### ***PROCEEDINGS***

of the American Academy of Forensic Sciences 72<sup>nd</sup> Annual Scientific Meeting

The *Proceedings* of the American Academy of Forensic Sciences is an official publication of the American Academy of Forensic Sciences (AAFS). It is devoted to the publication of the abstracts of technical oral papers and posters presented at the AAFS Annual Scientific Meeting. These include various branches of the forensic sciences such as anthropology, criminalistics, digital evidence, engineering, immunology, jurisprudence, odontology, pathology, psychiatry, questioned documents, and toxicology. Similar submissions dealing with forensic-oriented aspects of the social sciences are also included.

Please note that some of the abstracts included in the *Proceedings* deal with topics, results, and/or conclusions that are controversial. The publication of abstracts does not imply that the AAFS, its sections, or the individual section program chairs/committee members have verified or agree with the studies, results, and/or conclusions of each abstract. During the process of planning a scientific program, it is impossible to “peer-review” each abstract and presentation to the degree that is accomplished during manuscript review. Abstracts and presentations are accepted, in part, so they can be critiqued and reviewed by other scientists. Thus, a forum is created to discuss controversial issues.

The views expressed in this publication are not those of the AAFS. The data and opinions appearing in the published material were prepared by and are the responsibility of the contributor(s), not of the AAFS nor its respective employees, employers, officers, and agents. The AAFS does not supply copies of meeting papers. Please write directly to individual authors to obtain copies of specific papers. Presentation of some abstracts may have been scheduled or canceled after the publication of this document.

English is the official language of the AAFS and its meetings; neither oral nor written translations will be provided.

Copyright 2020 by the AAFS. Unless stated otherwise, non-commercial *photocopying* of editorial material published in this periodical is permitted by the AAFS. Permission to reprint, publish, or otherwise reproduce such material in any form other than photocopying must be obtained from the AAFS.

Articles from the AAFS *Proceedings* should be officially cited in the following format:

### S1 Interdisciplinary Symposium: Progress in the Forensic Sciences Since the 2009 National Academy of Sciences (NAS) Report

Jan Seaman Kelly, BA\*, Forensic Dynamics LLC, Las Vegas, NV 89147; Kristy Kadash, PhD, Jefferson County Regional Crime Lab, Golden, CO 80401; Vanessa Antoun, JD\*, National Association of Criminal Defense Lawyers, Washington, DC 20036; Joye M. Carter, MD\*, San Luis Obispo County Sheriff-Coroner Office, San Luis Obispo, CA 93401; Eoghan Casey, PhD\*, University of Lausanne, Lausanne, Vaud 1015, SWITZERLAND; Stephanie Domitrovich, JD, PhD\*, Sixth Judicial District of Pennsylvania, Erie, PA 16501; Gregory Dutton, PhD\*, National Institute of Justice, Washington, DC 20531; Barbara L. Needell, DMD\*, Monument, CO 80132; Sharon L. Plotkin, MS\*, Miami Dade College, Miami, FL 33167; Michael J. Salyards, PhD\*, Compass Scientific Consulting LLC, Sharpsburg, GA 30277; John L. Lentini, BA\*, Scientific Fire Analysis, LLC, Islamorada, FL 33036; Tobin A. Tanaka, BS\*, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA; Robert M. Thompson, MFS\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Sheila Willis, PhD\*, National Institute of Standards and Technology, Gaithersburg, MD 20899

---

**Learning Overview:** Attendees will have an appreciation of the impact the 2009 Report by the NAS entitled *Strengthening Forensic Science in the United States: A Path Forward* has had on several forensic disciplines.

**Impact on the Forensic Science Community:** Forensic sciences have been under the shadow of the NAS Report for the past ten years. This symposium will impact the forensic science community by providing an update on the state of many disciplines with respect to method reliability and testimonial boundaries, both of which were called into question by the NAS Report.

The NAS Report, *Strengthening Forensic Science in the United States: A Path Forward*, commonly referred to as the NAS Report by the forensic community, was released in February 2009 during the Annual Scientific Meeting in Denver, CO. This Report was unprecedented because it brought to light many issues that had been hampering the evolution of forensic science. It provided 13 comprehensive recommendations, starting with the establishment of a National Institute of Forensic Sciences (NIFS). This was described as an independent federal entity designated with the responsibility of supporting and overseeing forensic science across the country. The authors advocated that law enforcement agencies should no longer be the primary administrators of their crime laboratories and that medical examiner systems should replace coroner's offices. Laboratory accreditation, individual examiner certification, and standardization of procedures were additional recommendations proposed in the NAS Report. Two significant recommendations to the forensic sciences, more specifically to the pattern-based evidence disciplines, revolved around: (1) improving their scientific foundations and reliability through research and validation, and (2) ensuring the accuracy of testimony offered by experts in court. Many of the NAS recommendations have not come to fruition, including the creation of NIFS. However, changes have occurred in response to some of the recommendations. Various questions can be posed to assess the impact of those changes. Has the community devoted time and resources to validating current techniques and methods? Are new disciplines embracing the scientific method? What does a "match" or an "identification" mean today? How conclusively are examiners allowed to state their results? What does the future hold for forensic expert testimony? Have court systems outside of the United States taken any notice of the changes occurring here?

This year's symposium will feature 13 speakers across both scientific and national borders who will provide their perspectives on how the NAS Report has changed (or not) their business practices over the past decade. Many of the forensic disciplines discussed in the report will be addressed, including DNA, friction ridge, firearms, documents, odontology, and digital/multimedia evidence examination. Responses in crime scene analysis and medicolegal investigations will be presented as well. Members of the legal community will also share their thoughts on how they interpret the conclusions made by forensic experts in written reports and in trial. In addition, the efforts of the National Institute of Justice (NIJ) to fund research in these areas will be discussed. This symposium intends to be a valuable session to forensic science practitioners, managers, and legal representatives.

#### National Academy of Sciences, Validation, Testimony

### S2 YFSF: 25 Years of Crossing Borders: Young Forensic Scientists and Their Collaborations

*Zain Bhaloo, MSc\**, Canada Border Services Agency, Ottawa, ON K2E 7M6, CANADA; *Catherine O. Brown, MSFS\**, Center for Forensic Science Research & Education, Willow Grove, PA 19090; *Hannah N. Simmons, BS\**, Raleigh, NC 27616; *Brittany N. Beyer, MS\**, Houston Forensic Science Center, Houston, TX 77002; *Amber J. Smith, MSFS\**, Houston Forensic Science Center, Houston, TX 77002; *Cheryl D. Hunter\**, Florissant, CO 80816; *Zeno J. Geradts, PhD\**, Netherlands Forensic Institute, Den Haag, SH 2497 GB, NETHERLANDS; *Steven C. Batterman, PhD\**, Cherry Hill, NJ 08003-2906; *Douglas H. Ubelaker, PhD\**, Smithsonian Institution, Washington, DC 20560; *Thomas W. Vastrick, BS\**, Apopka, FL 32703; *Dirk Vastrick, BA\**, Dirk Vastrick Presents, Spokane Valley, WA 99016; *Christian Crowder, PhD\**, Southwestern Institute of Forensic Sciences, Dallas, TX 75207; *Melissa A. Connor, PhD\**, Colorado Mesa University, Grand Junction, CO 81501-3122; *Nikolas P. Lemos, PhD\**, Lemos Toxicology Services, San Francisco, CA 94114; *Patrick Buzzini, PhD\**, Sam Houston State University, Huntsville, TX 77340; *Vincent J. Desiderio, Jr., MS\**, United States Postal Inspection Service, Washington, DC 20260; *Emily D. Gottfried, PhD\**, Medical University of South Carolina, Charleston, SC 29407; *Alex J. Krotulski, MS\**, Center for Forensic Science Research & Education, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will better understand forensic science and how everyone's work can impact and enhance other scientists, and vice versa, regardless of the discipline. In addition, attendees will learn about the advantages and importance of proper resume writing and interviewing skills.

**Impact on the Forensic Science Community:** The Young Forensic Scientists Forum (YFSF) has historically provided a venue for those forensic scientists with less than five years of professional experience to interact with, and further integrate into, their prospective fields, as well as to learn about all the other disciplines. The YFSF should provide the space and opportunity for attendees/speakers to grow, develop, network, and learn from one another. This will allow young scientists the confidence to progress in their fields and one day hopefully provide the same opportunity to another young scientist.

Every year, the American Academy of Forensic Sciences (AAFS) draws in thousands of globally recognized experts and professionals to present research, hold workshops, and showcase the various disciplines represented within the Academy. Further, the YFSF offers two opportunities for young forensic scientists to present their own work or research: the Bring Your Own Posters (BYOP) Session and the Bring Your Own Slides (BYOS) Session.

Currently celebrating its 25<sup>th</sup> anniversary, the YFSF presents for the 72<sup>nd</sup> Annual Scientific Meeting in Anaheim, CA, *25 Years of Crossing Borders: Young Forensic Scientists and Their Collaborations*. This Special Session will be held on Tuesday, February 18, 2020, and will feature speakers from many of the AAFS sections who will discuss their work and how they crossed borders, figuratively and literally, to collaborate with other disciplines. Through these presentations, attendees will learn how experienced practitioners and professionals have contributed to forensic science as a whole and how their work has benefitted from and was helped by interdisciplinary combining of knowledge bases. With a rapid push for specialization within a given discipline, it has remained vital for leaders in forensic science to remember the importance of cross-discipline collaboration and partnership. Through this Special Session, forensic experts will provide mentorship to young forensic scientists by inspiring interdisciplinary cooperation in casework, research, and community engagement.

Finally, in the spirit of interdisciplinary collaboration and to honor our commitment to improving and advancing communication, for the first time, the YFSF is seeking to provide the opportunity to attendees to network with AAFS members and many others to encourage the sharing of information and experiences. This year's Special Session has been re-designed to incorporate a networking morning coffee break where all YFSF attendees and distinguished members from the AAFS sections can meet, mingle, and have discussions. Further, the discussion and resume review panel has been lengthened and will be enhanced by the addition of a speaker specifically addressing resumes and interview preparation, so don't forget to update and bring several copies of your resume with you!

#### YFSF, Research, Education

### BS1 Ethno-Cultural and Religious Considerations in the Management of the Dead

*Sakher J. AlQahtani, PhD\**, College of Dentistry, Riyadh 11545, SAUDI ARABIA; *James F. Goodrich, FFOMP\**, Cambridge, Waikato 3496, NEW ZEALAND; *Amber D. Riley, MS\**, San Diego, CA 92131

---

**Learning Overview:** After attending this presentation, attendees will have a greater knowledge of the ethics, customs, norms, and taboos surrounding death and the dead for many minority cultures and religions within their professional and personal communities. This presentation will describe several cultures and religions that forensic professionals may encounter in their jurisdictions, both in the United States and worldwide, along with each respective approach to the management of their dead, based upon this better understanding.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving to assist the forensic professional in overcoming some of the obstacles that are present when identifying, investigating, and examining a decedent that is a member of these ethno-cultural communities.

Culture and religion profoundly influence many aspects of modern life. These factors also carry forward after death and may affect our management of the deceased. It is recognized that increasing human migration across global geographical borders results in decedents sometimes being managed within a culture and community that is foreign to them. Loved ones, family, and members of the integrated community of the deceased also bring expectations, norms, and taboos to a forensic setting and these influences may at times increase the complexity of and even hinder the process of examination, identification, and release of the dead. Although it is impossible to be intimately familiar with all religions and cultures, we as forensic professionals should be educated and sensitive to the roles each may play in our respective areas of expertise while avoiding the risk of stereotyping the deceased.

It is important to the process and to the outcome that the forensic professional understands not only the ethno-cultural and religious considerations associated with the deceased, and other members of the affected community, but also their own, and how these may relate to the context and perhaps to any biases that may be subsequently introduced. So, the complexity of the juxtaposition of different cultures and expectations may be multiplied in a situation where the forensic practitioner is anything other than the ideal of absolute neutrality.

The interplay of the deceased's culture and the forensic professional's legal and ethical responsibilities can pose significant challenges when experienced against a backdrop of factors including gender and acculturation, notably in cases in which there are multiple and/or commingled fatalities being examined at one time in one spatial setting. Varied cultural and religious mores for managing the dead also dictate appropriate disclosures, privacy, and communication with the relatives of the deceased. Some difficulties can, at least, be partially overcome with an understanding of these sensitivities.

This presentation hopes to highlight many of the unique aspects of the belief systems and social constructs that may be encountered during the career of a forensic professional in the context of the management of the dead and provide tools and a framework for increased sensitivity and understanding. This, in turn, will provide an opportunity to allow the dignity and basic human rights of the deceased to perhaps be respected more fully.

Examples will be drawn from many cultural and religious backgrounds, including Islam, Judaism, Christianity, Hinduism, Buddhism, Native American, Maori, and Pasifika peoples.

---

### Religion, Culture, Management of the Dead

### BS2 The Working Stiffs: Writing and Publishing the Experiences of a Forensic Pathologist in Both Fiction and Non-Fiction

*Judy Melinek, MD\*, PathologyExpert, Inc, San Francisco, CA 94121; T.J. Mitchell, BA\*, PathologyExpert Inc, San Francisco, CA 94121*

**Learning Overview:** The goal of this presentation is to demonstrate how a collaboration between a scientist and a writer can effectuate the communication of complex forensic concepts to a lay audience.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping attendees be able to communicate scientific concepts to a lay audience, in writing and in testimony, and by navigating issues pertaining to the confidentiality of medical information.

The thesis of this presentation is the importance of reflecting scientific rigor in writing both non-fiction and fiction for a lay audience. The challenges of writing while continuing to testify as an expert witness in real-life criminal and civil court cases will be explored. In addition, the perpetual tension between fiction and science—maintaining a balance between narrative demands and medical verisimilitude—will be discussed.

Journal writing can be an effective way of documenting what a scientist encounters in clinical detail. Other ways of tracking forensic cases include spreadsheets and medical databases. In some offices, it is not uncommon to collect newspaper clippings of the deaths that are investigated and picked up by the media and place them in the case file. However, newspaper accounts may not be accurate and examples will be presented of how eyewitness statements and assumptions made by the police or death investigators can be found to be in error when the body is taken to autopsy. Writing and documenting what a pathologist sees at the time of autopsy is crucial for clinical decision making and peer review, including review by outside experts. Furthermore, taking written notes about one's daily experiences and what one learns through those experiences can also become a psychological outlet: a way to “decompress” after a long day of working in extreme conditions, or a way to deal with the grief and anger of family members.<sup>1,2</sup> Writing can be a therapeutic exercise that supplements formal training in forensic pathology and should be encouraged in forensic fellowship training.<sup>3</sup>

Working in an understaffed and underfunded environment can also put stress on the forensic team and may incubate intramural tension. Mass fatality response, along with a backlog of routine cases delayed by ancillary lab studies, can add to the pressures pathologists experience. Journaling can help forensic professionals deal with the stresses of the job, but non-disclosure agreements and privacy policies may restrict professional communication and publication in a public forum. In academic writing, de-identification is used when sharing case reports, and this method can be used in writing non-fiction for public consumption. Fictionalizing actual forensic cases can allow scientists with a way to explore the work they do and share their experiences, both with other professionals and with the lay public.

A case report will be presented of a petty thief who stole a laptop and was chased down and shot dead in public by its owner. This case involved a complex gunshot wound trajectory analysis and the collection of property as evidence. Forensic-noir mystery writers, such as Kathy Reichs, Patricia Cornwell, and Jon Jefferson and Dr. William Bass, all of whom worked in various capacities in the forensic sciences professional discipline, inspired this presentation to explore ways to educate the public about real-world forensic science through the use of a fictional narrative voice.

### BS3 The Science Behind Traffic Accident Reconstruction With Real-World Crashes

*Kurt D. Weiss, MS\*, Case Study Collision Science, LLC, Santa Barbara, CA 93190; Darren Franck, MSME, Advanced Engineering Associates, Inc, Charleston, WV 25304*

**Learning Overview:** The goal of this presentation is to share with the forensic science community the data sources and detailed methodology used in traffic collision reconstruction.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating through real-world case studies the data used and methodologies applied to the reconstruction of traffic collisions.

An analysis of four real-world crashes will demonstrate the science behind traffic accident reconstruction. Reconstructing a crash is a multidisciplinary process. The reconstructionist gathers objective and subjective information, performs case-specific research, then applies the fundamental principles of physics to determine, for example, impact classifications, vehicle heading, impact configuration, impact (closing) speed, velocity change or Delta-V (DV), rollover distance, roll count, and roll rate. The reconstruction results are important input to the injury analysis and the assessment of injury patterns, risk, and prevention.

The primary information source is the Traffic Collision Report, which may provide: (1) objective party information (e.g., occupant and vehicle year, make, model, Vehicle Identification Number (VIN)); (2) objective site information (location and roadway, intersection, and Global Positioning System (GPS) details), scene diagrams with measurements of physical evidence (tire friction marks, fractured glass, roadway scrapes and gouges, scarred tree bark, fractured signs or light posts, disturbed dirt and/or vegetation), point of impact and vehicle rest locations; (3) at-scene police photographs of site evidence and vehicle damage; and (4) subjective information (e.g., party statements, vehicle code violations, police collision summary and primary collision factor identifying party and cause).

Case-specific research may include: (1) at-scene witness photographs, which are often taken with cell phone cameras; these photographs are crucial absent police photographic documentation of site and vehicle evidence; (2) security videos that help refine the analysis by providing objective evidence of vehicle movements prior to and after the crash; (3) aerial photography from online image archives that orient and supplement scene diagrams; (4) drive-through videos that provide a street view of the roadway and/or intersection; (5) site inspections that clarify roadways, controls, and obstacles; (6) subject vehicle inspections with crush profile measurements that document property damage and reveal relative impact alignment or vehicle movement; (7) Airbag Control Module (ACM) data that quantify pre-crash vehicle speeds and accelerations, and driver actions (e.g., swerving, braking); (8) subjective information (e.g., witness statements and deposition testimony) that help qualify collision events and estimates of vehicle speeds, distances, and movements; these sources may also provide prior useful site, vehicle, or occupant history; and (9) exemplar vehicle inspections, scaled vehicle drawings, specifications, and crash test data that may be used to determine the collision severity.

An analysis of four real-world crashes demonstrate the science behind traffic accident reconstruction.

**Case 1**—fatal collision: vehicle crush measurements quantify collision severity.

**Case 2**—vehicle-motorcycle crash: download of ACM yields pre-crash data.

**Case 3**—wrong-way, intoxicated driver in a high-speed crash: patrol car's on-board video quantifies vehicle impact speeds.

**Case 4**—vehicle-motorcycle crash: stationary security videos quantify vehicle impact speeds.

---

#### Traffic Accident Reconstruction, Data Sources, Real-World Crashes

### BS4 A Tour of a Cannabis Extract Manufacturing Facility in Maine

*Jennifer A. Paris, BS\*, New Hampshire State Police, Concord, NH 03305; Anna K. Weaver, BS, Concord, NH 03305*

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the operation of a small state-licensed and inspected cannabis extract manufacturing facility.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting an understanding of the processes used to concentrate cannabinoids, how products are diluted, prepared, and packaged in order to comply with the relevant laws and regulations, and may be helpful for attendees who are assisting in building a local or state jurisdiction's medical or recreational marijuana program.

The state of Maine enacted a medical marijuana law after a citizen-led ballot initiative passed in November 1999. Since that point in time, multiple amendments have been made to the statute following feedback from patients, caregivers, medical providers, and a specially developed task force. Although a 2016 law was passed to allow for the recreational use of marijuana, and a 2017 law was passed concerning taxation and other regulations surrounding recreational marijuana, the commercial sale of the plant and products made from it have not yet begun.

Today, Maine permits both growing and processing of marijuana by individuals holding a medical card (i.e., "patients"). In addition, patients and caregivers are allowed to use a third-party manufacturing facility to convert their harvested marijuana or hemp into concentrated forms. These facilities are registered, inspected, and licensed by the state of Maine. Patients and caregivers are expected to adhere to strict procedures regarding site safety and security, the quantity and type of plants on site, the quantity of harvested product on site, the use of "inherently hazardous substances," and the disposal of waste materials, among other standards.

This presentation will briefly cover the regulations in place for Maine's program, then focus on the specifics with respect to a small, registered manufacturing facility. Chemists from the New Hampshire State Police Forensic Laboratory were given the opportunity to tour one such facility in the summer of 2019 while extractions were in progress. This cannabis extract manufacturing facility employs super critical carbon dioxide processing of harvested marijuana and/or flowering hemp grown by patients or their caregivers to produce highly purified concentrates devoid of terpenes. In addition, the facility was equipped with a closed-loop extraction system to produce butane honey oil, shatter, and "diamonds." Discussions regarding purity, concentration, cannabinoid profiles, and all aspects of the operation, including the evolution of the facility's practices over time, took place with the owner/operator of the facility. Attendees will be shown the outdoor grow area, extraction and purification processes, preparation of food products, and product packaging materials at the visited facility.

Given the increased number of states where cannabis products are legal for medical or recreational use, it is important for those involved in the analysis of seized drugs to have an understanding of the processes used to concentrate cannabinoids from harvested marijuana and flowering hemp. Furthermore, it is helpful to be familiar with how products must be diluted, prepared, and packaged in order to comply with relevant laws and regulations.

---

### Cannabis, Extract, Manufacturing

### BS5 Practical Aspects of Developing and Incorporating a Postmortem Computed Tomography (PMCT) Service Into a Medical Examiner's Office

*Lauren Edelman, MD\**, Travis County Medical Examiner, Austin, TX 78724; *Keith Pinckard, MD, PhD*, Travis County Medical Examiner, Austin, TX 78724

**Learning Overview:** After attending this presentation, attendees will understand the concepts and considerations involved in incorporating PMCT into the practice of a medium-sized, regional medical examiner's office, including staffing, scanning protocols, triage of cases, study interpretation, and novel and alternative data storage solutions. Developing and incorporating a PMCT service is a complex project, with broad implications for many aspects of an individual office.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework and blueprint that can be used to incorporate and implement this burgeoning technology within the scope of death investigation for medical examiner's and coroner's offices.

The services of a consultant were engaged as part of the budget request associated with purchasing a Computed Tomography (CT) scanner. The consultant provided guidance for technical and structural considerations critical for drafting the purchasing bid documents and review of the bids for the purchase of the CT scanner and associated equipment. After installation by the vendor, the consultant also provided the basic scanning protocols that are programmed into the scanner for ease of use and include protocols for standard adult, bariatric, pediatric, charred remains, skeletal remains, and decomposed remains. This is a key component, since standard protocols that are provided by CT scanner vendors are designed for clinically based studies on living patients.

As part of the purchasing contract, forensic autopsy technicians, none of whom had formal radiology technology training, received in-person instruction in the practical aspects of operating the equipment. Performing the scans with the appropriate protocols requires minimal direct management by the forensic autopsy technicians. Once the protocols are in place and validated, scanning proved to be relatively simple and straightforward. Scanning is performed during routine working hours on a rolling basis as decedents are brought into the office; scans are completed prior to the processing and external examination of the body. All decedents who are physically capable of fitting into the CT scanner are imaged. The rationale for this is two-fold. First, scanning every decedent as a matter of routine may guide how the pathologist approaches the case. Second, scanning creates a permanent 3D radiographic record of the body that can be reviewed long after the body has been permanently altered by autopsy.

The scans are reviewed and interpreted by the forensic pathologists as a group during a morning conference prior to performing examinations and again individually when medical examiner reports are written. The medical examiners in the office received training in CT interpretation by two physicians with prior PMCT experience who were already on staff. The learning curve of CT interpretation is very steep; familiarity with visualizing cross-sectional anatomy in three dimensions simultaneously comes surprising quickly. Furthermore, because all decedents are scanned, each pathologist gets immediate feedback by comparing autopsy findings to what was observed on the scans—a practice that rapidly builds interpretive skills and confidence. Once the medical examiner staff is comfortable with reading CT scans, decisions can be made regarding which types of cases may be able to be supplanted by PMCT.

A novel cloud-based storage and image-viewing software solution was purchased rather than a traditional Picture Archiving and Communication System (PACS). It has virtually identical capabilities, including permanent long-term storage with system redundancy, at a fraction of the cost of a standard PACS solution. Per this research, PACS is a vastly more sophisticated and ultimately far more expensive solution than what is actually required for death investigation purposes. For offices affiliated with medical centers, it may be possible and cost-effective to "partner" and obtain a node on a hospital's PACS. However, offices without this benefit have struggled to devise a system tailored to the unique needs of death investigation without the associated burdensome cost of a PACS—a cost factor that may deter an office from obtaining PMCT capability altogether. Per this research, this is the first office to pilot and utilize this type of storage and viewing solution.

As more death investigation offices around the country begin to integrate CT imaging as part of the physician's toolkit, it is critical to share operating procedures and innovative solutions to common problems to assist others in participating in this exciting advancement in the field of forensic pathology.

#### Postmortem Imaging, Computed Tomography, PACS

### BS6 Is a Soldier's Combat Stress a Reason to Commit Five Murders?

*T.L. Williams, MFS\*, Fredericksburg, VA 22406-8446; Phillip M. Curran, MFS\*, United States Army Criminal Investigation Command, Quantico, VA 22134; Celia M. Gallo, MFS\*, United States Army Criminal Investigation Command, Quantico, VA 22134; Rick Malone, MD\*, N5 Forensic Behavioral Science, LLC, Woodbridge, VA 22191; Angel L. Miles, MA\*, United States Army Criminal Investigation Command, Fayetteville, NC 28314*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of locating, identifying, and collecting evidence and the documentation of the crime scene associated with a mass casualty investigation. Attendees will also be aware of the policies and procedures for conducting a crime scene investigation (timeliness, thoroughness, and timely reporting) and casualty liaison briefings provided to the primary and secondary next-of-kin. This presentation will also enable attendees to understand how the psychological evaluation of the subject may or may not have affected the outcome of the trial by court-martial and the results of the court-martial.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that a mass casualty investigation must be conducted in a timely and thorough manner in order to provide the court with the best evidence for conviction. The psychological evaluation will assist in determining if the subject was mentally responsible, and, if so, whether he should receive life with or without parole or the death penalty.

SGT John M. Russell had been seen at the Combat Stress Center (CSC), Camp Liberty, Iraq, on three separate occasions and had a noon appointment on May 11, 2009. At approximately 1:41 p.m., on May 11, 2009, the United States Army Criminal Investigation Command (CID) was notified of the shooting of several personnel inside the CSC. The investigation revealed that at approximately 12:30 p.m. on May 11, 2009, SGT Russell, Camp Stryker, Iraq, entered the CSC and methodically shot and killed five United States Service Members (a Navy Commander and an Army Major, a Sergeant, and two Private First Classes). SGT Russell was also listed for the offense of attempted murder and aggravated assault when he fired at two soldiers and missed. The Navy Commander was the only victim known to SGT Russell. SGT Russell, who did not have a weapon, gained possession of his escort's weapon (an M16 rifle), ordered his escort from the vehicle, then drove back to the CSC where he opened fire on unarmed personnel. Due to the regulatory requirements, all soldiers were required to carry their assigned weapons at all times in the combat environment on most camps; the only exception was a medical facility. Soldiers entering the CSC were required to place their weapons in an arms room while being treated; therefore, all soldiers in the Combat Stress Center were unarmed and vulnerable. SGT Russell was subsequently disarmed and placed under apprehension.

More than 28 CID special agents in Iraq were involved in processing the crime scene and interviewing the victims, witnesses and subjects. More CID special agents around the world were involved in the autopsies, background investigation of the subject, and developing information for the court-martial. The preliminary crime scene reconstruction took about one week (the crime scene was maintained for many years, until it had to be bulldozed). The special agents conducted bloodstain spatter analysis, ballistic reconstruction, and a plethora of other forensic analyses of the five separate areas where the victims were murdered.

SGT Russell was evaluated and determined not mentally competent to stand trial, so SGT Russell was placed in a mental health facility where he was evaluated for approximately four years. During this time, he was seen by several mental health professionals, questioned to determine his mental status, and medicated until he was considered restored to competency and returned to military custody.

On May 15, 2012, prosecutors decided to seek the death penalty and SGT Russell's defense stated he would pursue an insanity defense. On May 18, 2012, I Corps, Joint Base Lewis-McChord (JBLM) released the General Court-Martial Convening Authority (GCMCA) findings. The GCMCA referred court-martial charges against SGT Russell to a General Court-Martial empowered to adjudge a capital sentence.

During the court-martial proceedings, the defense blamed the combat mental health professionals for SGT Russell's actions and indicated that they could have prevented this mass casualty. SGT Russell was subsequently found guilty and on May 16, 2013; an Army judge sentenced SGT Russell to life without the possibility of parole for the shooting death of two care providers, two patients, and an escort. The judge stated "You are not a monster, but you have knowingly and deliberately done incredibly monstrous things."

### Murder, Investigation, Stress

### L1 The Disappearance and Murder of Sierra LaMar: A Multidisciplinary Case Study

*Melissa A. Dupée, MSFS\*, Santa Clara County Crime Laboratory, San Jose, CA 95110; Michelle L. Bell, BA\*, San Jose, CA 95110*

---

**Learning Overview:** The goal of this presentation is to inform attendees of a complex homicide investigation that was heavily fueled by physical evidence examinations, including DNA, trace evidence, digital and video evidence, latent prints, and questioned documents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showcasing the ability for multiple forensic disciplines to work together to achieve the maximum potential of the evidence items submitted in a missing person case turned homicide.

Fifteen-year-old Sierra LaMar left her Morgan Hill, CA, home on March 16, 2012, but never made it to school. Her school bag, containing the clothes she'd been wearing the day she disappeared, and her discarded cell phone were found a short time later. Thus began an investigation that utilized multiple crime lab disciplines, culminating in a months-long 2017 trial that found Antolin Garcia Torres guilty of kidnap and murder, even though Sierra's body has never been found.

DNA was instrumental in identifying a suspect. Biological evidence found on Sierra's clothes matched to Garcia Torres in the Combined DNA Index System (CODIS), and a later search of his vehicle yielded additional evidence. The DNA testing for this case, much of which was developed in the first few days following Sierra's disappearance, utilized a plethora of DNA techniques and resulted in a variety of conclusions, each of which required a different type of statistical analysis, including mixtures, paternity testing, and Y-chromosomal Short Tandem Repeats (Y-STRs).

Trace evidence played a big part in this case. The trace evidence analyses required travel to assorted sites in Morgan Hill to collect comparison samples for testing. Examinations of Sierra's clothing and Garcia Torres' vehicle revealed various types of trace evidence, including hair, fibers, glass beads, soil, botanicals, and insect parts. Extensive examinations were performed on Sierra's cell phone, which had turned on and off several times following her disappearance. This prompted a visit to the Samsung® facility in South Korea by an investigator involved in the case.

Questioned documents examination was performed when a notebook of Sierra's was discovered at school, with notes written in it suggesting she was thinking of running away. Video evidence was paramount in this case. At the beginning of the investigation, video evidence from near the school bus stop and from the school bus itself was reviewed to see if Sierra had made it that far that morning. Later, video from the parking lot of the defendant's home and from his transactions at a bank were converted to a format that could be more easily viewed in court. In addition, video showed the defendant a few nights before Sierra's disappearance purchasing only a gallon of bleach and a turkey baster—a strange purchase for a 21-year-old male to be making by himself at night.

Prior to the abduction of Sierra, there were multiple attempted kidnappings in Morgan Hill. Investigators, interested to see if they could somehow link these attacks to Sierra's disappearance, requested that a Taser®, left at one of the scenes by the perpetrator, be processed for latent prints. A latent fingerprint was developed on the battery of the Taser® and was identified as Antolin Garcia Torres' print. Therefore, these attempted kidnappings became a part of the Sierra LaMar trial, showing that the defendant had a history of attacking women, and he was found guilty of these crimes as well. The work conducted by all these forensic disciplines in conjunction helped find a suspect, connected him to other crimes, and put to rest several defense theories. Antolin Garcia Torres was sentenced to life in prison without the possibility of parole.

**Multidisciplinary, DNA/CODIS Hit, Trace Evidence**

### L2 Fingerprinting the Brain: Mind, Memories, and Malingering

Charles Scott\*, University of California, Davis School of Medicine, Sacramento, CA 95817; Jorien Campbell, MD\*, University of California, Davis Medical Center, Sacramento, CA 95817; Gary Ciuffetelli, MD\*, University of California, Davis Medical Center, Sacramento, CA 95817; Ambarin Faizi, DO\*, University of California, Davis Medical Center, Sacramento, CA 95817; Bethany Hughes\*, University of California, Davis Medical Center, Sacramento, CA 95817

**Learning Overview:** After attending this presentation, attendees will better understand the role of brain fingerprinting to detect concealed information in forensic criminal cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing the competence of attendees through increasing the ability to interpret an emerging scientific method used to detect concealed information stored in the brain via the use of Electroencephalographic (EEG) brain responses/brainwaves.

Between 10% and 70% of criminal defendants claim crime-related amnesia; there is limited published literature on objective assessments of memory loss in a criminal setting. Interview techniques combined with psychological testing have been developed to assess possible malingering of memory loss. Investigators have long sought a reliable means of detecting deception. The Guilty Knowledge Test (GKT) is an early predecessor to brain fingerprinting and measures the individual's autonomic response to information known or not known about a crime.<sup>1</sup>

Recently, brain fingerprinting techniques using brain wave response have emerged as a scientific method to detect potentially concealed information stored in the brain. Brain fingerprinting techniques measure EEG brain responses/brainwaves and compute a determination of "information present" (the subject knows the critical information) or "information absent" (the subject does not).<sup>1</sup> According to this theory, if the individual is familiar with the information presented, a P300 brainwave is emitted and measured by an EEG.<sup>2</sup>

Dr. Farwell reports that in more than 200 test cases, brain fingerprinting yielded a 100% accuracy rate with a 0% error rate in distinguishing those who possessed specific target knowledge from those who did not.<sup>1</sup> As an example, in an experiment on 17 Federal Bureau of Investigation (FBI) agents, analysis using this P-300 brain fingerprinting technique yielded a 100% identification rate of FBI agents with FBI-relevant knowledge.<sup>1</sup> Dr. Farwell has coined the term "Farwell Brain Fingerprinting" (FBF) that he proposes has the ability to detect concealed information.<sup>1</sup>

The application of this FBF technique to forensic criminal cases was highlighted in the 2003 case of *Harrington v. State*.<sup>3</sup> Terry Harrington sought to overturn his 1978 murder conviction on several grounds, including new evidence in the form of FBF that was not available at his original trial. Dr. Farwell administered his test to Mr. Harrington and rendered a report to the Iowa District Court analyzing Mr. Harrington's responses to information about the crime. Dr. Farwell asserted that his analyses supported Mr. Harrington's assertion that he was not guilty and, therefore, it should be allowed into evidence to help overturn his conviction. In contrast, the district attorney challenged these results, noting several factors that could have impacted the FBF outcome. The panel will review how the admissibility of this newly emerging FBF technique was addressed by the district and appellate courts and its impact, if any, on the legal outcome of Mr. Harrington.<sup>4</sup> The strengths and limitations of this approach will be discussed and admissibility under the *Daubert* standard will be highlighted.

#### Brain Fingerprinting, Lie Detection, Malingering

### ES1 Dracula, Twilight, and Blood Cults: Why Is It That Vampires Never Die?

Corina Freitas, MD\*, Syracuse, NY 13202; George D. Annas, MD\*, State University of New York Upstate Medical University, Syracuse, NY 13202; Jarrod A. Marks, MD\*, Tufts Medical Center, Boston, MA 02111

**Learning Overview:** After attending this presentations, attendees will: (1) gain knowledge in the historical, medical, and psychoanalytic theories behind vampire beliefs; (2) advance skills regarding the manner in which “vampirism,” “vampire cults,” and “vampire communities” may present clinically and forensically; and (3) improve knowledge in historical reports of sadistic mass murder that may have contributed to vampire lore.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the existing knowledge of the fundamentals of the current field and thus improve forensic competence and performance.

From the ancient world to the present, vampires have held a tight grip on our fascination and fear and this has yet to be released. Traces of the legend are found in some of the oldest surviving mythologies and have spilled over into history and lore. Such mythology associated vampires with female figures representing potential destruction and with children in a state of dependency and helplessness. Similar beliefs are traced to ancient cultures across the globe, often depicting demonic female figures who fused relationships between the living and the dead, expressed through blood rituals as well as sexualized and aggressive exchanges.<sup>1</sup>

However, it was Bram Stoker who introduced us to the great Dracula in the late 19<sup>th</sup> century, and it was this quintessential Byronic hero who fathered countless other characters. From the monstrous presentations of Nosferatu, and Underworld’s Markus, to the charming Lestat and adorable sparkly Edward, and everything in between, our fascination with Dracula and his ever-evolving progeny shows no signs of decay.

In the modern era, some vampires have been transformed from evil beasts to misunderstood, and ostracized, supernatural heroes.<sup>2</sup> With this change, some of their ideologies went from that of those cursed with tormented “un-deadness” to those having (and sometimes offering) immortality; from forced isolation to offering a new community; from subhuman viciousness to displaying animal traits that convey energy and natural instincts. Flaunting the appeal of the aristocrat or outlaw and inciting adventure at once terrifying and safe, the vampires in these stories have “evolved” into uncannily irresistible figures.<sup>3</sup> What is it that so intrigues us about them? This presentation will lead us on a journey where we can explore this fascination via culture and psychoanalytic theory, as well as historical figures purported to have inspired the legend—tales of which include sadism and mass murder eclipsing any terror found in fiction.

Also discussed will be cases from the early 1800s where the misperception of infectious illness caused mass hysteria, leading to the belief that the dead were rising from their graves and literally sucking vitality out of the living. This hysteria ultimately culminated in the cannibalistic rituals of the recently deceased to stop the dead from harming the living. However, such a ritual has been documented as recently as 2003, proving that these seemingly old beliefs from a forgotten time of darkness and irrational superstition for some reason draw appeal to this day.

Indeed, we are far from immune to such seeming madness. Modern vampire “cults” tragically show us how an obsession with these creatures can go too far. What drives such people into these alternate realities? Mental illness? Sadism? Or is there more complexity to these stories? Perhaps we will never know, but one thing is certain: while legends postulate many ways that vampires may be killed, time has proven that they will, indeed, live forever.

### W1 Drug Delivery Homicide: Prosecution, Defense, and Expert Testimony

Barry K. Logan, PhD\*, NMS Labs, Willow Grove, PA 19090; MJ Menendez, JD\*, NMS Labs, Horsham, PA 19044-2208; Gregory G. Davis, MD\*, Jefferson County Medical Examiner's Office, Birmingham, AL 35233-1601; Michael J. Hunter, JD\*, Department of Justice Organized Crime Drug Enforcement Task Force, Columbus, OH 43215; Christopher Young, JD\*, Dallas County Public Defender's Office, Dallas, TX 75207

**Learning Overview:** The goals of this presentation are to: (1) discuss the theories of prosecution and defense under “drug-delivery-resulting-in-death” statutes and sentencing; (2) describe and explain the nuances of the Supreme Court of the United States (SCOTUS) decision in *Burrage v. United States*; (3) analyze the strengths and weaknesses of fact patterns drug-delivery-resulting-in-death cases; (4) identify and articulate the limitations of toxicological and medical testimony in these cases; and (5) prepare for testimony and direct and cross-examination in drug-delivery-resulting-in-death cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing background on the legal challenges for charging, defending, or providing opinions and testimony in cases in which an individual's death is alleged to have resulted from another individual's actions in supplying the drugs that caused the death. Prosecutors, defense attorneys, and testifying experts will be better prepared to provide scientifically supported evidence in the appropriate context to triers of fact in these cases.

With the advent of the opioid crisis, in addition to traditional prosecutions for drug possession and trafficking, there has been an increasing move toward prosecuting specific individuals who obtained or procured the drugs used by a decedent proximate to the time of their death for drug delivery resulting in death, also known as drug delivery homicide, and “but-for” causation. In addition, under federal law, in large-scale drug trafficking cases, drug distributors, or purveyors, including prescribing physicians in “pill mill” cases, members of transnational organized crime groups and illegal drug distribution syndicates, are liable for significant enhanced penalties including 20-year mandatory minimum sentences if deaths resulted as a direct result of their involvement in the distribution of their product.

In 2014, the United States Supreme Court handed down *Burrage v. United States*, which constitutes prevailing authority on the standard of causation required for imposition of the federal sentencing enhancement.<sup>1</sup> The court focused on the specific text found in 21 U.S.C. § 841(b), the federal law requiring heightened sentences for drug sales causing death or serious bodily injury. In a unanimous decision, the Court ruled that a defendant cannot be held liable under the penalty enhancement provision of the Federal Controlled Substances Act unless a “but-for” cause of death or injury is established due to the distribution of a particular drug or drugs. The Court also held that the federal sentencing enhancement applies when it is proven beyond a reasonable doubt that the drug or drugs distributed by the defendant are “an independently sufficient cause of the victim's death or serious bodily injury.” The opinion states that the Government does not have to prove that the drug/drugs were the only cause of the decedent's death; but it must have been “the straw that broke the camel's back.”

The *Burrage* opinion has engendered differential interpretations in lower federal and state courts, which has resulted in corresponding ambiguities and incertitude among the scientific community called to testify in such cases. Among the challenges of presenting this evidence is the fact that many of these cases involve deaths of individuals who have been using multiple drugs that may or may not have come from the same supplier, and the timing of ingestion of the specific substances, the decedent's potential tolerance to the effects of the drug, and other factors are unknown.

This workshop will review the underlying Federal and corresponding state statutes that address these issues and how cases are being charged and prosecuted. The complex nature of certification of drug-related deaths, especially in the context of multiple mixed drugs being detected in the toxicological analysis, will be reviewed. Some exemplar case scenarios, and identifying key corroborating elements of physical evidence scene investigation, medical history, or eyewitness testimony that may weaken or strengthen the introduction of expert testimony will also be reviewed.

The expert panel will provide perspectives on the nuances of the terms “independently sufficient cause,” “resulting from,” “but-for causation,” and the interpretation of the “straw the broke the camel's back” analogy from both a legal and an applied science perspective. This presentation will lead the attendees to appreciate that the importance of the evidence that supports or undermines confidence in the expression of these scientific opinions in the context of charging, prosecuting, defending, testifying, and achieving just sentences in cases of this type.

### W2 Statistical Learning Algorithms for Forensic Scientists

Alicia L. Carriquiry, PhD\*, *Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011*; Heike Hofmann, PhD\*, *Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011*; Michael J. Salyards, PhD\*, *Compass Scientific Consulting LLC, Sharpsburg, GA 30277*; Robert M. Thompson, MFS, *National Institute of Standards and Technology, Gaithersburg, MD 20899*

**Learning Overview:** The goals of this workshop are to: (1) introduce attendees to the basics of supervised learning algorithms in the context of forensic applications, including firearms and footwear examination and trace evidence, while placing emphasis on classification trees, random forests, and, time permitting, neural networks; (2) introduce the concept of a similarity score to quantify the similarity between two items; (3) show how learning algorithms can be trained to classify objects into pre-determined classes; (4) discuss limitations of Machine Learning (ML) algorithms and introduce methods for assessing their performance; and (5) discuss the concept of a Score-based Likelihood Ratio (SLR): computation, advantages, and limitations.

**Impact on the Forensic Science Community:** The use of learning algorithms will increase as measurement of features in various types of evidence improve. This is particularly true in the case of pattern evidence. Forensic scientists will greatly benefit from understanding the basic ideas that underpin statistical learning since these types of methods have already been proposed for firearms examination, fingerprints, glass comparison, and shoe print evidence.<sup>1,2</sup> Most quantitative training for forensic scientists emphasize classical statistical ideas, so a workshop in which forensic practitioners are exposed to learning algorithms is novel and timely.

When a task consists of deciding whether two items are similar enough to suggest that they could have a common source, an alternative approach is to use statistical or machine learning. Machine learning is the term used to refer to a family of statistical methods and computer algorithms that find patterns in data and has been around for decades.<sup>3</sup> There are many different types of algorithms, but a basic taxonomy is to distinguish between *supervised learning* algorithms and *unsupervised learning* algorithms.<sup>4</sup> The focus of this presentation is on supervised learning methods.

Supervised algorithms rely on training data, for which ground truth is known, and on test data, on which the performance of the algorithm can be tested. In a simple example, several bullets are fired from a large number of guns. To train an algorithm to recognize whether a pair of bullets was fired from the same or from a different gun, one might begin by creating all possible pairs of bullets, and compute, for example, the difference in the average striation depth for each pair. This difference is a feature, and perhaps it takes on low values when two bullets were fired from the same gun and high values otherwise. Presented with the value of the feature for pairs of bullets known to have been fired from the same or from different guns, the algorithm then “learns” that same-gun bullets tend to exhibit values of the feature in a certain range that is different for different-gun bullets. With this knowledge, the algorithm can then classify other pairs of bullets for which it does not know in advance whether the bullets were shot from the same or from a different gun.<sup>5</sup>

In real applications, the number of features can be very large, and the number of classes can also be large. In classification examples, the response variable—or class—is discrete, but algorithms can also be used when the response is continuous; in this case, the problem is to predict the value of a variable given information on a large number of features.

### W4 The Impact of the 2018 Farm Bill on the Forensic Analysis of Cannabis

*Sandra E. Rodriguez-Cruz, PhD\**, Drug Enforcement Administration, Dulles, VA 20166; *Linda C. Jackson, MS\**, Department of Forensic Science, Richmond, VA 23219; *Shawn K. West, MSFS\**, Colorado Bureau of Investigation, Pueblo, CO 81007; *Richard P. Meyers, MSFS\**, Drug Enforcement Administration, Springfield, VA 22152

**Learning Overview:** After attending this presentation, attendees will understand the legal and forensic landscape of marihuana/hemp analysis and also understand a validated analytical approach that meets these new requirements.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework for meeting the forensic requirements of the 2018 Farm Bill.

In December 2018, the President of the United States signed into law the Agriculture Improvement Act of 2018 (Farm Bill). This law introduced two significant changes to our drug laws. First, the term “hemp” was defined as, “the plant *Cannabis sativa* L. and any part of that plant, including the seeds thereof and all derivatives, extracts, cannabinoids, isomers, acids, salts, and salts of isomers, whether growing or not, with a delta-9 Tetrahydrocannabinol (THC) concentration of not more than 0.3 percent on a dry weight basis.” Second, the law excluded the term hemp from the definition of marihuana in the Controlled Substances Act. In response to the changes at the federal level, states have enacted their own varied legislation to allow for hemp cultivation and processing and the sale of hemp products. This also led to additional analytical challenges for the states.

This workshop will provide an overview of changes in the law, describe an analytical approach to providing reliable results that conform to the new legal requirements, and provide an overview of the work conducted to validate the methods incorporated into the analytical approach. State laboratory managers will describe their varying approaches to meeting these new challenges from a state that had legalized marijuana prior to changes in federal law and a state that had not.

Analytical testing requirements of suspected cannabis submissions to seized-drug laboratories have changed. Formerly used testing protocols—analytical schemes—included tests such as macro/microscopical analysis, the Duquenois-Levine color test, and separation analyses like thin-layer- Gas Chromatography/Flame Ionization Detector (GC/FID) and Gas Chromatography/Mass Spectrometry (GC/MS). These testing procedures allowed for the identification of cannabis, but they are no longer sufficient to distinguish between marihuana and hemp because of the new requirement to quantitatively analyze the sample and assess the THC content (the quantitative property that separates hemp from marijuana).

To address the new legal requirements, Drug Enforcement Administration (DEA) scientists developed a new testing protocol. The new analytical scheme includes macro/microscopical analysis (to identify cannabis plant material), a cannabis typification color test (to assess the ratio of THC to Cannabidiol (CBD)), and GC/MS (to identify THC and assess THC concentration at the 1% level). This workshop will guide attendees through the background and design of this new testing protocol, including the method development and validation and implementation processes, as well as revised reporting language.

Additionally, scientists from the Virginia Department of Forensic Science, where marijuana has not been legalized, collaborated with the Drug Enforcement Administration (DEA) in the development and validation phases of the project. Validation studies were performed on the 4-aminophenol color test with a variety of concentration combinations of CBD reference materials and their acids, as well as non-controlled substances. The DEA 1% assessment method was further evaluated to include GC/MS instruments with a second chromatographic column and FID. This allows comparisons of peak height and peak area data from both detectors.

In Colorado, recreational marijuana and hemp were allowed by legislation passed in 2012, known as Amendment 64. As scientists considered the draft of the 2018 Farm Bill, the Colorado Bureau of Investigation selected an instrument and developed and validated a method to quantify THC in plant materials. This workshop will describe the process and the many lessons learned in the evolving area of forensic analysis.

---

### Marijuana, Hemp, Forensic Analysis

### W5 The Psychopathology of Homicide

Alan R. Felthous, MD\*, Saint Louis University School of Medicine, St. Louis, MO 63104-1027; Felice F. Carabellese, MD\*, University of Bari, Bari 70124, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department Public Health Sciences, Torino 10126, ITALY; Carlo P. Campobasso, MD, PhD\*, University of Campania, Napoli 80138, ITALY; Gabriele Mandarelli, MD, PhD\*, University of Rome "Sapienza," Rome 00100, ITALY; Ilaria Rossetto, PhD\*, Residences for Execution Safety Measures, Castiglione delle Stiviere 46043, ITALY; Silvia Trotta\*, Institute of Legal Medicine, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the relationship between psychopathology and the phenomenon of homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the identification of the features of psychopathology of homicide can inform treatment planning.

**Introduction:** Homicide is the most serious form of antisocial behavior. Despite its personal, social, and economic impact, homicide is among the least studied comprehensible forms of antisocial and violent behavior. The relationship between major psychiatric disorders and homicides has been much debated in the scientific literature.<sup>1-4</sup> Although it is known that most extreme violent acts are committed by subjects without any history of psychiatric pathology, some research suggests there is a correlation between schizophrenia spectrum disorders, severe personality disorders, and homicide.<sup>2,4</sup>

The homicides associated with a psychotic dimension present specific characteristics.<sup>3</sup> The relationship between the murderous ability to plan an antisocial act does not necessarily exclude a possible diagnosis of schizophrenia. Even more controversial is the relationship between the psychopathic dimension and homicide. Psychopathic homicides are usually goal-oriented. A non-psychopathic murderer usually commits a crime with a different type of violence, often as a result of frustration. Moreover, some gender differences can also be observed in the homicide phenomenon, whether the murder is committed by an offender affected by a psychotic disorder or is committed by a man or a woman with a psychopathic personality profile. Besides the diagnosis, it is important to point out that usually women express this antisocial behavior in a different way compared to men.<sup>3</sup>

In homicide, suspected homicide, and other suspicious or obscure cases, the role of an experienced forensic pathologist at the scene of death is generally to assess the environment, the local circumstances, and the position and the condition of the body.<sup>5-7</sup> Homicide grows out of a transaction between individuals, which is a product of the individuals and their relationship. Behaviors can thus be seen to follow a definite pattern that can be related to underlying psychological principles, which closely relate to how an offender interacts with the victim at the crime scene.<sup>8-10</sup>

Homicide can occur together with suicide in the same episode. An earlier classification of combined homicide-suicide, which considered the perpetrator's psychopathology and relationship with the victim(s) will be updated to incorporate recent studies. Individual acts of homicide-suicide can be understood by considering three contributing factors: (1) ego weaknesses or psychopathology of the perpetrator, (2) stressors, and (3) the psychological vector directing this specific act. Studied attention will be given to female homicide-suicide perpetrators and gender differences. Within this context will be considered homicide-suicide terrorists and female bombers in particular.

