophe - B170  
Chan, Chi Hin Marco - K40  
Chan-Hosokawa, Ayako - K46  
Chany, Christopher P. - B16, B102  
Chaski, Carole E. - D18, D22, D29  
Chaudhry, Irfan - H101  
Chauhan, Mohit - C24  
Chen, Qiang - D10  
Cheng, Kevin - H95  
Chesson, Lesley A. - A109  
Chetney, Kaitlyn - B168  
Cheverko, Colleen M. - A42  
Chien, Joseph - I12  
Chighine, Alberto - H24  
Chowdhury, Siddharth S. - C35  
Christensen, Alexander F. - A169  
Christensen, Angi M. - A118  
Christy, Brenda B. - B178  
Chu, Elaine Y. - A30  
Chu, Sarah - F14  
Chung, Hee-Sun - K21  
Cioffi, Andrea - E91  
Cipolloni, Luigi - E12  
Cirillo, Laura E. - A128  
Ciuffetelli, Gary - L2  
Clark, Michelle S. - E29  
Clark, Randall - W26  
Clause, Hannah - B201  
Clay, Michael - G42  
Clegg, Laurel - A80, A83  
Coberly, Samantha W. - A74  
Cochrane, Katherine - H4  
Cocimano, Giuseppe - H62  
Coffman, Sarah R. - E111  
Cole, Mary E. - A165  
Cole, Stephanie J. - A9  
Collins, Cheyenne - A138  
Collord-Stalder, Hailey - A73  
Comella, Mollie S. - B85  
Congram, Derek - A83  
Conner, Elizabeth C. - K47  
Connor, Melissa A. - S2  
Coppo, Elena - G16  
Coppone, Mauro - E53, E90  
Cordasco, Fabrizio - D2, E83, E96, H18, H33, H74, I27  
Cordoni, Allyson - E21  
Cornelison, Jered B. - H143

Correa, Heitor - H20  
Corron, Louise K. - W12  
Costa, Gustavo - B65  
Coticone, Sulekha - B45, B135  
Coulter, Jaime - I20  
Cox, Joseph A. - K39, K72  
Cox, Billy S., Jr. - D28, D31  
Crabb, Crystal L. - A147  
Craig, Alba E. - A13  
Crawford, Amy M. - J20  
Crimmins, Danielle M. - E73, E100  
Cromartie, Rosa L. - B64  
Crosby, Sarah N. - W8  
Crouse, Andrew N. - C9  
Crowder, Christian - S2  
Cruse, Courtney - B97  
Cuchara, Breanna M. - E32  
Cuerrier-Richer, Elisabeth - A18  
Cunningham, Lloyd - W23  
Curran, James M. - B100  
Curran, Phillip M. - BS6  
Curti, Serena Maria - E18, E120, I31  
Cusack, Nicole S. - B109  
Czado, Natalia - B44

### D

Dabbs, Gretchen R. - A135  
Dadour, Ian - H131  
Daniels, Alyssa - B40  
D'Anjou, Corinne - G34  
D'anna, Giuliana - K24  
Dar, Mariam - D21  
Das, Siddhartha - H156  
da Silva, Sandra G.G. - G39  
Dastan, Kadir - B147, B148, Y23, Y24  
Davidson, J. Tyler - B188  
Davis, Bailey - K9  
Davis, Gregory G. - W1  
Davoren, Jon - B108  
De Alcaraz-Fossoul, Josep - B160, W7  
De Aloe, Luigi - H33  
Debolt, Haylea - B177  
Decker, Lauren A. - H169  
Decker, Summer J. - W24  
Decrisce, Dean - I20  
De Giorgio, Gianni - D14, H63  
De La Paz, Jade S. - A7  
Dela Rosa, Armando B., Jr. - W8  
Delattre, Veronique F. - G25  
Del Fante, Zoe - H14  
Delger, Dana - F15  
dell'Aquila, Massimiliano - E89  
Depp, Randi M. - A141  
Derrick, Sharon M. - A168  
Desiderio, Vincent J., Jr. - S2  
DesPortes, Betty Layne - W22

## Presenting Author Index—2020

Desranleau, Sylvain - G18  
Dettman, Josh - B197  
De Ungria, Maria Corazon A. - E86