In the light of these premises, it can be understood how the forensic expert evaluation of the criminal responsibility of murder defendants presents specific difficulties, as well as having a significant impact in the criminal trial. Crime scene investigation requires a multidisciplinary approach by an expert team in order to shed light on difficult cases, such as murders staged as suicides or accidents.

This workshop's speakers will debate from different point of views the scenarios outlined above. The psychopathology of men and women who kill; psychopathology of men and women of criminal organizations, such as the Sicilian mafia; combined homicide suicide; the Not Guilty by Reason of Insanity (NGRI) killers—a national sample; forensic psychiatric evaluation of defendants in homicide cases—literature analysis and forensic cases; and treatment outcomes following a conviction of killing. Several general pathologists will speak on topics that pertain to the killer's mental state from the perspective of forensic pathology and investigation of homicide. The criminological and psychiatric data from a multicenter national Italian sample of forensic psychiatric patients will be also discussed.

**Conclusions:** The main purpose of this workshop is to highlight the pathological aspects of homicide: attendees will acquire information about the psychopathology of homicide from the different presentations, in which there will be an opportunity to describe the history of the disease, the treatment, the outcomes, and the criminal history of individuals who committed the crime of murder without mental responsibility because of their psychiatric illness. The speakers with different professional experiences will include in their presentations original data from recent not-yet-published investigations.

### W6 High-Impact Practices in Forensic Science Education

Gina Londino-Smolar, MS\*, Indiana University–Purdue University Indianapolis, Indianapolis, IN 46202; Karen S. Scott, PhD\*, Arcadia University, Glenside, PA 19038; Dwight E. Adams, PhD\*, University of Central Oklahoma, Edmond, OK 73034; Uzoma A. Okafor, PhD\*, Chemistry & Forensic Science, Albany, GA 31705; Caitlin E. Porterfield, MS\*, Forensic Science Institute–University of Central Oklahoma, Edmond, OK 73034; Joseph Levi White, MS\*, Defense Forensic Science Center, Forest Park, GA 30297; Dean J. Bertram, PhD\*, The University of Southern Mississippi, Hattiesburg, MS 39406; Amy N. Brodeur, MFS\*, Boston University School of Medicine, Boston, MA 02118; Carraugh Reilly Nowak, MFS\*, Hilbert College, Hamburg, NY 14075; Douglas A. Ridolfi, MS\*, Buffalo State College, Buffalo, NY 14222; Mark R. McCoy, EdD\*, University of Central Oklahoma, Edmond, OK 73034

**Learning Overview:** After attending this presentation, attendees will learn how High-Impact Practices (HIPs) can be used in forensic science education and discover how to adapt their courses using common programing for students by: (1) identifying and describing a variety of HIPs; (2) recognizing useful HIPs dependent on the environment; and (3) discovering innovative HIPs that could be incorporated into their classroom.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exploring a variety of HIPs and gaining insight into a broader scope of common methods useful in forensic science teaching. By discussing multiple types of HIP techniques and the application of these practices in forensic science education, attendees will be able to incorporate tools into their forensic science classrooms and programs.

HIPs are defined as active learning practices that promote deep learning through student engagement. Based on this definition, there are ten different learning experiences identified as HIPs: (1) first year seminar and experiences; (2) common intellectual experiences; (3) learning communities; (4) writing intensive courses; (5) collaborative assignments and projects; (6) undergraduate research; (7) diversity/global learning; (8) service learning or community-based learning; (9) internships; and (10) capstones courses / projects. These increase student engagement and success throughout their college career. Students should participate in at least two experiences throughout college, but it is highly recommended they participate in one experience per year.<sup>1</sup> Due to the importance of these experiences in students' college careers, these are also required for forensic science programs accredited through Forensic Science Education Programs Accreditation Commission (FEPAC). This workshop explores seven ways these can be incorporated in forensic science curriculum.

Over the years, there have been issues on student success, retention rate and attrition rate. A detailed insight on the impact of First-Year Seminar Experience (FYSE) on the forensic science program at Albany State University that resulted in increased retention and graduation rate will be provided. Data will be shown on the impact of FYSE and the way forward to repositioning of the program to enable greater learning experiences for students.

Living-Learning Communities (LLC) promote collaborative learning experiences by grouping students of a similar interest or major within the same area of a residence hall. LLCs focus on students' curricular experiences to create purposeful connections between the academic and social environments of college life. The development and organization of the LLC at the University of Central Oklahoma and examples of student growth and transformation will be discussed.

The "Forensic Science Seminar at Sea" and "Field Study in Forensic Science" are two programs implemented by the School of Criminal Justice, Forensic Science, and Security at the University of Southern Mississippi. These programs provide student-centered instruction by working with forensic scientists across multiple agencies. Topics will include program planning, curriculum development, risk management, benefits, and meeting guidelines for academic accreditation.

The case practicum model provides students with information to independently perform evidence assessment and laboratory analysis in a realistic forensic case setting. Active involvement from forensic science practitioners, an extensive peer review process, and completion of a forensic proficiency test contribute to this hands-on course. An overview of Boston University's practicum course, including insight into planning, delivery, and assessment, will be shared.

Project-based learning promotes critical thinking and problem-solving skills. Coupling this concept with casework and scholarly research bridges the real expectations and outcomes in forensic investigations and research expected in academia. Using current missing person cases, students complete an experiential learning project and their work has the potential to impact a real case.

A series of semester-long projects are used to create problem-solving methods used in a forensic chemistry course. The project supplements lecture and labs in crime scene and laboratory forensics with separate tracks related to bloodstain pattern interpretation, gamification of a forensic chemistry lab, and developing contemplative methods to enhance observational skills. The lectures, projects, and assignments that accompany these three tracks will be discussed.

The University of Central Oklahoma's (UCO's) Student Transformative Learning Record (STLR) is a non-proprietary model with a proven track record for increasing retention, student academic achievement, and workforce readiness. An overview of the STLR process, how it is assessed, and examples of transformational learning experiences within the UCO Forensic Science Institute will be shared.

### W7 New Advances in Forensic Human Identification. Issues and Approaches

*Sara C. Zapico, PhD\**, Florida International University, International Forensic Research Institute, Miami, FL 33199; *Sarah Ellingham, PhD\**, International Committee of the Red Cross, IRAQ; *Joe Adserias-Garriga, DDS, PhD\**, Mercyhurst University, Erie, PA 16546; *Douglas H. Ubelaker, PhD\**, Smithsonian Institution, Washington, DC 20560; *Josep De Alcaraz-Fossoul, PhD\**, University of New Haven, West Haven, CT 06516; *Leslie E. Fitzpatrick, PhD\**, Mercyhurst University, Erie, PA 16546; *Alexander S. Forrest, FFOMP\**, Queensland Health Forensic and Scientific Services, Coopers Plains, Queensland 4108, AUSTRALIA

**Learning Overview:** After attending this presentation, attendees will have a heightened understanding of: (1) the factors affecting human identification; and (2) how the application of new, innovative, and cross-disciplinary techniques have the potential to overcome these issues, which will be detailed through case examples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the presentation of multidisciplinary approaches toward human identification, pointing out the novel techniques suitable for this purpose, encouraging collaboration and innovation among different forensic specialties to document and integrate several lines of evidence.

Human identification always has been a complex task; the degree of complexity, however, is highly dependent on the context in which death occurred. Phenomena such as the human mass migration and displacement witnessed in the past years add challenge, such as an increased difficulty in tracing an individual's geographical origin, thus complicating antemortem data and reference sample collection.

The traditional identification approaches of forensic anthropology and odontology, as well as their advantages and limitations, will be covered before delving into the introduction of new forensic procedures. Additionally, challenging cases of human identification will be presented, and step-by-step approaches on how to tackle them from different disciplines will be delivered.

Time frame and geographical origin of the remains are crucial data to achieve a positive identification of the unknown. New advances in microbiota characterization can provide insights about the time-since-death; additionally, the analysis of radiocarbon can offer important information regarding when the individual was born and died. The estimation of a fingerprint's age can provide valuable information that can help relate an individual temporally in a certain location.

Geographical origin can be established by isotope analysis, also providing information about the diet of the deceased.

New trends in forensic genetics point out the use of Small Nucleotide Polymorphisms (SNPs) to determine eye and hair color and ancestry, leading to a facial approximation based on genetic traits. In the past years, 2D and 3D imaging techniques have been developed and have been very useful in forensic science, especially for comparison of postmortem and antemortem images, and several of these techniques will be demonstrated.

This workshop will further cover the topic of appropriate documentation and temporary disposition of unidentified remains in order to maximize the potential for future identification.

All these new and innovative methods will help forensic scientists create the biological profile of human remains and achieve a positive identification.

This workshop will demonstrate how the awareness of the problems faced in human identification and thinking out-of-the box and applying and integrating new techniques with traditional procedures are essential to facilitate the correct identification of the victims. This is particularly important in mass disaster scenarios, where the large number of deceased pose challenges to this task as human remains are often incomplete, commingled, and sometimes only fragmentary remains are present. Such complexities require comprehensive approaches and new tools that contribute to obtaining different lines of evidence to positively identify the deceased. Thus, this workshop will provide a step toward finding solutions to these complications by improving the knowledge on the most state-of-the-art procedures available to forensic identification.

---

#### Human Identification, Multidisciplinary Approach, State-of-the-Art Forensic Technique

### W8 Death Investigations in the Military: Case Studies From Around the World

*Steven Geniuk, MS\**, United States Army Military Police School, Fort Leonard Wood, MO 65473; *Precious JeanBatiste, MS*, United States Army Criminal Investigation Command, Fort Meade, MD 27055; *Armando B. Dela Rosa, Jr., MA\**, United States Army Criminal Investigation Command, Fort Carson, CO 80913; *Derek J. Kingsbury, MBA\**, United States Army Criminal Investigation Command, Joint Base Lewis-McChord, WA 98387; *Vanessa R. Neff, MS\**, United States Army Criminal Investigation Command, Fort Hood, TX 76544; *Joshua L. Adams, PhD\**, United States Army Criminal Investigation Command, Fort Myer, VA 22211; *Sarah N. Crosby, MS\**, United States Army, Arlington, VA 22213; *John W. Dunlap, MSFS, MSCJ*, U.S. Army Criminal Investigation Division, Joint Base Lewis-McCord, WA 98433; *Adam C. Armstrong, MS\**, United States Army Criminal Investigation Division, Fort Bragg, NC 28310; *Keith M. McCullen, MFS\**, Black River, NY 13612-0624; *Edmund D. Tamburini, MFS\**, McDonough, GA 30252

**Learning Overview:** After attending this presentation, attendees will understand: (1) processing a variety of death scenes; (2) forensic capabilities of military investigators; (3) investigative considerations in foreign countries; (4) coordination with international agencies; (5) domestic violence impact on child death; (6) staged suicide; (7) scene reconstruction; and (8) laboratory capabilities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through detailed accounts of a variety of death investigations as described by Army Special Agents who participated in the cases. The investigations represent various circumstances and illustrate the worldwide capabilities and responsibilities of military investigative agencies, along with legal and laboratory support.

In June of 1956, a soldier assigned to Fort Riley, KS, failed to show up to his assigned place of duty and was declared Absent Without Leave (AWOL). Fifty years later, a family in New Brunswick, Canada, came forward with the information that their grandfather was the missing soldier from Fort Riley. Army Criminal Investigation Command (CID) working with numerous agencies verified (through DNA) the grandfather in Canada was the missing soldier from 1956. The investigation helped bring some answers and closure to both families.

In 2018 an 11-year-old committed suicide at an Army installation. Investigation into the death of the child found numerous law enforcement interactions with the family at different Army installations, including child abuse involving the victim and his siblings. Domestic violence by the stepfather and biological mother included a firearm-related incident. The firearm was returned by law enforcement and was used in the suicide.

During the draining of a lake, a vehicle antenna appeared on the surface. Divers identified a submerged car and found a foot stuck under the driver's headrest. Identifying the victim, recovering data from a cell phone, and following leads more than five years old led to a suspect. The suspect ultimately confessed to strangling the victim, driving the car onto post, and submerging the car in the lake.

In March 1991 a soldier's wife was found dead with a single gunshot wound to the head, pistol in hand. Several suicide notes and a history of depression and marital problems led to a closed suicide. Later information developed, including a possible earlier attempted murder by arson. The soldier was tried for murder and attempted murder.

A case study examines a unique multiple gunshot wound suicide of a 36-year-old, Caucasian male Army service member who shot himself nine times with a Walther® P22 pistol (.22LR). Entrance wounds included the head, neck, and chest.

A soldier used a network of friends to help harass and stalk his estranged soldier wife. After seeing her with male friends, the subject and an accomplice broke into one of the other the men's residence and killed two of them.

On Christmas day, 2005, a United States soldier was attacked by a translator in Mahmoudiya, Iraq. The translator opened fire, striking the soldier, who luckily survived the attack; he returned fire, striking and killing the translator.

### Homicide Investigation, Forensics, Suicide

### W9 Interpersonal Violence and Elder Abuse: Maltreatment That Crosses All Borders

*Amy Y. Carney, PhD\**, California State University San Marcos, San Marcos, CA 92078; *Patricia M. Speck, DNSc\**, Hoover, AL 35226; *Debra Holbrook, MSN\**, Academy of Forensic Nursing, Baltimore, MD 21225; *Kathleen S Thimsen, DNP\**, Goldfarb School of Nursing, Barnes Jewish College, St. Louis, MO 63110; *Rachell A. Ekroos, PhD\**, Center for Forensic Nursing Excellence International, Las Vegas, NV 89128; *Stacey A Mitchell, DNP\**, Texas A&M University, Bryan, TX 77354; *Diana K. Faugno, MSN\**, Dallas, GA 30321; *David A. Williams, DDS\**, Randallstown, MD 21133; *Joyce P. Williams, DNP\**, Randallstown, MD 21133

**Learning Overview:** After attending this presentation, attendees will be able to identify multiple forms of abuse and mistreatment, recognize the impact of abuse across the lifespan, and specify key points for the prosecution of abusers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by broadening the education of those working with victims of violence. This presentation will enhance not only the ability to intervene in maltreatment but to prosecute the abuser.

Interpersonal violence and maltreatment are recognized criminal and social problems both in the United States and internationally. Most societies considered child abuse and interpersonal violence, once called “domestic violence”, private family matters. As more research became available, intervention increased, with cases of both child and adult abuse moving into law enforcement and the criminal court system. The actual study of elder abuse is relatively recent in the United States. Mentions of elder mistreatment date back to the mid-1970s, but research and resources were years in coming. Similar to child abuse and domestic violence, harm to an older relative was considered a family matter and stayed behind closed doors. Much of early theory was based on patterns of family violence that had been studied in child abuse and the battered wife syndrome. With the growing understanding of the nature and extent of elder mistreatment came the awareness of the lack of forensic and medical markers that could be useful in the identification of abuse. There was no research that could assist investigators in establishing lacerations, bruising, fractures, or decubiti as elements of abuse or neglect. The aging patient frequently has physiological characteristics or medical conditions, which can mask or mimic markers of neglect and abuse, making it even more difficult to detect or evaluate. Unless an actual crime could be proven, such as homicide, charges were rarely filed against a suspected abuser. Arrest and prosecution for financial abuse or neglect was unheard of. Testimony in both young and older patients could be difficult to obtain.

Multiple aspects of abuse have been examined in the research, including measures for detection, assessment, and documentation, and yet crimes of abuse continue to be difficult to document and prosecute. In this workshop, attendees will learn the challenges of detection and intervention of abuse and the tools that lead to successful prosecution in criminal cases of abuse. The impact of trauma on the victim’s health will be discussed, with specific examples of the impact of strangulation, neglect, and self-neglect. Examples from the literature on child abuse will be used as illustrations. Age-related changes and co-morbidities will be presented, with emphasis on differentiating abuse from other conditions. The intersection of elder abuse and interpersonal violence will be explored. Investigating abuse and neglect in health care facilities is presented, with an intensive case review of elder sexual abuse. The response to the elderly in disasters will be described, with a panel review at the end of both the morning and afternoon sessions.

---

#### Interpersonal Violence, Abuse, Maltreatment

### W10 The Investigation and Analysis of Health Care Serial Killers

*Laura M. Labay, PhD\**, NMS Labs, Willow Grove, PA 19090; *Donna M. Papsun, MS*, NMS Labs, Willow Grove, PA 19090-2910; *Michael M. Baden, MD*, New York, NY 10019 *Beatrice Yorker, JD\**, California State University, Los Angeles, Los Angeles, CA 91103; *Steven M. Marcus, MD\**, Montville, NJ 07045; *Tim Braun\**, National Center for Missing & Exploited Children, Alexandria, VA 22314; *Paul Uribe, MD\**, Armed Forces Medical Examiner System, Dover Air Force Base, DE 19902; *Kevin M. Legg, PhD\**, Center for Forensic Science Research and Education, Willow Grove, PA 19090; *Vincent Marks, DM\**, University of Surrey, Guilford, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will: (1) state the different motivations of health care serial killers; (2) understand some of the challenges associated with analytical testing and result interpretation; (3) list the agents that have been used in medical killings and describe their mechanism of action; and (4) understand how to best prepare for case presentation in a legal proceeding.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a multidisciplinary approach to understanding, identifying, and investigating health care serial killers.

A health care serial killer, sometimes referred to as an Angel of Death or an Angel of Mercy, is a unique type of criminal offender who, while employed as a medical provider, intentionally ends the life of a patient. Infamous examples include: physician Michael Swango, who is estimated to have killed more than 60 people; LVN Genevieve Jones, who murdered infants and children; and physician Harold Shipman, who killed hundreds of patients. The motivations are varied, but include ending the suffering of a patient who likely will not recover, minimizing the emotional toll on relatives and loved ones, achieving recognition from their colleagues by accomplishing life-saving resuscitation measures, and exerting dominance over a helpless or weaker individual.

These cases are challenging to recognize as they typically occur over an extended period of time, involve different employers, and include patients who are severely ill and/or have a terminal diagnosis. The latter situation means that because a reasonable competent cause of death already exists, the death may not be heavily scrutinized. Furthermore, analytical evidence or proof may be lacking since hard-to-detect substances, such as epinephrine, succinylcholine, insulin, and heparin, may be used. Instead, identification and in-depth investigations tend to occur when a correlation between a care provider's presence and a cluster of deaths is observed. A high-profile prime example is the Cullen case. Cullen was a nurse who was able to move from facility to facility in New Jersey and Pennsylvania in spite of his questionable employment record and even though suspicions were raised by coworkers that he was harming patients. He eventually confessed to killing more than 40 patients over the course of 16 years.

Medical and forensic science practitioners must be well-versed in detecting these deaths and, when required, be equipped to perform a thorough and lengthy investigation. Due to the complexity of these cases, most will require a multidisciplinary approach and include input from legal investigators, toxicologists, and forensic pathologists. Another facet is the prevention of these deaths. For example, what systems are in place at care facilities to monitor the dispensing and use of medications, and are there any mechanisms or safeguards from a psychiatric standpoint that allow for the profiling and identification of at-risk care providers? Greater insight learned from previous cases and more understanding about the perpetrators may aid in limiting future deaths and helping direct investigations.

#### Medical Killers, Health Care Serial Killers, Angels of Death

### W12 KidStats: Improving the Subadult Biological Profile

*Kyra E. Stull, PhD\**, University of Nevada, Reno, Reno, NV 89557; *Heather M. Garvin, PhD\**, Des Moines University, Des Moines, IA 50312-4198; *Alexandra R. Klales, PhD\**, Washburn University, Topeka, KS 66621; *Louise K. Corron, PhD\**, University of Nevada, Reno, Reno, NV 89557; *Michael H. Price, PhD\**, Santa Fe Institute, Santa Fe, NM 87501

---

**Learning Overview:** After attending this workshop, attendees will be trained on the most up-to-date techniques to estimate subadult age and sex and on KidStats, a freely available web-based graphical user interface.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with applied experience in collecting subadult data from 3D printed remains of individuals between birth and 15 years and the application of these data in a statistical framework.

A lack of modern subadult samples has greatly limited the development and validation of subadult biological profile techniques, as well as practitioners' experiences working with subadult remains. The computer tomography sample of more than 1,100 individuals aged between birth and 20 years, collected from the University of New Mexico Office of the Medical Investigator and from the Office of the Chief Medical Examiner in Baltimore MD, enabled this study to collect more than 200 variables (i.e., age and sex indicators) from most individuals, resulting in an extraordinary amount of knowledge regarding skeletal and dental growth and development and variation within a large, modern sample of North American children. This workshop will take the attendees through the subadult skeletal research experience, from research design challenges to the results obtained, as well as a discussion on how the project results vary from previous publications.

Although subadult age estimation has been historically considered a reliable practice, current age estimations continue to face limitations. For example, methods tend to focus on only a single variable, such as dental development. One of the main methods that will be discussed is the mixed cumulative probit algorithm that was designed specifically for dealing with continuous (diaphyseal dimensions) in conjunction with ordinal age indicators (epiphyseal fusion and dental formation) to predict a continuous outcome variable (age). Previously in subadult age estimation techniques, the age estimation methodology has been limited to a single variable and a single indicator without any statistical way to combine different age estimations. This model enables individuals to enter any combination of data for epiphyseal fusion, diaphyseal dimensions, appearance of ossification centers, or dental formation and yields one age estimate with 95% confidence intervals, thus meeting the best practices of our field. Not only is this novel algorithm applicable in KidStats, it is also freely available in an R package that has been released. While the main focus of the workshop is on age estimation and KidStats, other topics (or research) will be presented, including the utility of the subadult pelvis for sex estimation, subadult body mass estimation, and subadult stature estimation.

Overall, this workshop seeks to provide attendees with experience working with subadult remains, familiarize them with modern techniques in estimating subadult biological profile parameters, and ensure they understand both the capabilities and challenges in performing such analyses. Three-dimensional (3D) prints of subadult remains will be used to guide attendees through the newly proposed age and sex methodologies. Because subadult skeletal samples are rarely available, the 3D printed material provides a unique opportunity for attendees to see how age and sex indicators vary throughout ontogeny.

---

### Forensic Anthropology, Biological Profile, Juvenile

### W13 A Primer on Multidisciplinary Investigations of Pediatric Injuries and Deaths

*J.C.U. Downs, MD\**, *forensX, LLC, Savannah, GA 31406*; *Joanna L. Collins, MFS, LINUS Investigations & Consulting, San Antonio, TX 78258*; *Bonnie Armstrong, BS\**, *The Shaken Baby Alliance, Boyd, TX 76023*; *Robert N. Parrish, JD\**, *Salt Lake County District Attorney's Office, Salt Lake City, UT 84111*

**Learning Overview:** Attendees will be able to demonstrate the ability to analyze and evaluate available data in a pediatric death or injury case to formulate a viable hypothesis regarding the actual mechanism of the pathology in question. After attending this presentation, attendees will be better able to differentiate and implement effective investigative techniques from lesser alternatives.

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by exposing practitioners to an effective multidisciplinary team approach to prospectively work through investigations as they progress to a conclusion.

Pediatric cases are some of the most difficult cases for investigators to work, particularly those involving the injury and/or death of a young child. Multiple intersecting stressors can impact the investigation, as well as the investigator. Medical findings may be equivocal or complicated. Subtle and/or minimal findings pose diagnostic challenges, while physical injuries, especially to vulnerable victims, can be emotionally challenging. Existing medical conditions can add a layer of confusion while excluding possible mimics, or other conditions may prove labor intensive. In addition, parents, families, and communities want answers. Thorough investigations require enough time to ascertain the truth—whatever that might be. All these, and other, aspects tax the limited resources available to the investigator. In cases where the justice system becomes involved, all the myriad elements receive further intense scrutiny.

Multidisciplinary teams have proven popular in providing a retroactive analysis in dealing with such cases, due to their significant successes. Key elements in such cases involve the clinical medical team, forensic pathologist, social workers, advocacy center, law enforcement, legal community, and others. These teams are obviously targeted at deceased individuals; however, there exists no reason why the same concept cannot be applied with equal effort to living victims. Likewise, if applied at the inception of a case moving forward, as the investigation is ongoing, such multidisciplinary collaboration can achieve excellent investigative conclusions.

This workshop will condense a two-day workshop into a one-day overview of how this concept can be applied in practice. All these cases begin with the medical recognition of suspicious child deaths and injuries and, as such, a review of common findings may help in isolating elements that make some deaths “suspicious” or worthy of further scrutiny. Once concerns are raised in a case, the typical investigation escalates from routine to a more intensive and focused search for answers. A large part of attempting to ascertain the truth of events will arise from informal and formal interviews of persons with knowledge about case particulars. A critical element to better understand events is the development of a timeline allowing visualization of potential inclusionary and exclusionary information. Such a process is very similar to the singularly most important diagnostic element in medicine—establishing a patient history based on open-ended, direct questioning of person(s) with direct knowledge about the patient’s condition.

Using this investigative model, the technique will then be demonstrated in one of the more challenging and contentious areas of forensic medical practice: pediatric head injuries. Recognizing that there are differing points of view about how such trauma occurs and presents is critical to understand an individual case. Reflex application of dogma can hinder impartial case analysis. As such, an objective overview of present medical knowledge will be mixed with investigative techniques and timeline development to arrive at an investigative endpoint, regardless of whether it tends to inculcate, exculpate, or provide no definite answer.

This workshop is intended to enhance attendees’ knowledge of excellent techniques for the multidisciplinary investigation of pediatric injury and/or death, positioning them to better implement objective analysis and appraisal of case data to formulate an overall evaluation for potential subsequent action(s), if needed. Such a strategy would improve patient outcomes by enhancing the final investigative conclusions.

---

#### Multidisciplinary, Pediatric, Trauma

### W14 Mass Disasters and Disaster Victim Identification (DVI)

*John A. Williams, PhD\**, Western Carolina University, Cullowhee, NC 28723; *Victor W. Weedn, MD, JD\**, The George Washington University, Washington, DC 20007; *Jason M. Wiersema, PhD\**, Harris County Institute of Forensic Science, Houston, TX 77054; *Anthony B. Falsetti, PhD\**, College of Science, Forensic Science Pro, Fairfax, VA 22030; *Kenneth W. Aschheim, DDS\**, New York, NY 10065; *Bryan Johnson, MSFS\**, Federal Bureau of Investigation, Quantico, VA 22135; *Taylor M. Dickerson III, MSFS\**, SNA International, Armed Forces DNA Identification Laboratory, Dover Air Force Base, DE 19912; *Jason H. Byrd, PhD\**, University of Florida, Gainesville, FL 32608; *Cynthia Gavin, PhD\**, Parkville, MD 21234

**Learning Overview:** After attending this presentation, attendees will be able to: (1) understand the historical background of DVI, (2) recognize the need for standards and best practices, (3) understand the integrated contributions of the various forensic sciences to DVI, and (4) understand the critical relationship of the Victim Information Center to the identification process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with an understanding of the current state of mass fatality victim identification as it exists in the United States. Presentations will encompass the breadth of the forensic sciences, including ethical considerations and the role of the Victim Information Center in mass fatality identifications.

DVI is the comprehensive process of human identification as applied to mass fatality events. Although by definition a mass fatality event is any situation that overwhelms local resources, we generally think of a situation in which identification is hampered by the event and recovery process. Human remains that have been badly traumatized, heavily decomposed, or recovered outside of their normal context are examples that fit this description.

In 2014, responding to the 2009 NAS Report, the United States Department of Commerce's National Institute of Standards and Technology (NIST) established the Organization of Scientific Area Committees (OSAC) to assist the development of standards in the forensic sciences. The OSAC includes a DVI subcommittee that has promulgated recommended standards. In 2016, the American Academy of Forensic Sciences' American Standards Board (ASB) was established as a Standards Development Organization (SDO). The ASB includes a DVI Consensus Body to produce American National Standards for DVI. Using the OSAC DVI recommendations, the ASB has published several DVI standards and best practices.

While DVI may take place locally, it is by its nature a governmental process (i.e., based in the office of a coroner or medical examiner). At the United States Federal level 15, Emergency Support Functions (ESF) outline how the public and private sectors respond to national emergencies. Buried in the scope of ESF#8 is the role of the Public Health Service in disaster response, specifically mass fatality management and DVI. Here is where standards or best practices of DVI would prove highly beneficial in providing guidance to the varied agencies that may be involved in a mass fatality event.

Human identification, and by association DVI, has changed over the past century. In the not-too-distant past, visual identification was the norm. The advent of fingerprints and later odontology led to dramatic improvements in identification, especially after decomposition or traumatic injury has taken place. Today, these so-called traditional methods, along with anthropology, still dominate the field of human identification. Continued improvements in DNA technology point to the direction that the future of DVI will be taking. Time and cost are deciding factors in DVI; expedient and cost-effective methods will not be falling by the wayside any time soon.

An often neglected, but immeasurably critical, aspect of DVI is the gathering of antemortem information concerning the victims. Identification would be impossible, or nearly so, without the Victim Information Center. Interviews of family members and others acquainted with the victim's identifying features, as well as medical and dental records, are collected and compared against the biological profile of the victim's remains.

DVI therefore is the concerted and combined efforts of dedicated scientists, specialists, and governmental and private agencies. It is practiced under far less-than-perfect conditions under circumstances that are often politically and culturally charged.

---

#### Identification, Disaster, Victim

### W15 Dementia Workup for Forensic Pathologists Following a Condensed National Institute on Aging-Alzheimer's Association (NIA-AA) Protocol

Desiree A. Marshall, MD\*, University of Washington Medical Center, Seattle, WA 98195; Rebecca A. Yoda, MD\*, University of Washington Medicine, Seattle, WA 98104; Nicole A. Yarid, MD\*, King County Medical Examiner's Office, Seattle, WA 98104; Rebecca Folkert, MD\*, New York City Office of Chief Medical Examiner, New York, NY 10016; Richard C. Harruff, MD, PhD, King County Medical Examiner Office, Seattle, WA 98104; C. Dirk Keene, MD, PhD\*, UW Harborview Medical Center, Seattle, WA 98104

**Learning Overview:** After attending this presentations, attendees will: (1) become familiar with the diagnostic workup and grading schemes for common classes of dementia; (2) be able to accurately identify and sample appropriate regions of the brain according to the Condensed Protocol for dementia workup; and (3) understand the benefits and limitations of the Condensed and NIA-AA Protocols for dementia workup.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a method that reduces the cost of histopathologic dementia workup while maintaining diagnostic performance.

Alzheimer's Disease (AD) is the fifth most common cause of death for Americans ages 65 and older.<sup>1</sup> In the United States, the number of people affected by AD and related dementias is projected to increase substantially, rising from an estimated 5.4 million in 2015 to 11–16 million by 2050.<sup>2</sup> Individuals who die with dementia may be susceptible to non-natural factors such as neglect, abuse, or accidental injury, and investigation into potential dementia cases will likely be increasingly common in the forensic autopsy setting. Definitive diagnosis of a specific type of dementia necessitates neuropathological examination, which if performed according to the Original NIA-AA guidelines (20 blocks and 13 special stains from key brain regions), may be cost-prohibitive in a forensic setting.<sup>3,4</sup> In response, a Condensed Protocol was developed that consolidates the sampling and staining proscribed by the Original NIA-AA Protocol into five cassettes for a single round of histochemical or immunohistochemical staining, resulting in approximately 75% lower cost (institution specific) while maintaining diagnostic performance.<sup>5,6</sup> The Condensed Protocol has been studied for use in a forensic setting and was found to be a useful tool in diagnosing a wide range of neurodegenerative diseases.<sup>6</sup> One drawback of the Condensed Protocol is decreased sensitivity for detecting Microvascular Lesions (MVL), which can be remedied by submitting additional Hematoxylin-Eosin (H&E) sections when MVL represents a strong consideration. While not intended as a replacement for the original NIA-AA guidelines, the Condensed Protocol serves to make the guidelines accessible to forensic practices, maintaining reasonable diagnostic performance for various types of dementia while conserving precious resources.

This workshop will walk attendees through specific considerations for dementia evaluation in the forensic setting. There will be an overview of the Original NIA-AA guidelines for the diagnosis of AD and related neurodegenerative disorders and the creation of the Condensed Protocol. The application and performance of the Condensed Protocol at a large urban medical examiner's office will be highlighted and compared to that observed at an academic medical center clinical autopsy service. Finally, there will be a practical demonstration of the use of the Condensed Protocol with an interactive session.

### W16 Forensic Multimedia Authentication: Real-Life Challenges

*Catalin Grigoras, PhD\**, Denver, CO 80202; *Zeno J. Geradts, PhD\**, Netherlands Forensic Institute, Den Haag, SH 2497 GB, NETHERLANDS; *Jeff M. Smith, MS\**, National Center for Media Forensics, University of Colorado Denver, Denver, CO 80204; *Leonid I. Rudin, PhD\**, Cognitech, Pasadena, CA 91117; *Gregory S. Wales, MS\**, United States Department of Interior, Office of Inspector General, Lakewood, CO 80228

**Learning Overview:** After attending this workshop, attendees will: (1) become familiar with the latest developments in forensic video and audio authentication, enhancement, and restoration; (2) understand criteria used for media authentication; (3) understand how to conduct analysis within a forensic framework; and (4) explore the latest technologies in the generation of synthetic imagery, including deepfakes, face2face, and others.

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by: (1) explaining the scientific approach in forensic media authentication, enhancement, and restoration; (2) demonstrating an authentication investigation framework; and (3) discussing tools used to create and combat multimedia forgery.

Digital multimedia authentication seeks to determine the validity of digital multimedia containers and contents by investigating their format, structure, time, frequency, and pixel and/or sample level features. This workshop will discuss the multimedia authentication process, providing the user with methods of authenticating both video and audio, including deepfakes and deepvoices. This workshop will also demonstrate the incorporation of multiple tools and techniques into unified frameworks appropriate in forensic examinations where reducing examiner bias and error is crucial.

This half-day workshop will cover video and audio authentication analyses. The goal of this workshop is to provide an overall view of conducting comprehensive examinations that rely on the results of multiple analyses to inform an ultimate finding or opinion. First covered will be a video authentication framework, focusing on camera verification/identification and image and video attack detection. This includes a quick overview of the digital video file creation chain for contextual information of the artifacts that influence the final digital media streams based upon a general description of camera sensor noises for both complementary metal-oxide-semiconductor and charge couple device type sensors. Photo Response Non-Uniformity (PRNU) are small artifacts of the sensor and can be used as a sort of fingerprint for the sensor. For video and images, it can be determined with a high likelihood that a certain image or video has been made with a specific camera. PRNU can also be used for detecting deepfakes. Splicing, copy-move, and removal artifacts are also investigated in a complex video authentication process and will be discussed and exemplified with original and manipulated videos.

The use of articulated 3D face models is a double-edged sword: it can be used to make deepfakes, but it also can be used to recover true image/video details. A theory and the method for video resolution enhancement restoration with data adaptive 3D facial models will be presented. This method starts with a generic facial 3D model, then simultaneously recovers the finer facial feature details in the video frames and also adapts the 3D model to fit the observed face in the video.

In the second section of the workshop, real-life audio challenges and solutions will be presented. The proposed audio authentication framework combines both container and content analysis to determine authenticity of the recording as well as the purported source. Audio container analysis will exploit characteristics of the multimedia file format and structure while content analysis will cover time and frequency domain techniques, including quantization level, power, direct current offset, butt splice, spectral and Multidetector Computed Tomography (MDCT) analysis.

#### Multimedia Forensics, Authentication, Deepfake

### W17 The Murder of Women: A Global Issue That Demands Action

Cinzia Gimelli, PsyD, PhD\*, *Science & Method, Reggio Emilia 42124, ITALY*; Vivian Shnaidman, MD\*, *10 Vreeland Drive, Skillman, NJ 08558*; Luciano Garofano, PhD\*, *President of Accademia Italiana di Scienze Forensi, Parma 43100, ITALY*; Maurizio Saliva, MD\*, *Pozzuoli 80078, ITALY*; Ariel V. Tabachnik, BS\*, *Rutgers Robert Wood Johnson Medical School, Piscataway, NJ 08854*

**Learning Overview:** After attending this presentation, attendees will understand and recognize how discrimination against women prevails throughout the world and how violence against women, a serious violation of human rights, is the most severe consequence of such discrimination. The Inter-American Court of Human Rights defined femicide as “the murder of women by gender” considering that these deaths result from structural and social attitudes, rooted in a culture of gender-based violence and discrimination. Acts of violence against women based on their status as women demand the serious and specific attention of the international community.

**Impact on the Forensic Science Community:** Attendees will become more aware of the various types of violence that are manifested in many ways. Most victims are raped and many are mutilated, tortured, or dismembered. Femicide is a complex phenomenon, ranging from the murder of women by their partners or ex-partners, to their kidnapping followed by rape and subsequent killing committed by unknown perpetrators, to ritual crimes performed by sects or other groups.

This presentation will impact the forensic science community by empowering attendees to understand that is an obligation of the European Union, the United States, and the entire world to prevent and eradicate femicide and to adopt administrative, legislative, and judicial measures to prohibit gender discrimination. States must ensure the exercise of the rights of women and pursue, by all appropriate means and without delay, policies that prevent, punish, and eradicate violence against women. States have the obligation to standardize all their protocols and manuals; to update their research criteria; and to restructure the administration of justice related to investigate disappearances, sexual violence, and murder of women. These measures have implications not only for the United States, but also for other systems of human rights protection, such as the European Court of Human Rights. After implementation of various policies addressing this crucial issue, states should be held responsible for lack of diligence in investigations, lack of access to justice for the families of the victims, and, therefore, for the impunity of the perpetrators. To sum up, states are responsible for taking the necessary steps to ensure a life free of violence for women.

The study shows that is reasonable to create scientifically based monitoring with a proper strategy together with all national and international partners.<sup>1-5</sup> Such a structure must promote the creation of comparable national databases, while also systematically involving existing international systems of data collection and their experience. The database is designed to provide easy access to comprehensive and up-to-date information on measures undertaken by governments to address all forms of violence against women; increase opportunities for the exchange of experiences in addressing violence against women; strengthen the knowledge-base for effective policy responses to prevent and address violence against women; and encourage the further collection, availability, use and dissemination of data on violence against women, as well as analysis of such data.

Data are collected using a survey based on interviews of women who turn to support centers who were asked about their experiences of physical, sexual, and psychological violence, including incidents of intimate partner violence (“domestic violence”).

The research highlighted that the collection of police data alone would not be sufficient for analyzing the cases in the detail needed for prevention and intervention. Therefore, the strategy of collecting information on all the cases known to the media and collating it with the criminological data and, insofar as is possible, data recorded by health and support systems. All data together provide the opportunity to obtain more background information on femicides, which is important for future prevention and early interventions.

### W18 Injury Biomechanics: An Interdisciplinary Approach and Forensic Applications

*Amanda M. Agnew, PhD\**, *The Ohio State University, Columbus, OH 43210*; *Angela L. Harden, MA\**, *The Ohio State University, Columbus, OH 43210*; *John H. Bolte, PhD\**, *The Ohio State University, Columbus, OH 43210*; *Yun-Seok Kang, PhD\**, *The Ohio State University, Columbus, OH 43210*

---

**Learning Overview:** After attending this workshop, attendees will comprehend the advantages of using an interdisciplinary team to address questions concerning injury biomechanics and associated trauma analysis. Attendees will be exposed to the applications of injury biomechanics across multiple scientific disciplines through presentations and hands-on experiences. Additionally, attendees will be introduced to the value of experimental testing in developing and validating forensic methods of injury analysis and the importance of scientific validity and error rates.

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by providing attendees with an introduction to injury biomechanics and the applications of this research to forensic anthropology, engineering and applied sciences, and forensic pathology.

Injury biomechanics is the science that relates mechanical forces to disruption of anatomical regions of the human body. As a multidisciplinary field encompassing engineering, physiology, anatomy, and medicine, an understanding of injury biomechanics would benefit forensics, specifically in regard to analyzing injuries, the mechanisms that cause them, and recreating traumatic events.

The focus of this workshop is to introduce the principal aims of injury biomechanics research and discuss how these aims are relevant in forensic fields and methods. The utilization of a multidisciplinary team encompassing injury biomechanics, forensic anthropology, forensic pathology, and human anatomy allows for a holistic approach to investigating the relationships between injury and physical mechanical properties. By doing so, identifying mechanisms of injury will satisfy *Daubert* standards and provide quantifiable methods to support expert testimonies. Ultimately, this interdisciplinary pursuit will increase accuracy and precision in the reconstruction of traumatic events.

Presentations will begin with an introduction to injury biomechanics and the importance of an interdisciplinary team of scientists. Following the introduction, attendees will learn about the applications and limitations of forensic injury biomechanics. The development of injury criteria, injury risk assessment, and injury thresholds of the human body will then be discussed. Experimental design will next be presented in detail, addressing what goes into the design, interpretation of experiments, and the importance of quantitative data and error rates. Experimental testing methods and applications will then be addressed; specifically, the role of experimental testing in the development and validation of forensic methods. Attendees will be presented with current injury biomechanics research conducted in the Injury Biomechanics Research Center focusing on the injury mechanisms of different anatomical body regions. Each research presentation will address the following: objectives and hypotheses of the project, interdisciplinary contributions, applications of the research to various fields and professions with an emphasis on forensic applications. Attendees will be provided the opportunity to observe and discuss the soft tissue and skeletal trauma associated with each presentation and discuss interpretations. At the end of this workshop, attendees will be provided with the opportunity to discuss injury biomechanics in general and direct questions to the panel of experts who are engineers, anatomists, and forensic anthropologists.

---

#### Trauma, Methods, Fracture

### **W19 Think Tank on the Leading Edge of Forensic Science, Including Robotics, Drug Intelligence, Analytical Chemistry, Technology Rules, Bayesian Approach, Legal Technology Developments, Research and Development (R&D) in a Forensic Lab, Veterinary Forensics, and Aquatic Death Investigation**

*Laura L. Liptai, PhD\**, BioMedical Forensics Headquarters California/Florida, Moraga, CA 94556; *Annemieke de Vries, PhD\**, Netherlands Forensic Institute, The Hague 2497 GB, NETHERLANDS; *Jeri D. Roper-Miller, PhD\**, RTI International, Research Triangle Park, NC 27709; *Ivo Alberink, PhD\**, Netherlands Forensic Institute, The Hague, Zuid-Holland 2497 GB, NETHERLANDS; *Sheila Willis, PhD\**, National Institute of Standards and Technology, Gaithersburg, MD 20899; *Stephanie Domitrovich, JD, PhD\**, Sixth Judicial District of Pennsylvania, Erie, PA 16501; *Andrea Zaferes, BA\**, Dutchess County Medical Examiner Office/Team LGS, Shokan, NY 12481; *Arian C. Van Asten, PhD\**, University of Amsterdam, Amsterdam 1098XH, NETHERLANDS; *Kevin W.P. Miller, PhD\**, Hamilton Robotics, Reno, NV 89501; *Martha Smith-Blackmore, DVM\**, Forensic Veterinary Investigations LLC, Boston, MA 02116; *Zeno J. Geradts, PhD\**, Netherlands Forensic Institute, Den Haag, SH 2497 GB, NETHERLANDS

---

**Learning Overview:** After attending this presentation, attendees will better understand the various new advances in forensic science that promise to have an important impact on their work.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the absolute latest new developments in robotics, drug intelligence, analytical chemistry technology rules, Bayesian approach, legal technology developments, R&D in a forensic lab, veterinary forensics, and aquatic death investigations. This workshop will help attendees be on the leading edge.

The history of forensic science dates back thousands of years. Ancient Chinese were credited with being the first to attempt to define the difference between natural death and criminal intent. By the early 1800s, the recognition of fingerprint patterns was studied, but decades would pass before that observance was applied to criminal and personal identification. Now, in today's world, new developments are being established in a single year, not decades, but the real question is how long it will take for disruptive technologies and the leading edge to obtain general acceptance in the scientific community.

Legal technology developments and technology rules are expanded on by a prominent state judge with decades of experience so that the forensic community can keep up with the quickly advancing frontiers of legal technology and innovations. Analytical chemistry, statistical revelations, and R&D in the forensic lab are improving and expanding. However, the limitations and the error rates of the algorithms utilized need to be closely monitored. Artificial intelligence and robotic advancements may help us better monitor algorithm error rates.

Aquatic death/abuse investigations are also discussed to reveal how the investigators have been revolutionizing scene investigation standards. The use of proper and specialized training, while it may take up more time initially, will provide better accuracy and understanding of the common errors repeated for decades in scene and aquatic death investigations.

With regard to investigating animal abuse, neglect and cruelty will also be discussed, including how veterinarian forensic experts are able to properly interpret evidence and ensure animal welfare.

Drug intelligence has been an important topic of interest due to the increase of distribution of synthetic novel drugs. Exploration is needed in how government agencies, law enforcement officials, forensic laboratory personnel, medical examiners/coroners, researchers, and other experts can collaborate in order to respond to increasing problems that are seen with drug abuse.

This year's think tank is a collection of topics and speakers that will make us all work smarter in response to an awareness of what is happening on the leading edge of forensic science.

---

#### **BioMedical Engineer, Drug Intelligence, Aquatic Death/Abuse Investigations**

### W20 Genetic Genealogy: Science, Law, and Ethics

*Donald E. Shelton, JD, PhD\**, University of Michigan-Dearborn, Dearborn, MI 48128-2406; *Henry T. Greely, JD\**, Stanford University, Stanford, CA 94305; *Frederick R. Bieber, PhD\**, Brigham & Women's Hospital, Boston, MA 02115; *CeCe Moore\**, Reston, VA 20190; *Ellen M. Greytak, PhD\**, Parabon NanoLabs, Inc, Reston, VA 20190; *Ted R. Hunt, JD\**, United States Department of Justice, Washington, DC 20530; *Russell S. Babcock, JD\**, Law Office of Russell Babcock, San Diego, CA 92101; *Roderick T. Kennedy, JD\**, Los Ranchos, NM 87107

---

**Learning Overview:** After attending this workshop, attendees will have a better understanding of how genetic genealogy works, how it is used by law enforcement, its admissibility in court, and the ethics of using personal DNA data of relatives to solve crimes.

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by providing a clear understanding of the use of genetic genealogy to solve crimes and to better equip forensic scientists to appreciate the legal and ethical issues that it presents.

Since the identification and arrest of the suspect in the “Golden State Killer” investigation in early 2018, using novel DNA and genealogy tools, dozens of law enforcement investigators in North America have effectively used such methods in high-profile cold cases. A combination of advanced DNA methods, using thousands of Single Nucleotide Polymorphisms (SNPs) along with searching of ancestry databases has allowed genealogists to assist investigators in identifying possible persons of interest as suspects in unsolved crimes. These tools have significantly changed the face of genealogical searching and those changes now offer new investigative methods of crime solving.

Several DNA-based public genealogy databases can be searched for even distant relatives of those who leave crime scene DNA evidence, regardless of whether their profile is in a law enforcement database such as the Combined DNA Index System (CODIS). Investigators can submit the raw data files from the crime scene DNA profile to one of these new genealogy databases to help identify individuals who could be biological relatives of the person who left the evidence. While the suspect may not be in CODIS and have never submitted their DNA to any ancestry company, the DNA of relatives who submitted their own data for genealogy search purposes can lead police to a range of possible persons of interest. Confirmatory Short Tandem Repeat (STR) testing is then needed before any arrest is made.

This workshop includes a description of the DNA technology used, the database search process itself, and the methods of genealogy searching from expert leaders in those fields. The results of DNA-based genealogy searching still require careful data analysis and follow-up investigation by police to further narrow the range of possible persons of interest based on age, locale, and other factors associated with the crime. Law enforcement officials will describe how police investigators follow up on the possible suspect(s) generated by the genealogical research to obtain a current DNA specimen upon which to seek a warrant. The entire process may raise potential issues under the 4<sup>th</sup> Amendment, particularly considering the recent *Carpenter* United States Supreme Court opinions, as well as online privacy laws. These admissibility issues will be presented from both the prosecution and defense perspectives. There are also significant ethical questions presented by this process and those will be discussed by biomedical experts, particularly considering recent actions seeking to expand the “informed consent” for DNA contributors or even to legislatively prohibit the use of genetic genealogy to solve crimes.

---

### Genetic Genealogy, DNA Genealogy, Genealogy Crime Solving

### W21 A Decade of Designer Drugs: Lessons Learned and Future Directions

*Donna M. Papsun, MS\**, NMS Labs, Willow Grove, PA 19090-2910; *Barry K. Logan, PhD\**, NMS Labs, Willow Grove, PA 19090; *Michael H. Baumann, PhD\**, Intramural Research Program, National Institute on Drug Abuse, National Institutes of Health, Baltimore, MD 21224; *Michael B. Gatch, PhD\**, University of North Texas Health Science Center, Fort Worth, TX 76107; *Alex J. Krotulski, MS\**, Center for Forensic Science Research & Education, Willow Grove, PA 19090; *Christopher Moraff, MS\**, Temple University, Philadelphia, PA 19122; *Amanda L.A. Mohr, MSFS\**, Center for Forensic Science, Willow Grove, PA 19090; *Marilyn A. Huestis, PhD\**, Huestis & Smith Toxicology, LLC, Severna Park, MD 21146; *Jennifer Bonetti, MS\**, Virginia Department of Forensic Science, Norfolk, VA 23510; *Aaron Urbas, PhD\**, National Institute of Standards and Technology, Gaithersburg, MD ; *Donna M. Iula, PhD\**, Cayman Chemical, Ann Arbor, MI 48108; *Robert A. Middleberg, PhD\**, NMS Labs, Willow Grove, PA 19090

**Learning Overview:** After attending this workshop, attendees will be able to: (1) discuss current and past trends in Novel Psychoactive Substances (NPS); (2) describe and explain the means by which new substances are assessed for their potency and toxicity; (3) identify resources and strategies for the investigation of NPS toxicity outbreaks and impacts on user populations; (4) assess the available analytical techniques for resolving the identity of positional isomers of new drugs; and (5) apply best practices in the use of standard reference materials and proficiency testing for forensic NPS casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a ten-year perspective on how forensic and research sciences responded to the phenomenon of designer drugs, later NPS, the tools and workflows that have been developed, current approaches to evaluating drug toxicity, the impact of NPS on drug user behavior, and best practices for the future identification of structural identity and detail of newly emergent substances.

The emergence of novel stimulants mephedrone and methylene in 2007, followed by the first wave of synthetic cannabinoids in 2008, marked the outbreak of the “designer drug” phenomenon. Due to the number of terms used to refer to the different substances, including “legal highs”, K2, Spice, “bath salts,” and others, the scientific community agreed to refer to emergent substances as Novel Psychoactive Substances or NPS.

Attempting to agree on a universal term for emergent substances was the first of many challenges associated with NPS, and the field still struggles with consistent naming. The large number of substances are diverse in terms of their effects and chemistry, and this has created significant analytical challenges resulting from unavailability of standard reference materials and availability of the necessary technology. There have also been significant impacts on drug user practices and behaviors as a result of the changing market.

This workshop will begin with an overview of the challenges, successes, opportunities, and future threats posed by NPS and will introduce the tools and workflows that have developed to more quickly identify new substances and their potential harms, including *in vitro* and *in vivo* studies that help categorize new substances and their potency and toxicity, that are essential to decisions about scheduling these substances. Later presentations will cover examples of how investigators and laboratories have mobilized to respond to the investigation of NPS toxicity outbreaks and how the analytical data are used to support public health measures. Other speakers will provide perspective on how the lack of consistency in the drug supply have led users to change their behavior and take precautionary measures in their drug procurement and how successful or otherwise these strategies have been. While analytical methods are now becoming well established for many types of NPS detection, identifying the absolute configuration of the drug analogs is now receiving more attention, and the latter part of the workshop will assess emerging analytical techniques for resolving the identity of positional isomers of new drugs. The last part of the program will look at how the forensic community and their partners have addressed issues of rapid access to standard reference materials and expanding proficiency testing programs, including NPS detection.

#### Novel Psychoactive Substances, Designer Drugs, Emergent

---

### W22 “All Rise”: Successfully Navigating the Judicial System as an Expert Witness

*Laura C. Fulginiti, PhD\**, Forensic Science Center, Phoenix, AZ 85007; *Daniel G. Martin, JD\**, Superior Court of Arizona, Phoenix, AZ 85003; *Betty Layne DesPortes, JD, MS\**, Benjamin & DesPortes, PC, Richmond, VA 23220; *Kristin Larish, JD\**, Maricopa County Attorney’s Office, Phoenix, AZ 85003; *Kristen Hartnett-McCann, PhD\**, Office of the Chief Medical Examiner, Farmington, CT 06032; *Katelyn L. Bolhofner, PhD\**, Arizona State University, Glendale, AZ 85306; *Andrew C. Seidel, PhD\**, Arizona State University, Tempe, AZ 85287-2402

---

**Learning Overview:** After attending this workshop, attendees will be well-versed in the decorum, procedures, expectations, and environment of a modern United States courtroom through active participation in the process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering real-world experience in expert testimony in an environment conducive to productive learning without the stress of an actual trial.

Forensic scientists are trained in the techniques, theory, history, and standards associated with their particular discipline. Often lacking, however, is training in the application of those skills to the courtroom setting and, in particular, the presentation of expert testimony. A forensic expert’s ability to effectively communicate in a courtroom setting is vital if that expert is going to make meaningful contributions to the justice system.

This workshop seeks to improve courtroom communication skills by providing a combination of lectures and hands-on learning that will introduce the basic foundations of the United States court system, the roles of the participants, the types of pre-trial and trial processes that occur, and the opportunity for attendees to practice testifying in a true-to-life courtroom environment with case-based scenarios.

Discussion will include the structure of the judicial system and the expert’s role in it. This brief introduction will be followed by a number of different legal proceedings that may be encountered by an expert witness. Pretrial hearings (such as *Daubert* hearings) and trial testimony are among the topics that will be explored. This workshop will be set up as a traditional courtroom with a judge, jury, court reporter, clerk of the court, and bailiff. Two experienced attorneys will perform direct and cross-examination derived from real-life scenarios. The attorneys will demonstrate common techniques used in court, such as focused direct examination, impeachment based on prior statements, personal interests or biases, and detailed cross-examination about the limitations of the discipline or analysis. Time permitting, the judge and jury will be allowed to ask questions as well (as occurs in many jurisdictions). The cases will all be criminal cases in order to provide the most commonly encountered scenarios in forensic science practice.

The goal of this workshop is to provide as many attendees as possible with a real-life courtroom experience. To that end, registrants will be selected to participate in the “trials,” “hearings,” and other legal proceedings. The jury will be peopled with registrants as well in order to provide real-time feedback, critique, and suggestions. All attendees will be actively engaged in the process in some way, with the end result that all will feel more comfortable and familiar with the courtroom. This workshop is geared toward scientists who have not yet testified, those that have limited experience, and those that have a lot of time at the Bar (the Bar, not the bar ...). This mix of experience will benefit all attendees and provide active, engaging interactions.

---

#### Expert Witness, Judicial System, Testimony

### W23 Dispelling the Myths About the Forensic Examination of Handprinting

*Linton Mohammed, PhD\**, Forensic Science Consultants, Inc, Burlingame, CA 94010-2017; *Lloyd Cunningham\**, Alamo, CA 94507; *Katelyn E. Bruno, MFS\**, Quantico, VA 22135; *Linda L. Mitchell, BS\**, Forensic QDE Lab, LLC, Escondido, CA 92025-4116; *Brett Bishop\**, Cheney, WA 99224

**Learning Overview:** After attending this workshop, attendees will be informed about the development of manuscript handprinting, motor-control theories regarding how handprinting is learned, examination techniques with handprinting, and will conduct hand-on examinations of genuine and simulated handprinting.

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by informing attendees on the history and development of manuscript handprinting and will enhance their abilities to conduct handprinting examinations. Attendees will also be prepared to defend the reliability of handprinting examinations in court.

Handprinting examinations have been conducted successfully for many years by Forensic Document Examiners (FDEs). However, there have been some recent court decisions in which handprinting evidence was deemed to be inadmissible due to a perceived lack of testing of the reliability of FDEs in handprinting examinations. This workshop will seek to dispel the myths created by these court decisions and statements of some critics of handprinting examination.

This workshop, which has a significant hands-on component, was designed to address the history and development of manuscript handprinting, the various styles of manuscript handprinting, and its fine and subtle elements. Research in handprinting together with casework examples will be presented. Motor-control theories of the development of handprinting will be presented and discussed. A review of empirical research conducted into the reliability of handprinting examinations will also be conducted.

Are there different examination techniques and methodologies applied to manuscript handprinting than applied to cursive writing? The transition from manuscript handprinting to cursive writing will be covered as will the similarities and dissimilarities between the different styles of handwriting.

Critics of the forensic identification of handwriting have now attempted to create an illusion that manuscript “handprinting” is not identifiable. As one critic stated recently, “Handwriting is different from handprinting as typewriting is different from either.” Unfortunately, some in the legal profession have accepted this absurd illusion, and the identification of manuscript “handprinting” is now separately under attack. One judge stated, “Typical handwriting analysis involves cursive writing, and the record is devoid of evidence that there is even a recognized field of expertise in the identification of handprinting.”<sup>1</sup> Another court opined, “Ultimately, the limited testing that exists is inconclusive as to the reliability of handprinting analysis.”<sup>2</sup> Recent court decisions and statements by critics of handprinting examination will be discussed and critiqued.

The issue of the techniques used to simulate manuscript handprinting and the difficulty factors in simulating cursive handwriting versus manuscript handprinting will be the main focus of this workshop, which will also include the study and examination of practical problems by the attendees.

### W24 Forensic Postmortem Radiology: Crossing the Border Between Radiology and Pathology

*Summer J. Decker, PhD\**, University of South Florida Department of Radiology, Morsani College of Medicine, Tampa, FL 33606; *Edward Mazuchowski II, MD, PhD\**, Joint Trauma System, Joint Base San Antonio-Fort Sam Houston, TX 78234; *Lars C. Ebert, PhD\**, Universitat Zurich, Zurich 8057, SWITZERLAND; *Rachel M. Carew, MSc*, University College London, UCL Security & Crime Science, London, UNITED KINGDOM WC1H 9EZ; *Jonathan M. Ford, PhD\**, Department of Radiology, Tampa, FL 33606-3571; *Frances E. Hollingbury, MBChB\**, East Midlands Forensic Pathology Unit, Leicester, Leicestershire LE2 7LX, UNITED KINGDOM; *Jeroen J.F. Kroll\**, Maastricht University Medical Center, Maastricht 6229HX, NETHERLANDS; *Natalie L. Adolphi, PhD*, McCormick Lab, Albuquerque, NM 87131; *Chris O'Donnell, MD\**, Victorian Institute for Forensic Medicine, Melbourne 3006, AUSTRALIA; *Lars Oesterhelweg\**, Institut für Rechtsmedizin der Charité, Berlin 10559, GERMANY; *Rick R. Van Rijn, MD, PhD\**, Amsterdam University Medical Center & Netherlands Forensic Institute, Amsterdam, Noord Holland 1105AZ, NETHERLANDS; *Michael Thali, MD\**, Universitat Zurich, Zurich 8057, SWITZERLAND

**Learning Overview:** After attending this workshop, attendees will: (1) learn the basics in how to get started in the field of forensic radiology, (2) understand the current state of the art and levels of evidence in forensic radiology, (3) learn about applications to assist forensic pathologists and practitioners in medical death investigations, and (4) finally, will be made aware of potential resources available to interested practitioners.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with expertise from around the world on the use of best practices and the evidence base of forensic postmortem radiology.

It has been nearly ten years since the publication of the National Academy of Sciences Report calling for the strengthening of the forensic sciences. In their report, the National Academy of Sciences stated the critical role that imaging plays in the documentation of findings sufficient for courts, for providing the opportunity for review by outside experts, as well as for allowing for reevaluation of evidence as medical knowledge advances. Since then, forensic radiology and imaging has grown significantly as a field around the world.

The “virtual autopsy” or “virtopsy” utilizes Multislice Computed Tomography (MSCT) or Postmortem CT (PMCT) and Magnetic Resonance Imaging (MRI) combined with 3D imaging technology to create vivid images of the interior of the human body. CT scanning and MRI have been shown to present better visual pictures of some injuries, reduce the number of autopsies conducted to rule out occult injury, and document the extent of injury in accidents in greater detail. The advantages of the virtopsy are that it is not invasive or destructive to tissues and can provide clear pictures of skeletal and soft tissue injury. It also provides some information when there is a religious objection to autopsy. Additionally, virtopsy has the potential to detect internal bleeding, bullet paths, bone and bullet fragmentation, fracture patterns, brain contusion, and gas embolism, as well as occult fractures that are technically difficult to demonstrate during the traditional autopsy.

In the United States, only a few Medical Examiner’s (ME’s)/coroner’s offices (approximately 13) have access to this advanced medical imaging at this time and very few have the budget to purchase the expensive equipment or to build a suitable facility with staff to maintain it. The current public health crisis of opioid deaths is stretching an already strained ME’s system with regard to autopsy caps set by the National Association of Medical Examiners (NAME) standards. Postmortem medical imaging can play a critical role in easing these demands for full autopsy on offices through triage screening from PMCT.

Within the past year, the National Institute of Justice (NIJ) has fully supported forensic imaging as a supplement to the traditional autopsy and as a triage and long-term evidence documentation tool. NIJ efforts have attempted to bring field standards from around the world and establish major research areas of need in order to help facilitate the field’s growth in the United States since it lags behind other countries in the field. Additionally, the post-AAFS 2018 attendee survey indicated in several places the desire of members for more information on assisting forensic pathology workloads with the use of CT scans/documentation of trauma via imaging, even going as far as suggesting modifying of NAME guidelines to accomplish this. With the field well established in practice outside the United States, lessons learned from experts will help those interested in incorporating these technologies into their facility’s everyday practice. Exposure to emerging technologies in the field will also help practitioners be exposed to potential applications that will alleviate their workflow in an already overtaxed death investigation system.

This workshop will show how to start a program, give an overview of the current state of forensic imaging in the world, and demonstrate how future technologies may impact the field of forensics.

### Forensic Pathology, Forensic Radiology, Postmortem Computed Tomography

### W25 Working Toward a Wellness Mindset for Forensic and Investigative Personnel: Addressing Stress and Trauma in the Workforce and Taking Steps to Change Agency and Professional Culture

*Amanda L. Farrell, PhD\**, Marymount University, Arlington, VA 22207; *Jonathan D. Bethard, PhD\**, University of South Florida, Tampa, FL 33620-8100; *Timothy J. Ainger, PhD\**, University of Kentucky, Lexington, KY 40536; *Christopher J. Scallon, MS\**, Survival Mindset Consulting, LLC, Newport News, VA 23602; *Daniel E. Katz, MFS\**, Maryland State Police, Pikesville, MD 21208; *Lurena A. Huffman, BS\**, EMDC Forensics, LLC, Hampton, VA 23666

**Learning Overview:** After attending this workshop, attendees will understand and recognize how stress and trauma are tied to the forensic professions, including in the form of vicarious trauma, and how exposure to trauma and stress impacts an employee's personal and professional performance.<sup>1-7</sup> Attendees will also learn evidence-based strategies to mitigate and reduce the impacts of stress and trauma, as well as learn from the experience of the anthropology program at the University of South Florida and the Maryland State Police's Crime Laboratory efforts to address stress and trauma. Attendees will be more aware of the various types of trauma that investigators and investigative personnel routinely encounter and the potential impacts this may have, not only on the individual, but on the investigation and/or service provision. This workshop builds upon and expands the content of the half-day workshop presented at the American Academy of Forensic Sciences Annual Scientific Meeting in 2019.<sup>8,9</sup> Paths forward and the implementation and incorporation of Evidence-Based Policy (EBP) will also be addressed so attendees can examine what policies and assistance are available in their own agencies or assist in policy development.<sup>10-18</sup> This workshop will address concerns related to both line-level and supervisory personnel.<sup>19</sup>

**Impact on the Forensic Science Community:** This workshop will impact the forensic science community by providing attendees with the understanding that the human experience is variable, and trauma exposure and symptoms even more so, leading to behavior patterns that can be complex and abstract and by recognizing the manifestations of a variety of psychological—both behavioral and cognitive—impacts as a reaction to trauma and stress exposure on the job. This workshop will also address the concept of trauma-informed agencies, ensuring that appropriate resources are available to employees, focusing on evidence-based interventions. By attending this workshop, attendees will be better equipped to understand the potentially short- and long-term impacts of trauma, as well as how to adapt investigative approaches and provide resources that will lead to increased chances of not only a positive work environment, but likely a more efficient and cost-effective solution to maintaining employee health and well-being to avoid burn-out and decreased cognitive abilities that may impact service provision and job performance.

In seeking to serve communities as forensic professionals, individuals are exposed to things the average citizen cannot understand; sometimes these experiences stay with the individual. Recognizing that trends (e.g., the opioid crisis) can exacerbate levels of stress and trauma faced by personnel, best practices suggest that a trauma-informed agency has made preparations for employees and will have better success in terms of employee resilience and productivity. This discussion is still in its infancy, due largely to issues of mental health stigma and the lack of research exploring how forensic personnel experience trauma.

This workshop aims to broaden and continue discussions on a topic often considered taboo and highlights the variety of traumatic experiences faced by personnel. Similar conversations have begun in different arenas associated with forensic sciences, evidenced by the creation of the American Society of Crime Laboratory Directors (ASCLD) Stress and Trauma Task Force, the development of the Forensic Technology Center of Excellence (FTCoE) webinar series, attention of the Organization of Scientific Area Committees (OSAC) Human Factors Committee, and mention in the forthcoming Department Of Justice (DOJ) Needs Assessment of Forensic Laboratories (NAFL) report.<sup>20-23</sup>

Cognitive implications subsequent to traumatic exposure are varied in presentation and require management, but may be difficult for forensic professionals to detect. Amnesic complications of dissociation, as well as shifts in cognitive schemas following trauma have implications on both cognitive functioning and possible treatment.<sup>24,25</sup> The cognitive impact of trauma can be seen in both primary and vicarious/secondary trauma exposure (e.g., peers, treating clinicians).<sup>26</sup> Some research has suggested a negative impact on executive functioning and memory, which may be compounded by repeated exposure to trauma.<sup>27-30</sup> These cognitive skills (necessary for effective forensic job performance) are being shown in the literature to be impacted by trauma exposure.<sup>31,32</sup>

Employee burnout can represent the loss of an employee, but also an agency's financial investment in individuals (e.g., training, development). This highlights the importance of striving for well-developed, empirically supported policies protecting the financial interests of the agency and jurisdiction, in addition to the well-being of personnel. Even if the employee impacted by stress/trauma does not leave the agency, they may represent a financial loss in terms of decreased productivity, workers' compensation, litigation, absenteeism, and other similar costs.<sup>33-35</sup> Professionals may not recognize the psychological impacts of trauma exposure or cumulative stress, and the easiest response may be identifying these impacts as an individual problem.<sup>36,37</sup> These effects may also relate to the human factors discussion taking place in the Academy.<sup>38-49</sup> Research suggests cost-effective approaches, and EBP should involve effective training, preparation, and swift intervention to avoid personnel developing longitudinal cognitive and/or psychological deficits following trauma exposures. Utilizing Seamone's argument to apply intervention and prevention programs, this workshop will discuss multiple EBP options, as well how appropriate training can have preventative effects.<sup>50-67</sup>

This workshop will help attendees identify factors associated with these aforementioned needs, in addition to implementing empirically supported strategies for proper management of cognitive/psychological concerns. This will impact the forensics community by elucidating that the human experience is variable (as are symptoms of trauma exposure), leading to complex and abstract behavior patterns. This workshop addresses the concept of trauma-informed agencies and ensuring that appropriate, evidence-based resources are available to employees. Attendees will be better equipped to

understand potential impacts of trauma, leading to increased chances of a positive work environment, increased efficiency, and maintaining employee well-being cost-effectively.

This workshop will use many cases, videos, and discussion points to illustrate the conceptual and applied understanding of how trauma and its impacts manifest. Given the nature of the material, this workshop is not recommended for those persons who are sensitive and/or in some form of crisis.

### Stress/Trauma, Wellness, Resilience

### W26 Overcoming Analytical Challenges Inherent in New Psychoactive Substances With Gas Chromatography Coupled With Vapor Phase Infrared Detection (GC-IRD)

*Agnes D. Winokur, MS\**, Drug Enforcement Agency, Southeast Laboratory, Miami, FL 33182; *Reta Newman, MA\**, Pinellas County Forensic Laboratory, Largo, FL 33778; *Randall Clark, PhD\**, Auburn University, School of Pharmacy, Auburn, AL 36849; *Jose R. Almirall, PhD\**, Florida International University, Department of Chemistry, Miami, FL 33199

**Learning Overview:** The goals of this presentation are to obtain: (1) a more comprehensive awareness and understanding of the analytical challenges inherent in the analysis of novel and emerging drugs; (2) an overview and better understanding of the role of GC-IRD applications in the analysis of seized drugs; and (3) knowledge and tools for the optimization of GC-IRD methodology for the analysis of opioids, synthetic cathinones, and synthetic cannabinoids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that GC-IRD is a useful alternative for the rapid detection and identification of novel substances when routine analytical techniques yield limited information.

After attending this session, participants will gain comprehensive knowledge and understanding on the unprecedented analytical challenges associated with the influx of novel psychoactive substances in the illicit market during the past several years. Synthetic substances, such as synthetic cannabinoids, opioids, and synthetic cathinones, continue to be illicitly manipulated to create more and new substances of equal or greater toxicity and potency.

With the emergence of these novel compounds, forensic crime laboratories are facing analytical challenges for the reliable detection and identification of these substances. Due to their structural similarities, routine analytical methodology (e.g., gas chromatography/mass spectrometry) is often not sufficient. To increase the complexity of the problem, a large number of seized drug evidence is now poly-drug, creating another challenge in the separation of these substances. Laboratories have had to explore other options to increase their scientific capabilities.

Forensic scientists are frequently finding themselves turning to GC-IRD as a suitable alternative to routine instrumental techniques. Understanding the theory and application of GC-IRD methods for the analysis of seized drugs will assist forensic scientists in better addressing the analytical challenges that are inherent with today's emerging psychoactive substances. Many of these substances generate the same or significantly similar mass spectra, present co-elution problems, or may have associated thermally degradable concerns.

While the technology of GC-IRD is not new, its application to the forensic analysis of seized drugs continues to increase. Attendees will be introduced to the most current analytical challenges associated with seized drugs analysis and will be introduced to GC-IRD background and theory. Attendees will learn how to optimize GC-IRD methods and apply them to overcome existing challenges associated with synthetic cannabinoids, opioids (specifically, fentanyl-related substances), and synthetic cathinones. Attendees will also learn how modern technological advances can be utilized for even complex mixtures, such as the volume programmable temperature vaporization inlet and light pipe temperature options.

An overview of the role of GC-IRD in forensic laboratories will be provided, and how its applications are increasing their capabilities and making them better equipped to address our nation's opioid crisis and influx of novel and unknown substances.

#### GC-IRD, Psychoactive Substances, Opioids

## A1 Collaborative Approaches in the Identification of Transgender and Gender Variant Decedents

Amy Michael, PhD\*, Durham, NH 03824; Mariyam I. Isa, MA\*, Michigan State University, East Lansing, MI 48824; Lee Redgrave, Athol, MA 01331; Anthony Redgrave, MS, Athol, MA 01331

**Learning Overview:** After attending this presentation, attendees will have learned about a non-traditional, collaborative approach to aid positive identifications in unsolved cases involving transgender and gender variant decedents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) opening discussion about obstacles to positive identification of transgender victims; and (2) presenting a collaborative forensic anthropology/genealogy approach to assist in recovering and honoring the identities of these victims.

In cases involving skeletal remains, positive identification requires both osteological expertise and the ability to translate biological and contextual information into a culturally appropriate representation of gender identity expressed during life. Anthropologists are uniquely suited to address the issue of identifying transgender and gender variant individuals in forensic cases.

As osteological specialists, forensic anthropologists routinely estimate sex as part of the biological profile, often the first step toward identification. However, an increasing percentage of the United States population (up to 3.0% or 9.8 million people) identifies as transgender or gender variant, thus complicating the estimation of sex as a factor in positive identification.<sup>1</sup> Traditional sex estimation methods, while largely successful for cisgender individuals, may be insufficient for cases involving transgender individuals.<sup>2,3</sup>

A recent report demonstrates that as a result of systemic discrimination, transgender individuals experience disproportionately high rates of fatal violence and suicide.<sup>4</sup> This same discrimination also creates barriers to identification in death. Missing persons may be unreported or incorrectly reported because authorities or families refuse to acknowledge their gender identities.<sup>4</sup> Furthermore, transgender people may be mis-gendered on medical or legal documents on file; 68% do not possess identification that accurately reflects both their name and gender.<sup>4</sup> As a result, transgender Does may be described as either Jane or John, which may not match their lived gender or descriptions provided for them.

The Anthropology section of the American Academy of Forensic Sciences (AAFS) has actively worked toward increasing diversity and inclusion in the section and in anthropological research in recent years. However, the problem of identifying transgender and gender variant decedents remains underexamined in our field. This presentation focuses on one potential avenue toward identification resolution: collaboration with the Trans Doe Task Force (TDTF), an organization created to find and research cases involving transgender decedents to assist the non-profit forensic genealogy-focused DNA Doe Project. Both organizations are focused on generating positive identifications for John and Jane Does, though the TDTF focuses on researching and identifying Doe cases who were likely transgender or gender variant during life. Forensic genealogy is, in part, the application of genealogical research to the positive identification process. To date, AAFS does not recognize forensic genealogy as a forensic discipline due to an insufficient number of practitioners in its membership. This study posits that the TDTF is an important component of the growing conversation around challenges in identifying transgender victims in the field of forensic anthropology.

To illustrate the potentially productive collaboration between forensic genealogists and anthropologists, this presentation will present a case study in which a creative and collective approach to identification was pursued. The Doe involved was likely mis-gendered via forensic art and the original police investigation in the 1980s. The TDTF has identified this particular case as one that reflects the challenges surrounding cold cases involving gender variant decedents. The necessary steps in case identification are presented to illustrate a successful research process and submission to the DNA Doe Project. Traditional (e.g., the National Missing and Unidentified Persons System (NamUs)) and non-traditional means (e.g., archived LGBTQ+ zines, Trans Day of Remembrance lists, Facebook® pages dedicated to missing and murdered transgender victims, etc.) are used during case research; these factors will be of interest to forensic anthropologists who suspect they may be working on cases involving transgender individuals. Additionally, the case study will demonstrate why and how sex estimation methods should be augmented in cases of transgender victims. Finally, a discussion of the possible privacy concerns and case access issues involved in a combined forensic genealogy/anthropology approach will be reviewed.

In some cases, the translation of forensic genealogical data, in association with thorough police investigation and forensic sex estimation, are all necessary to resolve identities of transgender decedents. A thoughtful, culturally informed approach anchored by an appreciation of gender diversity and identity in marginalized populations will better serve the victim by more quickly resolving identifications and honoring the lived identity of the decedent.

### Transgender, Sex Estimation, Positive Identification

## A2 The Frontal Versus Basal Region of the Cranium: A Comparison of the Best Sex Prediction Parameters Using Discriminant Function Analysis

Preetika M. Chatterjee, PhD, Guru Ghasidas Central University, Bilaspur 495551, INDIA; Kewal Krishan, PhD\*, Panjab University, Chandigarh 160 014, INDIA

**Learning Overview:** After attending this presentation, attendees will understand the usefulness and methodology of sex estimation, especially from various measurements of the cranium, which will help attendees choose the preferred parameters for different regions of the cranium and enable them to conduct further research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting standards for sex estimation from various measurements of the cranial regions when the cranium as a whole or its parts, especially the frontal or facial and basal regions, is brought for forensic examination.

One of the primary goals of any medicolegal investigation of human skeletal remains is to ascertain its identity. To achieve this goal, estimation of the biological profile is the first step, which helps to narrow the area of search and potential number of suspects and, thus, helps in the medicolegal investigation. A biological profile includes estimation of age, sex, stature, and ancestry. Sex determination needs to be performed ahead of age, stature, and ancestry estimation as these factors are sex dependent. The cranium is among the most dimorphic parts of the skeleton, followed by the pelvis, when it comes to sex determination from skeletal remains. However, implications of factors such as age, stature, and secular trends in craniofacial morphology are yet to be understood and controlled completely and thus this variability in skull is so important that it has a direct bearing on the accuracy and reliability of forensic anthropology tools. These variations are population-specific due to their genetic, environmental, and socio-economic dependence. In this context, the present study was conducted to make discriminant function equations for determination of sex from the frontal and basal region of the cranium in a central Indian population. The study is based upon a random sample of 187 adult crania (116 male, 71 female) aged from 18 to 50 years. A total of 33 cranial measurements have been taken on each sample (24 on the frontal region; 9 on the basal region) according to the standard procedures. The data were statistically analyzed using the Statistical Package for the Social Sciences (SPSS) computer software. Sex differences in frontal and basal measurements were analyzed using Discriminant Function Analysis (DFA) and discriminant equations were calculated. The best parameters for sex prediction were estimated from various measurements of the two regions of the cranium using linear and stepwise DFA.

Statistically significant differences ( $p < 0.001$ ) were observed between males and females for most of the measurements of the cranium in both regions. A DFA was run on the measurements taken from both regions of the cranium separately. Mastoid breadth followed by bi-mastoid breadth proved to be the best assessors of sex among nine parameters of basal region when subjected to direct (80.7%) as well as stepwise (79.1%) DFA. However, in the frontal region, basion-bregma height followed by nasal height gave the best sex prediction among 24 parameters, with an overall accuracy of 81.8% with linear analysis and 78.1% when subjected to stepwise DFA. Height measurements showed higher degree of sexual dimorphism in the frontal region. However, the cranium showed maximum univariate sexual dimorphism in breadth parameters such as mastoid breadth and foramen magnum breadth. The present study shows that both the regions can be helpful in sex determination with almost comparable accuracy, the only difference being the dominant parameter in the frontal region is height dependent while that in the basal region is breadth dependent. Thus, in cases, where cranial fragmentary remains are from the basal region, breadth measurements should be preferred over other measurements and when only frontal parts of cranium are encountered, height measurements should be preferred over width measurements.

### Forensic Anthropology, Sex Estimation, Cranial Measurements

## A3 Sex Determination Through the Evaluation of Foramen Magnum Measurements on an Italian Population

Carmelinda Angrisani, MD\*, Institute of Legal Medicine, Bari, ITALY; Federica Mele, MD, Institute of Legal Medicine, Bari, ITALY; Roberto Maselli, Istituto di Medicina Legale Bari, Bari, Puglia 70124, ITALY; Francesco Introna, MD, Dim Sezione Di Medicina Legale, Bari 70124, ITALY; Antonio De Donno, PhD, Bari 70124, ITALY

**Learning Overview:** After attending this presentation, attendees will understand a new system for sex determination using head Computed Tomography (CT) scan measurements of the foramen magnum.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new metric sex determination for Caucasians from ages 18 to 90 years.

This method is applicable for complete remains (cases in which it is comparable to other parameters) and incomplete ones due to dismemberment, trauma (with no affection of the cranial base), and advanced states of decomposition.

Sex determination is an important initial step in forensic identification of unknown skeletal remains and it could be reached in different ways. One of these, less described, is the morphometric evaluation of the foramen magnum. A few studies have been published, both on dry skull and on CT scan evaluations. In the literature, CT scan measurements of the foramen magnum have been obtained on Turkish, Swiss, South Indian, and Iraqi populations, but no study has been conducted on an Italian population. Furthermore, measurements taken into consideration in the present study were used in only one study on a Saudi Arabian population.<sup>1</sup>

The CT images included in the present study were obtained from Caucasian patients undergoing head CT for medical or surgical reasons. The sample was composed of 50 adults, 25 males and 25 females. Subjects with congenital or acquired cranial deformities were excluded. Measurements were made using Horos™ Software Version 3.0. The following measurements of the foramen magnum were taken: Length of the Right Occipital Condyle (LROC), Length of the Left Occipital Condyle (LLOC), Width of the Left Occipital Condyle (WLOC), Width of the Right Occipital Condyle (WROC), Maximum Bicondylar Distance (MBD), Length of the Foramen Magnum (LFM), Width of the Foramen Magnum (WFM), Area of the Foramen Magnum (AFM), and Minimum Bicondylar Distance (MiBD).

The parameters 1 to 8 were evaluated from the Saudi Arabian study; the MiBD was a new parameter chosen for a more complete evaluation of bicondylar distances.<sup>1</sup>

The primary purpose of this study was to validate the use of Saudi Arabian measurements even on an Italian Caucasian sample. Another goal was determining whether the new measurement (MiBD) could also be used in sex determination. In the Saudi Arabian study, concordance was assessed for sex with LROC, LLOC, LFM, WFM, and AFM. In this study, results from preliminary statistical analysis suggest a statistical association of sex with LROC, LLOC, LFM, WFM, and AFM. Furthermore, no statistically significant concordance was found between sex and this new parameter (MiBD).

In conclusion, results were encouraging; therefore this study's goal is to broaden the sample in order to obtain more statistically significant results. Furthermore, this method could be reliable and repeatable and may provide forensic anthropologists with an additional tool for sex determination, especially in situations where remains do not include other bones, especially the long ones.

### Anthropology, Sex Determination, Foramen Magnum

## A4 Assessing the Utility of Vertebral Body Heights as a Sex Indicator in United States Whites and Koreans

Yangseung Jeong, PhD\*, Middle Tennessee State University, Murfreesboro, TN 37129; Eun Jin Woo, Sejong University, Seoul, Gwangjin gu, SOUTH KOREA; Simon Pergande, Middle Tennessee State University, Murfreesboro, TN 37132; Omar Aly, Middle Tennessee State University, Murfreesboro, TN 37132

**Learning Overview:** After attending this presentation, attendees will understand that the vertebrae have a potential to be used for sex estimation in United States Whites and Koreans. However, their utility differs between the two populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by testing for the utility of United States White and Korean vertebral body heights as a sex indicator, which has not been studied previously. Sex estimation using the vertebrae will enhance the likelihood of identification of unknown skeletal remains, particularly when other sex indicators are missing or damaged. Additionally, this study emphasizes that the vertebrae-based sex estimation methods need to be population-specific.

Sex estimation is a crucial part of a biological profile in forensic anthropology. The cranium and pelvic bones are regarded as the most useful sex indicators. Other parts of a skeleton are also used for sex estimation, mostly due to size differences between sexes. The vertebrae have been studied for this purpose, but it has been reported that the accuracy of sex estimation using the vertebrae may vary in different populations.<sup>1</sup> This study explores how significant the contributions the vertebrae can make to sex estimation are in United States Whites and Koreans.

Vertebral body heights from C2 to L5 were measured from 140 Koreans (75 males and 65 females housed at eight institutions in South Korea) and 102 United States Whites (51 males and 51 females at the Bass Donated Skeletal Collection of the University of Tennessee) following Raxter et al.<sup>2</sup> Then, the discriminant function analyses were conducted on the individual vertebrae, followed by the stepwise analyses to find a set of the most influential vertebrae.

Discriminant equations using the Korean samples yielded decent-to-good Correct Classification Ratios (CCRs) ranging from 65% (L2)–92.1% (stepwise analysis). The CCRs of 75% or greater were obtained from 19 out of 24 equations (i.e., equations with the C2–T11, L1, and stepwise analysis). On the other hand, the performance of the equations using the United States White samples was poorer, with the CCRs ranging from 48% (L2)–81.4% (stepwise analysis). Only four equations (i.e., equations with the C4, C6, T2, and stepwise analysis) yielded the CCRs of 75% or greater. For both the United States Whites and Koreans, the lumbar-involved equations tend to yield lower CCRs, except for the Korean equation with the L1.

In this study, the United States males (176.2cm) and Korean males (162.2cm) are taller than the United States females (163.3cm) and Korean females (148.4cm) by 12.9cm and 13.8cm, respectively. The summed vertebral body heights correspond to approximately 30% of the total stature in both populations. In Koreans, the difference in the summed vertebral body heights between sexes (4.2cm) explains 30.3% of their stature difference; however, in the United States Whites, only 20.2% of the stature difference can be explained by the difference in the vertebrae (2.6cm). These findings indicate that the vertebral column of the United States Whites does not contribute to the stature difference as much as that of the Koreans. Poorer performance of the United States discriminant equations may also be explained by the smaller differences in the vertebral body heights between the United States males and females. Vertebral body heights have potential as a sex indicator. However, their utility appears to depend on the biological characteristics of the target population. Therefore, if the vertebrae are used for sex estimation, population-specific methods need to be generated and validated before use.

### Sex Estimation, Vertebrae, Population Specific

## A5 Estimation of Sex Based on Postcranial Elements in North American and Latin American Populations

Sara C. Zapico, PhD\*, Florida International University, International Forensic Research Institute, Miami, FL 33199; Joe Adserias-Garriga, DDS, PhD\*, Mercyhurst University, Erie, PA 16546

**Learning Overview:** After attending this presentation, attendees will have gained a better understanding of the potential use of postcranial elements for sex determination in North American and Latin American populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the usefulness of the ulna and humerus for sex estimation with high accuracies.

Sex estimation is one of the first components to be assessed toward the determination of the biological profile in skeletal remains. Classically, the visual analysis of the pelvis is the preferred indicator of sex with a high degree of reliability. However, different scenarios render incomplete skeletons, leading to the examination of various parts of the body and the application of different techniques for the correct assessment of this parameter.

Although different studies pointed out that the skull is the second best estimator of sex through visual assessment, when applied to statistical models, it was not possible to reach the same accuracies as the pelvis. In fact, some studies indicated that postcranial sex estimates are generally superior to skull estimates. Consequently, several studies have been focused on the analysis and measurement of long bones toward this purpose, including, in some of them, the clavicle and scapula, and on increasing the accuracies of sex estimation. Although these studies indicated an improvement in sex estimation when using postcranial elements, an issue is the scarce work on Latin American populations, since the majority of these studies were developed on African- and European-Americans.

Previously described metric traits (maximum length of clavicle; cranial-caudal diameter of clavicle; diameter of humerus head; humerus condylar breadth; scapular height; scapula breadth; femur epicondylar breadth; and ulna minimum breadth of the olecranon) and a new one (olecranon-coronoid distance from ulna) were measured from 72 North American individuals (41 males and 31 females) and 59 Latin American individuals (32 males and 27 females) from the American Museum of Natural History Collections in New York City and the Texas State University Collections in San Marcos, TX. Statistical analyses were performed using the Statistical Package for Social Science (SPSS) version 15. Comparison between groups was conducted using parametric or non-parametric tests. Discriminant function analysis models were performed to develop specific formulas for sex estimation.

Three independent measurements in three independent days were taken. After statistically corroborating that there was not intra-observer error, the average of these three independent measurements was calculated and used to analyze their significance between males and females. In both populations, all parameters showed significant differences between these two groups. However, when these measurements were introduced into discriminant function analysis in the North American population, only the minimum breadth of the olecranon correctly classified 91.3% of individuals and through cross-validation 89.9% of individuals. When this parameter was combined with the diameter of the humeral head, 98% of individuals were correctly classified and 98% through cross-validation.

In the Latin American population, the introduction of all parameters into discriminant function analysis retrieved the same results, although with lower classification accuracies. Again, the minimum breadth of the olecranon provided the highest classification accuracies (82.4% of individuals) and through cross-validation (80.4%). In contrast, in this case the diameter of the humeral head correctly classified 79.4% of individuals, with the same through cross-validation. This discrepancy with respect to the North American population could be due to the reduced number of analyzed individuals (71 vs. 59).

These results are in agreement with previous studies, which pointed out the humerus as one of the potential bones to take into consideration for sex estimation based on its accuracy. In addition, the minimum breadth of the olecranon in the ulna showed a high accuracy toward this purpose, rising in combination with the diameter of humeral head, at least in the North American populations. Thus, these two anatomical regions could be used alone or in combination with other methodologies for sex estimation, which is particularly important in situations of fragmentary remains. Future research may be able to expand on these results, increasing the number of individuals to improve the estimation accuracies.

### Postcranial Elements, Sex Estimation, Ulna

## A6 Evaluating Sexual Dimorphism Among South African Groups Using Dentition

Goodness P. Shakoane, BS, University of Pretoria, Anatomy, Pretoria 0084, SOUTH AFRICA; Ericka N. L'Abbe, PhD\*, University of Pretoria, Pretoria 00084, SOUTH AFRICA; Marie Christine Dussault, PhD, Brampton, ON L6Z 4B6, CANADA

**Learning Overview:** After attending this presentations, attendees will have gained knowledge of sexual dimorphism in dentition among South African groups and the use of dentition, particularly canines, for sex estimation. Sex estimation is an important component of the biological profile as other parameters, such as age-at-death, ancestry, and stature, are dependent on it. This presentation illustrates how teeth are a good source of information on sex for extremely fragmented remains, owing to their postmortem longevity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the application of knowledge of sexual dimorphism among three major South African groups. A more in-depth knowledge of sexual dimorphism within and between South African populations can assist in the creation of biological profiles for unidentified persons with the use of large dental databases and statistical software, as well as for improving dental implants and orthodontic treatment.

Human variation is a core component of an accurate biological profile from a heterogeneous population. South Africa is a poly-linguistic society with more than 49 million people and is ideal for evaluating human variation, particularly sexual dimorphism, among diverse populations. Within the last 500 years, various groups, such as the Dutch, French, Malaysian, and Indian, have migrated to the country. Apartheid segregation laws affected gene flow among indigenous and migrated groups, which contributed to distinct social/political designations including Black, White, "Colored," and Indian South Africans. Today, approximately 80% of the population identify themselves as Black; 9% "Colored"; 8% White; and 3% Indian. "Colored" refers to a social group primarily from the Western Cape who are descendants of slaves from Indonesia, India, Malaysia, and Asia, and who were mixed with Europeans and indigenous Khoi and San. The purpose of this study was to examine sexual dimorphism among the dentition of modern South African populations and to assess whether observed dental variations were useful for developing population-specific sex estimation formulae for Black, "Colored," and White South Africans.

All available teeth (excluding third molars) were used from 906 adult crania with a known demographic profile (526 males, 380 females, 318 Black, 312 White, and 276 "Colored" South Africans). Data was obtained from three large modern 20<sup>th</sup>-century skeletal collections in South Africa (the Pretoria Bone Collection, the Raymond A. Dart Collection, and the Kirsten Skeletal Collection). Four permanent crown dimensions were taken: maximum mesiodistal, maximum buccolingual, and two molar diagonal diameters (mesiobuccal-distolingual and mesiolingual-distobuccal).<sup>1</sup> Technical Error of Measurement (TEM), Analysis of Variance (ANOVA), sympercents, and Linear Discriminant Analysis (LDA) were computed in R (R. Core Team, 2014) to describe the data and to generate population-specific sex estimation formulae.

All dental dimensions are highly repeatable with low inter- and intra-observer errors. All dimensions show statistically significant differences between sexes, with males possessing larger dimensions than females. All dimensions and all groups exhibited sexual dimorphism. Canines had the highest degree of sexual dimorphism, followed by molars, premolars, and incisors. Black and "Colored" South Africans presented with more sexual dimorphism than White South Africans for all variables. LDA provided cross-validated correct classification rates up to 87%. Mandibular models performed best for Black South Africans (79.45% to 87.50%) and White South Africans (60.71% to 85.71%), while models including upper and lower canines and premolars performed best for "Colored" South Africans (73.68% to 83.33%).

Despite much research into sex and ancestry estimation among South Africans, less attention has been paid to human variation in the dentition within and among these groups.<sup>2</sup> While all teeth were sexually dimorphic, the best multivariate combinations yielded accuracies similar to those of the cranium (<90%). The long bones, scapula, and pelvis outperform the skull and dentition.<sup>3</sup> In any forensic investigation, the pelvis and long bones, respectively, take preference over teeth. However, the dentition can be useful in circumstances of extreme fragmentation, burning, and/or commingling.

### Linear Discriminant Analysis, Human Dentition, Biological Profile

## A7 The Relationship Between Soft Tissue Anatomy and Skeletal Sexual Dimorphism in the Cranium and Clavicle

Jade S. De La Paz, MS\*, University of Otago, Department of Anatomy, Dunedin, Otago 9016, NEW ZEALAND; Stephanie Woodley, PhD, University of Otago, Dunedin 9016, NEW ZEALAND; Nawaporn Techataweewan, PhD, Khon Kaen University, Khon Kaen, THAILAND; Hallie Buckley, PhD, University of Otago, Dunedin, Otago 9016, NEW ZEALAND; Siân Halcrow, PhD, University of Otago, Dunedin 9016, NEW ZEALAND

**Learning Overview:** After attending this presentation, attendees will understand the relationship between muscle, ligament, and skeletal enthesis size as it relates to human skeletal sexual dimorphism in both the cranium and clavicle.<sup>1-3</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying how soft tissue affects the morphology of the underlying skeleton and how this relates to sexual dimorphism at three skeletal landmarks: the nuchal crest and the mastoid processes of the cranium, and the rhomboid fossa of the clavicle. Additionally, the forensic science community will have the opportunity to discuss future directions for establishing a metric sex estimation method from the dissection phase of this study, which will be the focus of this presentation.

The overall goal of this research is to explore ways of establishing accurate metric sex estimation methods from the cranium and clavicle, through the dissection of donated human cadaveric material and analysis of skeletal and soft tissue sexual dimorphism. In forensic anthropology, an absent pelvis requires sex estimation from other areas of the skeleton, and many morphological and metric methods are available.<sup>1-4</sup> However, morphological sex assessment can sometimes lack reliability due to the subjectivity and experience required for scoring skeletal morphology.<sup>5-8</sup> It is important to have accurate sex estimation methods to help with identification in modern forensic cases and to understand populations in archaeological settings. Metric methods can provide not only accuracy, but also limit the subjectivity and expertise that is required for morphological methods.<sup>4</sup> This is a multidisciplinary research project, which approaches a forensic anthropology question from an anatomical perspective.

This presentation focuses on the dissection phase of this project and the analysis of soft tissue associated with sexually dimorphic skeletal landmarks. Relevant soft tissue attaching to the nuchal crest includes the upper trapezius (distal limit at the clavicular attachment), semispinalis capitis, and the nuchal ligament. Muscles of interest for the mastoid processes are the sternocleidomastoid, splenius capitis, and longissimus capitis. Soft tissue related to the rhomboid fossa includes the clavicular head of the pectoralis major, sternohyoid, subclavius, and the costoclavicular ligament.

A total of 22 bequeathed cadavers from modern European New Zealand and Thai populations were dissected using standard dissection equipment. Right and left sides of each element, where available, were dissected for a total of 406 elements: 352 muscles and 54 ligaments. Muscles were dissected by individual fascicles, which were measured for length and weighed for mass (converted to volume, per muscle density constant: mass/1.0576g/cm<sup>3</sup>). This was used to calculate the physiological cross-sectional area, or overall size, of the muscle (fascicle volume/length). Ligaments were measured for cross-sectional area (overall volume/length) and assessed separately from muscles.

Skin and fascia were removed to expose the relevant superficial muscles: the upper trapezius, sternocleidomastoid, and pectoralis major. Following their dissection, further muscles, such as the rhomboid major and minor, were removed to expose the deeper muscles: the splenius capitis, longissimus capitis, and semispinalis capitis. After the removal of each muscle, a grease pencil was used to outline all areas of attachment on the skeleton, providing the footprint of the entheses.

A 3D scan of the specimens was then taken, using a 3D scanning tablet attachment, to measure the total area of each enthesis as they related to the muscles and ligaments, as well as the skeletal landmarks with which they are associated. Following this, the sternum, clavicles, and partial first ribs were removed en bloc to access the sternohyoid, subclavius, and costoclavicular ligament for dissection. After all muscles and ligaments were dissected and recorded, the remaining elements were 3D scanned. Finally, the skull, vertebral column, clavicles, and sternum/manubrium were prepared for maceration for future analysis of the dry skeleton.

Preliminary results indicate that males show generally larger muscles than females, with some exceptions. Following standard methodology, the individuals are consistent with the male and female skeletal morphology.<sup>1-3</sup> Even muscularly robust females show standard female characteristics, skeletally. The implications for this muscular data can provide further insight into human sexual dimorphism in these well-understood skeletal landmarks, in addition to the lesser-understood sexual dimorphism of the neck muscles. Future development of a population-specific metric sex estimation method from these data will contribute to improving the accuracy of sex estimation from the cranium and clavicle.

## A8 Sexual Dimorphism in the Shape of the Auricular Surface of the Ilium

*Madeline Parker, MS\*, Columbus, OH 43232-5451; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN 46227-3697; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227*

**Learning Overview:** The goals of this presentation are for attendees to: (1) develop a better understanding of the factors influencing the shape of the auricular surface; and (2) recognize the limitations of using the shape of the auricular surface to determine the sex of the decedent from skeletonized remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a statistically rigorous study of the shape of the auricular surface using a large recent skeletal sample, helping to resolve the contradictory findings of prior research.

The following null hypotheses are tested: the shape of the auricular surface does not covary with any independent (profile) variables, including: (1) sex, (2) age, (3) collection of origin, (4) body size, or (5) the interaction between sex and collection of origin.

The coxa is considered to be the most sexually dimorphic bone in the adult human body and one of the most useful for sex determination from the skeleton. The auricular surface of the ilium preserves well and is often present in archeological assemblages and forensic cases. While the shape of the auricular surface has been analyzed with both metric and non-metric techniques, these studies tend to simplify the feature's complex shape or else rely on the use of a number of arbitrarily defined landmarks, which can limit the researcher's ability to describe subtle shape differences or to elucidate the causal effects of independent variables.

In this current study, the auricular surfaces of 964 identified "White" individuals from the United States (Bass Collection and Hamann-Todd Collection) and Portugal (Coimbra Collection) were photographed, outlined, and subjected to elliptical Fourier analysis and principle component analysis. Analysis of Covariance (ANCOVA) was then applied to the resulting eigenvalues for each principle component to tease out the effects of each independent (profile) variable on auricular shape. Five effective principle components were distinguished. The first principal component (PC1) explains ~38% of the variation in the shape of the auricular surface and reflects the posterior extension and curvature of the posterior border; it is not influenced by any of the tested independent variables and may reflect difficulty in accurately locating the vaguely defined posterior edge of the surface. PC2 explains ~18% of the variation in the shape of the auricular surface and depicts what has traditionally been described as its "C-shaped" or "L-shaped" appearance. PC2 is significantly affected by sex, with male surfaces being straight and "L-shaped" and females being more curved and "C-shaped".

The stature of the decedent is also significant in females, where taller females tend to have more "feminine" auricular surfaces. PC3 explains ~14% of the variation in shape and describes the pinching of the caudal limb and whether the center line running through the apex is twisted, creating an asymmetrical appearance. Females have a more pinched caudal limb and the apex is oriented toward the cranial limb (asymmetrical), while males have a less pinched caudal limb and the apex is oriented directly above/in front of the posterior indentation (symmetrical). The collection of origin is a significant influence, with individuals from the Bass Collection having less pinched caudal limbs than individuals from the Coimbra or Hamann-Todd Collections. PC4 explains ~6% of the variation in shape and describes the thickness of the cranial limb relative to the caudal limb. Only the collection of origin was found to influence the shape variation described in PC4, where the bulbous cranial limbs in the Bass Collection differ from the thinner cranial limbs of the other groups. PC5 explains ~5% of the variation in shape and describes whether both limbs are pointed or bulbous and whether there are one or two indentations in the posterior border. Again, only the collection of origin was found to influence the shape, where the double indentation of the Bass Collection differs from the single indentation of the other groups.

Overall, the best predictor of the shape of the auricular surface is the sex of the individual, but this factor only accounts for ~0.6% of the total shape variation as described by the effective principal components. Therefore, while the traditional understanding of sexual dimorphism in the shape of the auricular surface is verified here, anthropologists should give priority to other pelvic features over the auricular surface when determining the sex of a decedent.

### Forensic Anthropology, Sexual Dimorphism, Auricular Surface

## A9 Application and Evaluation of Adult Morphological Sex Traits Using the Subadult Innominate

Stephanie J. Cole, MS\*, University of Nevada, Reno, Reno, NV 89557; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will understand the age at which adult morphological sex traits of the innominate can be applied to subadults without compromising accuracy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing that the innominate can be used to estimate the sex of individuals younger than previously thought possible.

Sex estimation is arguably the most important parameter of the biological profile, as accurate estimates of age, ancestry, and stature are often contingent on sex. Morphological evaluation of the ventral arc, subpubic contour, and medial aspect of the ischio-pubic ramus, as originally described by Phenice and later modified by Klales et al., has shown to consistently provide accurate estimates of sex when applied to adults.<sup>1,2</sup> However, Phenice has warned against applying these traits in individuals younger than 20 years of age.<sup>1</sup> Further, it is fairly ubiquitous among anthropologists that sex indicators are not valid and/or sex estimation is not applicable in individuals less than 18 years of age. Indeed, attempts to estimate sex in subadults have routinely yielded low classification accuracies and, therefore, it is advised against, especially in forensic contexts, for fear of misidentification. Unfortunately, this has led to a paucity of research on the subject and stagnation in contributions to this area of the field.

To evaluate the performance of these three traits when applied to subadults and to determine the age at which adult levels of accuracy are achieved, the Klales et al. method was applied to a sample of 301 individuals aged between 8.29 and 20.96 years using Multi-Slice Computed Tomography (MSCT) postmortem scans.<sup>2</sup> Age cohorts were created using two-year intervals for individuals 11 years and older, and a three-year age cohort was created for individuals aged 8.29 to 10.9 years to help increase the comparatively small sample sizes for younger individuals. Fisher's exact test with Monte Carlo simulation was used to test for sexual dimorphism in trait score frequencies between subadult males and subadult females for each trait in each age cohort. To determine at which age trait score frequencies are comparable within the sexes (e.g., subadult and adult females), subadult score frequencies for each cohort were compared to adult score frequencies previously reported in a comprehensive global study.<sup>3</sup> A Kruskal-Wallis test was applied and if rejected, a Dunn's test with Holm's stepwise adjustment was used to determine which age cohorts differed.

Significant differences in score frequencies between subadult males and females were observed for all traits and all age cohorts ( $p < 0.001$ ) with the exception of subpubic concavity for the 8 to 10.9 year cohort ( $p = 0.827$ ). Score frequencies between subadult and adult males differed in all cohorts, but only for the medial aspect of the ischio-pubic ramus ( $p \leq 0.018$ ). Differences in score frequencies between subadult and adult females were more common than in males and significant differences were observed in all traits in all cohorts ( $p \leq 0.01$ ), with some exceptions in older cohorts. Subadult accuracy rates for combined sexes showed an extreme bias toward male classification for the 8 to 10.9 year and 11 to 12.9 year cohorts, with males achieving perfect accuracies and females achieving 55.6% and 66.7% accuracies, respectively. A notable change was observed in the 13 to 14.9 year cohort, with males achieving an accuracy of 92.9% and females achieving an accuracy of 86.4%. By 15 years, both sexes in all remaining cohorts classified at rates at or above 90%, with sex biases switching to favor female classification. The accuracies achieved by 15 years are comparable to those obtained for adults, and sex biases in favor of female classification are consistent with results observed in adults.<sup>2,3</sup>

The results of this study suggest that adult morphological sex traits of the innominate can be used to estimate sex in individuals as young as 13 years, though comparable performance of the indicators are not observed until 15 years of age. The findings suggest sex can be estimated prior to individuals reaching skeletal maturity, which is minimally five years younger than previously advised. While these results are encouraging, it is recommended that more research be conducted to corroborate these findings before widespread application of the Phenice/Klales et al. methods to subadults in forensic casework.<sup>1,2</sup>

*This research was funded in part by a National Institute of Justice (NIJ) grant.*

### Sex Estimation, Innominate, Subadults

## A10 Sex Estimation of the Subadult Pelvis Prior to Acetabular Fusion

Heather M. Garvin, PhD\*, Des Moines University, Des Moines, IA 50312-4198; Katherine A. Marciniak, BS, Des Moines University, Des Moines, IA 50312; Laura E. Cirillo, MA, University of Nevada, Reno, Reno, NV 89557; Michala K. Stock, PhD, High Point University, High Point, NC 27268-4260; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will understand the limitations in sexing the subadult pelvis prior to fusion of the acetabulum.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing sex estimation results and recommendations for ilium outlines and basic pelvic measurements on a large sample of modern United States subadults.

The Scientific Working Group for Forensic Anthropology (SWGANTH) suggests that sex estimation should not be performed on subadults less than 12 to 14 years of age. A review of the literature, however, reveals multiple studies on the subadult pelvis that report significant levels of sexual dimorphism and suggest a potential utility for subadult sex estimation, particularly using variables related to the ilium. The goal of this study was to test the ability of ilium outlines, greater sciatic notch measurements, and pelvic length indices to differentiate males from females in a large, modern sample of subadults.

Pelvic 3D surface models were extracted from postmortem Computed Tomography (CT) scans of 392 subadult individuals obtained from the University of New Mexico Health Sciences Center, Office of the Medical Investigator aged 0 to 14 years. Only individuals in which the tri-radiate cartilage of the acetabulum remained unfused were included in the study. Once orientation was standardized, 2D images of the internal/visceral surface of the ilia were extracted from the 3D models, and elliptical Fourier analyses were performed on the ilium outlines (contours), followed by a Principal Component (PC) analysis. Pubic length, ischial length, iliac height, maximum ilium breadth, and minimum ilium breadth were collected from the virtual specimens, as were five measurements from the greater sciatic notch. The PCs and various indices of the pelvic and greater sciatic notch measurements were subjected to Multivariate Analysis of Variance (MANCOVA) analyses to test for sex differences given age as a covariate. Discriminant Function Analyses (DFAs) were performed to evaluate correct sex classification rates. It was hypothesized that sexual dimorphism in the pelvis should increase with age; thus, analyses were rerun systematically eliminating the youngest one-year cohort one at a time in an attempt to determine a minimum age at which the subadult pelvis can be sexed.

MANCOVA results indicate significant sex differences in ilium outline shape and pelvic measurements ( $p < 0.05$ ), and Analysis of Covariance (ANCOVA) results revealed sexually dimorphic features related to greater sciatic notch shape and relative pubic length. Despite significant sex differences, less than 70% of the individuals could be sexed correctly with the DFAs, regardless of the variables included. Eliminating the youngest cohorts did not improve results. Scatter plots illustrate a large overlap between males and females in all variables. These results highlight the fact that statistically significant sex differences do not equate to forensically acceptable classification results. Previous studies may be confounding those results or their sample biases may be contributing to their positive results. When limiting analyses to only those individuals over the age of five years in the current study, sample sizes were greatly reduced; thus, additional samples and analyses should be performed to evaluate potential sex classification in subadults over the age of five years. Individuals aged five years or less, however, do not have high enough levels of sexual dimorphism in overall ilium shape, greater sciatic notch morphology, or pelvic length indices to have utility in forensic anthropological assessments. Age was a significant covariate for almost all variables, and morphological variation related to growth and development likely obscures any potential sex-discriminating variables at these young ages.

### Sex Estimation, Juvenile, Os Coxae

### A11 3D Models of Paranasal Sinuses to Establish Age, Sex, and Ethnicity Across Three Modern Populations

*Madeline H. Robles, MS, MRes\*, University College London, London, England WC1H 9EZ, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, London WC1H 9EZ, UNITED KINGDOM; Carolyn Rando, PhD, University College London, London WC1H 0PY, UNITED KINGDOM*

**Learning Overview:** The objective of this research is to assess if the shape or size of the paranasal sinuses provide patterns that distinguish between age, sex, and ethnicity on unknown remains that may assist with victim identification in forensic reconstructions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community as attendees will leave with an understanding of the production, accuracy, and utility of Three-Dimensional (3D) modeling as a primary visualization technique for 3D entities and the ability of using this method for human identification. Attendees will be introduced to the findings of preliminary research that highlights the potential of 3D modeling as a novel method for examining the paranasal sinuses to identify patterns that may assist with distinguishing between individuals and victim identification.

The identification of unknown human remains can be an essential element to a forensic investigation or crime reconstruction. Technological advances have furthered the development and understanding of trace evidence such that DNA and fingerprints have become the foundation of human identification. However, when a body undergoes extreme damage, such as in cases of arson, these methods of identification may not be possible. In conditions such as these, alternative methods of identification become critical.

Previous research has quantified the variability of the frontal sinus between individuals and has likened the distinctiveness of this structure to that of fingerprint comparison. As a result, the frontal sinus has been successfully used as a primary source for identification supported by expert testimony in the court of law. Therefore, examining the effectiveness of the paranasal sinuses in determining age, sex, and ethnicity is a valuable next step. However, the existing literature on the paranasal sinuses are targeted toward practicing physicians for medical care and not explicitly intended for human identification in a forensic context. For example, morphological patterns of the ethmoid sinus between populations has been documented solely as a precautionary guide to mitigate complications during endoscopic sinus surgery. Consequently, the ability of the paranasal sinuses to provide biological information to assist with forensic identification is under-researched. Therefore, there are no standard approaches for measuring or analyzing these structures.

This study addressed this gap by developing a new approach for human identification using 3D models of the paranasal sinuses. Models were produced from a database of modern Computed Tomography (CT) scans provided by University College London Hospital (UCLH). Elliptic Fourier and linear analysis of 30 3D models produced from the CT data demonstrated notable variations and patterns with regard to discriminating age, sex, and ethnicity across three distinct ethnic groups. The most promising classification rates ranged from 93% ( $p=.000$ ) to 70% ( $p=0.05$ ). This study also aimed to assess the correlation between these variables to determine if one particular sinus has a more successful prediction rate than others to assist with identification.

The findings from this study lay the foundations for developing the means for fast and reliable identifications to be made as a result of computer-assisted methods based from 3D reconstructions of the paranasal sinuses.

#### Identification, Three-Dimensional Reconstructions, Paranasal Sinuses

## A12 Assessing the Accuracy of Current Ancestry and Sex Estimation Methods on a Japanese Sample

Cassie E. Skipper, MA\*, University of Nevada, Reno, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, Reno, NV 89557-0096

**Learning Overview:** After attending this presentation, attendees will have gained a better understanding of the accuracy of current ancestry and sex estimation methods on a Japanese skeletal sample.

**Impact on the Forensic Science Community:** This study will impact the forensic science community by investigating the suitability of currently available reference samples. As these reference samples serve as the basis to estimate ancestry and sex within a medicolegal context, it is critical to understand their accuracy in estimating these parameters on known skeletal samples. This work also highlights the diversity present in skeletal populations and the need for large diverse reference samples.

According to the Migration Policy Institute, from 1960 to 2014 there was a 2,597% increase in Asian migrants to the United States, thus representing 30% of the United States' foreign-born population.<sup>1</sup> Further, the 2010 Census reported that the Asian population is the fastest growing of any population in the United States. Specifically, the Japanese population experienced an increase of up to 59%.<sup>2</sup> However, most current biological profile estimation methods in the United States are based on individuals of European and African ancestry, which are then used to estimate the biological profile of unknown decedents in forensic cases. Despite studies stating the need for population-specific biological profile estimation methods, there is a scarcity of research that has focused on ancestry and sex estimation methods for Asian populations. As Asian migration into the United States continues to rise, so will the necessity for Asian-specific methods and reference data.

Heritable traits under investigation in biological anthropology include four major data types: craniometrics, cranial non-metrics and macromorphoscopies, odontometrics, and dental morphology. Each data type reflects different biological, environmental, and evolutionary influences. While similar research projects typically utilize only one or two data types, this study includes all four data types in a single project to present a holistic approach to analyzing ancestry and sex estimation methods on an Asian sample. The aims of this study are: (1) to test the accuracy of current ancestry and sex estimation methods on a Japanese sample, and (2) to explore the applicability of available reference populations when estimating the biological profile of unknown Asian decedents.

Data were collected from a modern Japanese sample curated at the Jikei University School of Medicine in Tokyo, Japan ( $n=33$ ). Data for each individual were input into various statistical estimates typically used by forensic anthropologists. Craniometric data were assessed using FORDISC® 3.1 to estimate sex and ancestry.<sup>3</sup> Cranial non-metric and macromorphoscopic data were analyzed using tetrachoric Mahalanobis distance and visualized using multidimensional scaling to assess population affinity.<sup>4</sup> Odontometric data were compared to data presented in Pilloud et al. using FORDISC® 3.1 to estimate sex and ancestry.<sup>5</sup> Dental morphological data were input into the statistical program rASUDAS to estimate ancestry.<sup>6</sup>

Preliminary results using the craniometric, odontometric, and dental morphology datasets produced correct classification rates from 21.10%–36.40% for ancestry, and the craniometric and odontometric datasets produced correct classification rates from 24.20%–36.40% for sex. The craniometric dataset produced the most accurate estimates of ancestry, while the odontometric dataset provided the most accurate sex estimates.

These varied results likely stem from inappropriate or insufficient reference samples, unexplored variation in the study sample, and/or the statistical treatments used in the current ancestry and sex estimation methods. Within forensic anthropology, there is a need to establish more robust reference samples that represent a broad range of global variation. It may also be necessary to explore additional statistical treatments and the incorporation of more than one type of data to accurately quantify population variation and sexual dimorphism.

### Ancestry Estimation, Sex Estimation, Asian Population

## A13 Crossing the Borders of Linguistics, Ancestry, and Race in the Field of Forensic Anthropology

Alba E. Craig, BA\*, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227

**Learning Overview:** The learning objectives for this presentation include: (1) attendee appreciation of the linguistic complexities of applying biological information obtained from the human skeleton to medicolegal statements regarding racial identity; (2) a discussion of the strengths and limitations of current terminology utilized in scientific publications; and (3) a call for further discussion regarding the language used to describe ancestral affiliations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating that the presence and acceptance of the overlap between biological ancestry and social race should be used as a way to open discussion about appropriate usage of terminology to reach a more holistic way of defining an individual's ancestry and racial identity based on their skeletal traits.

Forensic anthropologists must often navigate the borders between a holistic, theoretical science and the practical applications of the United States medicolegal system. On the one hand, forensic anthropologists recognize that humans display normal human variation that is not categorical in nature; yet, on the other hand, they provide medicolegal authorities with ancestral assessments to aid in the identification of unidentified human remains. To do so, forensic anthropologists rely on correlations between the expressions of certain biological traits and an individual's social race. While forensic anthropologists should be cognizant of the differences between assessed skeletal ancestry and social race, the scientific literature suggests otherwise, as the terminology for ancestry and the terminology for social race are often used interchangeably in the context of human identification and human identification research.

As the field of forensic anthropology continues to grow and populations continue to change, an emphasis on the use of terminology used to define an individual's ancestry and race becomes increasingly important to discuss. A review of forensic anthropology articles in the *Journal of Forensic Sciences* and the *American Journal of Physical Anthropology* from 2008 to 2019 demonstrates a notable shift in how ancestry is defined and discussed. This may reflect larger trends in terminology and thinking in the field of anthropology as articulated by the American Anthropological Association statement on race.<sup>1</sup> Some authors have actively made the decision to emphasize that the specific terminology used in their publication may not be encompassing of all individuals classified within said group. While this emphasis in terminology is more commonly geared toward minority groups (such as Hispanics and Blacks), this idea can and should be applied to all ancestral groups of focus in the field. If the terminology used to describe an ancestral group cannot fully embrace the variation that exists within the group, a push toward a change in terminology should be the next step.

Anthropologists recognize that social race is complex, personal, and political. Colleagues in the American Association of Physical Anthropologists have recently articulated concerns regarding the overly simplistic equating of skeletal biology and social race and the potential sociopolitical consequences.<sup>2</sup> This presentation serves as an avenue to present questions and concepts to consider, such as: Why do researchers continue to narrow the definition of Hispanic and Black into distinct smaller and smaller subpopulations (for example: Caribbean Black, South Carolina Slave, Mexican, or North American Hispanic) while the definition of White seems to encompass individuals from a variety of geographic, cultural, and linguistic backgrounds? Why are these distinctions never addressed or discussed in forensic anthropology reports aiding in the identification of human remains? Should the Anthropology Section of the American Academy of Forensic Sciences consider standardizing racial terminology used in forensic anthropology reports? What is the obligation of the forensic anthropologist to consider the broader cultural ramifications associated with the use of certain racial terminologies in their reports in regard to identification and investigation efforts?

The data in this presentation collected from the scientific literature supports the hypothesis that social race is culturally defined and evolves over time. Therefore, forensic anthropologists should consider not only how racial terminology impacts identification, but also the ways in which skeletal variation and social race are understood—or misunderstood—by the larger medicolegal community. Not only is this type of discussion important to the field of forensic anthropology in relation to biological profile construction, but its importance also expands to the medicolegal system, as improved terminology could ultimately lead to an improved identification process for unidentified human remains.

### Forensic Anthropology, Biological Ancestry, Social Race

## A14 The Use of Eye Tracking Technology in Forensic Anthropology: An Empirical Approach to Advancing the Understanding of Complex Visual Tasks in Cranial Macromorphoscopic Trait Evaluations

Sherry Nakhaeizadeh\*, University College London, London WC1H 9EZ, UNITED KINGDOM; Micayla C. Spiros, MS, East Lansing, MI 48823; Joseph T. Hefner, PhD, Michigan State University, East Lansing, MI 48824; Tim Thompson, PhD, Teesside University, Middlesbrough, Cleveland TS1 3BA, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, London WC1H 9EZ, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will gain insights into the successful usability of eye tracking technology in forensic anthropology, method development in ancestry assessments specifically, and visual skeletal assessments more broadly.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how eye tracking approaches have the potential to be utilized to measure empirically the extent of visual attention used in complex tasks. The goal of this presentation is to demonstrate to attendees the usability of eye tracking technology as a research tool in forensic anthropology to study empirically visual gaze patterns involved in the interpretation of skeletal remains.

This presentation provides insight into the application of eye tracking technology in forensic anthropology by first, providing an overview of key research that has been conducted within this area in forensic science and, second, by presenting specific eye tracking data collected from a preliminary study in visual Macromorphoscopic (MMS) trait analyses for ancestry estimations.

The use of eye trackers as a research tool has increased in recent years, with a growing interest from a number of different disciplines.<sup>1</sup> Eye trackers are measurement devices used to capture eye movements and have been applied to assess tacit knowledge from human experts and their performance within multiple domains.<sup>2</sup> In forensic science, however, the use of eye tracking technology as a tool to study forensic decision-making is largely underutilized, with only a few published studies conducted to date.<sup>3-5</sup> Forensic anthropologists rely heavily on well-established visual methods when conducting the task of creating a biological profile. To some extent, this practice takes full advantage of the human perceptual system.

This presentation will showcase the results from an initial empirical study conducted using eye tracking technology to consider the MMS procedures used in ancestry estimation. This study sought to assess the capabilities of using eye trackers as a tool in studying visual processing and strategies involved in MMS procedures by looking at participants' *fixation points* (what features participants focus on), *fixation duration* (total time participants spend looking at the different features involved in the method), *scan path* (the order in which participants look at the features), and *visit count and duration* (the number of total visits and duration to particular areas).

The results of this preliminary study identified differences in gaze “strategies” with regard to fixation points, visit duration, and visit counts between the participants. The data generated provide a starting point for assessing how such technologies could be used in order to understand the decision-making processes involved in forensic anthropological interpretations and their role in forensic reconstructions more fully. These results will be discussed from an “applied” point of view, in terms of presenting the type of data collected, and how the data was quantified and analyzed.

Ultimately, the findings provide valuable insights into how to interpret and use the data in order to advance our understanding of the decision-making processes involved in the assessment of skeletal remains, and provide more transparent and reproducible evaluative reconstructions.

### Forensic Anthropology, Eye Tracking, Visual Attention

### A15 Eye Tracking to Assess Decision-Making in Cranial Macromorphoscopic (MMS) Trait Evaluation: Implications of Education and Training in Method Application

Micayla C. Spiros, MS\*, East Lansing, MI 48823; Sherry Nakhaeizadeh, University College London, London WC1H 9EZ, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, London WC1H 9EZ, UNITED KINGDOM; Tim Thompson, PhD, Teesside University, Middlesbrough, Cleveland TS1 3BA, UNITED KINGDOM; Joseph T. Hefner, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will better understand the impacts of experience and education on decision-making processes and how eye gaze behavior is associated with MMS trait analyses, method development, and method improvement.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how eye tracking technology can grant further insights into the application of forensic anthropological methods with a focus on ancestry estimation. Research in multiple forensic science disciplines delve into how technology can be used to understand decisions made by experts in their respective fields. Investigating anthropological methods from this cross-disciplinary approach can help researchers understand human decision-making, specifically how and when variance occur in method application and thus support the improvement of method development and training.

In this study, ten individuals with various education and experience levels assessed two skulls using the MMS scoring procedure while wearing Tobii Pro eye tracking glasses. Data from the glasses allowed the creation and analysis of eye fixation patterns. This includes time recorded for each of the 17 MMS traits, time spent on each individual skull, and the overall time of analysis. Individuals were assigned distinct groups based on a preliminary questionnaire. These groups are separated into the following categories: (1) education level, (2) MMS experience, and (3) a combination of both education and experience.

For this study, time was used as a proxy for confidence in decision making for the MMS method. A Kruskal-Wallis test was used to compare the times between the three groups. Kruskal-Wallis and pairwise Wilcoxon rank sum tests were applied comparing the times for each individual MMS trait between the groups. A two-way mixed-effects model for Intraclass Correlations Coefficients (ICC) was used to measure inter-observer reliability of the MMS scores on each skull.

When looking at the median times for each trait, the Nasal Aperture Width (NAW) was the quickest scored trait, with an overall median time of 14.59 seconds. The results also show that Nasal Bone Contour (NBC) took the longest to score, nearly 16 seconds slower than the next longest trait to score, the Transverse Palatine Suture (TPS).

When analyzing the median overall time to score both skulls, a Kruskal-Wallis rank sum test indicates individuals with <2 years of MMS experience and individuals with >2 years of MMS experience differed significantly ( $p=0.01052$ ). The results from the Kruskal-Wallis and Wilcoxon rank sum tests for individual MMS traits show that time differences between experience, education, or a combination of both are not significant. While none of these differences are significant, individuals with more than two years of experience were consistently quicker than individuals with less than two years of experience, with the exception of: (1) nasal overgrowth, (2) orbital shape, and (3) postbregmatic depression.

The results of inter-observer error using the single fixed rater ICC indicate reliability between the ten individuals is moderate ( $ICC=0.72-0.74$ ). When grouped by education level, the ICC results indicate good agreement between groups ( $ICC=0.86$ ). ICC results based on the experienced groups show good to excellent agreement ( $ICC=0.86-0.92$ ). Overall, when splitting the assessors into the four groups based on experience and education level, the ICC results indicate good agreement ( $ICC=0.82-0.88$ ), demonstrating that experience is the key to higher reliability between assessors. The ICC results indicate that the inter-observer reliability is high for the MMS method, with experience only slightly improving the agreement between groups.

Using the time data, ICC results, and heat maps created from the eye gaze patterns, eye tracking technologies allow researchers to visualize where variance may be occurring between assessors to identify critical parts of decision-making process. Through empirical decision-making studies, forensic anthropologists can move forward and improve practice by decreasing observer differences by targeting confusing or problematic aspects of a method. This allows training to focus on problematic traits when training forensic anthropologists.

### A16 Metric and Non-Metric Ancestry Evaluation Analysis of the Craniofacial Region in Greek-Cypriots: A Pilot Study

*Madyson R. Stephenson\**, Newberry, FL 32669; *Anna S. La Valley*, MS, Reston, VA 20190; *Xenia P. Kyriakou*, MA, Florida Gulf Coast University, Fort Myers, FL 33965-6565

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the need to create population-based standards for less-studied regions, such as Cyprus and the wider eastern Mediterranean. This study combines different ancestry evaluation techniques developed around the world in order to determine an ancestry profile for Greek-Cypriots. This study also discusses the value of the Greek-Cypriot population as a platform for the development of human identification standards that could server the rest of the eastern Mediterranean region.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a new composite method in ancestry evaluation that could serve as a population-based standard for human identification for Greek-Cypriots. This research utilizes a combination of metric analysis and non-metric observations to determine the skeletal “face” of Greek-Cypriots. This pilot study evaluates the relationship between different bones of the facial skeleton and their bordering landmarks. Thus, this study offers a unique insight of how different methods could work together to the development of a single ancestry evaluation approach for a newly studied population. Furthermore, the genetic makeup of Greek-Cypriots resembles that of its immediate neighbors; thus the results of this study, with little or no modification, could be applicable in establishing positive identification for unidentified remains retrieved in those areas.

Ancestry is a topic less studied in Europe and the Mediterranean region than in the United States. Little effort has been made to define the morphological parameters of the different populations that constitute the continent. The underlying hypothesis that we are all European-White in Europe has played a major role in ancestry being a less common research subject. However, open borders within the Eurozone and immigrant influx from war-afflicted countries have increased the need for ancestry standards to be developed as Europe and the Mediterranean are now characterized by mixed and admixed communities.

Combining both metrics and non-metric traits, the aim of this study is to create an objective methodological framework for analysis for this particular region of the cranium. The objective of this study is to define the craniofacial character of Greek-Cypriots and establish ancestry-related parameters. Methods focusing on more area-specific regions of the cranium can further aid in the evaluation of ancestry of fragmentary remains. In a pilot study of contemporary skeletons from the Cyprus Reference Research Collection (CRRC), focus was placed on the identification of macromorphoscopic and metric characteristics of the zygomatic bone in relation to the maxilla, orbits, and nasals.

A total of 50 crania were assessed using a total of 17 measurements, 5 of which aimed at recording size differences between males and females. The presence, frequency, and expression of ten non-metric traits from the zygomatic region was assessed macroscopically. While metrics show that a degree of sexual dimorphism in the overall size of this region of the facial skeleton is present, in some instances the overlap between male and female ranges was significant. Furthermore, when compared to other population groups, the mean average of bizygomatic breadth in Greek-Cypriots show distinct ancestral character specific to this population. With regard to non-metric observations, in many instances zygomatic traits classified within the low expression categories. However, some traits proved to be population specific. For example, a projecting zygoma was a predominant male (64%) and female (80%) characteristic, with an overall 72% incidence value; while the malar tubercle was greatly absent in both sexes. Additionally, the shape of the zygomatico-temporal suture was assessed, and a potentially a new non-metric trait was discovered during this research project.

In conclusion, the results of this study suggest that the combination of both metric and non-metric analysis is a useful tool in ancestry evaluation. The two approaches are complementary to each other and provide an objective framework for the determination of ancestry in skeletal remains but also reflect on the underlying similarities and differences between the sexes.

#### Ancestry Evaluation, Macromorphoscopic, Sexual Dimorphism

## A17 Craniofacial Modularity and Integration: Implications for Ancestry Assessment

Janet E. Finlayson, MA\*, C.A. Pound Human Identification Laboratory, University of Florida, Gainesville, FL 32610; Michala K. Stock, PhD, High Point University, High Point, NC 27268-4260

**Learning Overview:** The goal of this presentation is to evaluate the covariance of select craniofacial features to assess integration and modularity of the facial skeleton. After attending this presentation, attendees will better understand the morphological relationships between select facial features commonly used in ancestry assessment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an understanding of the degree of craniofacial morphological covariance, identifying boundaries of correlated traits, and recognizing the implications integration and modularity may have for interpreting skeletal ancestry.

Integration and modularity describe covariation of traits and are conceptually linked. Integration refers to the coordinated joint variation of traits. When such covariation of traits is tightly correlated and internally concentrated within a region, but remains distinct and relatively independent from other traits, this is recognized as modularity. While integration and modularity of the human cranium are well acknowledged in evolutionary and morphometric studies, researching these patterns of trait interactions remains valuable as they directly affect phenotypic trait expression. Quantification of these interactions is relevant to forensic anthropologists because the form and spatial relationships of craniofacial features are commonly analyzed to estimate an unknown individual's ancestral affiliation.

Three-Dimensional (3D) coordinate data were collected from 27 identified individuals analyzed at the University of Florida C.A. Pound Human Identification Laboratory. Selection of individuals included the following criteria: (1) 3D surface scans collected using a NextEngine™ 3D Laser Scanner were available; (2) the individual's age-at-death was  $\geq 18$  years; and (3) select craniofacial landmarks were not affected/obscured by pathological conditions, trauma, or taphonomic modification. Coordinate data of 16 standard craniofacial landmarks were collected for each individual and partitioned into "upper," "middle," and "lower" non-overlapping compartments (modules) of the face. Four possible scenarios of these subdivisions were organized, each demonstrating different boundaries defining facial compartments and thus including different combinations of landmarks within compartments.

The data were analyzed in R™ using a simultaneous-fit approach, in which a generalized Procrustes fit was performed on all coordinates, followed by a series of covariance tests to assess integration and modularity ( $\alpha=0.05$ ). Two-block Partial Least Squares (PLS) analyses of the Procrustes coordinates indicated that of the four compartment scenarios, modules of the face are best compartmentalized by visceral function rather than by the mere proximity of neighboring landmarks (i.e., this scenario showed the highest degree of independence between compartments). Accordingly, skeletal landmarks on the boundaries of the orbital, nasal, and oral cavities correspond to the upper, middle, and lower compartments, respectively. Of this visceral compartmentalization scenario, pairwise PLS analyses of Procrustes coordinates between each module yielded significant results for comparisons of the orbital:nasal ( $r_{PLS}=0.78$ ) and nasal:oral ( $r_{PLS}=0.89$ ) compartments; the comparison of the orbital:oral compartments approached significance ( $r_{PLS}=0.71; p=0.06$ ). The average degree of integration between the three visceral modules was not significant ( $r_{PLS}=0.80; p=0.77$ ), suggesting that integration among these modules occurs in a chain-link pattern, with those compartments that are more closely linked spatially and developmentally showing greater magnitudes of integration. Pairwise covariance ratio tests were conducted to quantify the degree of modularity of the facial compartments and yielded insignificant results in all comparisons. These results demonstrate that despite regions of trait correlations defined by visceral functions, covariation in facial traits crosses the borders delimiting the distinct organs of special sense.

The points selected for this study, while considered standard craniofacial landmarks, correspond directly to facial features that are regularly used in assessments of skeletal ancestry. Investigating the covariation between these traits can elucidate underlying processes that produce phenotypic variation, and in this context, aid the understanding of craniofacial traits and which are biologically meaningful for ancestry assessments. In summary, this study shows that the facial skeleton can be partitioned into three modules based on visceral function that show large magnitudes of integration with one another. Importantly, this integration is not uniform throughout the face, meaning that some traits are more highly correlated with each other to the exclusion of other traits. These findings have implications for ancestry assessment, wherein methods rely on relative relationships between traits, or assessing multiple traits that this study shows to be highly integrated and are consequently not independent of one another. Therefore, this research can serve as a foundation to advance approaches to ancestry assessment.

### Trait Covariation, Geometric Morphometrics, Morphological Variation

## A18 Re-Evaluating Skeletal Ancestry Traits Using Three-Dimensional Technology

Elisabeth Cuerrier-Richer, MSc\*, Brossard, PQ J4Z 0A5, CANADA; Tracy Rogers, PhD, University of Toronto at Mississauga, Mississauga, ON L5L 1C6, CANADA

**Learning Overview:** After attending this presentation, attendees will better understand the use of Three-Dimensional (3D) technology to quantify morphological ancestry traits on the human skull.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating possible advancements in the field of forensic anthropology, more specifically the development of a new, more precise, and standardized method of ancestry assessment using modern-day technology. With regard to competence and performance, this method can contribute to making ancestry assessments less dependent on an anthropologist's experience with human variation and more accessible to younger forensic anthropologists.

According to the Royal Canadian Mounted Police (RCMP), women of Canadian Indigenous descent, previously referred to as Aboriginal, are at a higher risk of being victims of violence than other women in Canada.<sup>1</sup> As of 2015, 204 cases of missing and murdered Indigenous women remained unsolved, making it a major concern for Canadian Indigenous communities, who are still pressing for the identification of these women.<sup>2</sup> Forensic anthropology can contribute to the identification of victims by establishing a biological profile of the skeleton, including the evaluation of sex, ancestry, and age from human remains.<sup>3</sup> Ancestry assessment describes population affinity based on two criteria: morphological analyses, which examine size and shape of bone features, and metric analyses, which use skeletal measurements.<sup>4</sup> Morphological analyses are difficult to reproduce and standardize, as they strongly depend on subjective judgments by anthropologists, based on their experience with human variation.<sup>5</sup>

The purpose of this research was to improve the rigor of morphological analyses of ancestry by using 3D technology to quantify relevant features on the human skull. More specifically, circumference/perimeter, surface area, and proportion ratios were used to characterize the 3D outline of the orbits, the nasal cavity, and the palate. The sample was comprised of 24 Canadian Inuit, 50 European-American, and 13 African-American adult female crania, for a total sample size of 87 individuals. The samples were imaged using photogrammetry, the 3D models were constructed in 3DF Zephyr, and the shape analysis was performed in 3DS Max. The data were statistically analyzed using a non-Parametric Multivariate Analysis Of Variance (PERMANOVA), a Linear Discriminant Analysis (LDA), and a Principal Component Analysis (PCA). Results showed that individually, the 3D measurements were not very informative, since there was significant overlap between groups for the different traits evaluated. However, major differences between groups were clearest when 3D measurements were combined using multivariate statistics. Overall, European-Americans were statistically different from the other two groups, while Canadian Inuit and African American individuals were harder to distinguish statistically. The current method presented a classification rate of 87.36% (jackknifed: 80.46%) and an average repeatability of 97% when all measurements were combined. Nevertheless, this project had limitations and further research should evaluate the current method with a larger sample size, more populations, other ancestry-related cranial traits, such as the oval window, and other 3D measurements, such as volume.<sup>6</sup> Despite its limitations, this new and simple method of 3D shape analysis has potential and shows promise for the future of ancestry assessment via 3D imaging.

## A19 A Comparison of Two Data Collection Methods for the (hu)MANid Program on a Diverse Sample of Mandibles

Paige A. Lynch, MS\*, University of New Mexico, Albuquerque, NM 87131; Luis L. Cabo, MS, Mercyhurst University, Erie, PA 16546

**Learning Overview:** After attending this presentation, attendees will better understand the differences in performance of 3D scans versus direct measurements in the (hu)MANid program to estimate sex using the mandible.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the different sex classification results that are produced for two methods of data collection, further helping to improve validation and the usage of (hu)MANid.

The (hu)MANid program is a free, web-based software developed by Berg and Kenyhercz that uses mandibular metric and morphoscopic variables to assess sex and ancestry through Linear Discriminant Analysis (LDA) or Mixture Discriminate Analysis (MDA).<sup>1</sup> The program's reference database contains 1,745 individuals from 15 different populations (including modern, historic, and prehistoric groups). Berg and Kenyhercz report that MDA renders the highest accuracies among the analytical methods offered by the software, with pooled sex estimation accuracies as high as 83.5%.<sup>1</sup> A relative limitation of (hu)MANid program is the use of some mandibulometer measurements, due to: (1) the error rates in some of them, and (2) the cost of the instrument.<sup>2,3</sup> 3D surface scans (3D scans) may provide an alternative method for data collection. The aim of this study was comparing the (hu)MANid accuracies of 3D scans and direct measurements of a diverse sample.

Six metric and morphoscopic mandibular measurements were collected from 3D scans of mandibles from recent United States Black, United States White and Portuguese, as well as medieval Nubian and prehistoric Native American of both sexes ( $N_{total}=555$ ). The same nine metric and morphoscopic measurements (including three mandibulometer measurements) were collected by direct measurement of mandibles from modern males and females from the Maxwell Museum Donated Body Collection ( $N_{total}=59$ ). These data were run through (hu)MANid for pooled sex classification. MDA was applied due to its higher reported correct classification and its consideration of both metric and nonmetric measurements.<sup>1</sup>

For both samples, no significant differences were detected between non-stepwise and stepwise options; therefore, non-stepwise option was employed in the remaining analysis. Overall, the direct measurements rendered average correct classifications similar to those originally reported for the program (85% vs. 83.5%, respectively), while those of the digital measurements were lower (65%). Males displayed similar correct classifications for the digital (93%), direct (92%), and direct-with-mandibulometer (93%) measurements; however, they differed in positive predictive power (60%, 90%, and 87%, respectively). Females varied significantly in their correct classifications for the digital (36%), direct (55%), and direct-with-mandibulometer (36%) measurements; furthermore, they differed in positive predictive power (82%, 60%, and 67%, respectively).

For pooled sex estimations, the (hu)MANid program is better than chance, but males are more likely to classify correctly with the direct measurements than females. Despite the smaller sample size, the direct measurements had higher correct classification, but the mandibulometer measurements did not increase the overall correct classification. However, further evaluation using more variables is suggested.

## A20 Craniometric Variation and FORDISC® Misclassification in Latin American and Asian Individuals

Miriam Rangel, BS\*, University of La Verne, La Verne, CA 91750; Kanya Godde, PhD\*, La Verne, CA 91750

**Learning Overview:** After attending this presentation attendees will better understand the impact of craniometric variation on the estimation of ancestry using a unique combination of Latin American and Asian samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the limitations of estimating ancestry for Latin American individuals using craniometrics in regions with population histories derived from both Latin American and Asian populations. This presentation will also demonstrate the need to include additional samples from these populations in FORDISC®.

This study explores cranial morphology and the usage of traditional morphometric ancestry estimation software to assist in the identification of deceased individuals in a Latin American sample. Recently, the complexity of morphological variation in Latin Americans has become increasingly discussed due to the changing demographics of the United States and the challenges admixture poses on identification cases.<sup>1</sup> Although the term Hispanic is traditionally used to classify individuals of Latin American descent, this classification fails to accurately describe populations in cultural and biological contexts, and this misrepresentation extends to modern methods of ancestry estimation.<sup>2</sup> In some areas of the United States, such as California, there are long histories of residency by both Latin Americans and Asians, which necessitates an ability to distinguish ancestry between the populations for cases in which context and visual examination do not point to a particular population. FORDISC 3.1® (FD3), a discriminant function analysis-based software, has been shown to misclassify Latin Americans as other ancestries, such as Japanese.<sup>1</sup>

In this study, FD3 was run on a sample ( $N=360$ ) of Latin Americans (from the Hanihara dataset and Latin American Craniometric Database) comprised of individuals from Mexico, Colombia, Peru, Chile, Venezuela, Bolivia, and Argentina, along with individuals of Asian origins ( $N=470$ , including Japan, China, Philippines, and Java from the Hanihara dataset) to ascertain its accuracy in distinguishing between these populations. Analyses were separated by sex and include Mahalanobis  $D^2$  (a biodistance measure), Principal Coordinates Analysis (PCoA), Canonical Variates Analysis (CVA), the Neighbor-Joining (NJ) method for construction of phylogenetic trees, and  $F_{st}$ . The hypothesis tested is that FD3 will be limited in classifying Latin Americans in the presence of selected Asian reference samples.

The results of these analyses show FD3 misclassifications exceeded 50% for Latin Americans as a group, and by individual sample, which is less than chance. The PCoA, which reflects the biodistance matrix, shows similarities between Asian and Latin American populations, and large differences among Latin American populations, such as Mexico and Peru. Further, CVA shows Asian populations spread across CV 1 and CV 2 in males, while Latin American samples were primarily constricted to positive values of CV 1 and the center of CV 2. Females yield similar CVA results where Asian and Latin American populations overlap one another with little clustering by sample. NJ analyses yield results consistent with CVA.  $F_{st}$  values (males=0.1152, females=0.1287) were high in comparison to populations around the globe.

FD3 as a tool is not currently helpful in scenarios in which context and visual assessment cannot narrow potential ancestries because the selection of reference groups may include both Latin American and Asian samples. For practitioners in areas such as California with a long and rich history of American Indian, Latin American, and Asian residents, among many others, these classification percentages leave much to be desired. These results join other studies that call for the need of representative samples, which can be applied to diverse populations and facilitate the work of forensic practitioners so that victims of homicide, genocide, exposure, and suicide can be identified and returned to their families. This is particularly critical for border crossers in the United States southwestern border.

### Cranial Variation, Admixture, Misclassification

## A21 Geographic Origin Estimation of Latin American Individuals Using Craniometric Data

Kari Helgeson, MA\*, Allen, TX 75002; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will understand how geographic origin estimation in forensic anthropology can provide a finer-grained approach than ancestry identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by further exploring the biological variation found in Central America and Mexico to help improve biological profile methods for unidentified migrants.

The lack of information surrounding the term “Hispanic” creates difficulties when attempting to estimate geographic origin due to the variation encompassed by this term. Exploring the biological variation between Mexican and Guatemalan populations allows for investigation of geographic origin rather than the classification systems currently utilized in forensic anthropology. If geographic origin can be estimated based on craniometric measurements, it could potentially narrow a missing person’s list. This could also be used to help facilitate and potentially expedite the identification and repatriation of unidentified migrants. The purpose of this presentation is to use positively identified and contextually documented individuals from Mexico and Guatemala to explore the variation within and among these two geographic regions, as well as sub-regions, to provide a foundation for improving ancestry estimation. Moreover, this research attempts to address the following questions: (1) Can a reference sample of Guatemalans, used as a proxy for Central America, be distinguished from a Mexican population via cranial morphology? (2) Can sub-regions (Central, North/West, and Southeast) of Mexico and Guatemala be distinguished from each other via cranial morphology?

To answer these questions, this research utilizes individuals from four institutions, including the Pima County Office of the Medical Examiner, the Forensic Anthropology Foundation of Guatemala, Operation Identification at Texas State University, and the School of Anthropological Sciences of the Autonomous University of Yucatán, at Mérida. Together, this sample includes individuals migrating to the United States from Guatemala and Mexico and indigenous Guatemalan Mayans. Howells inter-landmark distances were collected from each cranium using a MicroScribe® digitizer and the program 3Skull.<sup>1,2</sup> A discriminant function analysis and canonical variates analysis were performed to assess the variation and classify the individuals. The Guatemalan sample can be correctly classified 75.25% of the time when compared to Mexicans, and the cross-validation rate suggests that when the three Mexican regions are compared (Central, Southeast, and North/West), they can be differentiated 77.8% of the time. The Mahalanobis Distance matrix from the regional comparison indicates the Southeast Mexico group is statistically different from the Central and North/West groups ( $p < 0.001$ ). When Guatemalan Mayan individuals are included in the Mexico regional comparison, the cross-validation rate decreased, but the Mahalanobis Distance matrix showed that the Southeast group and the Guatemalans were statistically different from all groups. With Guatemala used as a proxy for Central America, complex craniometric patterns have begun to emerge that need further exploration. These results suggest that other regions of Central America are also distinguishable from Mexico. This research indicates that even though the three regional Mexican groups can be separated, the large difference in cranial variation is between the Southeast region and the remainder of Mexico. Considering these patterns, this research indicates geographic origin estimation can be used in lieu of broad ancestry estimation in forensic casework. This could potentially eliminate broad terms such as Hispanic, which are less informative in a forensic setting, particularly when considering migrant remains.

## A22 The Impact of Error in Femur Subtrochanteric Measurements on the Assessment of Population Affinity

Briana T. New, MA\*, Defense POW/MIA Accounting Agency, Honolulu, HI 96917; Emily S. Silverman, MA, Mililani, HI 96789; Sabrina C. Ta'ala, MA, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853-5530

**Learning Overview:** After attending this presentation, attendees will understand the implications of intra- and inter-observer measurement variability on the calculation of Platymeric Index (PI) and resulting ancestry classifications. This presentation focuses on the reliability of the required measurements and the consistency of index classifications.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the effect of measurement error on a commonly utilized method for assessing population affinity from postcranial skeletal remains.

When skeletonized remains are incomplete and/or fragmentary, the PI has been identified as a possible method for population differentiation.<sup>1,2</sup> This method serves as a part of the forensic toolkit for the estimation of ancestry and is most commonly utilized when cranial elements are missing or fragmented. However, previous research on data accuracy and reliability indicates that measurements utilized to calculate the PI, the subtrochanteric Anterior-Posterior Diameter (APD), and Medial-Lateral Diameters (MLD) of the femur have greater-than-acceptable error rates.<sup>3</sup> Despite reported error rates exceeding that of the published thresholds, the measurements remain necessary for assessing population affinity in forensic casework. Thus, it is important to understand the role of intra- and inter-observer error in the data collection process and how that variability may impact method application and classification results.

In this study, three observers independently collected three rounds of APD and MLD measurements on 53 left and right femora. The femora are part of a commingled assemblage of Vietnamese males derived from a C-130 aircraft that crashed in 1974. In an effort to emphasize replicability of the measurements across time and ensure that each round was performed independently with no relation to past rounds, a minimum of one week passed between each round.

Absolute and relative Technical Errors of Measurement (TEM) were calculated to assess measurement error within and between observers. APD and MLD measurements were then utilized to calculate the PI (APD/MLD x 100). Indices were classified as platymeric, eurymeric, and stenomic following sectioning points recommended in previous studies to demonstrate the role of inter-observer measurement variability on classifications, and as a result, the potential effect in ancestry estimation application.<sup>1,2</sup> Comprehensive Kruskal-Wallis and chi-square tests of significance were conducted to determine the degree of intra- and inter-observer error throughout the analyses.

Results mirror previously reported observer errors with absolute TEM ranging from 0.50mm to 0.77mm and relative TEMs ranging from 2.10% to 3.17% for intra-observer error. Inter-observer absolute TEM ranges from 0.88mm to 1.14mm and relative ranges from 2.98% to 4.65%. Despite greater-than-acceptable error in the raw measurements, no significant differences were found between measurement rounds or index calculations. Likewise, no significant differences were observed in the classification data for each observer.

These results highlight both the reliability and validity of subtrochanteric femur measurements when applied to PI classifications. While intra- and inter-observer error remains high in the raw measurements, it is not enough to significantly alter the platymeric classification results for this dataset. Thus, the present analysis argues that variation in how the PI of individuals or groups classify is not likely a result of measurement error, but rather a reflection of method application and the specific groups included in the given analyses.

### Platymeric Index, Subtrochanteric Measurements, Data Validation

## A23 Odontometric Variation of Male Skeletal Samples From the United States and South Africa

Dori E. Kenessey, BA\*, University of Nevada, Reno, Reno, NV 89557; Tatiana Vlemincq-Mendieta, MS, University of Nevada, Reno, Reno, NV 89557; G. Richard Scott, PhD, University of Nevada, Reno, Reno, NV 89557-0002; Marin A. Pilloud, PhD, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will better understand population variation in tooth size and how odontometrics can be used as part of the biological profile.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting tooth size variation across continents and its relevance to forensic anthropology.

The utility of dental crown measurements in the estimation of ancestry has proven to be a promising approach.<sup>1</sup> However, more work is needed to explore global modern human variation in terms of tooth size to better understand secular change and the role of evolutionary forces (i.e., gene flow and drift). To address this deficiency in knowledge, this study compares odontometric data from modern skeletal collections representing self-identified Black and White individuals in the United States and South Africa.

The South African samples were obtained from three collections: the University of Pretoria, the Raymond A. Dart collection, and the Kristen collection. Dental data from the United States were collected from the Bass Collection at the University of Tennessee, Knoxville, and the donated collection at Texas State University, San Marcos. Only individuals with known sex and ancestry were included; due to sample size constraints, only male individuals were included in this study ( $n=397$ ). Maximum crown dimensions and cervical crown dimensions were collected following Hillson et al.<sup>2</sup> Dental measurements were collected from the left side of the arcade using digital dental calipers. In cases of missing or damaged teeth, the right antimere was substituted. Population differences were explored using a Kruskal-Wallis test in the R statistical computing environment.

Dental measurements between South African Blacks and American Blacks differed significantly in nearly every maximum crown dimension. Differences in mesiodistal crown measurements were most pronounced, being present in all teeth except the upper and lower lateral incisors. Differences were less pronounced in measurements of the crown at the cervico-enamel junction. Overall, American Black dental dimensions were greater than those of South African Blacks. When comparing South African and American Whites, only two significant differences were present: in the buccolingual cervical measurement of the lower second molar (larger in American Whites) and in the mesiodistal cervical measurement of lower third molar (larger in South African Whites).

The results of this study suggest that American and South African Blacks differ considerably in their dental dimensions. These findings are consistent with the notion that American Blacks have been subject to considerable gene flow and may stem from a different source population in west Africa. These results are further in line with the finding that there is generally greater diversity within the African continent than the rest of the world. Conversely, the South African and United States White samples do not greatly differ and have on average smaller teeth, suggesting greater population affinity between these groups and less change over time. The impact of evolutionary forces and secular change on tooth size should be further explored and considered in ancestry estimation methods, particularly in the development of appropriate reference samples.

### Ancestry, Gene Flow, Tooth Size

## A24 Influence of Ancestry on Sexual Dimorphism in the Human Mandibular Canine

Brittney L. Blevins, MA\*, Lexington, KY 40504

**Learning Overview:** After attending this presentation, attendees will gain a better understanding of the ancestral differences in sexual dimorphism observed in measurements taken from human mandibular canines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternative method to estimate sex in skeletonized individuals.

Sexual dimorphism can be quantified using human mandibular canines, which allows these teeth to be used to estimate sex of skeletonized individuals. This study complements and expands on previous research by using the Mesiodistal Diameter (MD) and Buccolingual Diameter (BL) of human mandibular canines to assess sexual dimorphism between three ancestry groups. Measurements were taken from a sample of skeletal individuals from the Terry Collection ( $n=651$ ), the Maxwell Museum of Anthropology Skeletal Collection ( $n=61$ ), and a random sample of dental casts from the James K. Economides Orthodontic Case File (JKE) ( $n=599$ ), for a total of 641 males and 597 females. Three ancestral categories were used: American Black, White, and Hispanic. A total of 50 individuals of each ancestry were randomly selected for all reported statistical analyses.

Previous research using this data set has reported a significant difference between males and females for left and right BL measurements ( $p<0.0001$ ), indicating that males have significantly larger BL measurements of the mandibular canine than females from the study sample.<sup>1</sup> However, when individuals are separated by ancestry group (as recorded by each collection) only American Black individuals show significant levels of sexual dimorphism for the MD measurement ( $p=0.0012$ ) and BL measurement ( $p<0.0001$ ). Although race is a socially constructed concept, not a biological reality, there is a history of segregation between various groups of individuals that might explain the difference in the presence of sexual dimorphism shown between individuals of different ancestries. This study is consistent with other research in finding odontometric differences between different ancestral groups.<sup>2-4</sup> Since significant differences between males and females was only observed in American Black individuals, logistic regression equations were not created for other ancestral groups. Logistic regression equations were created to estimate sex based on measurements from either the left or right mandibular canine. These equations correctly estimated the sex of individuals in up to 73.33% of cases when using only the BL diameter measurement. Accuracy of the equations varies depending on whether the measurements are used individually (BL or MD) or combined (both BL and MD). Equations more accurately estimate the sex of male individuals than female individuals. This method may be useful for estimating the sex of skeletal individuals in forensic cases when traditional methods are not applicable but could only be used for cases whose ancestries have been estimated to be American Black. Future research will further explore the impact of secular change on sexual dimorphism and ancestral differences in the mandibular canines.

*This research was funded in part by a Robert C. West Graduate Student Field Research Award from the Department of Geography and Anthropology at Louisiana State University.*

### Odontometrics, Sexual Dimorphism, Ancestry

## A25 Human Trafficking: A Challenging Case of Age Assessment

Greta Cena, MD\*, University of Torino, Torino 10126, ITALY; Caterina Bosco, MD, Department of Public Health and Pediatrics, Torino 10126, ITALY; Luana Bonaccorso, MD\*, University of Turin, Turin 10126, ITALY; Davide Santovito, MD, Department of Public Health and Pediatric Sciences, Turin 10126, ITALY; Sara S. Racalbutto, PsyD, Dipartimento di Pediatria d'Emergenza, A.O.U. Ci, Turin, ITALY; Elena Coppo, MD, Department of Pediatric Emergency, Turin, Metropolitan City of Turin, ITALY; Giancarlo Di Vella, MD, PhD\*, University of Torino, Department of Public Health Sciences, Torino 10126, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the importance of careful clinical examination to uncover anomalies that could influence bone growth or dental maturation when the assessment of biological age is required.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enlightening the need of a multidisciplinary approach to age estimation. When a Victim of Human Trafficking (VHT) has to be evaluated, psychological maturity and physical appearance must be considered.

There are approximately 800,000 people trafficked across international borders annually. Due to its geographical position, Italy is one of the main countries of destination for human trafficking via the Central Mediterranean route.<sup>1</sup> According to recent estimates, the number of VHTs who arrived in Italy by sea for sexual exploitation has increased by 600% in the past three years. Nigerian girls aged between 16 and 17 are the most affected by this phenomenon, accounting for more than 90% of all victims.<sup>2</sup> The number of applications for forensic age assessment in undocumented VHTs drastically increased in the last period because of the prevalent involvement of minors close to 18 years of age. In Italy, the proof of being over or under the age limit of 18 years is required for legal decisions about procedural privileges and social benefits.<sup>3</sup>

A multidisciplinary evaluation, including a clinical, radiological, dental, pediatric, and psychosocial assessment, is recommended.<sup>4</sup> However, sometimes a discrepancy between physical and psychological maturity estimations occurs. In these cases, a comprehensive clinical examination is fundamental to disclose signs suggestive of conditions capable of interfering with the maturation rate of the individual.<sup>5</sup>

This presentation reports a challenging case of multidisciplinary age estimation of a six-month-pregnant VHT, who had been trafficked from Nigeria and sexually exploited in Italy. She claimed to be 20 years of age, but no identification document was provided.

The cognitive development resulting from the psychosocial assessment corresponded to a maturity degree consistent with adulthood, even considering the traumatic events she suffered. Skeletal radiology was not feasible due to the advanced stage of pregnancy. The absence of erupted lower third molars and their immaturity at Orthopantomogram (OPG), performed before the pregnancy, pointed to a minor age. A closer examination of the OPG images showed unusual alterations of mandibular trabecular bone and changes of tooth shape and size, particularly at the pre/molar level. Thus, further investigations were performed. Anemia with increased Red blood cell Distribution Width (RDW) and qualitatively abnormal Hemoglobin (Hb) were found. The diagnosis of Sickle Cell Trait (SCT) was reached through electrophoresis and genetic testing. SCT is a benign form of hemoglobinopathy with heterozygous inheritance affecting up to the 20%–30% of the Nigerian population. The homozygous form is known to cause impaired growth and a delay in teeth development.<sup>6</sup> Although individuals with SCT are normally asymptomatic, recent studies have demonstrated significant higher frequencies of radiological dental and bone changes, including hypercementosis of the roots, changes in tooth shape and size, and stepladder-pattern bone alteration.<sup>7</sup> In this case, OPG findings were consistent with these modifications rarely described in literature. The hematologic disease could cause a delay in teeth eruption and mineralization, leading to an underestimation of chronological age. Based on these findings, the age reported by the girl was deemed reasonable.

This presentation stresses the importance of including a careful clinical examination in age estimations to avoid ethically unacceptable mistakes. Physicians should be aware that some diseases can interfere with physical development; most of these conditions lead to growth delay, causing an underestimation of age.<sup>5</sup> Since, in Italy, being less than 18 years old ensures benefits from a wide range of protection measures, such underestimation would not disadvantage the person concerned. However, the main purpose of age assessment is to re-establish the identity of a VHT. Therefore, it is important to exclude these particular medical conditions to ensure an appropriate, reliable, and genuine social integration, consistent with the physical and psychological maturity degree of the VHT.

## A26 Age-Old Problems: Using the Pars Basilaris to Estimate Age-At-Death in Non-Adult Individuals

Claire M. Hodson, PhD\*, Highworth, Wiltshire SN6 7EU, UNITED KINGDOM; Rebecca Gowland, PhD, Durham University, Durham, County Durham DH1 3LE, UNITED KINGDOM

**Learning Overview:** Estimating the age at death of an individual is important within numerous anthropological, forensic, and archaeological disciplines to establish a biological profile. The pars basilaris has long been used and purported as a bone that can determine accurate age-at-death estimates for non-adult individuals. However, little is documented about why this bone should be used or the benefits of the age estimates generated from these metrics over other bones of the skeleton. Importantly, this study demonstrates to attendees how the biology of the growth and development of this bone makes the pars basilaris vital in generating accurate age-at-death estimates. Furthermore, it also establishes that the pars basilaris is more consistent with both chronological and dental age estimates than any age estimates generated by the long-bones. The goal of this presentation is to encourage practitioners to place greater value in estimating age from the pars basilaris than any other skeletal element.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the current limitations of using metric assessment of skeletal remains to estimate age. As a consequence, it will be demonstrated to attendees why and how using the pars basilaris has been found to be the most reliable skeletal element to assess to date. This is intended to influence current practitioners, encouraging them to consider age estimates derived from the pars basilaris with increased value.

The study of the growth and development of non-adults provides key insights into the age of the individual at death. Today, studies of non-adults have primarily focused on generating age-at-death estimates from dental development as this is known to be a reliable proxy for chronological age. However, the dentition is not always available, particularly in perinatal or infant skeletal remains, as the developing tooth buds and cusps are often lost or not recovered due to the larger tooth crypts. In the absence of the dentition, long-bone diaphyseal lengths are most commonly used to estimate age. This is problematic given the degree of genetic variability in diaphyseal length and because growth is strongly affected by adverse circumstances, such as malnutrition, resulting in large inaccuracies when used for estimating age at death.

Measurement of the pars basilaris has long been used to determine accurate age-at-death estimates for individuals less than 6 years of age as this is when it commences fusion to the pars lateralis of the occipital bone. However, little is documented about why the pars basilaris should be used or the benefits of the age estimates generated from these metrics. This study determined age estimates from metric assessment of the pars basilaris for individuals from both archaeological and historical collections where either chronological age is known ( $N=50$ ) or age estimates based on dental development are possible ( $N=173$ ) to test the accuracy of the pars basilaris in generating ages at death. Findings from this study support the conclusion that the pars basilaris is more closely correlated with chronological age than diaphyseal length because it is less susceptible to growth delay as a consequence of environmental adversity.

This study proposes that the pars basilaris is much more stable in its growth, providing more accurate and reliable age-at-death estimates for all individuals, regardless of their stress exposure and/or their disease/health status. Consequently, this presentation demonstrates the usefulness of the pars basilaris in estimating ages at death of non-adult individuals, particularly in lieu of the dentition being present, and encourages practitioners to use this element more widely within skeletal analyses.

### Aging, Juvenile, Infant

## A27 Why Cranial Sutures Should be Included in Adult Age-At-Death Estimates

Jessica L. Campbell, PhD\*, SNA International, Alexandria, VA 22314; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN 46227-3697

**Learning Overview:** After attending this presentation, attendees will better understand how cranial suture fusion counterbalances the age-at-death estimate when combined with more reliable and commonly used adult age-at-death indicators.

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community's ability to estimate age at death more accurately and precisely by minimizing overall mean error with the application of non-destructive and familiar macroscopic methods.

Cranial sutures are perhaps the least popular macroscopic age indicator for the human skeleton. With very few advocates, most scholars and practitioners only use cranial suture fusion when there are limited options to estimate age at death, and it is normally advised to use suture fusion with at minimum a second, more reliable indicator. Regardless of their vilification, cranial sutures do provide age-related information. They also persevere in research and practice because they are necessary in the event that other age indicators are absent or too damaged to provide reliable age estimates.

Research on the cranial sutures to date has focused on testing established methods or on evaluating which suture sites provide the most reliable information. However, most prior publications fail to place cranial sutures within the broader framework of age estimation or investigate how they perform when used with other well-known and relatively accurate and precise methods. The primary objective of the current research, therefore, is to determine how the inclusion of cranial sutures with other age-estimation methods can influence the final composite age-at-death estimate. Since there are multiple statistical strategies for combining multiple age-estimation methods, this research also tests whether the mode of statistical combination alters the outcome of the primary objective.

Data were collected from the Bass Donated Collection in Tennessee ( $n=120$ ) and the University of Pretoria Bone Collection in South Africa ( $n=132$ ), for a total sample size of  $n=252$  females and males of White and Black ancestries. Nawrocki's cranial suture fusion method, which scores ectocranial, endocranial, lateral, and palatal sutures was used to score all crania. The Suchey-Brooks Pubic Symphysis (PS), Osborne et al. Auricular Surface (AS), and İşcan et al. sternal rib end (Ribs) methods were selected because they are non-destructive and regularly used to estimate age. Each skeleton was scored blind using all four methods. Target age estimates and 95% prediction intervals were obtained for all individuals using published tables and equations; a summary age was calculated by averaging the target age estimates to allow comparisons. Mean measures of error (including bias and inaccuracy) were used to evaluate whether there was improvement in the age-at-death estimation when cranial sutures were incorporated. The final step evaluated alternate statistical strategies for consolidating individual target ages into a single summary age.

Mean absolute error (inaccuracy) was lowest when the cranial sutures were combined with the pubic symphysis, auricular surface, and sternal rib ends. When all four methods were averaged together, the mean absolute error was 12.1 years and the bias dropped to a low of -5.4 years. When the cranial sutures were excluded, mean absolute error increased to 14.4 years, with a bias of -11.2 years. The inclusion of cranial sutures in the consolidated age estimate was statistically significant for both inaccuracy and bias. These results were consistent when the data were grouped by binary sex and when the data were combined using alternate statistical strategies.

The positive influence cranial suture fusion had on the PS, AS, and Ribs can be explained by the fact that the sutures were the only independent indicator to return a positive bias in the total sample. In addition, the sutures returned the lowest inaccuracy and bias in the older decades of all the methods used in this study. These results indicate the cranial sutures act as a counterweight to help balance the expected tendency of the PS, AS, and Ribs to regress to the mean. To illustrate the implications of this finding, a bias level set to within +/-10 years allowed age to be predicted from approximately 42–70 years when sutures were included, as opposed to approximately 25–59 years when sutures were excluded.

As a result of this study, it is recommended that cranial suture fusion be included with the PS, AS, and Ribs when estimating the age of individuals that may be older than 40 years.

### Cranial Sutures, Age-At-Death, Multifactorial

## A28 A Comparison of Two Dental Age Estimation Methods Using Transition Analysis (TA)

Kelly R. Kamnikar, MA\*, Michigan State University, East Lansing, MI 48824; Amber M. Plemons, MA, Michigan State University, Anthropology, East Lansing, MI 48824; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX 78666; Jennifer E. Spence, PhD, Texas State University, San Marcos, TX 78666; Yann Heuzé, PhD, Université de Bordeaux, Bordeaux 33076, FRANCE; Joseph T. Hefner, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will be familiar with a revised application of TA for age estimation in subadults. The goal of this study is to validate the application of this method on a new populational dataset using a French dental radiographic sample ( $n=1,380$ ). This study is part of a larger project examining subadult dental age estimation using TA.

**Impact on the Forensic Science Community:** This study will impact the forensic science community through evaluation of the performance of TA analysis on dental age estimation, using original and revised reference frameworks. The evaluation of the performance of TA on this sample illustrates the complexities of subadult dental age estimation.

The dataset comprises panoramic dental radiographs from the University of Bordeaux.<sup>1</sup> Individuals are from southern France (336 females; 639 males) with ages ranging from 1 to 16 years. Radiographs were obtained from public orthodontist offices and private hospitals, representing a range of variation in socioeconomic status. The data excludes any pathological or anomalies in tooth numbers.

The sample was scored following the Demirjian et al. (DGT) method in which eight mandibular teeth are assigned a value from A to H, corresponding to crown and root development.<sup>2</sup> These scores were converted to the Moorrees et al. (MFH) scoring stages (1–14) following Phillips' conversion chart.<sup>3,4</sup> This system correlated DGT and MFH stages by aligning original definitions for each stage. DGT scores that fell between two MFH stages were compared using both MFH stages (rounding up or rounding down).

The MFH dental development scores were analyzed following the TA method for age estimation based on dental development by Shackelford and colleagues.<sup>5</sup> The data were run again through a revised method, which adapted the Shackelford et al. framework to modern reference sample data.<sup>6</sup> Here, maximum likelihood age estimates and Confidence Intervals (CI) at the 50% and 90% were compared with known age.

CIs were calculated for only 1,351 individuals due to instances of single tooth observations. When rounding scores up to the nearest MFH stage, coverage for the original method was 53.89% at the 50% CI and 90.16% at the 90% CI, while the same scores in the revised method performed at 30.87% and 72.17%, respectively. When rounding down, the original method underperformed at the 50% CI (44.90%) and the 90% CI (84.68%); however, the revised method performed better at 43.30% and 79.79%.

These results suggest that the original MFH transitions, especially when rounding up a stage, are outperforming the revised method for the Bordeaux sample. When compared to an earlier study, the original TA method underestimated age by up to three years on a test sample from the United States, while the modified sample reflected more accurate estimations. The revised method was developed on a geographically diverse sample and was assumed to perform better than the original MFH reference sample. The poor coverages may be due to the direct conversion of the DGT scores, or a lack of appropriate reference data in the revised method sample. Future work will focus on re-scoring the entire Bordeaux sample directly into the MFH system and reexamining CI coverages.

### Dental Development, Age Estimation, Biological Profile

### A29 The Ability to Obtain Full DNA Profiles From Nail Clippings After Long-Term Storage at Room Temperature Could Impact the Process of Human Identification

Jonah W.P. Stone, BS\*, Indianapolis, IN 46241; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Cynthia Cale, MS, Houston Forensic Science Center, Houston, TX 77002; Stephen P. Nawrocki, PhD, University of Indianapolis, Indianapolis, IN 46227-3697; Gay L. Bush, PhD, Strand Diagnostics, Indianapolis, IN 46241

**Learning Overview:** After attending this presentation, attendees will better understand how nail material obtained from both living and deceased individuals can provide informative DNA profiles following storage at room temperature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to a growing body of knowledge regarding the use of alternative and often neglected sources of DNA profiles utilized for positive personal identification.

Saliva and blood are commonly used in the medicolegal system to produce DNA profiles; however, these bodily fluids are no longer an option for decomposed or skeletonized human remains and must be stored in a refrigerator or freezer until the DNA purification process can take place. Bone can be utilized as a source of DNA without cold storage but, depending on the size of the skeletal element being held, can require a great deal of secure storage space. Additionally, the DNA extraction and purification processes destroy the hard tissue of the bone, which may be needed for subsequent forensic anthropological analysis. Nail clippings, if present, can serve as the source of a DNA profile when soft tissues are not present and when the bone is needed for additional forensic analysis.

Toenails collected from six deceased and ten living individuals were used to test the following null hypotheses: (1)  $H_{n1}$ —there is no relationship between DNA quantity from human nails and time stored; (2)  $H_{n2}$ —there is no relationship between DNA quality from human nails and time stored; and (3)  $H_{n3}$ —there is no difference in DNA quantity and quality between nails taken from living and deceased individuals.

DNA was extracted from the nails using the QIAGEN® QIAamp® DNA Mini Kit with modifications to the manufacturer's instructions to allow for an extended dissolution process. The samples were quantified using Quantifiler® Trio on an Applied Biosystems® 7500 Real-Time PCR System, amplified with the GlobalFiler™ PCR Amplification Kit, and analyzed on an AB SCIEX™ 3130xl genetic analyzer. The nails collected from living individuals were sampled for extraction three times during the two-year time period: after 1 month, 14 months, and 24 months of storage. The nails collected from deceased individuals were sampled for extraction at the beginning and end of ten months of storage.

This study failed to reject all three null hypotheses. Although the means for DNA quantity decrease over time, repeated measures of Analysis of Variance (ANOVA) indicates that these decreases are not statistically significant for either living or deceased individuals. All samples obtained from both groups produced full, single-source DNA profiles at each time of analysis. The samples obtained from living individuals were compared to reference profiles obtained from buccal swabs. All profiles remained consistent with the references at each time of analysis. Thus, there was no recognizable relationship between DNA quality and time stored. There was not a statistically significant difference ( $p < 0.05$ ) between the quantity of DNA obtained from the nails of living or deceased individuals. All samples produced full DNA profiles at each time variable. Therefore, there is no significant difference between the ability to generate a full DNA profile from nails taken from living versus deceased individuals.

These results indicate that nail clippings can be utilized for DNA analysis and serve as a viable alternative to more readily used tissues, such as blood and bone. However, the sample sizes were small, so this study should be considered a pilot study only. The use of these keratinized cells for genetic analyses could impact the way biological material is archived for identification purposes by: (1) reducing the need for cold storage, (2) decreasing the amount of necessary secure storage space, and (3) preserving the skeletal material for forensic anthropological analyses.

#### DNA Analysis, DNA Identification, Toenail Clippings

## A30 The Applicability of Intralimb Indices in the Subadult Biological Profile

*Elaine Y. Chu, MA\*, University of Nevada, Reno, Reno, NV 89557; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV 89557*

**Learning Overview:** After attending this presentation, attendees will understand how differences in skeletal growth through the lens of brachial and crural indices can assist in estimating aspects of the biological profile for subadult skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new perspective for estimating sex, age, and ancestry at country and subpopulation levels.

Body proportions are often used in areas of biological anthropology that explore modern human origins and human variation. Brachial and crural indices, comparisons of the upper and lower segments of the upper and lower limbs, respectively, have primarily been used to assess latitudinal differences in body size following Allen's and Bergmann's rules. The utility of intra-limb indices have yet to be explored as a tool for forensic skeletal estimation, especially in situations in which limited skeletal elements are recovered. The proximate aim of this study is to explore whether brachial and crural indices can be used to develop methods to estimate age, sex, and ancestry in subadults to facilitate positive identification. The ultimate aim of this study is to quantify the ontogenetic appearance of proportions; currently, all studies have looked at subadults as a homogeneous group rather than a heterogeneous group that experiences an exorbitant amount of skeletal change.

Diaphyseal dimensions were collected from roughly 900 contemporary children between the ages of birth to 20 years from the United States and South Africa. Brachial and crural indices were subsequently calculated using diaphyseal dimensions. Children were represented by four different ancestry groups with largely comparable age distributions: American Indian, Hispanic, White, and Black. Individuals were classified into one of four life history stages: Infant (birth to 3 years), Child (3 to 7 years), Juvenile (7 to 12 years), or Adolescent (12 to 16 years). Long bone lengths were also collected on individuals between 16 and 20 years of age to represent an older sample that is comparable to adults. Kruskal-Wallis tests were conducted to test for differences among mean brachial and crural indices by sex, life history stage, ancestry, and country. When showing statistical significance, a post-hoc Dunn's test was used for pairwise comparisons for a more in-depth analysis. Subsequently, Linear Discriminant Analysis (LDA) was then performed; the sample size was large enough that a training sample with k-fold cross-validation was used to create classification models for each area of the biological profile, then a test sample was used to generate realistic accuracy rates.

Results of the Kruskal-Wallis test revealed statistically significant differences between mean brachial and crural indices based on the life history stage, ancestry, and country. The LDA models produced accuracy rates ranging from 40%–90%, with brachial and crural indices showing the highest prediction accuracy for country, even in the younger ages, and population having the lowest accuracies.

Results demonstrate that proportional differences exist at a country level in early ages and this is in accordance with previous studies that use interlimb indices to evaluate Allen's and Bergmann's rules. While not all accuracy rates are at practically applicable levels, increased sample sizes and more uniform distribution of sub-groups may increase accuracy rates in future analyses. This study provides evidence for the importance of exploring the utility of methods for measuring body size variation that is not commonly used in forensic anthropology.

---

### A31 The Application of Non-Destructive Dental Age Estimation (DAE) Methods Using Root Translucency on Latin American Hispanics

Melinda V. Rogers, BS\*, Texas State University, San Marcos, TX 78666; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX 78666; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666; James P. Fancher, DDS, PhD, Forensic Anthropology Center Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will recognize DAE methods based on root translucency are efficiently accurate age estimating methods in that they are non-destructive and require minimal training or equipment. Attendees will be aware of current events, such as the humanitarian crisis along the United States' southern border, and be inspired to use their anthropological skills to make an impact and change locally and globally.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to underutilized aging techniques that apply to a commonly used skeletal element: dentition. Additionally, this presentation will demonstrate the versatility and applicability of said methods to the underresearched Central American Hispanic population. The age data generated from this research for an unidentified migrant population will be available for future investigations.

A humanitarian crisis is occurring along the United States-Mexico border as the number of apprehended and deceased migrants increases. Rarely are any forms of identification found with the migrant remains. Operation Identification (OpID) is a humanitarian effort created to improve the identification and repatriation process of deceased migrants by means of forensic anthropological methods. Very few of these methods have been validated on a Central American Hispanic population.

The purpose of this presentation is to explore the application of four non-destructive DAE methods proposed by Bang and Ramm, Lamendin et al., González-Colmenares et al., and Ubelaker and Parra on a representative adult Central American Hispanic population to aid this effort.<sup>1-4</sup> Age was estimated for 40 OpID forensic cases and Mean Absolute Error (MAE) for each method was compared. The methods performed from most to least accurate as follows: Lamendin, González-Colmenares, Ubelaker and Parra, and Bang and Ramm.<sup>1-4</sup> The age cohort comparisons followed similar patterns to previously reported findings where accuracy increased with the older age groups. DAE methods were the least accurate when compared to macroscopic and histological age estimation methods. Lamendin's method produces the most accurate age-at-death estimates; therefore, it is a recommended method for OpID forensic cases. Individuals aged 40–49 years of age are represented among the OpID forensic cases, making said DAE methods applicable for these individuals. Although individuals younger than 40 years of age are often overestimated, this research demonstrates that the age range based on MAE included the known ages for all identified individuals ( $n=10$ ). This suggests root translucency DAE methods are also applicable to the younger OpID cases.

In conclusion, the non-destructive DAE methods are informative when used to identify deceased individuals of Central American geographic origin.

## A32 Reevaluating the Use of Percentage of Bone for Histological Age Estimations

Mariah E. Moe, MA\*, New Braunfels, TX 78130; Timothy P. Gocha, PhD, Forensic Anthropology Center, San Marcos, TX 78666-4684

**Learning Overview:** After attending this presentation, attendees will understand the potential for using the percentage of non-remodeled bone tissue in the histological analysis of cortical bone for the estimation of age at death from human skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the use of non-remodeled bone allows for easier training of histological methods and provides a more time-efficient means for age estimation when compared to the more commonly used histological measures such as Osteon Population Density (OPD). In addition, this presentation will show how ArcGIS® software can be used to maintain accuracy and precision of data collection while allowing for ease of access for future analyses. Finally, this presentation will highlight the benefits of histology as an objective and highly sensitive tool that can be used in cases in which other macroscopic methods have failed or are unavailable.

Traditional macroscopic methods for estimating age at death from human skeletal remains can be highly accurate when applied to younger decedents but are notoriously inadequate when aging individuals over the age of 50 years. Primary, or non-remodeled, bone is produced during normal growth and development. Throughout life, individuals undergo the lifelong process of remodeling wherein primary bone is replaced with microstructures known as secondary osteons. As individuals age, the amount of primary bone tends to decrease as the number of osteons increases. Skeletal histology as a means for age estimation has the potential to overcome the challenges encountered with macroscopic methods and more accurately estimate age in older individuals.

This study quantified the percentage of primary bone from the anterior femoral midshaft of 30 modern cadaveric samples (15 males and 15 females) ranging in age from 21 to 97 years. All femora were digitally subdivided circumferentially into octants, and radially into periosteal, middle, and endosteal thirds. Specifically, the periosteal third of the anterior octant was examined, and the percentage of non-remodeled bone was evaluated using static images and direct microscopic observation in linearly polarized light as well as brightfield illumination. Quantification of the non-remodeled bone was accomplished using Geographic Information Systems (GIS) software, specifically the polygon feature tool within the ArcMap® interface of ArcGIS®. Polarized light assisted with the quantification of the primary bone in that it highlighted the parallel structure of this bone, clearly delineating it from the more concentric remodeled bone tissue. Often, a reversal line (the defining feature separating the secondary osteons and fragments from the surrounding primary bone) could be better visualized with fine adjustments of the slide using brightfield microscopy.

All statistics were performed using SPSS version 24 and/or 25. Independent samples *t*-tests demonstrated no significant differences between males and females based on age distribution. Normality of the data was evaluated using a Shapiro-Wilk test due to small sample size ( $n=15$ ) based on sex, where percentage of bone was the dependent variable and sex was the independent variable. The Shapiro-Wilk test revealed that the data were not normally distributed between the sexes nor with the sexes combined. The data were then transformed using the square root function in SPSS. Another Shapiro-Wilk test was performed and, as the test showed the transformed data to be normally distributed with maintenance of normality in the combined sex evaluations, all further analyses were conducted on the transformed percentage values with the sexes combined.

The data showed a statistically significant inverse relationship between percentage of non-remodeled (primary) bone and age at death. Regression analysis showed a linear relationship between the variables in the anterior, periosteal octant, accounting for 76% of the variability in age with a standard error of  $\pm 11.1$  years.

These results were compared to previous research conducted by Maat et al. that investigated a smaller Region Of Interest (ROI) and showed that increasing ROI size significantly improves its predictive power.<sup>1</sup> These results were also compared to the most widely utilized histological predictor of age, Osteon Population Density (OPD). Linear regression analysis of OPD data previously obtained by Gocha revealed a strong correlation between OPD and age, explaining 83% of the variability in age with a standard error of  $\pm 9.2$  years.<sup>2</sup> Quantification of the percentage of non-remodeled bone, however, requires less time and less training to implement than evaluating OPD and may be an adequate first step in histological analysis of age at death.

### Histology, Age Estimation, Non-Remodeled Bone

### A33 An Overview of the Camp Fire and Wildfire Situation in the West

*Colleen F. Milligan, PhD\*, California State University, Chico, Chico, CA 95929-0400; Ashley E. Kendell, PhD, California State University, Chico, Chico, CA 95929-0400; Alison Galloway, PhD, University of California, Santa Cruz, CA 95064*

**Learning Overview:** After attending this presentation, attendees will understand the scale and scope of the wildfire situation in the western United States and the critical need for planning for such future large-scale disasters.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of the preparation needed to access appropriate personnel, train teams in the identification of badly burned human remains, and establish support structures that facilitate the work on wildfire victims.

California, along with many western states in the United States, has experienced climatic changes with higher summer temperatures, a prolonged season without rain and, recently, winter rains that facilitated plant growth, thereby increasing the fuel load. These changes have been accompanied by increasing development of housing in once rural areas, often moving into heavily forested or wooded areas with limited access. These environmental and human factors have combined to produce conditions where wildfires can spread rapidly and have a fatal impact.

In recent years, California has seen a dramatic increase in wildfire deaths along with the acreage consumed. For example, in 2010 there were 17 wildfires over 1,000 acres in the state but no fatalities. In contrast, in 2017 there were 61 such fires and 34 deaths, and in 2018 there were 58 fires and 100 fatalities. Of the 20 largest wildfires on record in California, 15 have occurred since 2000. Likewise, 15 of the 20 most destructive fires (in terms of fatalities and structures destroyed) have also occurred since 2000. In the past, first responders were often those who died, but, increasingly, fires are sweeping through residential areas with little or no time to mount evacuations. The bulk of those dying have been trapped in houses or vehicles.

The Camp Fire, which started during a period of high winds in the early morning of November 8, 2018, epitomizes the problems. The fire swept through the small communities of Concow and Magalia but also demolished much of the city of Paradise. Limited egress trapped people in cars while the high number of elderly and/or disabled residents meant many were unable to flee. Those who could escape often did so with few possessions and limited means of communication, prompting frantic calls to the sheriff's office regarding missing relatives. In the aftermath, Butte County was faced with a huge number of "missing" and an unknown number of deceased in an area of more than 150,000 acres where downed power lines, ongoing fires, and poor communication systems were the norm.

As the frequency of fire deaths has increased, anthropologists, led by California State University (CSU) Chico, pathologists, odontologists, and other forensic scientists have developed strategies for search, recovery, and identification efforts that have proven to be effective and efficient. These approaches came into play with the Camp Fire and enabled systematic recovery and identification. Strategies balance the different contributions that members of the search and recovery teams bring along with the post-recovery analysis and identification. From this experience, lessons learned as well as potential pitfalls highlight the need for preparation, collaboration, coordination, delegation, and focus.

#### **Camp Fire, Wildfire Responses, Mass Fatality**

### A34 Butte County's Response to the 2018 California Camp Fire

Jennifer Celentano\*, Butte County Sheriff's Office, Oroville, CA 95965

**Learning Overview:** After attending this presentation, attendees will understand how the Butte County Sheriff's Office responded to the Camp Fire, now the deadliest wildfire in California history. This presentation provides information on the response operations of the Butte County Sheriff's Office.

**Impact on the Forensic Science Community:** The Camp Fire was the second of two back-to-back disasters in Butte County within 18 months. The first disaster took place in February of 2017 when the Oroville Dam Spillway failed. Knowledge gained from the spillway incident was subsequently applied when Butte County responded to the Camp Fire. This presentation discusses the lessons learned after responding to two mass disaster situations, but will primarily focus on the recovery efforts initiated in response to the Camp Fire, especially how Butte County navigated the ever-changing landscape of disaster response and the flexibility needed to adapt to unpredictable challenges.

The Northern California Camp Fire started around 6:15 a.m. on November 8, 2018, in a remote area of Butte County near the small community of Pulga in the Sierra Nevada foothills. From its origin, the fire was driven northwest by intense winds (up to 55mph). Jumping from ridge to ridge, it was estimated that the fire consumed approximately 80 acres per minute. The fire quickly pushed through the community of Concow. At 7:45 a.m., a spot fire was reported in eastern Paradise. By 8:45 a.m., the fire had progressed halfway through the town of Paradise and by noon, the California Department of Forestry and Fire Protection (CAL FIRE) had issued an order for fire resources to begin pushing cars off the roads to unblock escape routes. The fire continued to aggressively burn toward the surrounding communities of Oroville and Chico. At 9:08 p.m., fire personnel retreated out of Honey Run Canyon reporting that they "lost everything." In all, the communities of Concow, Paradise, Magalia, and Butte Creek Canyon were destroyed in less than 12 hours. Despite the danger and potential loss of life, Butte County first responders succeeded in evacuating 52,000 residents from the area.

Following the Camp Fire, a number of communication challenges arose. Dispatch centers became inundated with phone calls from people needing help or looking for loved ones. Coroner units were forced to use cell phones to communicate, but the fire had destroyed many cell phone towers, leading to widespread areas without cellular reception. Teams attempted to limit radio traffic to reduce the spread of information to the media.

As the magnitude of the incident became apparent, and the fatality count continued to rise, assistance was requested from throughout the state and neighboring states. Fifty-five of the 58 counties in California sent personnel to assist in recovery efforts. Search and Rescue (SAR) teams arrived from Oregon, Nevada, Texas, and Ohio. During the peak of the operation from November 9 to November 25, the daily personnel included 200 law enforcement officers, 500 SAR volunteers, 50 personnel assigned to SAR Overhead teams, 300 fire urban SAR personnel, 300 National Guard search personnel, 70 National Guard support personnel, 55 coroner investigators, 45 anthropologists, 4 forensic odontologists, 10 morgue personnel from Sacramento County, 5 DNA specialists, 3 crime analysts, 5 morgue support personnel, 3 pathologists, 25 canine units, one person from Alameda County doing aerial mapping, and approximately 200 miscellaneous support personnel.

As recoveries progressed, the focus shifted to decedent identification efforts. An ANDE® Rapid DNA machine was established at the Sacramento County Coroner's Office for victims' DNA. Butte County obtained next-of-kin DNA profiles to compare with the decedents' DNA profiles. By November 20, 17 of the 79 victims had been positively identified by DNA. One month later, by December 20, the fatality count had increased to 85 with 48 of the victims positively identified using DNA. Currently, nearly eight months later, the decedent count stands at 85 with 79 of the victims positively identified. Collaborative efforts are ongoing between Butte County and ANDE® to identify the remaining six victims.

Before it was ultimately contained on November 25, 2018, the Camp Fire consumed 153,336 acres and 18,793 structures, and resulted in the deaths of 85 people. To date, the Camp Fire is the deadliest and most destructive fire in California history, the sixth-deadliest wildfire in United States history, and the world's most costly natural disaster in 2018. From this fire, Butte County learned to navigate the ever-changing landscape of mass disaster response and how to best prepare for future mass fatality incidents.

#### Mass Disaster Preparation, Wildfire Victim Identification, Mass Fatality Response

### A35 Search and Recovery Protocols for Fatal Fire Victims of the 2018 California Camp Fire

*Eric J. Bartelink, PhD\**, California State University, Chico, Chico, CA 95929-0400; *Ashley E. Kendell, PhD*, California State University, Chico, Chico, CA 95929-0400; *Jacqueline L. Galimany, BS*, California State University, Chico, Chico, CA 95929-0400; *Karen Gardner, MA*, AECOM, Oakland, CA 94612; *Leigh Hayes, Greenville, WI 54942*; *Casey A. Hegel, BA*, California State University, Chico, Chico, CA 95929; *Vanessa C. Reeves, BA*, California State University, Chico, Chico, CA 95929; *Alyssa Straub, BA*, California State University, Chico, Chico, CA 95926; *Maura Timmons, BS*, California State University, Chico, Chico, CA 95929-0400; *Leah Tray, BA*, Chico, CA 95973

**Learning Overview:** After attending this presentation, attendees will understand protocols for the search and recovery of burned human remains from mass fatality fire scenes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of protocols used in the search and recovery of fatal fire victims from the 2018 Camp Fire disaster in northern California. This presentation will further discuss the need to adapt existing fire scene protocols to large-scale fire fatality events.

Fatal fire scenes are among the most complex and challenging contexts for forensic archaeological recovery. Thermally altered human remains are highly fragmentary and demonstrate a wide range of color changes, making it difficult to discern skeletal material from burned non-human remains and debris. Experimental research on fire scenes has resulted in detailed protocols for the efficient and thorough recovery of fatal fire victims. However, for large-scale mass fatality fire scenes, efficient processing of multiple residences requires a more flexible protocol, especially when the medicolegal focus is on victim recovery and identification.

In the early morning hours of November 8, 2018, high winds damaged power lines on Camp Creek Road in the community of Pulga, CA, resulting in a massive wind-fueled fire that devastated the adjacent rural communities of Paradise, Magalia, and Concow. The Camp Fire resulted in 85 fire-related fatalities and the destruction of more than 150,000 acres and 19,000 structures, making it the deadliest and most destructive fire in California's history. Although the search for and recovery of fatal fire victims was primarily coordinated through the Butte County Sheriff's Office, the effort enlisted the services of all available state coroner and search and rescue teams, the California Office of Emergency Services, the National Guard, the California Department of Forestry and Fire Protection (CAL FIRE), and multiple local and regional fire departments. Early in the recovery effort, the sheriff's office requested California State University, Chico's recovery team, which in turn requested additional anthropologists from California and Nevada.

The scale and complexity of the disaster required the deployment of several smaller teams to the three affected communities. The most effective team structure involved having anthropology team members embedded within coroner's teams, with CAL FIRE personnel available to assist with moving large debris from structures. Each day, the sheriff's office provided a list of residential addresses to search, based on reported missing cases. However, each team also received numerous call-outs throughout the day by search and rescue and canine teams to determine forensic significance during their systematic search of the 19,000 destroyed structures. The majority of the call-outs involved non-human remains (e.g., pets, wildlife, and food refuse), burned debris, or false-positive canine hits. Accuracy improved when anthropologists implemented training to assist searchers with recognizing burned and calcined remains. The size of the recovery team fluctuated significantly each day, requiring flexibility in team composition and selection of recovery scenes.

Over a 20-day period, forensic anthropology teams conducted targeted searches for human remains in hundreds of burned residential structures and automobiles. Search patterns began with a perimeter walk around the structure, followed by a minimally invasive foot survey through the structure with a small team, and finally, a thorough search with small hand tools using a larger team. This approach was efficient for locating remains, especially from trailer homes and one-story residences. Multi-story residences and apartment complexes required significant debris removal, as well as more in-depth excavation and searching to locate remains. In most cases, human remains consisted of small, calcined bone fragments, although residual charred tissue often adhered to the thorax, pelvis, and thigh region. Human remains were recovered using trowels, brushes, hand sieves, and other small hand tools, and screening stations were set up to ensure a thorough recovery of smaller remains. Coroner teams were responsible for scene documentation, photography, and recording the location of remains using a total station. In total, forensic anthropology teams assisted in the recovery of 75 of the 85 fire victims and, in some instances, assisted with secondary recoveries of scenes processed previously without anthropology teams. Three scenes involved multiple fire victims and showed extensive commingling. The recovery protocol implemented in the Camp Fire disaster was effective and efficient for locating and recovering all known fatal fire victims and further aided identification efforts by other forensic experts.

#### Forensic Anthropology, Mass Fatality Fire Scene, Burned Remains

### A36 Forensic Pathology, Identification, Morgue Operations, and Management of the Camp Fire Victims

*Kimbelry D. Gin\**, Sacramento County Coroner's Office, Sacramento, CA 95820; *Kathy Raven, MD\**, Sacramento, CA 95820

**Learning Overview:** After attending this presentation, attendees will understand some of the principles of forensic pathology utilized in examining wildfire victims, cause of death and certification, issues surrounding identifications, and the task of operating a morgue after a mass fatality event.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the issues faced and the solutions that were utilized when processing, examining, identifying, and certifying human remains after a wildfire. This presentation will also emphasize the need for a change in the way remains have been historically processed and examined to facilitate faster identification.

Mass fatality incidents are fraught with difficulties, from recovery to examination to identification. The larger the incident, the larger the issues encountered. On the morning of November 8, 2018, a wildfire, dubbed the Camp Fire, started in Butte County, CA, and quickly became the biggest mass fatality incident in California's recorded history for any wildfire. Butte County Sheriff Coroner requested assistance from Sacramento County with the examination and identification of the victims. The remains were transported to Sacramento County and were processed, examined, and various methods of identification were utilized. A team of Sacramento pathologists and two pathologists from surrounding counties examined 84 of the 86 victims. All examinations were completed within two weeks of the fire and the identification process began immediately. The causes of death ranged from fire-related injuries to gunshot wounds.

Within three months of the fire, 87% of the victims were positively identified despite the extremely poor condition of the remains. Five of the victims were able to be identified quickly by fingerprints; 15 were identified by dental comparisons; and 2 victims were identified by hardware. The majority of the fire victims were identified by rapid DNA, which had not been utilized in a mass fatality in the United States prior to this event.

The inclusion of rapid DNA into the identification process highlighted issues that had to be addressed. The conventional DNA testing, which is by nature a lengthy process, was replaced with rapid DNA, resulting in very quick identifications. Traditionally, DNA testing takes so long that the exams are completed and the causes of death are determined long before the DNA results are known so death certification is quick once the person is identified by DNA. With rapid DNA, the identification was completed before the cause of death was determined in most of the cases. This issue led to families having to wait to receive a death certificate to complete burial arrangements and complete federal paperwork for aid. Steps had to be taken to help expedite cause-of-death determinations and rushes were placed on toxicology in order to help the families with this process.

Another issue faced was the lack of anthropologists to handle examinations in the field and at the morgue. Some of the identification attempts were delayed due to this issue.

In the end, the lessons learned from this event will aid other agencies in similar mass fatality events. This incident is a real example of crossing borders with multiple agencies working together on so many levels, and the results were extraordinary.

#### Mass Fatality, Identification Methods, Forensic Pathology

### A37 Wildfire Search, Recovery, and Identification of Victims: Post-Recovery Anthropological Analysis and Identification

*Lauren Zephro, PhD\**, Santa Cruz Sheriff's Office, Santa Cruz, CA 95062; *James D. Wood, DDS*, Santa Rosa, CA 95404; *Alison Galloway, PhD*, University of California, Santa Cruz, CA 95064

**Learning Overview:** After attending this presentation, attendees will better understand the analytical and logistical challenges faced by anthropologists in the post-recovery analysis and identification of victims of a mass casualty wildfire. The primary goals of this presentation are to define the role of anthropology in this context and to present strategies for case documentation and maximizing evidence recovery.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing attention to the planning required for mass casualties from wildfire, which must include post-recovery analysis. Prior to any disaster, understanding the role anthropologists play in this context, how they integrate with the other team members, how to stage anthropological analysis within the identification process, and how and when to use anthropological services needs to be clarified and planned for.

The California wildfires tested the ability of agencies to plan and execute a systematic search, recovery, analysis, and identification of fire victims. As we plan for future fires, ensuring that there are personnel to cover the post-recovery operations is essential. Primary efforts are on positive identification of fire victims so that remains may be returned to grieving families as expeditiously as possible. The analytical and logistical challenges involved in post-recovery analysis and identification need to be addressed in order to smoothly integrate anthropology into morgue operations involving wildfire victims. This presentation offers procedures and strategies for the documentation and analysis of wildfire victims in the morgue setting.

Anthropologists are critical in the morgue analysis of wildfire victims, complementing the work of pathologists, odontologists, DNA analysts, and morgue staff. Anthropology's contributions include: (1) removal of non-osseous material from human remains, (2) separation of human and non-human material, (3) identification of incomplete recoveries, (4) identification of split recovery of remains, (5) identification of commingled remains, and (6) identification of elements useful for positive identification, such as appropriate DNA samples. Using examples from the Camp Fire, handled through the Sacramento County Coroner's Office, basic issues include the range of thermal damage to remains, the extent of commingling (human and non-human), and the difficulty of isolating material useful for identification.

In the Camp Fire analysis, anthropologists examined 69 of the 86 "cases" recovered. While some remains were partially burned, retaining significant soft tissue, most cases were severely impacted by the fire. Sorting calcined material became extremely important and resulted in fluctuating body counts as body segments were reunited or commingled remains identified.

Anthropologists began work in the morgue approximately nine (9) days after the outbreak of the fire. Often their analyses followed examination by the pathologists and odontologists. This sequence was problematic as anthropologists focused not only on the numbered remains, but also on the elements represented by addresses and the localities of where remains were recovered. Often commingled remains recovered from the same address were bagged "separately" but each container collected from the field represented a full intermingling of bodies from a specific locale.

In order to work efficiently, a systematic approach was developed. Bone fragments were separated by body segment, examined to ensure that full body recovery was present, and elements separated that may be useful for positive identification. Additionally, all remains found at a single address were analyzed simultaneously to address comingling issues. Peer review was accommodated by separate examination by one anthropologist, then cross-checking the work of the other. Potential disagreements or clarifications were discussed prior to sign-off. Case records were memorialized using extensive photo documentation and standard recording forms.

Given that major contributions of anthropology include identifying teeth, comingling, and appropriate samples for DNA, the integration of anthropology at the beginning of the analytical process is recommended. With these fragile remains, anthropologists should work prior to other disciplines (pathology, odontology, and DNA) to minimize damage and to maximize appropriate specimens for other experts. Another important lesson learned is the importance of small bones, such as carpals and tarsals, and bone fragments to identify comingling. Lastly, to prepare anthropologists for the complexity of burned bone analysis on a large scale, training opportunities are recommended to address these issues as a specialty area.

It is recommended that planning for future such disasters account for early anthropological analysis in the post-recovery efforts. Anthropologists should work on fully burned remains prior to the work of the pathologists and odontologists. Normal analysis is limited by the condition of remains and pace of identification, but valuable contributions are still possible. Training specific to burned bone analysis is recommended for anthropologists planning on contributing to wildfire mass disasters.

#### Forensic Anthropology, Burned Bone, Identification

## A38 Wildfire Search Protocols and Victim Recovery

Richard Selden, MD\*, ANDE Corporation, Waltham, MA 02451-1166; Rosemary Turingan Witkowski, ANDE Corporation, Waltham, MA 02451

**Learning Overview:** After attending this presentation, attendees will better understand the use of Rapid DNA for disaster victim identification and the integration of Rapid DNA identification with forensic odontological, pathological, and anthropological analyses. The primary goal of this presentation is to discuss the value of routine, coordinated utilization of Rapid DNA identification during and in the immediate aftermath of a mass disaster.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the use of Rapid DNA to generate DNA IDs (also known as DNA fingerprints or Short Tandem Repeat (STR) profiles) in real-time from unidentified human remains. By comparing a database of these DNA IDs to those generated from familial reference samples and antemortem victim samples, it is possible to assign identities to victims, often within hours of intake.

In November 2018, the Camp Fire raged through Butte County, consuming 800 acres of Northern California per minute. As with most mass disasters, conventional identification modalities (e.g., fingerprints, dental records, radiographic features, hardware) were utilized to identify victims. The intensity and duration of the fire severely degraded most of the remains, and, as a result, the conventional approaches were useful in only about one-quarter of the cases. In the past, the remaining cases would be subjected to laboratory DNA analyses, which typically requires months to years. Instead, Rapid DNA identification, was, for the first time, utilized to identify the majority of victims within hours to days following recovery.

Rapid DNA identification is the fully automated process of generating a DNA ID from a forensic sample, typically performed outside the laboratory by non-technical operators, with results available in less than two hours.<sup>1</sup> Rapid DNA identification is based on four integrated processes: purification of genomic DNA from a sample; rapid multiplexed amplification of the FlexPlex™ loci, a set of 27 STR loci (amelogenin, 3 Y-chromosomal STR (Y-STR) loci, and 23 autosomal loci); separation of the resulting STR amplicons by polyacrylamide gel electrophoresis; and data processing and locus and allele assignment using an onboard expert system.<sup>2</sup> DNA IDs generated from human remains were compared to DNA IDs generated from family reference samples using automated kinship software.

Rapid DNA identification expanded to take on a central role in victim identification. Faced with burn victims, among the most difficult types of remains to identify, the use of Rapid DNA led to surprising synergies, with work being performed in parallel in pathology, odontology, and anthropology. From the use of DNA IDs to triage efforts in these disciplines to the identification of comingled remains, Rapid DNA was shown to be an invaluable tool in the victim identification process. This presentation will describe results from the rapid processing of severely degraded bone, tissue, and blood samples and the use of familial searching software. Finally, the application of Rapid DNA in related forensic applications will be discussed.

### A39 Outside Agency Response to the California Camp Fire

*Timothy P. Gocha, PhD\**, Forensic Anthropology Center, San Marcos, TX 78666-4684; *Kyra E. Stull, PhD\**, University of Nevada, Reno, Reno, NV 89557; *Marin A. Pilloud, PhD*, University of Nevada, Reno, Reno, NV 89557-0096

**Learning Overview:** After attending this presentation, attendees will understand the ways in which anthropologists from agencies outside the state of California responded to offer assistance in the search and recovery efforts in the aftermath of the Camp Fire in northern California.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering insight into the logistical, financial, and ethical considerations faced by outside agency responders and offer recommendations for other anthropologists who may one day serve as responders from outside agencies to mass fatality incidents.

On the morning of November 8, 2018, a wildfire started in Butte County in northern California and began to spread. Termed the Camp Fire, it quickly grew to become the most destructive and deadliest wildfire in California history. By the evening of November 10, anthropologists responding to the incident from California State University, Chico recognized the need for additional anthropological resources and requested assistance from forensic anthropologists in northern and southern Nevada. Data for this presentation comes from the experiences of these forensic anthropologists. Similarities and differences will be noted and discussed.

Anthropologists responding from northern Nevada were primarily affiliated with the Department of Anthropology with the University of Nevada, Reno (UNR), including 2 faculty members and 15 graduate students. Due to their proximity to the camp fire, UNR anthropologists were able to begin assisting with recovery efforts on Sunday, November 11. They were also able to return to Reno to fulfill academic obligations during the week and return to assist as available. In total, UNR anthropologists deployed three times throughout the month of November to provide support over approximately nine days. The large number of individuals displaced by the wildfire resulted in no vacancies in local hotels in Chico and all UNR anthropologists stayed in personal residences of Chico State anthropologists. Financially, efforts from UNR anthropologists were initially self-financed, though students and faculty were eventually reimbursed for gasoline and some food expenses through UNR using funds received from local forensic anthropological casework.

Anthropologists responding from southern Nevada were affiliated with the University of Nevada, Las Vegas (UNLV), including one faculty member and three graduate students. However, in their response to the Camp Fire, these anthropologists were considered primarily affiliated with the Clark County Office of the Coroner/Medical Examiner (CCOCME), where they served as the forensic supervisor, two of the graduate students were part-time forensic staff, and one graduate student was a forensic anthropology intern. Because of their affiliation with a government agency, anthropologists from the CCOCME were subject to an Emergency Management Assistance Compact (EMAC) agreement between California and Nevada, which delayed deployment to the Camp Fire response. As such, CCOCME anthropologists were unable to respond as quickly as those from UNR and began assisting with recovery efforts on Monday, November 12, and stayed until November 17. Similarly to the anthropologists from UNR, CCOCME anthropologists also relied on Chico State anthropologists for lodging, and efforts were also initially self-funded. Although the EMAC initially delayed CCOCME response, it did allow for those anthropologists to be paid for their time and efforts in the field, as well as reimbursement for travel expenses by Clark County, which was later reimbursed by the state of California. Further conversations after the event with EMAC coordinators revealed that while EMAC does not have provisions for academics per se, if anthropologists are employed by a public university, accommodations could be made to ensure reimbursement for those individuals. It is recommended that anthropologists housed in academic units begin a dialogue with Emergency Management coordinators in their state prior to a mass fatality event, to establish a framework for reimbursement.

The response by anthropologists from both UNR and the CCOCME offered not only an important professional service to the affected communities, but also allowed for hands-on training and professionalization of students in the field. This ranged from practical experience of field operations in a series of changing environments to building skills of professional interaction with various law enforcement and responder agencies.

#### Camp Fire Response, Search and Recovery, Mass Fatality Response

## A40 Demography of the Camp Fire Fatalities

*Samuel A. Mijal, BS\*, Phoenix, AZ 85004; P. Willey, PhD, Chico State University, Chico, CA 95929-0400*

**Learning Overview:** After attending this presentation, attendees will understand which segments of a population are disproportionately impacted during catastrophic events. Such was the case involving foothills communities devastated by the November 2018 Camp Fire in northern California. There, older adults and those with mobility-inhibiting disabilities died in greater proportions than other groups.

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community by serving as a case study for identifying high-risk groups in wildfire mass fatality events. Employing these results and insights as a foundation, the most at-risk groups can be identified and slated for education, planning, and warning before catastrophic events occur. In addition to preparations, those at-risk groups should be the focus of resources during emergencies, as well as search and recovery and identifications following catastrophes.

Data for the Camp Fire Communities (Concow, Paradise, and Magalia) came from several sources. The 2010 United States census provided the communities' age and sex distributions. Economic and disability information were derived from the 2017 American Community Survey estimates. The Butte County Sheriff's Office provided the fatalities' ages (recorded to the most recently completed whole year), sex, and locations. Information concerning the victims' disabilities came from a local newspaper's accounts consisting primarily of personal recollections from family members and friends.

Approximately 38,000 inhabitants lived in the three Camp Fire Communities, with the largest town (Paradise) comprising about two-thirds of that total. Stereotyped as retirement communities, the foothill towns tended to have greater proportions of older adults, and many inhabitants lived on limited incomes in a community where the median income was \$10,000 below the national median and \$19,000 below the state medium (Community median income was \$47,743). In addition, these towns had a greater proportion of disabled community members. As examples, the Communities accounted for nearly double the rate of ambulatory and independent living-challenged members than the state or country.

Eighty-five individuals died in the Camp Fire, 83 of whom have been identified. This demographic work uses the identified individuals and omits the other two from further consideration. No infants, children, or adolescents died from the blaze. In addition, very few young and middle-aged adults expired. On the other hand, older adults represented a disproportionately high number of victims. The ages of the fatalities varied from 20 to 99 years, with a mean of 72.06 years. By sex, female fatalities exceeded male fatalities: 44 females, 39 males. The fatality age distribution by sex proved statistically similar. However, when four outliers were excluded from the data set (two younger outliers of each sex), a statistically significant difference occurs. Female fatalities averaged five years older than males. The ancestral makeup of the Camp Fire Communities was largely White (92%), with 6.94% self-identifying as Hispanic. Ten (12%) fatalities had Spanish surnames, a distribution greater than the census percentage and approached, but failed to achieve, statistical significance. Anecdotal evidence provided by personal accounts indicated that Camp Fire victims exhibited high rates of mobility-inhibiting disability.

The towns of Concow, Magalia, and Paradise represented communities with higher-than-average at-risk populations with advanced age and mobility-inhibiting disability being the main issues. Assessment of the Camp Fire victims' and Communities' demographic variables reinforced how these risk factors contributed to individual casualties.

---

### Demography, Camp Fire, Mass Fatality Event

## A41 Locational Analysis of the Camp Fire Fatalities in Communities and Residences

*Casey A. Hegel, BA\*, California State University, Chico, Chico, CA 95929; Samuel A. Mijal, BS, Chico, CA 95926*

**Learning Overview:** After attending this presentation, attendees will understand the application of Geographic Information Systems (GIS) to forensic anthropology for the spatial analysis of fatalities in a mass disaster.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the use of geospatial analysis to examine mass fatality events to assist communities in identifying vulnerability in a population and to aid in recovery efforts.

On Thursday, November 8, 2018, a brush fire in Pulga, CA, started early in the morning. Fueled by high winds and overall dry climate from significant droughts, the fire swept through the towns of Concow, Paradise, and Magalia. These towns are all foothill communities, with Magalia and Paradise having one arterial road, named the Skyway, to get in and out of the town. The Camp Fire is currently the deadliest and most destructive fire in California's history. The fire burned more than 150,000 acres, more than 18,000 structures were destroyed, and it resulted in 85 fatalities. With the increase of fire events, it is important to examine disasters to identify vulnerable individuals in communities in order to help prevent fatalities in future mass disaster events.

This analysis utilizes ArcMap® 10.7 to spatially examine the locations of the fatalities from the Camp Fire. Data on fire victims and the locations where these individuals were recovered was provided by Butte County Sheriff's Office. Information concerning the victims' disabilities came from local newspaper accounts that consisted primarily of personal recollections from family members and friends. The fire perimeter used for this analysis was obtained from the California Department of Forestry and Fire Protection (CAL FIRE) website. Shapefiles for roads and counties were downloaded from United States census data. Landsat 8 satellite imagery was also utilized.

GIS analysis allows for assessment of factors that could have contributed to the deaths of individuals in the Camp Fire. This includes the location of fatalities in relation to the spread of the fire across the communities. The victims' ages, sex, and any mobility-inhibiting disabilities are also assessed. Furthermore, the distance from home addresses to where victims were found in vehicles on arterial and secondary thoroughfares is evaluated to assess the relationship between the human response to the fire spreading and to evaluate how traffic congestion in the early hours of the fire contributed to the high fatality rate for this fire.

Results from spatial analysis led to several conclusions. Primarily, it is concluded from this study that proximity to arterial thoroughfares did not influence the Camp Fire victim demographics. In addition, this study identified a lack of relationship between age and distance of remains from the origin of the fire, contrary to expectations. This suggests victim age and disability played a significant role in victim demographics, while distance from the fire's origin and the warning time it afforded was less of a factor. Finally, sex of the individual and distance from the origin of the fire were found to have no relationship, supporting the conclusion that sex was not a strong factor in the response to the fire and subsequent evacuation of the Camp Fire communities. A spatial autocorrelation, using Moran's I to examine fatalities and the variable of age, shows a significant positive relationship for a clustered pattern in the distribution of fatalities. This supports victim age as playing a role in victim demographics and indicates that individuals are likely not randomly dispersed throughout the towns of Concow, Paradise, and Magalia.

Geospatial examination of fire fatalities, as applied in this study, can allow for identifying preventative measures for communities that are particularly at risk and vulnerable in mass disaster events. Also, the examination of location patterns in fatalities could aid in future mass disaster recovery efforts of human remains.

### Mass Fatality Incident, Spatial Analysis, Camp Fire

### A42 Anthropology and Mass Fatality Management in Wildfire Disasters

*Colleen M. Cheverko, PhD\*, Merced, CA 95343-5001; Colleen F. Milligan, PhD, California State University, Chico, Chico, CA 95929-0400; Melanie M. Beasley, PhD, Purdue University, West Lafayette, IN 47907-2059; Lisa N. Bright, PhD, Yuba City, CA 95991; Shannon J. Clinkinbeard, BA, 400 W 1<sup>st</sup> Street, Chico, CA 95929; Leigh Hayes, Greenville, WI 54942; Jessica Hotaling, BA, Chico, CA 95926; Mallory J. Peters, MA, State University of New York, Binghamton, Binghamton, NY 13905; Julia R. Prince-Buitenhuys, MA, California Department of Water Resources, West Sacramento, CA 95961*

**Learning Overview:** After attending this presentation, attendees will better understand the roles anthropologists play in managing both recovery and identification of victims from wildfire events. Wildfires are a type of mass disaster that requires the coordination of resources across numerous agencies to address fatality management.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of mass fatality policy development in response to lessons learned from mass disasters. The continued development of mass fatality policies affects both training and agency responses to future events.

The 2018 wildfire season in California was the deadliest and most destructive season in California Department of Forestry and Fire Protection (CAL FIRE) history. With a total of 310 incidents, California recorded 93 fatalities and more than 23,000 structures destroyed. The deadliest single incident of both the season and California wildfire history was the Camp Fire in Butte County, CA. The Camp Fire alone recorded 85 fatalities to date and more than 18,793 structures destroyed. Moving through the communities of Pulga, Concow, Paradise, and Magalia, the wildfire's speed and size also required the largest deployment of resources to a single mass fatality event in California history.

Mass fatality incidents are defined as any incident in which the number of dead immediately overwhelms local resources. In California, the local agency maintains operational control but can request assistance from both state and federal agencies in the event of a disaster, as well as other jurisdictions through a mutual aid system. Assistance can include subject matter experts, funding, and resources. Forensic anthropologists are often called to assist in both the recovery and identification process of victims in mass fatality incidents, along with medical examiners, coroners, odontologists, X-ray technicians, and other mortuary personnel. Traditionally, forensic anthropologists play a larger role during mass fatality disasters in the mortuary identification process than in field recovery operations. However, the 2018 Camp Fire utilized more anthropologists in field operations than in mortuary operations, inverting the more typical use of anthropologists. This resulted in the recovery of 85 victims across a 153,336-acre search area in under three weeks with no false positive cases sent to the mortuary.

Terrorism events, aviation disasters, pandemics, earthquakes, and hurricanes are usually the focus of mass fatality planning, whereas wildfires have not received the same amount of attention. However, the fatalities associated with wildfires present unique challenges to both the recovery and identification processes. Lessons from the 2018 fire season highlight the need to include anthropologists in operational planning in both pre-planning and incident response. This includes organization of victim search efforts, distinguishing between human/non-human/non-osseous materials, assistance in mortuary operations, field gear acquisition, field training for all search personnel, data logistics, and multi-agency coordination.

This study recommends an increased role for anthropologists in the pre-planning stage to increase the training sources available to law enforcement, search and rescue, CAL FIRE personnel, and medical examiner/coroner teams. In addition, involvement in planning would help with preparatory field gear acquisition for more rapid deployment during wildfire events. Also recommended is the inclusion of anthropology personnel in the active search for victims of wildfires, given the condition of remains in these instances. This recommendation reduces the number of false positive numbers in the field and increases the percentage of remains recovered, which in turn improves the speed and accuracy of positive identifications in the event.

## A43 The Infant Injury Database

Miriam E. Soto Martinez, PhD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Christian Crowder, PhD, Southwestern Institute of Forensic Sciences, Dallas, TX 75207; Jennifer C. Love, PhD, Office of the Chief Medical Examiner, Washington, DC 20024; Sharon M. Derrick, PhD, Texas A&M University-Corpus Christi, Corpus Christi, TX 78412; Christopher S. Greeley, MD, University of Texas Health Science Center at Houston, Houston, TX 77030; Marcella Donaruma-Kwoh, MD, Texas Children's Hospital, Houston, TX; Angela Bachim, MD, Baylor College of Medicine, Houston, TX 77030

**Learning Overview:** After attending this presentation, attendees will be aware of the Infant Injury Database (IID), the types of data archived in the database, the composition of the population sample, and the mechanism for requesting access to the data. This presentation provides a more detailed description of the database previously described by Soto Martinez et al.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating awareness of and providing information about a valuable resource for conducting evidence-based research on the recognition and diagnosis of child abuse.

The IID is a valuable data source for forensic and clinical practitioners interested in developing statistically sound, validated diagnostic models to inform decision-making with regard to abusive injury. It is a comprehensive collection of demographic information, investigative information (law enforcement, medical examiner death investigation, child protective services), scene observations, medical history, and autopsy findings from all pediatric (0–5 years) examinations conducted at the Harris County Institute of Forensic Sciences (HCIFS). To mitigate the introduction of selection bias, age was the only factor limiting inclusion into the IID. All data pertaining to Postmortem Examinations (PME) were prospectively collected from autopsy reports and gross rib exams or full pediatric skeletal exams conducted by an HCIFS forensic anthropologist. Full pediatric skeletal exams were conducted, per the pathologist's request, on cases of concern for abusive injury or suspicious circumstances.

For each case in the database, 2,071 fields of data (discrete and free-text) are collected with the ability to attach additional comments to any data field. General case information, such as demographics, height/weight, and manner/cause of death, is documented in the first 25 fields of the database. Ninety-nine fields describe the events leading up to the terminal event (i.e., co-sleeping, napping, traumatic injuries), and detail information such as who found the decedent (i.e., mother, father, parent's paramour, etc.) and where they were found (i.e., bed, bassinet, crib, couch). These fields also describe the decedent's physical appearance (i.e., lividity, rigor mortis, cold to the touch) upon discovery or assessment by medical personnel. If the decedent was not transported to the hospital, observations from scene photos are recorded in 27 fields, describing the decedent's sleep environment (when applicable) and general home environment (i.e., clean, unkempt, insect activity, etc.). Eighty-seven fields document the decedent's medical history (prenatal, birth, and postnatal) and family medical history. Parental/caregiver social histories (tobacco, alcohol, and illicit drug use) are documented in 21 fields. History with child protective services involving the decedent, sibling, and/or parent/caregiver are recorded in 157 fields, including number of investigations, associated allegations, and allegation determination. Medical examiner findings are recorded in 1,655 fields and are organized by location of injury, such as external body, internal body, and skeletal system. External injuries to specific body parts (i.e., face, lips, left hand, buttocks, etc.) are documented in 76 fields, including injury type (i.e., contusion, laceration, abrasion, etc.) and whether the observed injuries resulted from medical intervention. There are 106 fields for documenting internal injuries to body organs, and subcutaneous and intramuscular soft tissues, which includes descriptions of injury type (i.e., hemorrhage, pulpification, laceration). The largest number of PME fields ( $n=1,473$ ) are dedicated to the documentation of skeletal injuries. There are fields for recording fracture type, number of fractures, and stage of healing for almost every bone in the body. Free-text boxes are utilized for documenting injuries to the bones of the hands and feet as these types of injuries are uncommon.

Currently, the IID contains data on 710 pediatric cases (female=289, male=421) and the sample continues to expand. These data were collected intermittently from 2010 to 2013 and have been continuously collected from 2014 to the present. Infants form the largest group in the IID (<12 months=633, 89%), followed by children 1–2 years of age ( $n=32$ ), 2–3 years of age ( $n=22$ ), 3–4 years of age ( $n=15$ ), and 4–5 years of age ( $n=8$ ). With regard to ethnicity, African Americans form the largest group in the IID ( $n=305$ , 43%), followed by Hispanics ( $n=237$ ), White/European Americans ( $n=150$ ), and Asians ( $n=18$ ).

### Pediatric, Injury, Databases

## A44 Pediatric Posterior Rib Terminus Defects: An Investigation of a Potential Mimic of Traumatic Injury

Jason M. Wiersema, PhD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Dwayne A. Wolf, MD, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Aubrie M. Sanchez, MS, MPH, Columbus, OH 43201

**Learning Overview:** After attending this presentation, attendees will be aware of rarely identified mimics of posterior rib head fractures that are inconsistent with inflicted trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that posterior rib head fracture mimics are a fairly common finding and should be interpreted cautiously.

Posterior rib fractures are considered highly suspicious for abusive injury in infants due to the mechanism by which these injuries occur.<sup>1</sup> Numerous studies demonstrate an association between posterior rib fractures and inflicted injury in infants. While this association is clear, recent casework at the Harris County Institute of Forensic Sciences (HCIFS) requires that at least some posterior rib defects be considered in the context of growth and development as well as the presence and/or absence of other injuries and/or risk factors. At the HCIFS, standard autopsy protocol includes an *in situ* rib exam on all pediatric cases less than five years of age. In 55% ( $n=41$ ) of the 75 cases examined since January of 2019, at least one subtle linear defect was observed on the pleural surface of one or more ribs near their attachment to the vertebral column. Grossly, these defects have morphological characteristics suggestive of advanced healing, such as bone formation along the endosteal portion of the fracture surface. Similar defects have been previously described by Kemp as clefts that are “triangular-shaped defects in the primary spongiosa with the tip at the growth plate and the base at the periosteum.”<sup>2</sup> Kemp notes that the clefts are filled with an “amorphous, granular, eosinophilic acellular material of uncertain origin,” which was previously described by Dolinak and Matshes.<sup>2,3</sup> The exact content of the material is unknown, but Kemp hypothesizes the material is a response to inflammation and repair and contributes the clefts to microscopic fractures.<sup>2</sup> However, the characteristics of some of the pediatric cases at HCIFS complicate the interpretation of these defects. The defects were observed in one fetus and in several infants less than one week of age, as well as in infants with no other evidence of injury. Additionally, histological examination of these defects shows no cellular evidence of healing. As a result of these complications, a closer examination of the context in which these posterior defects are observed is warranted.

Manner and cause of death had been classified for 19 of the 41 cases with posterior defects. Cause of death was unrelated to trauma for 16 of the 19 cases. Only one of the three cases with a trauma-related cause of death was suspicious for abusive injury (Manner—Undetermined, Cause—Blunt force head trauma). Of the 41 cases with posterior defects, 16 had no other skeletal injuries, including rib fractures, and 17 had rib fractures but no other skeletal injuries. The fracture pattern in most of the cases with rib fractures was consistent with cardiopulmonary resuscitation.

A logistic regression model was used to examine the relationship between the presence of posterior defects as the dependent variable and age, sex, ethnicity, the presence of other rib fractures, and the presence of other skeletal injuries (excluding rib fractures) as the independent variables. The presence of posterior rib defects was significantly related to sex ( $p<.001$ ). The odds that females had posterior defects was 7.04 greater than males ( $OR=7.04$ , 95% CI [2.27, 21.83]). Age may also have a significant effect on the presence of posterior rib defects ( $p=.058$ ). The odds of observing posterior defects in older children were lower than in younger infants ( $OR=0.96$ , 95% CI [0.92, 1.00]). Age is statistically significant when entered as the only independent variable in the model ( $p=.047$ ). Neither ethnicity, the presence of other rib fractures, nor the presence of skeletal injuries had a significant relationship with the presence of posterior defects ( $p>.05$ ). These relationships are inconsistent with the general trends observed among the infants autopsied at HCIFS that die of abusive trauma or traumatic injury. The odds of traumatic death ( $OR=1.08$ , 95% CI [1.06, 1.10]) and abusive injury ( $OR=1.06$ , 95% CI [1.03, 1.08]) increases as age increases. Sex had no significant relationship with causes of death related to trauma or abusive injury ( $p>.05$ ).

### Child Abuse, Posterior Rib Fractures, Trauma Mimics

## A45 Evaluating Bone Fracture Healing and Variability Across Forensic Samples Using an Anabolic/Catabolic Model of Bone Repair

Donna C. Boyd, PhD\*, Radford University, Radford, VA 24142

**Learning Overview:** The goal of this presentation is to evaluate bone fracture healing and the staging systems that are currently used to estimate its progression and timing in a forensic context. Microscopic and macroscopic comparisons of healing fractures across a diverse forensic sample are used to document variability in timing and character of bone healing and illustrate the inadequacies and errors associated with current models and stages of bone repair. This variability is interpreted through a newer anabolic and catabolic model of bone repair focused on the coordinated and integrated processes of osteoblastic-driven bone deposition and osteoclastic bone resorption.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that research will enhance forensic scientists' recognition of variability in the bone fracture healing process and its outcomes as well as the factors that produce and influence this variability. Researchers and clinicians will recognize the importance of comorbidities for fracture repair and will be cautioned that reliance on the application of previously published fracture healing estimates across forensic samples of varying age, fracture and trauma type, and health may lead to inaccurate Time Since Injury (TSI) estimates and interpretations. Use of a more fluid and integrated anabolic/catabolic model for bone repair will aid in more accurate interpretation of bone fracture healing (including TSI).

Interpretation of non-accidental pediatric and elderly injury is often dependent upon evaluation of previous bone injury and its repair process and timing. Currently, a myriad of bone healing schemata have been published, with little understanding of their application to forensic contexts. It is hypothesized that demographic (e.g., age), biomechanical (e.g., fracture and trauma type and location), and biomedical (e.g., treatment of fracture, presence of comorbidities) factors significantly influence bone healing and complicate and, in some cases, nullify the use of these published staging systems in a forensic context.

This hypothesis will be tested by first conducting a comparative review of published bone fracture healing staging systems across major forensic and biomedical sources dating back to 1980. Bone healing schemata variables compared include stages of healing presented, terminology used to describe the healing process, timetable for repair, and modality on which the stages are based. These staging systems are then applied to the forensic fracture sample from the Radford University Forensic Science Institute's Antemortem Fracture Archive (RUFSA AFA). This forensic sample consists of more than 250 antemortem fractures of varying type and location derived from (currently) 20 individuals ranging in age from 27 days to 92 years. It contains more than 3,000 macroscopic and microscopic (5x–200x magnification, using a 3D digital light microscope) images illustrating all phases of the bone repair process.

Results of this study identify at least 13 distinct bone healing staging systems that have been applied to fracture healing interpretations in a forensic context. All, to some degree, derive from radiographic assessments of bone repair across a variety of cohort demographics, fracture and trauma types, and locations from non-forensic contexts. They employ inconsistent fracture repair terminology, rely on rigid classification systems, and consider the bone healing process a categorical progression through finite and mutually exclusive stages. Application of these published staging systems to the diverse forensic fracture sample produces widely varying and unclear characterizations of bone healing and its timing and interpretation.

Utilization of a microscopic anatomy-based anabolic/catabolic model based on a continuous, coordinated, and integrated process of bone repair involving osteoblastically driven bone deposition and osteoclastic bone resorption produces more accurate results. This model has the advantage of flexible adaptation to documented variability in demographic, biomedical, and biomechanical influences on bone fracture.<sup>1,2</sup>

It is concluded that both macroscopic and microscopic evaluations of bone healing are important components of fracture interpretation, as is the recognition of the significant effect of many variables upon the fracture repair process and timing. This research illustrates well the 2020 AAFS theme of *Crossing Borders*—the use of an interdisciplinary (in this case, biomedical and anthropological) approach and model produces more accurate interpretations of bone fracture healing, its outcome, and interpretation in a forensic context.

### Antemortem Fracture, Bone Healing, Comorbidities

## A46 Anthropological Examinations of the Hyoid, Thyroid Cartilage, and Cricoid Cartilage in Cases of Possible Neck Trauma

Christopher W. Rainwater, MS\*, Office of the Chief Medical Examiner, New York, NY 10016; Esther H. Choo, BA, New York University, New York, NY 10003

**Learning Overview:** After attending this presentation, attendees will understand the importance of evaluating the thyroid and cricoid cartilages, in addition to the hyoid, in cases of possible neck trauma. Attendees will also understand fracture patterns with respect to hyoid fusion, manner of death, and presence of soft tissue hemorrhage.

**Impact on the Forensic Science Community:** This retrospective study will impact the forensic community by providing data for fracture patterns of the hyoid, thyroid cartilage, and cricoid cartilage analyzed by anthropologists in a medical examiner's office.

The hyoid, thyroid cartilage, and cricoid cartilage are critical in trauma interpretation as fractures of the neck organ block are commonly associated with strangulation, hanging, and direct blunt force. Between 2001 and 2019, the Forensic Anthropology Unit (FAU) at the New York City Office of Chief Medical Examiner evaluated 187 cases in which some combination of the hyoid ( $n=168$ ), thyroid cartilage ( $n=89$ ), and/or cricoid cartilage ( $n=77$ ) were submitted for an anthropological analysis of possible peri-mortem blunt force trauma. The FAU protocol for examining these cases begins by radiographing the removed specimen in standard Antero Posterior (AP) and AP oblique views to visualize the horns. The hyoid is then macerated. The larynx is fixed in a 10% buffered formalin solution and the soft tissues and perichondrium are carefully removed with small forceps and a scalpel, often under magnification. Data from these cases has been retrospectively compiled to assess interactions between fracture location and frequency, age, fusion of the hyoid, manner of death, and presence of hemorrhage in the surrounding soft tissues.

Of the 168 hyoids evaluated, there were 66 fractures noted on 54 cases. Fractures of the hyoid were categorized by location: right greater horn midpoint ( $n=28$ ), left greater horn midpoint ( $n=25$ ), right joint ( $n=6$ ), left joint ( $n=7$ ), right posterior end ( $n=0$ ), left posterior end ( $n=0$ ), and the body ( $n=0$ ). Greater horn midpoints were the most frequently fractured location (80.3%) with no side preference. Similarly, no relationship could be determined between the fracture location and the state of fusion. The fracture side frequency was similar in cases where the greater horns were bilaterally fused and bilaterally unfused. When cases were unilaterally fused, there were six fractures on the fused side and four fractures on the unfused side. The average age of individuals with bilateral unfused greater horns was younger than those with the left, right, and both greater horns fused (39.7 versus 50.5, 54.8, and 55.2, respectively) but a significant relationship between age and state of fusion was not identified. The youngest individual exhibiting bilateral fusion was 27, while the oldest individual exhibiting bilateral non-fusion was 88.

Of the 89 thyroid cartilages evaluated, there were 82 fractures noted on 49 cases. Fractures of the thyroid cartilage were categorized by location: right superior horn ( $n=16$ ), left superior horn ( $n=19$ ), right base of the superior horn ( $n=11$ ), left base of the superior horn ( $n=12$ ), right inferior horn ( $n=3$ ), left inferior horn ( $n=4$ ), right lamina ( $n=5$ ), left lamina ( $n=8$ ), and midline lamina ( $n=4$ ). Of the 77 cricoid cartilages evaluated, there were 29 fractures noted on 20 cases. Fractures of the cricoid cartilage were categorized by location: midline ( $n=3$ ), right of midline ( $n=8$ ), left of midline ( $n=13$ ), right lateral ( $n=3$ ), and left lateral ( $n=2$ ). No fracture side preference was noted on either the thyroid or cricoid cartilages.

In total, at least one fracture was observed on nearly half of the cases (91/187). Trauma was noted on about half of the cases certified as homicide or undetermined. Suicides were more likely to exhibit trauma whereas accidents and natural deaths were less likely. The presence of hemorrhage in the surrounding soft tissues was slightly more likely to be associated with an underlying fracture (66 with trauma, 45 atraumatic). A lack of hemorrhage was about twice as likely to be associated with no trauma (36 atraumatic, 17 with trauma).

Of the 187 cases, 70 had both hyoid and laryngeal cartilages present for evaluation. Twenty-seven exhibited no trauma while 14 exhibited fractures of both bone and cartilage. Only 1 hyoid exhibited trauma when the cartilages were atraumatic, yet 28 cartilages exhibited trauma when the hyoid was atraumatic. This contrast underscores the importance of examining the thyroid and cricoid cartilage, in addition to the hyoid, in cases of possible neck trauma.

### Hyoid, Larynx, Blunt Force Trauma

### A47 Utilizing Reflectance Transformation Imaging (RTI) for the Analysis of Saw Mark Characteristics on Kerf Walls: A Comparison of Traditional Imaging Techniques.

*Britny Martlin\*, Victoria, BC V8W 1E4, CANADA; Carolyn Rando, PhD, University College London, London WC1H 0PY, UNITED KINGDOM*

**Learning Overview:** After attending this presentation, attendees will have some understanding of what RTI is and how to use it for analysis, the traditional approaches to saw mark analysis, and the potential advantages involved in including RTI in the forensic analysis of saw marks on bone.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting that RTI, an inexpensive and easy-to-use technology, can be used for saw mark analysis with comparable results to traditional methods and, in some cases, can more greatly enhance characteristics. RTI has the potential to expand upon traditional analytical techniques and ameliorate imaging difficulties associated with more traditional methods.

RTI is a computational photography technique which documents and enhances the 3D reflectance properties of the surface of an object. A series of digital photographs are taken from a stationary camera position while the light source is projected from a different known angle. These photographic sequences are synthesized as Polynomial Texture Maps (PTM) and can be viewed much like a conventional 2D photographic image. However, unlike a traditional photograph, a PTM is derived from the 3D properties of the object, allowing the user to virtually re-light the object using the designated viewing software. Although RTI has primarily been used in the cultural heritage sector, it has recently transitioned into the realm of forensic science.

Traditionally, saw mark analysis is completed macroscopically, with low-powered stereomicroscopes or, more recently, Scanning Electron Microscopes (SEM). To assess the viability of using RTI for saw mark analysis, three different handsaws were used to fully section porcine radii, resulting in 42 kerf walls. All kerf walls were examined with the three traditional methods, as well as with RTI, utilizing a saw mark analysis methodology derived from Symes et al.<sup>1</sup>

The results demonstrate that RTI has a greater capacity for digital alteration and examination than the traditional methods, with statistical analysis demonstrating comparable accuracy. Macroscopic examination resulted in a lack of identification of kerf wall characteristics due to the lack of magnification used for analysis. Characteristics were often obscured during microscopic analysis due to surface reflectivity, and characteristics were also occasionally obstructed during SEM analysis due to the underlying bone morphology visible with SEM technology. Due to the digital abilities of RTI, neither surface reflectivity nor underlying bone morphology were a difficulty during analysis.

Although great care must be taken when obtaining the photographic sequences necessary for detailed RTI analysis, this study proves that RTI is comparable in accuracy to both microscopic and SEM analysis. RTI is also relatively inexpensive, expeditious, and easy to use in comparison to the more traditional methods. By creating a digital record that can be utilized by experts and untrained observers alike, RTI allows for an accurate, interactive digital record to be shared with other experts or retained for future examination, comparison, and teaching. With further research, RTI has the potential to assist in a holistic order of forensic saw mark analysis, documentation, and presentation.

### A48 Micro-Computed Tomography (micro-CT) Analysis of False Starts on Bones After Prolonged Exposure to Fire: An Experimental Study

*Giovanni Cecchetto, MD, PhD\*, Legal Medicine and Toxicology Unit, Padova 35121, ITALY; Chiara Girardo, MD, Via giustiniani 2, Padova, ITALY; Ludovico Fava, MD, Padova, ITALY; Chiara Vignotto, MD, Padova, ITALY; Marco Bisceglia, MD, Modena, ITALY; Amalia Lupi, MD, Padova, ITALY; Paolo Fais, PhD, Medicina Legale Dipartimento Scienze Mediche Chirurgiche, Bologna 40126, ITALY; Massimo Montisci, PhD, Padova, ITALY*

**Learning Overview:** After attending this presentation, attendees will be aware of an application of micro-CT for the analysis of false starts on charred bones and its role in the identification of the inflicting tool.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the possible role of microradiology in the field of forensic pathology and anthropology.

**Background:** Recently, micro-CT was successfully applied for the morphologic and morphometric analysis of false starts on bone samples in order to identify the tool used for their production. It is well known that heat-induced transformations of bone tissue include color and dimension variations, fracture development from a macroscopic point of view, and microscopic histological changes.

**Goal:** The purpose of this study is to investigate the role of micro-CT in the identification and characterization of saw marks on human bones before and after exposure to fire, in order to establish if heat-induced changes of the bone may alter false starts.

**Materials and Methods:** A crosscut saw and a ripcut saw were used to produce two different false starts on 30 bone samples obtained from human fibulae. Marks were inflicted manually, sliding the saws and the knives perpendicularly to the long axis of the bone.

The bone samples were divided into two groups: (1) the first group was exposed to the flame of a burner camping stove fire for 3, 9, and 15 minutes; and (2) the second group was exposed to the flame of a burner camping stove for 6, 12, and 18 minutes. Each sample was photographed and scanned using a SkyScan 1172 HR Micro-CT analyzed by micro-CT before and after every period of burning. N-Recon software was utilized for reconstructions, and Digital Imaging and Communications in Medicine (DICOM® Converter® software was used to convert bitmap files in DICOM. OsiriX® open source software, version 7.0.1 was used to elaborate Multiplanar (MPR) reconstructions.

A morphometric assessment was manually performed on the sagittal plane by the same radiologist, measuring the following parameters: top kerf width, depth, bottom kerf width, angles degree, and floor width. The paired student's *t*-test analysis (level of significance set at  $p < 0.01$ ) was used to assess if a statistical significant difference occurred, for each parameter, between false starts produced by the same saw before and after fire exposure.

**Results:** Up to the maximum burning time tested, false starts were macroscopically recognizable after every fire exposure. MicroCT analysis did not show any statistically significant difference in the morphometric features required to identify which saw was used. Micro-CT was able to identify and measure bone marks both on fresh and burned bones. The morphology and number of the detected marks did not change after the burning trial. A minimal reduction of the height and depth was observed after exposure to fire.

**Conclusions:** The fire exposure neither hides the evidence of false starts on bone surface nor invalidates their micro-radiological analysis. MicroCT seems to be a solid technique for the qualitative and quantitative analysis of false starts, even in charred bones.

The preliminary results of this study suggest that micro-CT analysis could be useful for the identification of tool marks on human bones and also after exposure to fire. The possibility of assessing the morphometric features of each lesion indicates that this technique may provide accurate information about the characteristics of the inflicting tool. Although the morphometric analysis of the saw marks also seems feasible after burning, further experiments testing heat-induced changes of the bone at different temperatures and timing of exposure to fire are required to draw any definitive conclusion.

This present study shows that micro-CT is also able to characterize false starts produced by different saws after 18 minutes of exposure to fire. MicroCT seems to be a solid technique for the qualitative and quantitative analysis of false starts, even in charred bones.

### A49 Dehydration-Induced Quantitative Morphometric Alterations to Sharp Force Trauma on Bones

Taylor M. Flaherty, BS\*, Roseville, MI 48066; Carolyn Rando, PhD, University College London, London WC1H 0PY, UNITED KINGDOM; Rebecca Watts, PhD, University College London, London WC1H 0PY, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand how the taphonomic changes caused by dehydration alter the dimensions of bones as well as the v-shaped cross sections, commonly known as kerf marks, left on bone by sharp-edged objects.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating alterations resulting from a taphonomic agent that is often overlooked in the forensic literature. This presentation will also provide an increased understanding of the reliability of kerf mark data collected from skeletal remains that have been subjected to dehydration.

When human remains are recovered in a forensic context, there is a general understanding that taphonomic processes have affected the presentation of evidence on the body. As human bone is composed of 15%–25% water, dehydration is a taphonomic agent that may cause morphological alterations, including dimensional and volumetric shrinkage and fracture characteristics.<sup>1-3</sup> It has also been suggested that dehydration affects the presentation of striations in sharp force trauma wounds.<sup>4</sup> Despite these findings, dehydration as a taphonomic agent is often overlooked in forensic taphonomy research and forensic analysis.

To quantify the effects of the dehydration process, this study created a controlled experiment that subjected bone samples to lab-induced dehydration. It was hypothesized that the loss of water would affect the morphology of the bones and associated kerf marks, though it was unknown whether these changes would be significant. Domestic pig radii ( $n=9$ ) were macerated and sectioned into samples no wider than 1.5cm ( $n=43$ ). Sharp force trauma was then inflicted on each sample using a household steak knife with a serrated blade. One kerf mark was created on the medial aspect of each section, then immediately photographed to record the pre-dehydration measurements. Bone sections were then subjected to five 24-hour heating and cooling cycles using an Andrew James Food Dehydrator. Samples were weighed using a digital scale after each 24-hour cycle was finished to determine the percentage of water loss. Upon completion of the five heating and cooling cycles, each sample was photographed again to record the post-dehydration measurements. Using ImageJ, six measurements were taken from each sample's before and after photograph: (1) bone section length from the anterior and posterior midpoints; (2) bone section width from the superior and inferior midpoints; (3) bone section medial surface area; (4) kerf mark maximum length; (5) kerf mark maximum width; and (6) kerf mark area. Inter- and intra-observer error tests were completed to ensure consistency in landmark identification and measurements.

Results indicated that both bone sections and kerf marks were altered by the dehydration process. Following the completion of the five 24-hour cycles, the bone samples experienced an average of 22.8% reduction in weight ( $p<.001$ ) and an average of 8.8% reduction in size ( $p<.001$ ). Kerf marks experienced an average size reduction of 28.5% ( $p<.001$ ). This illustrates that kerf mark data obtained from dehydrated skeletal remains may not accurately represent the dimensions of the original wound, thus impacting conclusions regarding type of weapon and trauma infliction in forensic cases. Further, these results demonstrate the demand for future taphonomic research to consider the effects of dehydration on the morphology of bones and bone trauma.

#### Forensic Anthropology, Taphonomy, Sharp Force Trauma

## A50 Fracture Patterns Associated With an Airplane Propeller Strike: A Case From the West Tennessee Regional Forensic Center

Jenna M.S. Watson, MA\*, University of Tennessee, Department of Anthropology, Knoxville, TN 37996-1525; Benjamin J. Figura, PhD, West Tennessee Regional Forensic Center, Memphis, TN 38105

**Learning Overview:** After attending this presentation, attendees will understand the skeletal trauma patterns that result from propeller strikes and the importance of recognizing and interpreting propeller strike trauma in forensic cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a better understanding of the skeletal trauma patterns that result from propeller strikes in order to improve the ability of anthropologists to recognize this type of trauma in cases in which human remains are recovered from the water and propeller trauma is possible.

Death or injury due to propeller strikes from either a boat or airplane are not common, but they do occur. In 2017, the Coast Guard documented 172 accidents involving a boat propeller, and between 1980 and 2004, the National Transportation Safety Board (NTSB) documented 80 accidents involving airport ground crew struck by airplane propellers.<sup>1,2</sup> Previous studies of propeller trauma due to boat propellers have described severe blunt force injuries, such as longitudinal fractures and delamination to the cranium, and comminuted fractures or complete transection of the long bones.<sup>3,4</sup> Forensic anthropologists may be asked to interpret trauma patterns on remains recovered from the water; thus, it is important for anthropologists to be able to recognize propeller trauma patterns in the skeleton. To better understand propeller trauma patterns in bone, this study examines a case of airplane propeller trauma in a ground crew member who was fatally struck by a moving airplane propeller at the Memphis International Airport in 1998. Using this known case of airplane propeller trauma, this study aims to determine whether there are distinct patterns of skeletal trauma associated with propeller strikes, and if so, to describe and document those patterns.

The bones present consisted of a skull (cranium and mandible), right radius, and right ulna, which were retained at autopsy for anthropological analysis of trauma at the West Tennessee Regional Forensic Center. All elements required reconstruction due to extensive fragmentation. After reconstruction was completed, the trauma type and patterns were described, photographed, and compared to other cases of propeller trauma described in the literature.

The cranium exhibited a longitudinal fracture running transversely across the frontal bone, as well as radiating fractures to the right side of the cranium. An area of delamination was present on the frontal bone. Scalloping and external beveling were present on the frontal bone, and internal beveling was also present at the area of delamination and on the right frontal bone near the temporal line. There was also severe fragmentation of the midfacial region resulting in complete detachment of the maxilla. The right proximal ulna exhibited a comminuted fracture and complete transection at the proximal shaft. The distal right radius also exhibited a comminuted fracture. It was possible to determine at least one impact point on the frontal bone, as well as impacts to the right elbow (proximal ulna) and wrist (distal radius).

The trauma patterns observed in this case (multiple blunt force injuries from multiple high-speed impacts) are consistent with other cases of propeller trauma described in the literature.<sup>3,4</sup> A propeller strike is able to inflict multiple blows in a short period of time resulting in linear longitudinal fractures, delamination, radiating fractures, internal beveling of the cranium, and complete transection or comminuted fractures of the long bones.<sup>4-6</sup> While propeller injuries are uncommon, it is not uncommon for a forensic anthropologist to observe complex trauma patterns and be asked to determine the type and direction of force, as well as the minimum number of impacts. Propeller trauma patterns could mimic other mechanisms of blunt force trauma, thus care should be taken when making interpretations of complex trauma patterns. Given the ability of propellers to inflict multiple high-speed impacts, and the propeller trauma patterns observed in this case study, additional trauma studies that explore uncommon mechanisms of blunt force trauma, such as propellers, are needed.

### Airplane Propeller Trauma, Skeletal Trauma, Forensic Anthropology

## A51 A Survey of Peri-Mortem Vertebral Trauma in Historic Cases

*Andrea Palmiotto, PhD, Indiana University of Pennsylvania, Indiana, PA 15701; Brittany S. Walter, PhD\*, Defense POW/MIA Accounting Agency Lab, Offutt Air Force Base, NE 68113; Larkin F. Kennedy, PhD, Defense POW/MIA Accounting Agency Laboratory, Offutt Air Force Base, NE 68113-4006; Emily R. Streetman, PhD, Omaha, NE 68104*

**Learning Overview:** After attending this presentation, attendees will be aware of: (1) the value of incorporating vertebrae in trauma analysis; (2) how analysts typically describe and interpret peri-mortem vertebral trauma; and (3) the importance of standardization in descriptions of vertebral skeletal trauma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) facilitating analysis of vertebral trauma in skeletonized remains; (2) highlighting the importance of reconstruction and articulation of fragmented remains for trauma analysis; and (3) improving standardization of vertebral trauma analysis by presenting illustrative examples.

Vertebrae present challenges in trauma analysis because of their unique morphology and articulations within the thorax. Additionally, due to the complex structure of vertebrae, expectations based on biomechanics are of limited value. The forensic anthropological literature presents conflicting opinions regarding the importance and analytical potential of vertebral trauma. Experimental and retrospective trauma research primarily focus on the skull, long bones, and ribs. Several published case studies demonstrate that analysis of vertebral trauma can contribute significantly to overall trauma interpretation. However, in other cases, analysts cite fragmentation of the vertebral remains as precluding any useful interpretative analysis to be undertaken. The foremost objective of this study is to clarify discrepancies in the literature by assessing the value of vertebral trauma analysis in a sample of skeletal trauma analyses of various mechanisms.

Trauma analyses of historic cases associated with United States servicemen and civilians lost during World War II and the Korean War from the Defense POW/MIA Accounting Agency Laboratory are reviewed ( $n=51$ ). Analyses were completed in the blind, and unknown individuals have since been identified and associated with air ( $n=18$ ), ground ( $n=31$ ), and sea losses ( $n=2$ ). These cases display blunt force ( $n=10$ ), projectile ( $n=18$ ), extensive (e.g., deceleration or blast) ( $n=18$ ), or indeterminate ( $n=5$ ) trauma.

Overall, analyses of affected vertebrae are highly variable. The degree of fragmentation is rarely quantified. Most analysts include photographs of vertebral trauma (65%) and incorporate adjacent skeletal regions in their analysis (63%). However, reconstruction or articulation are undertaken in less than half of cases (41%). Vertebral trauma contributes to directionality interpretations in approximately half of cases (51%).

When these results are assessed by mechanism, photographs of vertebral trauma are included more frequently in blunt-force (70%) and projectile (100%) trauma cases than extensive trauma cases (33%). More often than not, analysts incorporate adjacent skeletal regions in vertebral trauma analysis no matter the mechanism (blunt force=60%, projectile=67%, extensive=72%). Vertebrae are reconstructed more commonly in projectile (78%) than blunt force (30%) or extensive (17%) trauma cases, and directionality is interpreted more often in projectile (67%) and extensive (56%) cases than in blunt force (20%) cases. These trends may reflect factors such as the condition (e.g., fragmentation) of vertebrae or the absence of standardized language and guidance for analysis of vertebral skeletal trauma. Additionally, in extensive trauma cases, analysts may not directly address vertebral trauma in an attempt to synthesize observations.

Results indicate that analyses of vertebral trauma are highly variable. Analysts are likely to consider the relationship between trauma observed on vertebrae and adjacent elements regardless of traumatic mechanism. Further, vertebral trauma analysis is underused in blunt force trauma cases, and analysts more often reconstruct vertebrae and infer directionality in projectile trauma cases.

Although vertebrae have received less attention than other elements in the trauma literature, preliminary results suggest that vertebrae are valuable in the interpretation of skeletal trauma regardless of the mechanism of injury. Reconstruction of fragmented vertebral remains and consideration of adjacent elements has the potential to improve analyses and result in more robust descriptions. Though many of the cases reviewed here present relatively complete sets of skeletal remains, these results suggest that vertebrae are valuable in cases with incomplete and fragmented remains as well. These findings facilitate a more comprehensive and standardized interpretation of injury patterns in skeletal remains and direct future research on vertebral trauma in forensic cases.

### Peri-Mortem Trauma Analysis, Vertebral Injury, Mechanism of Trauma

## A52 Prediction of Bullet Type From Cranial Gunshot Trauma

*Elizabeth A. DiGangi, PhD\**, Binghamton University, Binghamton, NY 13902; *Tessa Somogyi, MA\**, Binghamton University, Binghamton, NY 13902; *Elizabeth A. Evangelou, MA\**, Vestal, NY 13850; *Gary D. James, PhD*, Binghamton University, Anthropology, Binghamton, NY 13902

**Learning Overview:** After attending this presentation, attendees will have learned that it is possible to differentiate bullet type (full metal jacket vs. jacketed hollow point) from measurements of cranial entrance wounds.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the importance of experimental research with gunshot wounds.

Forensic anthropologists have long been interested in cranial gunshot wound interpretation. While being able to understand key extrinsic variables, such as velocity, caliber, distance, type of firearm, and that bullet construction would be useful to a forensic investigation, research has generally fallen short with ways to elucidate such variables from the analysis of bone alone. Retrospective studies that have mined forensic case reports for data have been somewhat useful in terms of establishing patterns, but an experimental approach is superior in its ability to precisely control for extrinsic variables.

Therefore, this project was designed to experimentally test the effect that bullets of the same caliber having two separate constructions (full metal jacket vs. jacketed hollow point) have on cranial gunshot trauma, with the goal being to ascertain whether it would be possible to differentiate between the two different types of bullets from resultant cranial trauma alone. These distinct bullet types are designed to fully penetrate and not fragment (full metal jacket) or penetrate and expand upon contact (jacketed hollow point). Based on the different physical properties of the bullets, it was hypothesized there would be some indication in the cranial trauma that would allow differentiation between the two, with damage from jacketed hollow point bullets being greater.

Forty-five donated adult human heads were obtained from an anatomical tissue supply company, specifically for the purpose of trauma research. A specialized shooting stand was built to support each head at the height of an average adult male, and each head was shot once by the same expert marksman at a distance of three yards either in the frontal bone or parietal/temporal bone, using a revolver with a 1<sup>7</sup>/<sub>8</sub>" barrel loaded with 0.38 caliber bullets. Bullet type (jacketed hollow point vs. full metal jacket) was distributed randomly yet evenly between individuals. Following the experiment, heads were autopsied and macerated using standard procedures.

Entrance wounds, exit wounds (if present), and resultant fractures were examined both endocranially and ectocranially. Three observers independently scored all 45 crania. Quantitative data were collected on the minimum and maximum diameter of the entrance and exit wounds. Qualitative data included evaluation of bevel characteristics, such as its relative size to the wound and whether bevel margins were smooth or crushed, wound shape (i.e., oval, round, or irregular), presence of circumferential delamination around wound margins, and the degree of any cranial fragmentation.

Given missing values from the qualitative data due to not every cranium having an exit wound and to maximize the sample size number of frontal shots ( $n=24$ ) and parietal/temporal shots ( $n=21$ ), only the quantitative data were analyzed here. Logistic regression was used to create a diagnostic test of the quantitative data to include sensitivity (i.e., ability to pick up true positives), specificity (i.e., ability to pick up true negatives), and accuracy; with the jacketed hollow point as the referent bullet. For entrance wounds to the frontal bone, a cut point of 11.0mm minimum diameter had a 90.9% sensitivity, 84.6% specificity, and 87.5% accuracy in determining the bullet type, with the jacketed hollow point entrance more likely to be above 11mm ( $p<.001$ ). For entrance wounds to the parietal/temporal bone, a cut point of 9.5mm minimum diameter had 100% sensitivity, 80% specificity, and a 90.5% accuracy in determining bullet type, with the jacketed hollow point entrance more likely to be above 9.5mm ( $p<.0001$ ).

These results indicate that for .38 caliber bullets, entrance wound diameter at different locations on the cranium is a very strong predictor of bullet construction, with jacketed hollow points creating a larger entrance wound overall. Further research should evaluate if this pattern holds for bullets of other calibers. Finally, these results demonstrate that it is possible to have significant findings with quantitative (and therefore non-subjective) analysis of gunshot wound trauma.

*This project was supported by an award from the National Institute of Justice.*

### Gunshot Wounds, Fracture Analysis, Forensic Anthropology

## A53 Atypical Gunshot Wounds in a Controlled Experiment

Elizabeth A. Evangelou, MA\*, Vestal, NY 13850; Tessa Somogyi, MA\*, Binghamton University, Binghamton, NY 13902; Kevin E. Sheridan, PhD, Binghamton University, Anthropology, Binghamton, NY 13902; Elizabeth A. DiGangi, PhD, Binghamton University, Binghamton, NY 13902

**Learning Overview:** After attending this presentation, attendees will be aware of the variability in cranial gunshot entrance and exit wounds and fracture patterns resulting from a controlled experimental study.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for controlled ballistic trauma studies to further elucidate and understand factors that produce variability in cranial gunshot entrance and exit wounds.

The interpretation of gunshot trauma is a key aspect of forensic anthropology, but few studies have systematically tested the effect of gunshot trauma on the cranium. Recently, there has been a push for experimental gunshot studies under controlled conditions in order to expand our knowledge.

This study presents three examples of atypical gunshot fracture patterns that were drawn from a sample of 45 heads belonging to a larger experimental study focusing on gunshot fracture patterns. Prior to shooting, each head was placed atop a six-foot-high shooting stand and held in place using luggage straps. The heads were shot using a Smith and Wesson® model 438 J-frame revolver with a 1<sup>7</sup>/<sub>8</sub>" barrel loaded with 0.38 caliber bullets each weighing 130 grains. Each head was shot once either anteriorly through the frontal bone or laterally through the temporal/parietal bone, using either a Full Metal Jacket (FMJ) bullet or a Jacketed Hollow Point (JHP) bullet. After shooting, the heads were macerated using standard processing techniques. Shot distance and bullet velocity were both controlled for, with each head being shot from three meters away and each bullet fired from the same weapon. Impact velocities ranged from 561f/s to 738f/s, which is considered low velocity. The three examples that follow are fracture patterns that were not expected, given the controlled conditions described above.

**Example 1:** Circumferential delamination around gunshot entrance wounds was observed in both FMJ and JHP bullets. It has been hypothesized that circumferential delamination only occurs in FMJ shots.<sup>1</sup> Presence of circumferential delamination by bullet construction was tested using a Pearson chi-square test with an alpha of .05 and was not significant ( $p=.682$ .) indicating that there is no relationship between the presence of circumferential delamination and bullet construction. These results suggest that the mechanism that causes circumferential delamination is not related to bullet construction. It was hypothesized that circumferential delamination may be related to impact velocity or shot distance, rather than bullet construction.

**Example 2:** A bone plug originating from a frontal entrance wound occurred once during the controlled study. Bone plugs are rarely described in ballistic trauma literature and are an uncommon finding. Additionally, when bone plugs are discovered, they are usually with exit wounds, not entrance wounds. The factors that cause bone plugs are not well understood, and it is thought that velocity plays a large role, with low-velocity gunshots more likely to produce cranial bone plugs. The impact velocity for the shot that produced the entrance wound bone plug was 676f/s, a low-velocity shot; although this was an average velocity for this sample. Further study into what factors of this shot are unique for this particular sample may provide more information about the factors that cause bone plug formation.

**Example 3:** Five of the 45 heads exhibited excessive fracturing or shattering of the cranial vault. For these five heads, the exit wounds did not display any characteristic evidence of normal external beveling. Rather, the observed fracturing appeared to resemble medium- or high-velocity gunshot trauma. Known impact velocities for these shots were average for the study and well within the low-velocity range. Additionally, these five heads had average bone density within the tested sample.

These examples are important to the study of gunshot trauma in forensic anthropology because they demonstrate unexpected results during a controlled experiment. These examples suggest that there is a need for more controlled studies to fully understand the variability of gunshot trauma.

### Forensic Anthropology, Gunshot Trauma, Controlled Experiment

## A54 Radiographic Evidence of Gunshot Defects in Skeletal Remains: A Preliminary Study

Naomi S. Levin, BA\*, Texas State University, San Marcos, TX 78666

**Learning Overview:** The goals of this presentation are to aid in the understanding of how forensic anthropologists utilize radiography for trauma interpretation of gunshot defects and to test the reliability of using radiography in trauma interpretations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating how the decomposition and maceration processes of human remains affect radiographic detection of Radiopaque Material (ROM), which may be useful in trauma interpretation.

Understanding trauma patterns provides forensic anthropologists with necessary contextual information about cause and manner of death. A difficulty in forensic cases for the medical examiner or forensic anthropologist is distinguishing trauma as a Gunshot Wound (GSW) or Blunt Force Trauma (BFT). This difficulty occurs when the remains are incomplete, are highly fragmented, present atypical trauma patterns, or have been exposed to taphonomic processes.<sup>1-4</sup> In some of these cases, ROM (e.g., metallic fragments from the bullet observed on radiographs) can serve as an indicator of a gunshot defect, aiding in trauma interpretation.

While radiographs are commonly used by forensic anthropologists in the detection of opacities to confirm the presence of a GSW, the validity of pursuing opaque material as an indicator of GSW in skeletal remains has not been extensively examined. Specifically, few studies have examined how often opaque materials are observed on radiographs of GSW, and fewer studies have focused on lead particles embedded in the gunshot defects as evidence in cases presenting atypical trauma patterns. The aim of this study is to validate the use of opaque materials detected using radiographs as an indicator of gunshot defects in forensic anthropological investigations involving skeletal remains. This study helps to determine if radiopacities are a reliable indicator of gunshot trauma.

To examine how frequent opacities are present in GSWs, a total of 13 donors from the Texas State Donated Skeletal Collection were radiographed. The donors were radiographed using a portable X-ray machine, or MinX-Ray, at the Osteological Research and Processing Lab at Texas State University. The regions of trauma include cranial, intraoral, and chest and torso. Twelve of these donors were radiographed after the decomposition and maceration processes, resulting in a detection frequency of ROM of 25% (3 donors presented material). One of the donors exhibited material after decomposition, but appeared negative in the radiographs after it was macerated and processed.

Understanding the frequency of ROM detection in GSWs is valuable to the forensic professionals who are involved in trauma interpretation. It is further necessary to understand how the decomposition and maceration processes affect radiographic detection of these materials. This preliminary study exhibits a 25% frequency of ROM detection after both decomposition and maceration, compared to a 33% detection rate only after decomposition. This difference shows that maceration affects detection. Variables that could not be controlled in these real-world cases include shooting range, ammunition type, weapon used, and exposure of remains during the postmortem interval. Further research should include radiographs of GSWs before decomposition, as well as a greater sample and more controlled variables, which may also affect detection but could not be controlled for in this study.

### Gunshot Defects, Radiography, Decomposition and Maceration

## A55 Fracture Pattern of Midface Ballistic Trauma

Casey File, MS\*, Knoxville, TN 37909; Deborrah C. Pinto, PhD\*, Harris County Institute of Forensic Sciences, Houston, TX 77054; Si Gao, MS, Harris County Institute of Forensic Sciences, Houston, TX 77054; Jason M. Wiersema, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Julie M. Fleischman, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054; Miriam E. Soto Martinez, PhD, Harris County Institute of Forensic Sciences, Houston, TX 77054

**Learning Overview:** After attending this presentation, attendees will be aware of midface fracture patterns that may assist in differentiating intraoral from submental gunshot wounds.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the research on gunshot wounds to the midface that have direct implications for dry bone analysis.

Gunshot injury signatures (i.e., entrance and exit wound) can often be diagnosed and interpreted at autopsy when soft tissue is present. In the absence of soft tissue, fracture patterns of the hard tissue may be interpreted; however, there is limited information regarding skeletal fracture patterning resulting from intraoral versus submandibular gunshot wounds. In 2005, Fenton et al. reported on five skeletal cases with self-inflicted gunshot wounds to the midline of the skull.<sup>1</sup> They identified a possible diagnostic pattern of bilateral fracturing that occurs as a result of shotgun, rifle, and handgun injuries. The limitation of the 2005 study was that it addressed only five cases, with different firearms: two intraoral rifle, two submandibular or possible submandibular shotgun, and one mid-frontal pistol. The purpose of the current research is to build upon the 2005 study by examining a focal region of the skull; (i.e., the palate; and mandible) of a larger study sample to identify possible distinguishing patterns between intraoral and submandibular gunshot wounds.

This study is a retrospective exploratory investigation of suicides in which a handgun was positioned either intraorally or submentally. The mandible and palate are the skeletal emphases since these are the main points of entry for these types of gunshot wounds. Additionally, this study addresses the relationship of the chambering of the firearm/projectile caliber to the injury pattern. The study sample comprised 187 suicides by intraoral or submental gunshot wounds autopsied from 2010–2019 by the Harris County Institute of Forensic Sciences in Houston, TX. These data were collected by reviewing radiographs, autopsy photographs, and autopsy reports for the presence or absence of a mandibular fracture and/or palate impact. Projectile caliber size was available for all but four cases. The variables investigated were palate impact, the location of the mandibular fracture (anterior, posterior, or both), and the projectile caliber. Logistic regression models were used to identify the relationships between the presence/absence of a mandibular fracture, palate impact, and location of mandibular fractures in relation to the point of entry (submental and intraoral wound). Pearson's chi-square test was used to evaluate the relationship between the presence of mandibular fractures and projectile caliber.

Of the 187 cases, 19 (10%) were submental and 168 (90%) were intraoral. Sixteen of the 19 submental cases (84%) displayed a mandibular fracture, while 31 of the 168 intraoral cases (18%) displayed a mandibular fracture. Of the 19 submental cases, 8 (42%) displayed only an anterior mandibular fracture, zero displayed only a posterior fracture, and 7 (37%) displayed both anterior and posterior fractures. Of the 168 intraoral cases, there were 26 (3.5%) with an anterior fracture, 4 (2.3%) with a posterior mandibular fracture, and 2 with simultaneous anterior and posterior mandibular fractures. Finally, palate impacts were identified in 18 of the 19 submental cases, and 132 of 168 intraoral cases.

The logistic regression model demonstrated that for submental entries, the odds of observing mandibular fractures were significantly greater than not observing mandibular fractures ( $OR=24.04$ , 95% CI [6.53, 88.52];  $p<0.001$ ). In addition, palate impacts were not a significant predictor of point of entry ( $p>0.05$ ). Mandibular fracture location was statistically significant for submental entries ( $p<0.001$ ), and the odds of observing simultaneous anterior and posterior fractures for submental entries was between 10 and 11 times greater than observing anterior and posterior in isolation. Chi-square analysis indicated there was no significant relationship between projectile caliber and the presence of a mandibular fracture ( $p>0.05$ ).

The results of this study are promising for identifying skeletal fracture patterns that may differentiate between intraoral and submental gunshot wounds. One study limitation is the small submental sample size. A larger sample size may provide additional statistical support for interpreting intraoral versus submental gunshot wounds based on mandibular fracture patterns. Future prospective studies—via autopsy and/or Computed Tomography (CT) scanning—should explore the fracture patterning of the entire skull using known cases of intraoral and submental gunshot wounds.

### Forensic Anthropology, Gunshot Trauma, Trauma Analysis

## A56 The Effects of Diabetes Mellitus (DM) on Bone Fracture Susceptibility and Repair With Applications to Non-Accidental Forensic Fracture Interpretation

Donna C. Boyd, PhD, Radford University, Radford, VA 24142; Sadie R. Friend\*, Radford, VA 24141

**Learning Overview:** The focus of this research is the examination of the effect of DM upon bone fracture risk and subsequent bone healing. The goals of the study are to identify the bony signatures of DM, determine whether they can be differentiated from other comorbidities affecting the skeleton, and evaluate whether the presence of DM increases fracture risk and alters fracture healing in diabetic individuals.

**Impact on the Forensic Science Community:** This research will impact the forensic science community by providing greater understanding of the influence of DM on bone fracture and healing and lead to the potential for identification of this condition in forensic remains. It will ultimately aid in improving accuracy of forensic trauma interpretations of accidental vs. non-accidental fracture and Time Since Injury (TSI).

Previous research has suggested that diabetes, a chronic metabolic disease characterized by increased blood glucose levels, can result in an array of deleterious effects upon the human skeleton, including irregular distribution of bone mass, decreased bone strength, increased fracture susceptibility, extended healing times, and poor bone regeneration. DM complications and treatments, including hyperglycemia, increased Advanced Glycation End product (AGE) formation, reactive oxygen species generation, inflammation, and the ingestion of insulin and oral antibiotic medicines, can compromise bone health, including its formation, mass, density, distribution, healing process, velocity, and overall healing outcome. DM has been associated with an increase in osteoclastic and thus resorptive bone processes at the expense of osteoblastic (bone forming) ones, although this interpretation has been questioned.<sup>1,2</sup>

However, the specific effects of DM on bone quality and strength, fracture risk, and fracture healing have rarely been studied from an anthropological perspective using known diabetic decedent collections. In the current research, 44 known diabetic decedents, ranging in age from 21 to 84 years, comprise the combined study sample, derived from the University of Tennessee William Bass collection (self-identified as diabetic), the Terry collection (diabetes informed by medical records), and the Radford University Forensic Science Institute (medical records). The majority are affected by Type 2 DM; however, at least two decedents are noted as Type 1. Variables recorded from this sample include presence, type, and location of fracture, character and status of bone healing, and microscopic evidence for bone distribution, density, and overall bone quality (using a 3D digital microscope at 5x–200x magnification).

It is hypothesized that this diabetic sample will manifest a higher fracture frequency and greater number of fractures in non-union or a non-advanced stage of bone repair and remodeling compared to that observed for the non-diabetic decedents in each collection.

Results generally support the stated hypothesis. Fracture frequency is significantly higher (44%) in the diabetic sample, accompanied by earlier (rather than later) fracture healing status for the majority of fractures. At least three decedents manifest amputations in their lower limbs. Microscopic analysis of exposed trabeculae reveals evidence for diminished bone volume in healing fractures, reflected by the presence of smaller bone calluses. Also evident is irregular bone distribution, macroporosity, and overall poor bone quality and strength in the diabetic sample.

However, a confounding limitation of the study was the presence of significant comorbidities associated with diabetic decedents. A majority of the diabetic individuals manifest evidence for osteoporosis, cancers, and other diseases that influence bone quality and complicate attempts to definitively identify bony signatures of DM.

Bone repair for the diabetic sample is interpreted using a model of anabolic compromise in conjunction with catabolic excess and informs the interpretations regarding TSI for fractures observed in diabetic decedents in a forensic context. In conclusion, given the increased fracture risk and fracture healing time variability, as well as decreased bone regenerative capacity for diabetic individuals, it is recommended that caution be exercised in interpretations of non-accidental bone fracture and its TSI in diabetic decedents, particularly for those who are elderly and manifesting associated comorbidities such as osteoporosis.

## A57 The Reliability of Morphoscopic Data From 3D Surface Scans

Sarah Schwing, BA, BS\*, Knoxville, TN 37996

**Learning Overview:** After attending this presentation, attendees will be more knowledgeable of the reliability and accuracy of obtaining morphoscopic data from 3D surface scans, in contrast with traditional methods of data collection utilizing physical human skeletal remains. This presentation will briefly discuss the advantages of 3D surface scans over other technologies, including radiography and Computed Tomography (CT) techniques.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the utility of 3D surface scans in place of physical bones when seeking morphoscopic data and will discuss the potential of 3D surface scans to increase accessibility of human skeletal collections worldwide through the creation of digital skeletal collections, as well as increase sample sizes for future research endeavors. Accordingly, this presentation will contribute to the discussion of the types of data that can be accurately gleaned from such digital skeletal collections.

Digitally formatted human skeletal elements represent an area of recent and increasing interest within forensic anthropology, particularly for the purpose of obtaining metric data.<sup>1,2</sup> Digital human skeletal elements, in the form of CT scans, photogrammetric images, and 3D surface scans, have been used in numerous studies employing geometric morphometric techniques to obtain metric data.<sup>1,2</sup> Research seeking morphoscopic data from similar digitally formatted human skeletal elements, particularly from 3D surface scans, however, is not prevalent within the literature, suggesting that this area has not been thoroughly explored.<sup>3</sup>

3D surface scans of human skeletal elements may be useful in providing morphoscopic data for various parameters of the biological profile, particularly for estimations of sex, age, and ancestry.<sup>4</sup> Previous studies utilizing 3D surface scans and focused on the collection of metric data through geometric morphometrics have reported results of high precision and accuracy.<sup>5-7</sup> Additionally, limited research focused on the collection of non-metric data from 3D representations of bones has also reported findings of high reliability and accuracy.<sup>4,8</sup> Such studies of non-metric data collection, however, have primarily employed a form of CT scan as their data source.<sup>4,9</sup> This study utilizes 3D surface scans as they are more readily produced by forensic anthropologists and others without easy access to clinical medical equipment.<sup>2,3</sup>

This study investigates intra-rater agreement of trait expression utilizing seven non-metric traits of the mandible, including pinching of ascending ramus, shape of inferior border, protrusion of mental eminence, undulation of inferior body, gonial eversion, height of coronoid process, and shape of mandibular notch. These traits were scored twice on a sample of 50 mandibles from the Bass Donated Skeletal Collection, once utilizing digital renderings of the mandibles in the form of 3D surface scans, and a second time using the bones themselves. This sample was comprised of individuals of European and Hispanic descent and included both males and females. 3D scans were synthesized using a NextEngine® 3D laser scanner. Cohen's kappa was used to assess agreement between both sets of scores and all individuals were pooled for statistical analyses, as inter-group differences were not a focus. Standard error and 95% confidence intervals were also calculated for each trait.

The results of these analyses suggest that shape of inferior border, undulation of inferior body, gonial eversion, height of coronoid process, and shape of mandibular notch demonstrate moderate to substantial agreement between 3D surface scans and physical mandibles. These five traits presented kappa values of 0.467 to 0.638 and *p*-values of  $\leq 0.001$ , indicating agreement for these traits was statistically significantly different from zero. Pinching of ascending ramus and protrusion of mental eminence demonstrated smaller levels of agreement. Among all traits included, gonial eversion and shape of mental eminence demonstrated the greatest agreement, with kappa values of 0.524 and 0.638, respectively.

This study serves to demonstrate the potential utility of 3D surface scans in place of physical bones when remains are inaccessible or no longer within an anthropologist's possession. Results demonstrated encouraging results, moderate to substantial agreement between formats, which may become more pronounced in studies of larger sample sizes. Further investigation through future research, as well as investigation of additional skeletal elements, however, is necessary before these techniques should be employed.

## A58 Experimental Assessment of the Surface Quality of 3D Printed Bones for Evaluative Interpretation in Forensic Anthropology Reconstructions

Rachael M. Carew, MSc\*, University College London, London WC1H 9EZ, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, London WC1H 9EZ, UNITED KINGDOM; Carolyn Rando, PhD, University College London, London WC1H 0PY, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will appreciate the utility of 3D printed replica bones and the challenges around 3D printing fine surface features in forensic anthropology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating challenges associated with the quality and validity of 3D printed bones to accurately portray forensic skeletal material.

The goal of this research was to investigate the surface quality of 3D printed bones, in order to determine if 3D prints can be a suitable proxy to human bones for demonstration of evidence in courts of law. It was expected that the overall shape of the prints would be accurate, but it was unknown whether the quality of the representation of fine surface details would be sufficient.

3D printed replicas of human remains have been shown to be useful tools in courtroom demonstrations of evidence and have been used in several court cases internationally.<sup>1</sup> 3D prints provide a medium that users (such as expert witnesses or jurors) can hold, touch, rotate, and even use to mimic mechanisms of injury.<sup>1,2</sup> Consequently, it is believed that using 3D prints as visual aids may assist laypeople in their understanding of expert/medical testimony.<sup>3</sup> While 3D printed bone replicas have been established as accurate and robust representations of skeletal elements, little research has investigated the representation of fine surface details, such as fracture lines, porosity or texture.<sup>1</sup> Such features are important in the forensic examination of remains, and especially so for exhibiting skeletal trauma in courtrooms.

In this study, nine human bones with differing morphology were digitized using Computed Tomography (CT) scanning on a Toshiba® Aquilion ONE™ Vision Edition scanner. The CT data were reconstructed using 3D Slicer and Blender software following Carew et al. to create 3D models.<sup>1</sup> The 3D models were 3D printed using Selective Laser Sintering (SLS) on an EOSINT® P100 with a white powder material. A three-phased approach was implemented to assess: (1) the metric accuracy of the 3D prints; (2) the viability of applying age and sex estimation methods (with multiple observers;  $n=8$ ); and (3) the surface quality compared to the dry bones, using a customized scoring method (with multiple observers;  $n=8$ ).

The results of phase 1 of this study indicated that the measurement data was reliable. The 3D prints were accurate to within  $\pm 2.0$ mm of the original dry bones, with no statistically significant difference observed between the dry bone and 3D print measurement data ( $p$ -value 0.75).

Phase 2 identified that multiple observers could successfully and confidently perform age and sex estimation methods on the four 3D prints tested when the method utilized gross features. Less success and confidence was seen when these methods utilized fine surface features. The customized ranked qualitative scoring method used in phase 3 found highest scores for surface quality were given for the general morphology of the 3D replicas, followed by detailed morphology, and texture received the lowest scores. Two of the prints (the cranium and mandible) were scored as accurate overall (average total scores  $>11$ ).

This experimental study confirmed the accuracy of the gross morphology of the 3D printed bones, but importantly demonstrated that fine surface details were not always well represented compared to the dry bones. These findings confirm the utility of 3D printed replicas for courtroom exhibition where gross features are required, but suggests caution is necessary for the use of 3D prints when fine detailing is important for evaluative interpretation.

### 3D Printing, Forensic Anthropology, Evidence Reconstruction

## A59 Investigating the Impact of Opioid Abuse on Intracortical Porosity and Bone Cellular Density: A Synchrotron-Radiation Micro-Computed Tomography (SR $\mu$ CT) Approach

Janna M. Andronowski, PhD\*, University of Akron, Department of Biology, Akron, OH 44325-3908; Reed A. Davis, MS, The University of Akron, Department of Biology, Akron, OH 44325-3908; Mary E. Cole, PhD, The University of Akron, Department of Biology, Akron, OH 44325

**Learning Overview:** The goals of this presentation are to: (1) describe how bone tissue pathology associated with opioid use (e.g., increased cortical pore density) is discernable in rib and femur microarchitecture; and (2) present high-resolution SR $\mu$ CT as a tool to characterize opioid-related bone microstructural pathology with a precision that exceeds traditional brightfield microscopy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by disseminating novel research related to the effects of chronic opioid use on bone microstructural integrity. As the opioid crisis is not showing any signs of slowing nationwide, it is critical that further research efforts be undertaken to understand the impacts on bone metabolism. Forensic anthropologists are specifically challenged by the confounding effects of opioid use on age-at-death estimation and fracture assessment from bone tissue.

Prolonged opioid use has been demonstrated to induce osteoporotic-like bone loss and increase the risk of bone fracture in chronic analgesic users. The current theory is that opioids act directly on opioid receptors of bone forming cells (osteoblasts), resulting in more bone resorption than formation. Indirect effects may be caused by lower serum levels of estradiol and testosterone in response to opioids, resulting in decreased bone mineral density and increasing the risk of osteoporosis.<sup>1-3</sup> With the current trend of opioid overdoses poised to expand its impact further, it is critical that additional research related to the impact of chronic opioid use on bone remodeling be undertaken to expand the forensic toolkit. The primary goal of this preliminary study was to describe how opioid use affects microscopic structures and overall porosity of cortical bone microarchitecture at two sites commonly used in histological age-at-death estimation: the mid-shaft sixth rib and anterior femoral mid-shaft. It was hypothesized that: (1) cortical bone porosity in chronic opioid users exceeds that of healthy controls; and (2) the abundance and density of cortical bone's cellular spaces (e.g., osteocyte lacunae) varies between controls and opioid users.

Osteocyte lacunae and cortical porosity were visualized in the anterior femur via SR $\mu$ CT at the Canadian Light Source synchrotron facility in Saskatchewan, Canada. Cortical porosity was visualized in the mid-shaft sixth rib using laboratory micro-CT at The University of Akron's National Polymer Innovation Center. Anterior femoral cores included known opioid users (ages 25, 27) and non-users (ages 21, 90, 93). Mid-shaft sixth ribs were age-matched for known opioid users (ages 24, 25, 27) and non-users (ages 21, 90, 94). Cylindrical Volumes Of Interest (VOIs) were isolated from reconstructed images of cortical bone via Bruker's CT-Analyser image processing software. Osteocyte lacunar spaces were separated from the high-density bone using global thresholding and segmentation. Standard nomenclatures for lacunar indices were applied for the analysis of 3D lacunar parameters within the VOIs. The variables measured included: Total VOI Volume (TV), total Canal Volume within VOI (Ca.V), average Canal Diameter (Ca.Dm), total Number of Lacunae (N.Lc), and average Lacunar Volume (Lc.V). To determine lacunar density per mm<sup>3</sup> (N.Lc/BV), Bone Volume (BV) was calculated as TV-Ca.V. Cortical porosity was calculated as Ca.V/TV.

In the anterior femur, pore density of young drug users (1,606–2,114 pores/mm<sup>3</sup>) considerably exceeded non-users (534–1,444 pores/mm<sup>3</sup>). In the rib, maximum pore density for young drug users (234 pores/mm<sup>3</sup>) similarly exceeded non-users (40–173 pores/mm<sup>3</sup>). Pore thickness in the rib for young drug users (91.7–115.3 $\mu$ m) resembled the young non-users (96.7 $\mu$ m) more than elderly non-users (24.1–24.5 $\mu$ m), as large pores were previously resorbed in the elderly via severe cortical thinning. In the anterior femur, osteocyte lacunar density of young drug users (range=40,213–42,262 lacunae/mm<sup>3</sup>) exceeds both a young non-user (34,834 lacunae/mm<sup>3</sup>) and elderly non-users (range=23,594–29,583 lacunae/mm<sup>3</sup>). These preliminary results suggest that opioid use may accelerate new pore accumulation. This study further detected a concurrent increase in cellular density.

This work represents the first examination of human bone tissue from known opioid users via SR $\mu$ CT. This ongoing research seeks to further characterize opioid use comorbidities such as osteopenia and osteoporosis. Results of this preliminary research have broader applications as they offer promise to identify risk factors for early-onset osteoporotic fracture that have both clinical and forensic applications for predicting and identifying skeletal trauma.

## A60 Oh Deer! Detecting Non-Human Skeletal Remains Using Bone Collagen Fingerprinting

Dana Austin, PhD\*, Tarrant County Medical Examiner Office, Fort Worth, TX 76104-4919; Miranda M. Ehlers, BS\*, Chico, CA 95928

**Learning Overview:** The goal of this presentation is to demonstrate through case example the utility of mass spectrometry bone collagen fingerprinting for species identification to distinguish between human and non-human skeletal remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on species identification of unknown bone using proteomic tandem mass spectrometry methods during medicolegal investigations.

A human skeletal case recovered in December 2018 in Parker County, TX, was complicated by the finding of a rib fragment containing 18 Sharp Force Trauma (SFT) kerfs. The remains were partially recovered and commingled with multiple non-human bones, primarily identified, by morphology, as deer (*Odocoileus virginianus*). During the analysis of the skeleton, it was determined that the remains belonged to a middle-aged Hispanic female. Aside from the single rib fragment with SFT, no additional information on the cause of death was observed on the skeleton. As the skeleton was incompletely recovered, it was not possible to immediately rule out the rib fragment as a possible rib of the unidentified female. Observation by the anthropologist suggested that the morphology was not human; however, the pathologist requested additional testing to determine the taxonomic origin of the bone fragment.

To distinguish skeletal remains as human or non-human, professionals in the forensic community use a variety of macroscopic, microscopic, and chemical methods.<sup>1-5</sup> Comparative anatomy differentiates human from non-human bone by examining gross morphological traits, a reflection of skeletal function. Ribs can be problematic to distinguish between humans and non-human mammals of a similar size.<sup>1</sup> Gross morphology can have limited utility when presented with fragmented remains. Histological analysis can reliably distinguish human from non-human bone by observing bone tissue type, primary (plexiform) or secondary (Haversian), as well as other microscopic features of osteon size, Haversian canal size, and density.<sup>2-4</sup> Disadvantages to histomorphometric methods include a need for undecalcified sections, a skill set frequently not available in a medical examiner setting. Additionally, fragmentary or burned remains may not include the exterior layer of bone where plexiform bone, considered diagnostic of non-human bone, is found.<sup>2,3</sup> Chemically, bone collagen is a genetically informative biomolecule. Even after taphonomic processes occur, small amounts of remaining collagen can be obtained and species identified.<sup>5</sup>

The identification of the rib fragment in this case was accomplished by the New York City Office of Chief Medical Examiner (OCME) using a method known as proteomic tandem mass spectrometry to analyze the amino acid sequences of proteins found in bone, soft tissue, and body fluids. Typically, very small bone samples (50mg) are required. In the case of the rib fragment, approximately 5mg of medullary bone was scraped from the rib, and the protein was extracted using 10 volumes of 8 M urea for 72 hours at 4°C and quantified using a bicinchoninic acid protein assay with bovine serum albumin as standard. Twenty µg of sample protein was reduced, alkylated, and digested overnight with trypsin. Peptides were separated by high-performance liquid chromatography using a 30 minute 5%–40% acetonitrile gradient and analyzed by tandem mass spectrometry on a SCIEX™ 6600 TripleTOF. Data were searched against an all-vertebrate National Center for Biotechnology Information (NCBI) database downloaded in April 2018 using SCIEX™ ProteinPilot™ 5 software. Forty-seven proteins were detected with a confidence score ≥95% per a personal communication with Dr. Donald Siegel. The sample submitted to Dr. Siegel at the OCME had a 122 peptide match identifying the rib fragment as *Odocoileus virginianus texanus*, commonly known as a Texas subspecies of the Virginia whitetail deer. The proper identification of this rib fragment with SFT as a deer bone, allowed for the medicolegal investigation to attribute the trauma/modification to an irrelevant behavior.

This case study shows that crossing borders between the fields of forensic anthropology, zooarchaeology, and forensic toxicology has allowed accurate differentiation of non-human skeletal remains of a critical component in a medicolegal investigation. Sharing information and technology across fields of study benefits all, even when each discipline uses the results to answer differing questions.

### Bone Collagen, Proteomic Mass Spectrometry, Species Identification

## A61 Investigating the Predictive Relationships Between Oxygen and Hydrogen Isotopes in Bottled Water and Human Hair in Mexican Populations

Chelsey A. Juarez, PhD\*, Department of Anthropology California State Fresno, Fresno, CA 93740; Belinda S. Akpa, PhD, North Carolina State University, Raleigh, NC 27607-4065

**Learning Overview:** The goals of this presentation are to: (1) explore the relationship between oxygen ( $\delta^{18}\text{O}$ ) and hydrogen ( $\delta^2\text{H}$ ) in bottled water samples and human hair samples of known Mexican origin; and (2) demonstrate the distribution of  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$  in bottled water samples across the major immigrant-sending states in Mexico to better understand the challenges of using hair as a tool for forensic geolocation in a Mexican context.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting data on the relationship between Mexican bottled water and human hair and the utility of this relationship to act as a predictor of region of origin.

Recently, Juarez et al. reported the application of semi-mechanistic models with adjustable parameters to relate  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$  in tap water to  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$  in human hair from Mexico.<sup>1</sup> This study demonstrated that for this modern Mexican sample, positive correlations between isotopes in hair and water were not significant:  $r=0.61$  ( $p=0.05$ ) and  $r=0.60$  ( $p=0.06$ ) for  $^{18}\text{O}$  and  $^2\text{H}$ , respectively. This clearly demonstrated that data from this Mexican population do not exhibit the strong relationships between isotope values of  $^{18}\text{O}$  and  $^2\text{H}$  in tap water and hair characteristic of other populations studied to date. A first order conclusion from this study is that in Mexico, tap water does not equal drinking water. In order to better understand the distribution and variation in  $^{18}\text{O}$  and  $^2\text{H}$  in probable drinking water samples, bottled water samples representing all brand varieties available per sample location (representing 18 total brands) were collected for 16 states in Mexico ( $N=90$  samples). In order to explore the relationship between bottled water and hair samples, this study used a subset of paired samples representing 8 states with  $N=62$  hair samples and  $N=70$  bottled water samples.

The results are reported here using delta notation and the Vienna Standard Mean Ocean Water (VSMOW) scale. General statistics were analyzed using SPSS version 25.0. Bottled water values spanned a range from +0.5‰ to -11.5‰ and +1.3‰ to -80.2‰ for  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$ , respectively. The lowest sample values came from Tepic Nayarit, but similarly low values were also found in Michoacán, Mexico City, Morelos, Oaxaca, and Campeche. The highest sample values were found in samples from Campeche and Tabasco. Isotope levels in bottled water samples differed in their standard deviation by collection location, ranging from 7.3‰ to 0.03‰ for  $\delta^{18}\text{O}$  and 48.6‰ to 0.3‰ for  $\delta^2\text{H}$ . Samples from Nayarit showed the highest level of deviation. Isotope values in hair ranged from +9.5‰ to +16.1‰ and -90.8‰ to -53.7‰ for  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$ , respectively. The most depleted  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$  hair values came from individuals in the state of Morelos.

Linear regression for the paired hair and bottled water samples were significant for H isotopes but not for O isotopes ( $\delta^2\text{H} = -18.09 + 0.828 * \delta^2\text{Hw}$ ,  $R^2=0.7$ ,  $R=0.84$ ,  $p=0.01$ ;  $R^2=0.43$ ,  $R=0.2$ ,  $p=0.6$ ). Correlation coefficients for statistically significant relationships were lower than those previously published for tap water/hair or precipitation/hair relationships from other regions.

The variation in bottled water samples by state suggests that multiple sources for bottled water exist for purchase in each locality. While bottled water has comparatively better fits to hair data by state than previously published tap water data, the inconsistent results between this study and those on other regions suggests shifting water usage. Mexico has the highest consumption of bottled water per capita in the world. This study clearly demonstrates that in order to use water isotopes in Mexican hair to determine region of origin, these cultural contexts must be taken into consideration, and a better understanding of bottled water variation and usage is needed.

### Bottled Water, Hair, Mexico

## A62 An Assessment of How “Predictive” Human Geolocation Models Perform When Compared to a “Known” Geolocated Human Enamel Data-Set

Momoko Ueda, MA\*, Simon Fraser University, Burnaby, BC V5A1S6, CANADA; Lynne S. Bell, PhD, Simon Fraser University, Burnaby, BC V5A 1S6, CANADA

**Learning Overview:** After attending this presentation, attendees will understand the forensic importance of analyzing oxygen stable isotopes in human enamel ( $\delta^{18}\text{O}_c$ ) for the utilization of stable isotope analysis for human geolocation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to the existing knowledge of the relationship between  $\delta^{18}\text{O}_c$  values and that of drinking water ( $\delta^{18}\text{O}_{dw}$ ) by presenting  $\delta^{18}\text{O}_c$  values in modern human dental enamel with known provenance.

The geographical life history of an individual can be determined by analyzing stable isotopes in human tissues. The isotopic compositions of tissues are reflective of the environment during tissue formation, with drinking water ( $\delta^{18}\text{O}_{dw}$ ) contributing significantly to  $\delta^{18}\text{O}_c$ . The current approach to human provenancing utilizes available tap or drinking water data as the base for placing individuals on a geographical map. This is believed to be possible through the understanding of the relationship between  $\delta^{18}\text{O}_c$  and  $\delta^{18}\text{O}_{dw}$ . However, limited data is available for known modern  $\delta^{18}\text{O}_c$ , and no known data exist for any Canadian city.

This study investigated the isotopic composition of oxygen stable isotopes in known modern human enamel collected from across Metro Vancouver (MV) and British Columbia, Canada, and tested the relationship between  $\delta^{18}\text{O}_c$  and  $\delta^{18}\text{O}$  of tap water ( $\delta^{18}\text{O}_{tap}$ ). Isotopic data were compared against known MV tap water values. Results were also compared against the range of  $\delta^{18}\text{O}_c$  values predicted from  $\delta^{18}\text{O}_{tap}$  values with linear models reported by other published studies. A total of 41 extracted human molar samples were collected from dental clinics across MV during the years 2015 to 2017. Information on location of residence and any relocations from birth to 25 years was also retrieved from each individual. This was to ensure that known geographical information was acquired from the individuals during the time of tissue formation. Enamel was extracted into powder form (~1mg) by gentle abrasion with a Dremel® diamond-tipped, hand-held drill. Samples were subsequently analyzed on a Delta® Plus XP isotope ratio mass spectrometer with an analytical precision of  $\pm 0.2\text{‰}$  for  $\delta^{18}\text{O}$ .

Twenty-four of the 41 individuals were of MV origin, two with mixed Canadian origins, and the remaining individuals were from various cities across Canada. The results revealed that  $\delta^{18}\text{O}_c$  values in tooth enamel from individuals residing in MV during the time of tissue formation showed a range of 3.8‰ with a mean of  $-8.7\text{‰} \pm 0.8$  ( $n=24$ ). Mean  $\delta^{18}\text{O}_c$  for all Canadian values were  $-8.7\text{‰} \pm 1.1$  ( $n=41$ ) with a range of 5.7‰.

The results from this study indicate there is a positive but weak ( $p>0.05$ ) correlation between  $\delta^{18}\text{O}$  values in known modern human enamel and  $\delta^{18}\text{O}$  values in known source tap water. Furthermore, the range of  $\delta^{18}\text{O}_c$  values observed for a single city of MV is greater than the range for an entire country such as Bulgaria, Japan, or the United Kingdom. The wide range in  $\delta^{18}\text{O}_c$  values from modern MV residents may be due to the contribution of multiple water sources for MV tap water, which also demonstrates the importance of establishing the isotopic range for individual cities beyond this study. Furthermore, up to 70% of MV individuals were identified as residing outside of MV when utilizing predictive models from other published studies. This finding has significant forensic importance as it demonstrates the weakness of current predictive equations. It is concluded that the theoretical isotopic relationship between human enamel formation and drinking water is valid, and that predictive models need to be built on a solid foundation of known samples.

### Stable Isotopes, Enamel, Human Geolocation

### A63 Subadult Body Mass Estimation From Skeletal Remains: Validation for Femoral Cross-Section Methods in a Contemporary Taiwanese Population

An-Di Yim, MA, MS\*, University of Illinois at Urbana-Champaign, Urbana, IL 61801; Lyle W. Konigsberg, PhD, University of Illinois, Anthropology, Urbana, IL 61801; Hsiao-Lin Hwa, MD, PhD, National Taiwan University, Taipei City 10051, TAIWAN, REPUBLIC OF CHINA; Jo-Yu Chen, MD, National Taiwan University Hospital, Taipei City 10002, TAIWAN, REPUBLIC OF CHINA; Hon-Man Liu, MD, National Taiwan University Hospital, Taipei City 10002, TAIWAN, REPUBLIC OF CHINA

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the validity of body mass estimation equations for subadult skeletons using femoral cross-section and whether it is suitable to apply such equations in different populations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing population data from an underrepresented area of the world and will promote better understanding of how cultural and ecological contexts affect subadult body mass estimation.

Body mass estimation for subadult skeletons is sometimes required in forensic anthropological analysis and can provide important and useful information in subsequent legal investigations. Several methods are available for estimating subadult body mass from skeletons, either using external measurements or cross-sectional measures of the femur. Specifically, past studies suggested that the two methods using femoral cross-section: age-structured equations developed by Robbins et al. and a panel regression-based equation developed by Robbins Schug et al. may yield more accurate results compared to equations using external measurements of the femur.<sup>1,2</sup> However, these methods have not been tested in contemporary samples of Asian descent, and their validity in these populations is largely unknown.

This study tested both the age-structured equations and the panel regression-derived equation for body mass estimation in a contemporary Taiwanese population. Computed Tomography (CT) scans of individuals aged 0 to 16 years of both sexes were collected from the National Taiwan University Hospital (NTUH). Individuals with fractured femur or visible anomalies were excluded. Cross-sectional properties were measured at approximately 50% length. Estimated body mass was compared to documented body mass to evaluate the performance of the two methods.

The results indicate that both methods performed relatively similarly in a contemporary Taiwanese population. The accuracy (absolute mean differences) for age-structured equations is 13.99kg while the accuracy from the panel regression equation is 19.64kg. The bias (mean differences) for age-structured equations is -6.83kg, while the bias for panel regression equation is 19.15kg. These values far exceed those observed previously in populations of mostly European and African descent. In general, the age-structured method tends to overestimate body mass while the panel regression method tends to underestimate body mass in the Taiwanese population. Moreover, Root Mean Squared Error (RMSE) was calculated for different age categories to investigate whether age has an effect on the estimation. Results show that as age category increases, deviation of estimated body mass from true body mass increases for the panel regression-derived equation, while the reverse is true for age-structured equations. Suggestions are made in light of these findings and statistical procedures are developed for future references.

While hospital samples may not be the best representation of a population, this study highlights the need to test the validity of methods for body mass estimation for subadult skeletons in different populations, especially in underrepresented areas of the world.

## A64 A Comparative Analysis of Nasal Profile Estimation Methods for Facial Reconstruction

Dong-Ho Eddie Kim, BSc\*, The Catholic University of Korea, Seoul, 06591, SOUTH KOREA; Hankyu Kim, Seoul, SOUTH KOREA; Deog-Im Kim, PhD, Keimyung University, Daegu 704701, SOUTH KOREA; Dae-Kyoon Park, MD, PhD, Soonchunhyang University, Cheonan-si, Seoul 31151, SOUTH KOREA; U-Young Lee, MD, PhD, The Catholic University of Korea, Seoul 06591, SOUTH KOREA; Yi-suk Kim, MD, PhD, The Catholic University of Korea, Seoul 06578, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will possess information of methods to investigate the nasal profile for enhancing the accuracy of facial reconstruction. In addition, attendees will better understand the importance of basal research for population-specific facial reconstruction.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing comparative research of the nasal profile for enhancing the accuracy of facial reconstruction.

The nose is an important facial feature that significantly affects the outcome of facial reconstruction and its recognition. For the 3D measurement analysis, the skin and bone of the nasal area were remodeled utilizing Computed Tomography (CT) images. Then the methods and results of previous facial reconstruction studies on the nasal aperture area with Korean adult samples were compared. One hundred CT scans of Korean adults were selected for this study. The subjects were patients who undertook craniofacial CT scans for clinical purposes at the Department of Radiology at St. Mary's Hospital in Seoul, South Korea. Patients with a history of head trauma, severe deformities, or asymmetry were excluded from this study. 3D models of the cranium and face were remodeled and measured by Mimics® software, version 14.1. Six studies were selected to compare various sample populations and materials for nasal profile reconstruction.<sup>1-6</sup>

The measurement system for 3D models was programmed with referring landmarks from previous studies to facilitate comparison process. In cases of referring measurements and landmarks of lateral cephalograms, the landmarks were positioned at the profile view of each 3D model. The paired *t*-test of corresponding measurement with previous studies showed there was a significant difference between actually measured values that are measured in the same manner as previous studies and predicted values that are calculated from regression equations of previous studies ( $p < 0.05$ ). As the results have shown, differences of research material, of whether to use cephalogram or 3D models, and a measurement method that involves 2D measurement and 3D measurement was an important factor in deciding its accuracy for nasal profile reconstruction. Moreover ethnic-specific differences in the field of facial reconstruction should be taken into considerable consideration since studies made quite different predictions.

*This research was supported by the Research and Development (R&D) program for Advanced Integrated-intelligence for IDentification (AIID) through the National Research Foundation of Korea (NRF) funded by the Ministry of Science and Information and Communications Technology (ICT).*

### A65 The Application of Morphometric and Morphoscopic Features of the Nose in Facial Reconstruction: A Study on a North Indian Population

*Tej Kaur, MSc\*, Department of Anthropology, Panjab University, Chandigarh 160014, INDIA; Bahadur Singh, MSc, Department of Anthropology, Chandigarh, AL 160104, INDIA; Kewal Krishan, PhD, Panjab University, Chandigarh 160 014, INDIA; Adarsh Kumar, MD, AIIMS, New Delhi, Uttar Pradesh 110029, INDIA*

**Learning Overview:** After attending this presentation, attendees will be better informed about metric and non-metric traits of the human nose, which may help to identify a particular population group or an individual.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new dataset on noses that will help in facial reconstruction and sex determination in forensic casework.

Forensic facial reconstruction is an ancillary method used to identify the dead. The goal of forensic facial reconstruction is to recreate the face of the deceased with the help of anthropological analysis of the skull followed by facial reconstruction. The face of the person has several different types of exclusionary features that are of great importance in the identification and recognition of a person. The nose is considered to be one of the conspicuous features for facial approximations during the recognition process. Therefore, subtle changes in nasal morphology may lead to considerable differences in the appearance and face characteristics of an individual. In cases of mass disasters, such as earthquakes, terrorists attacks, road accidents, and landslides, mutilated parts of the bodies are brought for identification. When part of the face is disfigured, ethnic-specific models can be of great help in reconstructing the face. In forensic facial reconstruction, both metric and non-metric data serve as the basis of reliable approximations by comparing antemortem and postmortem data.

The current study aims to provide a wide range of morphometric and morphoscopic data on the nose. The study was conducted on a total of 508 subjects (264 males and 244 females) on two ethnic populations, Rajputs and Brahmins (Highland Himalayan population), of the Himachal Pradesh State in North India. Morphometric variables of the nose include nasal height, nasal breadth, nasal depth, anatomical width of the nose, and total length of the nasal bridge; morphoscopic traits include nose size, nasal bridge profile, nasal root shape, tip of the nose, its projection, alare profile, nasal septum features, and the nasal cavity. Each measurement was taken with the help of a sliding caliper. The action was performed on all subjects by the same examiner. For non-metric traits, the subjects were first photographed from basal, lateral, and frontal nose view by a Sony Cyber-shot™ DSCW80 7.2MP digital camera, then studied. The results of the statistical analysis (descriptive) performed using SPSS reveal that mean values of nasal and facial parameters are larger for males. *T*-test and chi-square statistics confirm the significant sexual dimorphism in metric and non-metric variables, respectively. To keep this in mind, Binary Logistic Regression statistics were applied to formulate models for sex determination from these variables. The overall sex predictive accuracy from nose variables were 78.1%. For nose reconstruction from facial variables, regression models were prepared for each sex separately. The correlation coefficient for morphological and physiognomic facial length with nasal length was 0.539 and 0.382 for males; 0.349 and 0.251 for females, respectively.

Highland Himalayan populations are more prone to natural disasters resulting in mass deaths. In such cases, reconstruction of the nose from the remaining face can boost the identification process. The present study confirms the sexual dimorphism in facial features and forms. Robust statistical procedures were adopted for reliable construction of the nose from facial measurements.

#### Forensic Anthropology, Facial Reconstruction, Identification

## A66 Nose Approximation From Cone-Beam Computed Tomography (CBCT) Using a New Computer-Assisted Method

Alison F. Ridel, PhD, University of Pretoria, Anatomy Department, Pretoria 0084, SOUTH AFRICA; Fabrice Demeter, PhD, Musée de l'Homme, Paris 75116, FRANCE; Ericka N. L'Abbe, PhD\*, University of Pretoria, Pretoria 00084, SOUTH AFRICA; Dirk Vandermeulen, PhD, KU Leuven, Leuven B3000, BELGIUM; Anna C. Oettle, PhD, Sefako Makgatho Health Sciences University, Pretoria, Gauteng 0204, SOUTH AFRICA

**Learning Overview:** After attending this presentation, attendees will have gained knowledge on an automated landmarking method for the nasal substrate and the production of accurate statistical models, which are optimized with the inclusion of ancestry, sex, and age, for estimating nasal shape among two South African groups. Automatic landmarking, in addition to reducing errors, achieved better precision for Facial Approximation (FA), enabling a convenient prerequisite for geometric morphometrics and the future possibility of including more samples and populations with ease.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing a novel 3D approach to FA methods in South Africa. Recent developments in computer science and advances in medical imaging techniques, such as surface, Magnetic Resonance Imaging (MRI)-, Computed Tomography (CT)-, and CBCT-scanning resulted in large databases of 3D representations of hard- and soft-tissues of the crania of living people. Researchers in the field of FA can utilize these technologies to develop alternative computer-based techniques to improve objectivity of approximations for both criminal investigations and unidentified persons.<sup>1,2</sup>

South Africa is in a humanitarian crisis with vast numbers of unidentified persons buried in paupers' graves or incinerated each year. Because of socio-political and historical circumstances, the unidentified are often from impoverished communities with reduced access to medical and police services. Creative approaches are therefore required to improve identification of decomposed and skeletonized remains. FA techniques are often employed in these situations to communicate with the public, as the face is often the sole means from which a person is remembered and recognized. Main critiques of FA methods are inherent subjectivity, lack of standardization, few reference samples, and poor correlations between hard and soft tissues. In light of the great demand for the identification of unknown remains in South Africa, a need exists to establish reliable FA techniques that will not only take into account sex and age, but most importantly be specific for South Africans. The purpose of this study was to provide an automated computer-assisted method to create accurate statistical models for predicting nasal soft tissue from information about the underlying skull substrate using CBCT scans.

A total of 200 CBCT scans of 100 Black (67 male, 33 female) and 100 (35 male, 65 female) White South Africans were selected from the Oral and Dental Hospital, University of Pretoria, and the Life Groenkloof Hospital, Pretoria, South Africa. The acquisition and extraction of the 3D-relevant anatomical structures (hard and soft tissue) was performed by an automated 3D method based on an automatic dense landmarking procedure using MeVisLab® v. 2.7.1 software.<sup>3</sup> An evaluation of shape differences attributed to known factors (ancestry, sex, size, and age) were performed using geometric morphometrics, and statistical models of prediction were created using a Projection onto Latent Structures Regression (PLSR) algorithm. The accuracy of estimating soft tissue of the nose was evaluated in terms of metric deviations on training and on untrained datasets. Variability in the hard and soft tissue of the nose was noted for sex, age, and allometry among the two population groups. When using the landmark-to-landmark distances, prediction errors ranged between 1.769mm and 2.164mm for Black South Africans at the tip of the nose and the alae, and between 2.068mm to 2.175mm for White South Africans. The prediction errors on untrained data were slightly larger, ranging between 2.139mm and 2.833mm for the Black South Africans and 2.575mm to 2.859mm for White South Africans.

Global advances in 3D research into human variation and skeletal anatomy will improve creation of biological profiles and FA methods, which will be of particular relevance to identify unknown persons in disadvantaged groups in Africa. This study demonstrated the utilization of an automated 3D method as a convenient prerequisite for providing a valid and reliable nose prediction model independent of any artistic interpretations.

### A67 The First Recovery and Identification Project of Missing Casualties in the Korean Demilitarized Zone (DMZ)

*Yu Ryang Jang, PhD\*, MAKRI, Seoul 156-080, SOUTH KOREA; Nahyok Im, PhD, MAKRI, Seoul 06984, SOUTH KOREA*

**Learning Overview:** After attending this presentation, attendees will understand some principles of an unprecedented recovery and identification project of casualties from the Korean DMZ.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a key aspect for identifying the missing personnel recovered from an inaccessible area for a long period of time.

The Korean Peninsula has been divided into South and North Korea since the three-year Korean War ended in 1953. This peninsula is the last remaining divided territory within the same nation in the world. The Korean DMZ was established after the Korean Armistice Agreement was signed in 1953. Since then, for nearly 70 years, it has functioned as a militarized buffer zone between South and North Korea and has become a unique area untouched by humans for military reasons. After two Inter-Korean Summits (in April and September 2018), the Korean government commenced the recovery of war remains in the DMZ in October of 2018).

Based on the war's history, at the main recovery area in the DMZ, Arrowhead Ridge, Korean and United Nations forces fought against Chinese troops, resulting in more than 300 soldiers from South Korea, the United States, and France being killed. At first, both sides agreed to make a South-North Korea Joint Recovery Team. However, as the political situation became complicated, only the Ministry of National Defense Agency of KIA Recovery & Identification (MAKRI) is conducting recovery efforts in the DMZ. Before the excavation, land mines and other explosives were removed in the recovery area for safety reasons. At this point, more than 100 missing personnel have been exhumed and transported to the MAKRI Central Identification Laboratory (CIL) for further analysis. Remains recovered from the DMZ were probably all male, usually in their late teens to mid-twenties. One of the recovered was identified and returned to his bereaved family. In addition, one set of remains presumed to be a United Nations soldier (possibly from American or French troops) was recovered. Due to the fact that the DMZ has been kept intact, conditions of the recovered human remains and personal belongings are relatively suitable and the burial sites well preserved.

This study aims to examine human skeletal remains that were unexpectedly protected from external environmental changes, such as industrialization. For this purpose, burial context, ancestry, trauma, and pathological changes were assessed. This report will present valuable information concerning body decomposition and weathering processes after death. It is recommended that forensic specialists pay special attention to the Korean DMZ recovery and identification project.

### A68 Historical and Cultural Complications of Repatriating Forensic “Cases” in the Southeastern United States

*Alice F. Gooding, PhD\*, Kennesaw State University, Kennesaw, GA 30102; Jonathan Eisenstat, MD, Georgia Bureau of Investigation, Decatur, GA 30034-3830*

**Learning Overview:** After attending this presentation, attendees will understand some of the challenges facing the identification of historic Native American remains in the southeastern United States that have been submitted as forensic cases to a medical examiner’s office.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showcasing how a historical and cultural understanding of a region is vital to the appropriate classification of historic Native American remains in a medicolegal setting.

The Georgia Bureau of Investigation (GBI) houses the skeletal remains of unidentified individuals ( $N=272$ ) dating back to the 1960s. The GBI serves 153 of the 159 counties in the state, resulting in a wide and varied collection of remains that have since become cold cases. Legislation was passed in 2016 to allow for the burial of these cases. Prior to interment, it was decided that a thorough examination of every case was necessary to create a robust case file in the event that a lead on identification arises. Of these cold cases, anthropological analyses were used to determine that a small number ( $n=7$ ) were individuals of Native American descent whose deaths likely occurred before the present day. Each set of remains was photographed, inventoried, and analyzed using gross morphological techniques. Craniometric data was collected using a MicroScribe® digitizer and 3Skull analytical software. Each individual was compared to the Forensic Databank and Howell’s Dataset using FORDISC® 3.1. Four individuals were classified as “American Indian” with an F-typicality greater than 0.7. The remaining three individuals could not be reliably grouped with those in either dataset.

In addition to craniometrics analyses, the identification of historic Native remains in a forensic context requires a knowledge of the geomorphology and taphonomy unique to the various regions of Georgia. Georgia has a large piedmont region, coastal plain, and ridge and valley system. These taphonomic signatures, including red clay staining and increased friability from highly acidic soils, have yet to be documented in a medicolegal context.

Further, it is argued through this study that the historical and cultural environment in Georgia has increased the difficulty in identifying and repatriating these types of remains. While Georgia was one of the most highly occupied regions in the United States during the Mississippian Period (AD 800–1600), native Georgia Indians are not currently recognized as independent nations. In 1992, the Georgia Council on American Indian Concerns was created to mitigate and protect Native sites and help repatriate remains. The Council serves as the governing body for decisions concerning Native burials found in archaeological contexts; however, Native remains recovered in a medicolegal investigation are rarely brought to the attention of the Council.

In response to these issues, the GBI Office of the Medical Examiner has made it a priority to work in concert with the Native Council and develop a plan for transferring custody of these remains and establishing a concrete pipeline for future “cases.” Further, an educational program has been implemented to teach local law enforcement officers about the likelihood of recovering Native remains and appropriate protocols for reporting.

While all cases in the GBI’s unidentified collection will receive a thorough examination, it is suggested that the taphonomic signatures of this region are unique and should be documented to decrease misclassification of Native remains and expedite their repatriation through available channels.

### A69 Skeletal Preparation Using a Modified Steam Kettle: A Fast, Easy, and Low-Maintenance Method for Processing Human Remains

*Kerianne Armelli, MS\*, Department of Biomedical Science, Kent, OH 44240; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Carolyn V. Isaac, PhD, Michigan State University, East Lansing, MI 48824*

**Learning Overview:** After attending this presentation, attendees will understand the process of utilizing a steam kettle for skeletal preparation, including strategies that improve the final quality of skeletal remains and decrease overall handling and processing time, and will recognize the benefits of utilizing a modified steam kettle for skeletal preparation of human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a method for soft tissue removal developed at Western Michigan University Homer Stryker M.D. School of Medicine that improves the efficiency of processing human skeletal remains while decreasing the opportunity for damage to the skeletal remains.

The removal of soft tissue without damage to bone is an integral part of forensic anthropology, specifically in the analysis of skeletal anatomy and trauma. Forensic anthropologists assist with reconstruction of the biological profile, identification, and trauma assessment when examination of the soft tissue is no longer possible due to decomposition, thermal damage, or trauma. Typically, scalpels and other metal implements are used in the removal of soft tissues and disarticulation of the fleshed decedent before maceration. Crock-pots or pots heated over Bunsen burners are often used for warm water maceration with chemical agents, such as sodium carbonate, other detergents, ammonia, chlorine, and dish soaps to break down the proteins and fats. This process requires extensive disarticulation of the remains into small body segments to fit them in small maceration vessels. This prolongs the duration of disarticulation and increases the likelihood of creating processing artifacts such as cut marks to the skeletal elements and joints. Furthermore, if maceration is not appropriately monitored, burning of the skeletal material can occur, irreparably damaging the elements and potentially obscuring pre-existing trauma. Using a steam kettle with a basket insert allows large body segments, such as intact extremities and articulated head-torso-pelvis segments, to be placed directly on an elevated basket in the steam kettle. This method demonstrates the ability to easily macerate skeletal remains without the use of chemicals, minimizing the risk of damaging bone, and greatly reducing the amount of hands-on time spent disarticulating and subsequently cleaning the bones.

Study materials include 18 donors of the Western Michigan University Homer Stryker M.D. School of Medicine Body Donation Program who elected to be included in the Skeletal Research and Teaching Collection. The water temperature, steam kettle settings, and duration of maceration were recorded throughout each skeletal processing and were varied between donors to understand the impact on the quality of the skeletal remains. In addition, the length and type (cooler vs. freezer) of storage and the condition of the decedent were recorded to explore the impact of storage temperatures and durations on bone quality. Donors were macerated at water temperatures that varied between 40°C and 94°C. The duration of maceration varied between two and nine days. The conditions that produced the best bone quality were a maceration temperature of 90°C, with no temperature fluctuation, for a duration of two days.

The preparation of skeletal material for analysis by the removal of soft tissue is an important part of skeletal analysis in forensic anthropology. Forensic anthropologists should be cognizant of the advantages and disadvantages of the different methods of skeletal preparation in order to utilize the method that best suits their needs and decreases the likelihood of damaging bone. This method produces skeletal elements that are in excellent condition for analysis. This new approach to skeletal preparation will improve the efficiency and final disposition of the skeletal remains.

## A70 Salary, Wage Transparency, and Forensic Anthropology

Nicholas V. Passalacqua, PhD\*, Western Carolina University, Cullowhee, NC 28723; Elaine Y. Chu, MA, University of Nevada, Reno, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, Reno, NV 89557-0096

**Learning Overview:** After attending this presentation, attendees will understand the current distribution of salaries of forensic anthropologists in the United States as well as the primary factors that affect forensic anthropologists' salaries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the salaries of practicing forensic anthropologists in the United States within the context of the need for increased wage transparency and salary equity.

Forensic anthropology, like all forensic sciences, is a discipline meant to serve the public. As such, nearly all forensic anthropologists in the United States are employed as public servants, with individuals being employed by government-funded institutions either at the state or federal level. In the United States, the salaries of government employees are considered to be public information and because of this, these salaries are often freely available in publicly accessible databases or via requests for information using such avenues as the Freedom of Information Act (FOIA).

The reason salary information is important is because salary transparency narrows wage disparities, reduces favoritism and discrimination, increases the bargaining power of employees, and potentially causes employers to focus more on salary differentiation in terms of productivity and seniority; essentially wage transparency generates greater equity among employees.<sup>1</sup> Estlund states: "accurate information about other people's salaries in one's own and other organizations is crucial to decisions about seeking a better opportunity elsewhere, asking for a raise, or simply staying on the job and accepting the status quo."<sup>1</sup> Employers currently benefit from a lack of transparency in salaries through asymmetrical information, as there is no largely accessible data on salaries in forensic anthropology, within academia or applied institutions.

In order to examine the salaries of forensic anthropologists in the United States, salary information for current members of the anthropology section of the American Academy of Forensic Sciences (AAFS) were searched for on freely accessible public internet databases. In addition to this data, the following information was also examined for each individual: sex, terminal degree, certification by the American Board of Forensic Anthropology (ABFA), type of position (academic vs. applied), academic institution classification (using Carnegie Classifications), and rank of employee (e.g., assistant professor, director, etc.).

Results found that salary information was available for 120 individuals ( $n=78$  females and  $n=42$  males) from various academic ( $n=82$ ) and applied ( $n=38$ ) institutions within the United States. For academic individuals, most had traditional ranks ( $n=15$  term positions,  $n=27$  assistant professors,  $n=15$  associate professors, and  $n=21$  full professors), although a number had additional administrative duties ( $n=16$ ). In order to standardize individual salaries, each salary was divided by the composite cost of living index for each state (from the Missouri Department of Economic Development), followed by the term length of each individual (creating a "Salary Index"). Salary Index was compared within variable groups using Kruskal-Wallis rank sum tests, and Analysis of Variance (ANOVA) was used to compare Salary Index between groups. There was a statistically significant ( $p<0.01$ ) difference between mean Salary Index of Academic and Applied forensic anthropologists, and two sub-groups using rank of employee were used for further analysis. Linear regression equations were created using available data as having independent and interactional effects to estimate Salary Index for Academic ( $R^2=0.7268$ ) and Applied ( $R^2=0.07486$ ) forensic anthropologists. Even with a strong  $R^2$  value for the Academic sub-group, a high residual sum of square value demonstrate this model has limited ability for Salary Index estimation.

The results of this research demonstrate inconsistencies in pay for forensic anthropologists, especially for those working in the Applied sector. Variables such as basic classification of institution and rank of employee were statistically significant factors ( $p < 0.001$ ) that affected Salary Index of Academic forensic anthropologists. Additional information such as time in a position/at an institution may provide insightful information as to Salary Index for future research. Finally, wage transparency paired with increased standardization into the qualifications of forensic anthropologists may assist in future wage equity in the discipline.

### Salary, Wage Transparency, Professionalism

### A71 Learning From Our Casework: The Forensic Anthropology Database for Assessing Methods Accuracy (FADAMA)

*Cris E. Hughes, PhD\**, University of Illinois, Department of Anthropology, Urbana, IL 61801; *Chelsey A. Juarez, PhD*, Department of Anthropology California State Fresno, Fresno, CA 93740; *Katharine Chapman Pope, MA*, Division of Forensic Science, Georgetown, DE 19947; *Brian F. Spatola, MA*, National Museum of Health & Medicine, Silver Spring, MD 20910

**Learning Overview:** After attending this presentation, attendees will understand how data from the FADAMA is informing research on methods use and accuracy, how other researchers can use and access the data, as well as the new data and platform additions to the database in the past two years.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing practitioners on how FADAMA supports a vital aspect of the discipline's ability to self-assess its progress and success in terms of casework outcomes.

In 2013, the development of the database was initiated by the Society of Forensic Anthropologists in order to provide a comprehensive and centralized open-source database on methods use and accuracy in forensic anthropology casework. Previously, there existed no formal, organized space for the forensic anthropology community to share approaches to casework and casework outcomes (e.g., method-derived versus actual biological profile information).

This presentation will introduce user platform additions to FADAMA as well as new collaborative opportunities and strategies for data collection support. Additions to the user platform for the database include data on method-specific outcomes, which allows for the assessment of method-specific accuracy. Beginning in the spring of 2020, a trained technician will be available to travel to interested laboratories to assist with data input, alleviating time constraints on participating facilities.

Furthermore, this presentation will address the following research questions with the current data included in the database: (1) accuracy of practitioner-generated estimates of the biological profile, (2) the trends in method use, and (3) decedent demographic trends.

As of August 1, 2019, a total of 243 cases representing a wide range of case data are present in FADAMA, with continued commitments from several high-caseload offices to submit their cases, such as the University of North Texas Center for Human Identification and the New York City Office of Chief Medical Examiner. The current reported case demographics are as follows: Case Year (range=1981-2018,  $\mu=2009.7$ ), Sex ( $n_{\text{female}}=73$ ,  $n_{\text{male}}=169$ ), Age (range=14-94 years,  $\mu=42.6$ ), Ancestry ( $n_{\text{Asian}}=14$ ,  $n_{\text{black}}=65$ ,  $n_{\text{hispanic}}=39$ ,  $n_{\text{other}}=2$ ,  $n_{\text{white}}=107$ ), and Stature (range=48-77 inches,  $\mu_{\text{females}}=63.5$  inches,  $\mu_{\text{males}}=69.5$  inches). Trends in biological profile estimation accuracies are as follows: Age=98%, Stature=90%, Sex=99.9%, Ancestry=92%. Additionally, more than 30 forensic anthropological methods were reported by practitioners to assess the biological profile. This presentation will review trends in method use for age, sex, ancestry, and stature, as well as biological profile accuracy statistics for the submitted cases. Furthermore, this presentation will review the submission process, including case eligibility, appropriate case data, and permissions and responsibilities of FADAMA users.

As case data continues to accumulate, interested forensic anthropologists/researchers can access and analyze the anonymized case data (electronically available for download at: <http://sofainc.org/sofadb/index.php>). This presentation will include a live demonstration of the database for interested attendees.

*This research was funded by the National Institute of Justice (NIJ). Opinions, points of view expressed in this research, and products discussed represent a consensus of the authors and do not necessarily represent the official position, policies, or endorsement of the United States Department of Justice (DOJ) or NIJ.*

#### Database, Case Reports, Accuracy

## A72 3D Slicer as a Tool for Creating Virtual Bone Models From Computed Tomography (CT) Data: Toward Validating a Step-By-Step Method

Madeline H. Robles, MS, MRes\*, University College London, London, England WC1H 9EZ, UNITED KINGDOM; Rachael M. Carew, MSc, University College London, London WC1H 9EZ, UNITED KINGDOM; Ruth M. Morgan, PhD, University College London, London WC1H 9EZ, UNITED KINGDOM; Carolyn Rando, PhD, University College London, London WC1H 0PY, UNITED KINGDOM

**Learning Overview:** The goal of this presentation is to provide insight into how the step-by-step method developed in this study can increase availability of 3D models that are consistent, reproducible, and accurate for application in forensic anthropology.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a method that can improve a user's ability to handle CT scan data and develop 3D modeling performance.

This research sought to create an easy-to-use, step-by-step method for modeling CT data and to validate its application to the production of 3D models through testing the robustness of 3D models produced by first-time and experienced users.

CT scans are becoming more widely available and are offering significant opportunities for both traditional and novel methods of identification in forensic anthropology. At the moment, there are a wide range of software packages designed to build 3D models using CT data; however, these have not been validated or tested for their reproducibility in forensic anthropology. Therefore, this study sought to develop a method using open source (free) software to establish a valid technique for producing reliable, accurate, and reproducible 3D models from CT scan data.

A step-by-step method was developed for creating 3D models using 3D Slicer, a free open-source CT reconstruction software. The five observers selected for this study included three individuals with no prior experience in handling or producing 3D models and two with limited experience. The observers tested this method by producing 3D crania models from 20 clinical sinus CT scans of ten female and ten male living patients. The scans were obtained from University College London Hospital (UCLH), having received appropriate ethical approvals. The robustness of each model produced by each observer was assessed through a qualitative assessment and a comparison of sex-determination scores. Each observer scored their models using standard sex-determination methods.<sup>1,2</sup> To further validate this method and the utility of the 3D models, an additional four observers with a background in forensic anthropology were selected to take part in examining and scoring the sex of the original models. To demonstrate the accessibility of this method in a global sense, videos of the models in rotation were provided electronically to the additional four observers. Statistical analysis investigated the degree of observer agreement using Fleiss's kappa and Kendall's coefficient of concordance.

The results demonstrated that all observers successfully produced 20 exportable Stereolithographic (STL) 3D models by following the step-by-step method provided. A qualitative inspection of the models found no major differences to the morphology of the crania models produced by each observer, but some minor discrepancies were seen, for example, in modeling the orbital bones. Statistical analyses showed there was high observer agreement between crania features in the sex-determination scoring and the observer video test scoring.

The findings demonstrated that: (1) users with little to no experience of 3D modeling (or using CT data) could create 3D models using the step-by-step method presented, and (2) consistent and robust crania models were produced, which overall verified the reproducibility of the step-by-step method developed. This method has the potential to provide a standardized visualization procedure, using open source software, that can be implemented reliably in future research and forensic human identification casework.

### Forensic Anthropology, 3D Modeling, Computed Tomography

## A73 Gerdy's Tubercle Shape and Associated Biomechanical Factors

Hailey Collord-Stalder, BA\*, Buda, TX 78610; Nathan Blair, BS\*, Manassas Park, VA 20111

**Learning Overview:** After attending this presentation, attendees will better understand the implications of how various shapes of Gerdy's Tubercle (GT) may indicate degenerative changes or habitual activity in an individual, which may contribute to identifying unknown remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing the relevance of GT shape in reference to the biological profile and pathological analysis.

The Iliotibial Tract (IT) is a longitudinal band of fascia that runs from the ilium along the lateral thigh down to the proximal tibia. It has a number of purposes, including stabilizing the knee as well as extending, abducting, and laterally rotating the hip.<sup>1</sup> The IT band inserts distally at GT. Because a number of pathologies due to hyperactivity, such as Osteoarthritis (OA), are associated with the IT band, this research attempted to address several questions.<sup>2</sup> First, is knee OA associated with shape changes of GT? Second, is Body Mass Index (BMI) associated with the shape of GT? Third, does having a physically intensive occupation (e.g., fieldworker) change the shape of GT?

Data was collected on 126 curated tibiae (63 right, 63 left) of both male and female adults from the Texas State donated skeletal collection. GT shapes were separated into four discrete categories: triangular, oval/round, irregular, and unobtrusive.

Data on GT shape, progression of arthritis on the distal femur, patella, and proximal tibia, labor intensity, and BMI were collected for each individual ( $N=63$ ). Each right and left tibia was run separately as many individuals had varying GT shapes and levels of OA per side.

Arthritis was scored using Calce et al.<sup>3</sup> Labor was scored as either non-labor or labor by assessing the individuals' reported jobs or industries. Individuals with unknown work were removed from the dataset.

R-studio was used to analyze the collected data, utilizing a General Estimating Equation (GEE) package. This GEE test was used to analyze any possible correlations between GT shape and side and the various scored factors. A second analysis was run, including side as a factor for possible correlation.

There was no significance when GT was compared with BMI, labor, and femoral and tibial OA. When GT was compared with BMI, labor, and patellar OA, there was significance between GT shape and patellar eburnation ( $\alpha=0.05$ ,  $p=0.0027$ ). However, only one individual had any indication of patellar eburnation, so these results are inaccurately significant due to a small sample size.

A major forensic goal of this research was to assess modern activity patterns and provide a further line of evidence for possible past occupational field or activity level of unidentified individuals. The results, however, provided no clues toward what significance the shape of GT might hold, if any. Future research is needed to diversify the sample and shore up some of the limitations faced with self-reporting.

### Gerdy's Tubercle, Biological Profile, Degenerative Changes

## A74 Fatal Shotgun Trauma to the Cranium With Discrimination Between Manners of Death

Samantha W. Coberly, MA\*, Arbor Park, Gainesville, FL 32603

**Learning Overview:** The objective of this research is to better understand the fracture patterns associated with Shotgun Trauma (SST). This presentation will allow attendees to recognize the differences in expression of trauma between suicide and homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of examining SST.

Features of cranial Gunshot Wounds (GWS) have been examined for decades, including beveling, fracture patterns, trajectory, wound size to caliber size, and multiple GWS.<sup>1-6</sup> These studies focused on handguns with little-to-no mention of SST, yet approximately 1% of the population dies from SST.<sup>7</sup> Medical Examiners (MEs) often use osteological reports to help inform manner of death, thus anthropologists should be able to recognize the patterns associated with SST.

C.A. Pound Human Identification Laboratory (CAPHIL) cases between 1974 and 2018 were examined for SSTs; 17 cases were found with 15 identified individuals and 2 unidentified. Trauma description was taken from the case report; if the report lacked detail, an analysis was performed using case images. Manner of death was determined by the ME. Fracture characteristics and intrinsic characteristics were also noted.<sup>8</sup> Chi-square tests were done to test for significance.

Sixteen individuals were shot peri-mortem and one postmortem. The postmortem case was not considered further. Of the 15 identified individuals, males ( $n=12$ ) were significantly more represented than females ( $n=3$ ;  $p=.00159$ ). White individuals ( $n=14$ ) were significantly more represented than Blacks ( $n=1$ ;  $p=2.56977E-05$ ). Five of the cases were suicides, two were declared undetermined, and nine were homicides. The weapon was present on scene in all of the suicides and one of the homicides ( $p=.0302$ ). There is no significance between type of pellet and manner of death ( $P=.699969$ ). All cases had comminution, diastatic fractures, and fracture lines crossing suture borders.

Of the suicides, four had trauma documented. All had intraoral or submental entrances; three with an anterior to posterior trajectory and one with an inferior to superior trajectory. Fracturing was too extensive to determine exit. Most of the buttressing elements of the skull were not recovered in three of the cases.<sup>9</sup> Elements such as the occipital were highly comminuted with destruction of the buttressing area.

All homicides had some trauma documented. All but one case had one GSW; the outlier had two GSWs. Three cases had posterior-anterior trajectories; two had left-right; three had right-left; and one was unknown due to trauma. In cases with damage to the frontal bone, nearly half had symmetrical fracturing of the frontal, two had asymmetrical fracturing, and the rest had comminution or were missing the frontal. Half had fracture lines through the buttressing of the temporals. Six had damage to the buttressing of the occipital. All had damaged or missing orbits. One case had fracturing at the buttresses of the zygomatics and one at the mental eminence. Three cases had a LeFort fracture of some type.

Current practice associates distant and/or multiple shots with homicides and close contact shots with potential suicides.<sup>10,11</sup> Three CAPHIL homicides were found with the wad in the cranium, indicating a close distant shot.<sup>8</sup> Multiple SSTs are also considered homicide only; only one CAPHIL case had multiple shots.<sup>10,11</sup> These factors will not help in these cases. Location of SST may be more helpful. Suicides had intraoral/submandibular entrances with an anterior-posterior or inferior-superior trajectory; this is the most common suicide pattern.<sup>13</sup> Homicides had an occipital or parietal entrance with a posterior-anterior or lateral trajectory. There were no anterior entrances, unlike other studies.<sup>14</sup> Another difference between homicides and suicides is the lack of symmetrical fracturing in suicides. The force of the contact shots destroyed the thicker areas of the skull. The face and frontal were often not recovered, possibly due to the fact that these fragments can be ejected from the body from the force of the projectile.<sup>15</sup> Fractures from homicides were more likely to follow cranial buttressing and exhibit fracture symmetry. Examining entrance wound location, trajectory, and fracture patterns is likely to aid in differentiation between suicide and homicide. A larger sample size, including accidental deaths, would be necessary for confirmation. Undetermined deaths will be included in future studies to examine if manner of death may be determined.

### A75 Comparing Dental Indicators of Developmental Stress in Unidentified Migrant Remains to Narratives From Living Migrants: A Cross-Disciplinary Approach

Lauren G. Koutlias, MA\*, University of Tennessee-Knoxville, Knoxville, TN 37996; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX 78666; Diana Newberry, MA, South Texas Human Rights Center, Falfurrias, TX 78355; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX 78666; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will understand how skeletal indicators of childhood stress in unidentified migrants can be used in conjunction with narratives from living migrants to aid the humanitarian efforts at the United States-Mexico border.

**Impact on the Forensic Science Community:** This presentation will impact attendees by discussing the importance of using cultural data collection methods in addition to skeletal data collection methods in humanitarian forensic contexts.

Individuals can biologically embody an adverse sociocultural environment. At a populational level, this can result in physiological health inequalities between groups. This project is an investigation of the concept of embodied inequality in the timing, severity, and duration of Linear Enamel Hypoplasia (LEH) in the dentition of modern presumed migrant individuals found deceased along the Texas-Mexico border and modern White individuals who donated their skeletal remains to the Texas State Donated Skeletal Collection (TXSTDSC). Additionally, narratives collected during interviews with migrants waiting for asylum decisions along the United States-Mexico border are compared to the skeletal data. Using cultural anthropological narratives in conjunction with the biological stress data can be impactful and humanizing, and it can aid in highlighting the ongoing humanitarian forensic crisis at the border.

For analysis of LEH, 30 mandibular canines (15 male, 15 female) were chosen from unidentified migrants curated by Operation Identification (OpID) at Texas State University and 29 mandibular canines (13 male, 16 female) were chosen from donated individuals from the TXSTDSC. These specific teeth are the most likely to show LEH if early life stress is experienced. Teeth were not used from migrants if the individual was positively identified, if DNA sequencing was pending, or if dental analyses had not yet been completed by OpID staff. All canines were viewed under a DinoLite™ for observation and measurement of macroscopic LEH and were subsequently viewed under a scanning electron microscope for identification of microscopic LEH. All LEH was measured and age-at-formation of the stress episode was calculated.

All interviews were conducted at a shelter along the United States-Mexico border, which will remain unnamed to protect the identity of the participants. All permissions were acquired (IRB #17-025). The purpose of the interviews was to better understand the journey that migrants undergo on the way to the United States, and a focus was placed on those who lost a loved one somewhere along the way. Interviews were conducted as conversations, with the participants being allowed control over the flow of the discussion and no pre-established round of questions were asked. Narratives were analyzed for content specifically mentioning children and childhood experiences.

Out of 29 skeletal individuals from the TXSTDSC, 10 (34%) possessed macroscopic LEH and 24 (83%) possessed microscopic LEH. In the migrant individuals, 29 (97%) possessed a macroscopic LEH and 28 (93%) possessed a microscopic LEH. Males (3.13 years) and females (3.34 years) in the TXSTDSC possessed different averages as did the males (3.86 years) and females (3.00 years) curated by OpID. These results can be potentially framed in the biocultural context of child upbringing in Central America versus the United States; however, emphasis is placed on the staggering difference in the stress experiences of migrants and White Americans. Migrants that die while attempting to cross the United States-Mexico border have been experiencing physiological stress since early childhood. This is also reflected in the narratives recounted from living migrants at shelters in Mexico. They discuss the danger and stressful situations their families undergo while living in Central American countries, ranging from threats to murder.

Cross-disciplinary approaches and skeletal stress data are uncommon pairings in forensic anthropology, but they can be quite useful in humanitarian forensic contexts. Narratives can add documented human experiences to quantitative data, which can ultimately yield a more humanitarian or humanizing approach, rather than oversimplifying and inferring stress experiences that cannot be directly observed. Furthermore, while this project does not attempt to positively identify deceased migrants, skeletal stress data and living narratives can aid the ongoing humanitarian crisis at the border in other ways, such as bringing attention to the reasons for migration, the biological costs of migration, and informing policy changes based on quantified and experiential data.

#### Physiological Stress Indicators, Living Narratives, Operation Identification

## A76 Impacts of Biosocial Environment on Developmental Plasticity Among Unidentified Presumed Migrant Skeletal Remains Recovered Along the United States-Mexico Border

Caroline Znachko, MA\*, Forensic Anthropology Center, Knoxville, TN 37996-1525; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX 78666; Bruce E. Anderson, PhD, Pima County Office of Medical Examiner, Tucson, AZ 85714; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666; James Watson, PhD, Arizona State Museum - University of Arizona, Tucson, AZ 85719

**Learning Overview:** After attending this presentation, attendees will better understand the variation in Vertebral Neural Canal (VNC) asymmetry in samples of presumed migrants from Texas and Arizona, as well as how it relates to potential differences in social disparities relative to region of origin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the utility of incorporating skeletal indicators of stress into holistic forensic casework. Additionally, this presentation will contribute to an understanding of the skeletal variation in migrant populations that developmental plasticity has the potential to influence.

Stressors experienced during an individual's lifetime (e.g., malnutrition, illness, structural violence, and epigenetic accumulations of trauma) can modify the skeleton.<sup>1</sup> Development of the VNC anteroposterior (AP) and transverse (TR) diameters begins *in-utero* and continues through adolescence, making these structures susceptible to developmental plasticity.<sup>2</sup> While an individual may experience catch-up growth with improved conditions into early adulthood, VNC AP and TR diameters will remain stable after maturation, making them ideal indicators of these earliest stress experiences.<sup>2</sup> VNC asymmetry, the degree of fluctuation in the VNC dimensions from an expected normal, allows for analysis of these stress experiences at the individual and population levels. The continuing humanitarian crisis along the United States-Mexico border demands attention for the expansion of methods employed in the identification process. While studies indicate that unidentified presumed migrants recovered in Texas are increasingly from the "Northern Triangle Countries" and fleeing political instability, gang and drug violence, presumed migrants recovered in Arizona are primarily from Central and Southern Mexico and reflect a displaced rural demographic escaping similar forms of violence.<sup>3-5</sup> The purpose of this research is to improve understanding of the impact the biosocial environment has on developmental plasticity among presumed migrants by examining VNC asymmetry, and to consider how these interactions can inform future forensic anthropological methods employed in this humanitarian crisis.

The skeletal remains assessed in this research are comprised of willed body donations of modern Americans in the Texas State Donated Skeletal Collection (TXSTDSC) ( $n=76$ ), unidentified presumed migrant forensic cases curated at the Forensic Anthropology Center at Texas State under the Operation Identification (OpID) project ( $n=104$ ), and at the Pima County Office of the Medical Examiner (PCOME) ( $n=32$ ). VNC AP and TR diameters of available thoracic and lumbar vertebrae (T1-L5) unobstructed by pathology were recorded according to Watts' method.<sup>2</sup> Demographic information was collected via self-reported questionnaires of willed body donations in the TXSTDSC, and biological profiles were completed by forensic anthropologists at OpID and the PCOME.

These measurements were stratified by sex prior to statistical analysis, and VNC AP and TR diameters were standardized by calculating sample means and individual z-scores. *T*-Tests ( $p<0.05$ ) for vertebrae (along the T1-L5 series) indicate significant difference between the VNC AP and TR diameters of females and males in each sample, yet the vertebrae that differed varied. Analysis of Variance (ANOVA) tests ( $p<0.05$ ) for the VNC AP and TR means between samples found a significant difference between them in both the VNC AP, ( $p=2.1E-13$ ) and VNC TR diameters, ( $p=4.85E-14$ ). Patterns in the spread in variation (z-scores) of the VNC AP and TR dimensions within individuals indicate differences between early childhood and adolescent growth and stress between the samples.

Differences in developmental disruption of the VNC AP and TR diameters among unidentified presumed migrants and modern Americans indicate different early life stress experiences. These processes may inform forensic anthropological methods employed to estimate the biological profile and may indicate an additional avenue to improve population-specific identification methods for the humanitarian crisis along the United States-Mexico border, and beyond. Improved understanding of these skeletal indicators of inequality also hold potential to help the living by providing evidence of the biological repercussions of social disparity and the various forms of violence that migrants seek to escape.

### A77 The Use of Paid Informants in Post-Conflict Human Rights Contexts

Hugh H. Tuller, MA\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853-5530; Popi Chrysostomou, MSc, Committee on Missing Persons in Cyprus, Nicosia 1590, CYPRUS

**Learning Overview:** After attending this presentation, attendees will have a fuller understanding and appreciation of how the use of paid informants in post-conflict human rights contexts can prove, on some occasions, essential in locating clandestine burials.

**Impact on the Forensic Science Community:** Exploring the nexus of: (1) post-conflict forensic investigations; (2) ambiguous loss theory; and (3) critical discussions in the fields of criminal justice and political science, this presentation will impact the forensic science community by introducing the concept of compensating informants to reveal the location of clandestine burials. Enactment of such a proposal would not be without controversy as informants knowledgeable of such burials could have been involved in the crime to some degree, or may even potentially be the perpetrators themselves.

The International Committee of the Red Cross defines Humanitarian Forensic Action as the application of science to the search and identification of missing persons after disaster or conflict. The premise of such work is to mitigate suffering of surviving kin by accounting for the missing, and in the context of post-conflict investigations, is linked to the family's right to *know the fate of the missing* under the Geneva Conventions. Over the past four decades, forensic science has become increasingly engaged in post-conflict investigations, gaining experience in large-scale identification efforts and developing innovative techniques and methods unique to these scenarios. However, one of the hard lessons learned has been that regardless of the efforts and developments put forth by forensic science, search and identification efforts falter when information on clandestine burial locations is exhausted. While scientific methods may find some graves, the prime source of location data continues to be from first and secondary witnesses. Once witness information has been depleted, the search and identification process radically slows, often leaving the investigative organization scrambling to develop additional means of finding graves and struggling to explain the drop in their identification rates to family groups, financial donors, and other supporters.

This presentation proposes compensating informants to reveal the location of clandestine burials in post-conflict investigation contexts. Hold-out informants, those that have not come forward previously with information, are likely individuals that know about the circumstance of disappearance second-hand yet choose not to reveal their information, have been directly involved in the disappearance of the victim to some degree, or may even potentially be the killer. Critics would point out that compensation rewards perpetrators and enablers for their actions, and perhaps it is; however, one can argue that it is wrong *not* to consider incentivizing witnesses in light of the continuing trauma these absences deal to surviving family members and society as a whole.

The loss that family members feel, not knowing if loved ones are alive or not, is a psychological malady known as ambiguous loss, and can prevent survivors from grieving, prolonging their agony. Mass disappearances may also impact the social and economic life of a population for generations, leading to misinformed narratives of the past conflict, mistrust in current governance, and even suspicion about the forensic investigation/ identification process. Thus, ambiguous loss can undermine the very efforts to mitigate the trauma of the conflict that originally motivated the humanitarian forensic investigation.

One can argue that when the point of diminishing returns is reached in an identification process, government/organization leaders should then consider implementing a compensatory policy to entice informant hold-outs to come forth with their information. Further, one can argue that there is precedence of paying informants for their knowledge in the fields of criminal justice and political science. Specifically, police departments regularly pay known criminals to gain information on illegal activity. In international kidnapping/hostage situations, payments to perpetrators for the release of their captives is a common practice, and even unofficial policy for some governments. To enact this compensatory system, a framework must carefully be crafted that includes how best to introduce the policy to the public, protection of informant identities, and a process to validate informant information prior to compensation in order to avoid abuse of the system.

The introduction of a compensatory policy is expected to be controversial; paying potential perpetrators to tell where they buried the body will be viewed as rewarding their actions. Yet, there is solid precedence of rewarding perpetrators for their cooperation in order to allay further harm. To do nothing is to condemn surviving family members to a liminal state of unending trauma, a moral impasse in its own right. Further discussion on this topic will be encouraged.

---

#### Paid Informants, Ambiguous Loss Theory, Post-Conflict Investigations

### A78 The Use of an Integrated Multidisciplinary Approach to Resolve Non-Identified Human Skeletal Remains in Cyprus

*Aikaterini Papaioannou, MS\*, Committee on Missing Persons in Cyprus, Nicosia 1590, CYPRUS; Popi Chrysostomou, MSc, Committee on Missing Persons in Cyprus, Nicosia 1590, CYPRUS; Gulbanu K. Zorba, MS, Committee on Missing Persons in Cyprus, Nicosia 1590, CYPRUS; Mine Balman, MS, Committee on Missing Persons in Cyprus, Nicosia 1590, CYPRUS*

**Learning Overview:** After attending this presentation, attendees will be familiar with a novel multidisciplinary approach designed to minimize or resolve cases of unidentified human remains in large-scale humanitarian projects. The model proposes a more interactive and continuous use of investigatory information from the early stages of recovery operations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) introducing attendees to the challenges faced by the Committee on Missing Persons (CMP) in identifying missing persons when the DNA of the recovered remains does not match with any of the Family Reference Samples (FRS); and (2) introducing an integrated multidisciplinary approach for minimizing or resolving cases of unidentified human remains.

In most humanitarian projects, a percentage of the recovered human skeletal materials, after a general search is made in the database of the FRS, remains unidentified. In Cyprus, the list of the missing persons was compiled by the CMP. This was achieved mainly through the cross-checking of the missing persons reported by family members, the army, and by a community member in a position to know all his co-villagers (i.e., the mukhtar of each village). However, soon after the commencement in 2006 of the CMP's Project on the Exhumation, Identification and Return of Remains of Missing Persons, it became evident that not all human remains recovered in the field matched with the FRS related to the initial list of 2,002 missing individuals. By mid-2017, while 886 individuals had been identified, there was a minimum number of 137 individuals that either had no match in the database or did not yield enough scientific evidence to proceed with an identification. Many of these cases remained unresolved for more than a decade in the storage areas of the CMP anthropological laboratory.

This presentation outlines all steps taken to not only reduce this number to one-third in less than two years (current MNI=46), but also to act in advance in order to prevent the occurrence of the no-matches. In this model, the interaction between the investigators and the geneticists was strengthened and included the following: (1) generation of hypotheses on candidates who could be related to a burial site upon recovery of remains, (2) checking the availability of the candidates' FRS even prior to the commencement of the anthropological analyses, (3) revision of all available pedigrees, (4) requests of additional FRS when needed—to accomplish this a project was initiated whereby many skeletal samples were collected from deceased relatives, (5) revision of hypotheses on candidates once the biological profile was completed, and (6) verification of hypotheses once the genetic data was obtained. This resulted in an increased number of the matches during the first round of the genetic database search, thus minimizing the no-match cases and expediting the identifications.

For the generation of the hypotheses, a new approach was introduced whereby missing persons were mapped and linked to events. This led to a better understanding of the context and produced more targeted and limited lists of candidates. In commingled cases, bones were mapped and studied in relation to the identifications/investigative data to produce a better understanding of the expected number of individuals. In addition, in cases in which there was an indication that the remains were not relevant to missing persons (e.g., remains associated with cemeteries or archaeological contexts), the radiocarbon sampling was expedited.

In Cyprus, the human remains recovered by CMP are not always associated with a closed group of missing individuals. By using a multidisciplinary approach, where investigative information plays a central role, it is possible in most cases to either reach an identification or conclusively eliminate the possibility that the remains belong to a reported missing person. Since the genetic identifications have many limitations, such as incidental findings, no available or no informative FRS, partial profiles or very common alleles and so forth, a greater emphasis on the investigatory information can improve the percentage of identifications. Greater awareness on this topic, within the humanitarian forensic world, can reduce the number of unidentified remains.

#### Multidisciplinary Approach, Unidentified Human Remains, Identification of Missing Persons

### A79 What Happens to Unidentified or Unclaimed Human Remains Within the Contexts of Five Asian Medicolegal Systems?

*Sherry C. Fox, PhD\**, International Committee of the Red Cross, Bangkok 10110, THAILAND; *Laurel Clegg, MSc*, International Committee of the Red Cross, Islamabad, PAKISTAN; *Lay See Khoo, PhD*, National Institute of Forensic Medicine, Kuala Lumpur, Wilayah Persekutuan 50586, MALAYSIA; *Rijen Shrestha, MD*, Maharajgunj Medical Campus, Kathmandu, NEPAL; *Alex Starkie, Frome, Somerset BA11 4DD*, UNITED KINGDOM; *Panjai Woharndee, MD, PhD*, Ministry of Justice, Bangkok, THAILAND

**Learning Overview:** After attending this presentation, attendees will better appreciate the diversity in the medicolegal systems in Asia, the challenges mass disasters can present in identification, and the manner in which Malaysia, Nepal, Pakistan, the Philippines, and Thailand each manage unidentified human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting how there is not one universal medicolegal system in Asia that will work within every country and how each medicolegal system manages the disposition of unidentified human remains differently.

Asia is a dynamic region that boasts countries with the two largest populations in the world. As such, the medicolegal systems in the region must cope with large numbers of deaths and potential large numbers of death investigations. Due to different histories, and reflecting the cultural diversity in the region with respect to languages, religions, ways of life, and burial customs, different medicolegal systems have been established that respond to the various needs within their geopolitical structures.

This study aims to demonstrate the diversity in the medicolegal systems of Asia by comparing what autopsy means, when autopsy is performed, the mandate for death investigation, and what happens to unidentified human remains, among others, in the contexts of the following five countries: Malaysia, Nepal, Pakistan, the Philippines, and Thailand. In addition to the variables outlined above of language, religion, ways of life, and burial customs, among others, these countries vary in size, population, major religion, and geography—one is landlocked and another is an island nation, for example.

One constraint that appears to be common among all of the countries under study, however, is the lack of storage facilities for long-term, unidentified, or unclaimed bodies. How each country manages their unidentified or unclaimed human remains varies, in part depending upon the dominant religious beliefs of each country. Burial customs in these contexts in Asia range from inhumation burial common among Muslims and Christians to cremation burial common among Hindus and Buddhists. The disposition of unidentified and/or unclaimed human remains in these contexts include marked common graves and mass burials. The timing of when these burials take place also varies within each context. There are a multitude of reasons for why a body is not identified or left unclaimed. One related factor in Asia is that the region is prone to natural disasters in the form of cyclones, tsunamis, floods, and earthquakes. These natural disasters present a risk to the lives of the inhabitants, and further, the risk of not being identified, especially in the case of mass casualties. As an example, there are yet unidentified human remains from the mass disaster that resulted from the 2004 earthquake/tsunami in Indonesia.

What is clear, as the results of this study demonstrate, is that while there is no universal medicolegal system that would work within every country, the various medicolegal systems in Asia presented in this study meet the basic requirements within their own regulations and contexts. Finally, how each country solves the issue of unidentified and/or unclaimed bodies varies vastly, as will be presented.

#### Medicolegal Systems, Asia, Unidentified Human Remains

### A80 Antemortem Data Collection in West Africa as Part of the Effort to Identify Deceased Migrants: A Humanitarian Dilemma

*Laurel Clegg, MSc\*, International Committee of the Red Cross, Islamabad, PAKISTAN; Carolina Pagnini, MD, UML, Pointe à Pitre 97110, GUADELOUPE; Derek C. Benedix, PhD, Nicosia 2039, CYPRUS; Ivett Kovari, PhD, Paris 75014, FRANCE; Bilal Sablouh, MD, International Committee of the Red Cross, Tunis 1053, TUNISIA; Jose P. Baraybar, MSc, PhD, International Committee for the Red Cross, Paris, Ile de France 75014, FRANCE*

**Learning Overview:** After attending this presentation, attendees will better understand the technical and ethical challenges involved in the collection of antemortem data for deaths related to migration for humanitarian purposes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing the different elements that need to be considered concerning antemortem data collection for migrants from West Africa.

According to the most recent figures from the International Organization for Migration, since 2014 at least 14,000 migrants lost their lives while crossing the Mediterranean Sea.

In January 2017, the International Committee of the Red Cross (ICRC) and the Italian Red Cross signed a Tripartite Agreement with the Office of the Special Commissioner of the Italian Government for Missing Persons to support in the efforts of identification of dead migrants recovered in Italy, with an exclusive humanitarian purpose.

Within this framework, an ICRC project was launched to assist with identification of the victims of one of the largest incidents in the Mediterranean Sea. On April 18, 2015, an estimated 1,000 migrants lost their lives. As part of the project, families of missing migrants potentially affected by this shipwreck are sought in their countries of residence and/or countries of origin, and, if located, are interviewed to aid identification efforts. In Western African countries, where many of the victims are believed to be from, the search for the families remains extremely difficult due to the limited information available.

Moreover, the specific challenges in the collection of the antemortem data from the relatives who reside not only in Africa, but across the globe, has highlighted the need to reframe what is considered useful information for identification. Generally, antemortem data is collected with the underlying assumption that individuals possess specific attributes that will allow them to stand out from a group of individuals. The logic is that physical traits, medical treatment, and lifestyle imprint specific elements to individuals that may, together with other elements, assist in the identification process. This assumes, unfortunately, that most people have access to services that leave a record (e.g., dental records, hospital records, X-rays, etc.). Depending on an individual's and his or her community's circumstances, such services are not always accessible.

Besides the lack of medical and physical information available, differences in culture, language, religion, and family structure references between the interviewer and the interviewee challenge the medicolegal approach to collection and reporting. Not always acknowledged is the collector scientist's expectation that the available data will respond to his/her needs, while the data provided does not easily have an equivalent. For example, a "window" observed between front teeth (emic) as described by a relative, could be described as a diastema or a missing tooth in the dental or postmortem examination (etic). The comparative data that is required for scientific identification may exist, but not in a format familiar to the scientist.

At the same time, genetic identification in the migration transnational context has its own challenges in terms of how data is shared and stored as well as how collection is planned. For example, in the collection of genealogical data to support collection of Biological Reference Samples (BRS) from surviving family members, several assumed categories such as cousin, brother, or sister may not correspond to biological relationships needed for genetic testing. In addition, common to West African culture, any child adopted into the family automatically becomes a son or a daughter and will be referred to as such. Even descriptions of personal effects (specifically clothing) may be unreliable as these are easily changed after departure up to embarkation.

Experience has shown the need for an innovative, pragmatic humanitarian approach to antemortem data collection in the migration context. Usually antemortem data includes information on missing persons, notably personal, physical, medical, and dental information, as well as information on circumstances related to the disappearance. A reflection is needed, though, on methods to better exploit circumstantial and contextual information (e.g., the trip itself, fellow travelers) coupled with the usually scarce individual biological data.

---

#### Migration, Antemortem, West Africa

### **A81 Climate, Conflict, and Migration—Applications of Forensic Science to Address Humanitarian Issues in a Growingly Complex Global Environment**

*Oran Finegan, MSc\*, International Committee of the Red Cross, Geneva 1202, SWITZERLAND; Pierre M.M. Guyomarc'h, PhD, International Committee of the Red Cross, Geneva, GVA 1202, SWITZERLAND; Davette N. Gadison, MA, Tulane University, Department of Anthropology, New Orleans, LA 70118*

**Learning Overview:** After attending this presentation, attendees will better understand the broader connection between the growing challenges brought about by climate change, and how it is impacting armed conflict and migration, and the humanitarian challenges that stem from these issues. Attendees will learn about the importance of understanding cultural and religious diversity, how this impacts on a transnational problematic, and how forensic sciences can transcend these issues and help address these growing humanitarian challenges.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the importance of introducing thinking surrounding cultural and religious issues on how they work and look to address the growing challenges in identifying human remains through understanding the root causes of this problem and will help forensic practitioners develop better models for approaching this complex issue.

When we think of crossing borders, we often see this as simply a physical barrier; for example, passing from one state into another. The movement of people globally, whatever the reason may be, has created much greater borders than simply physical ones. We live in a growingly globalized world, and the impact this has when we look at the problematics of migration, conflict, and climate only go to reflect this. Our connectivity plays a great role in this, breaking down what were traditional borders and allowing us to live in a very interconnected ecosystem. This same connectivity allows us as forensic scientists to attempt to address what often seem insurmountable challenges, especially when they relate to trying to determine the origin and identity of someone who is found dead along the large number of human paths that transverse our planet.

Pushed out of their homelands by the growing impact of climate change, which often fuels conflict over already-scarce resources and land, the numbers of persons perishing throws down some of the greatest challenges facing us as forensic scientists as we grapple with the task of trying to find a way to ensure the handling and disposition of the dead, in line with the legal, cultural, and religious needs of someone we may know nothing about, and the task of attempting to give this person back their name.

With communities now living transregionally, connected by a growingly integrated communications network, the idea of country of origin and destination for migrants tends to blur. The efforts of forensic science can bring together an interconnected network of family members to try and piece together the many fragments of information in the efforts to identify a missing relative. However, this can leave forensic practitioners and all those involved in the search process trying to navigate the complex patchwork of culture and society.

A growing recognition and engagement of the forensic community in humanitarian and human rights issues is providing hope. Advances in areas such as forensic genetics, the use of stable isotopes, and complex network analysis of population movement all are playing an important role. However, forensic science alone will not address these challenges. Major legal considerations must be understood, for example, in terms of cross-border transfer of data. With such divergent systems in place across the globe, this only further underlines the need for the harmonization of systems and procedures between and within states to allow for better transfer of necessary information in a format that can be used both practically and legally by all concerned.

Understanding climate change and how it will impact conflict through the battle for scarce resources, forced displacement from flooded areas, or cities no longer able to provide sufficient water for inhabitants will be essential as we look to the real impact this will have on the death of civilians in the years to come. Understanding how this will impact communities will be essential as we try to understand what role forensic science will inevitably play in trying to recover and, where required, identify the victims of these realities of the future.

---

#### **Climate Change, Armed Conflict, Humanitarian Forensics**

### A82 Crossing Borders: Conflict Evolution and Climate Change—The Humanitarian Consequences on Human Migration

Sarah Wagner\*, George Washington University, Washington, DC 20052

**Learning Overview:** After attending this presentation, attendees will understand how displacement and its temporal dimensions affect processes of recovery and identification of persons missing as a result of violent conflict, specifically in relation to delayed responses and prolonged uncertainty.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the temporal elements and obstacles inherent in forensic efforts to recover and identify missing/unknown persons and how those, in turn, affect surviving kin and their perception (and reception) of the forensic processes. In doing so, it highlights the asymmetrical relationship between those controlling and implementing the forensic response and those awaiting its results.

From the pressure to locate remains, collect and analyze evidence, and deliver definitive results, humanitarian responses to incidents of mass fatality are often cast—understandably so—in terms of the urgency of time. A race against the proverbial clock, forensic efforts grapple with time-sensitive conditions as varied as environmental exposure and degradation and the fading memories of potential witnesses to clandestine burial. Yet time is a complicated metric when applied to the identification of victims of mass fatalities, particularly when it comes to the social consequences of violent conflict and mass displacement.<sup>1</sup> Grounded in the premise that “time and space are integral to each other,” this presentation focuses on these consequences to illustrate how such displacement introduces obstacles and often delays in processes of recovery and postmortem identification.<sup>2</sup> It also invites a more nuanced consideration of how prolonged uncertainty shapes the way families perceive and evaluate the efficacy of forensic responses. Finally, time as an analytic sheds light on the interplay between humanitarian and political aims underwriting forensic efforts to reclaim and return the remains of victims of violent conflict.

Time unfolds unevenly, in war and its aftermath. The seconds it takes to destroy a single life or the hours involved in the illicit disposal of bodies may require years, even decades, of investigation—archaeological, anthropological, and genetic—to reassociate an individual identity with a set of unnamed remains. All the while, relatives of the missing wait: for news of life, of death, and eventually of recovery and return. The disparity between these temporal dimensions is compounded when conflict scatters not only the bodies of the missing, but also those who survived them. Two examples document this asymmetry and its import. The first relates to forensic efforts to identify the 31,000 missing persons from Bosnia and Herzegovina, specifically the more than 8,000 Bosnian Muslim (Bosniak) men and boys missing as a result of the Srebrenica genocide, where mass displacement of surviving relatives complicated both the DNA-led forensic response and the community’s ability to mourn for and commemorate its victims.<sup>3</sup> In the Srebrenica case, the tension between the urgency of immediate postwar humanitarian action and the longer-term memory politics of national belonging emerge most sharply at the annual commemoration and mass burial of identified victims in the communal cemetery of the Srebrenica-Potočari Memorial.

The second example addresses the United States military’s decades-long efforts to account for its service members Missing In Action (MIA) and presumed dead from the Vietnam War. Akin to the recent initiative to identify Argentina’s unknown soldiers buried on the Malvinas Islands, although set to the political calendar of shifting administrations and geopolitical relations, the American MIA accounting mission in Southeast Asia is explicitly termed a “humanitarian” program. Gradual diplomatic rapprochement has indeed opened doors for archaeological recoveries and eventual identifications. But time has also adversely affected the mission’s results. Landscapes are altered; remains are degrading; witnesses are dying, and memories fading. Beyond these physical and social forms of decay, time also troubles surviving kin. Some go to their own graves without burying their loved ones. Outsized expectations further fray trust in expedient results and prolonged uncertainty exacts tolls that not even the most certain of forensic evidence can assuage.<sup>4</sup>

In examining the temporal dimensions of conflict, displacement, and delayed care for the dead through the examples of postwar Bosnia and Herzegovina and contemporary United States, this presentation demonstrates the sociopolitical complexities of humanitarian forensic intervention when time is continually of the essence, but results come decades later.

#### Displacement, Humanitarianism, Time

### **A83 Crossing Borders and Conflict: The Complex Circumstances of Those Who Disappear in Armed Conflict and the Simple Duty of Care to Bring Them Home**

*Laurel Clegg, MSc\*, International Committee of the Red Cross, Islamabad, PAKISTAN; Derek Congram, PhD\*, International Committee of the Red Cross, Bogota, D.C., COLOMBIA*

**Learning Overview:** After attending this presentation, attendees will better understand how cases from different past and contemporary conflicts can address questions of how, why, and when to seek out the remains of the “military” dead and how they ought to be treated. Attendees may also understand how modern borders are reconciled to ensure that different forms of care for the dead (identification, commemoration, repatriation), without making judgements about their motives for, or agency in, crossing borders is both respectful and sustainable.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by reexamining the treatment of military dead through the lens of migration and uses several cases: a woman who longs to give dignified burial to her family that was killed in conflict in their homeland; a mother who clandestinely recovered the remains of her soldier son buried abroad; and the ramifications of nationality and place of death on how governments and families commemorate their dead. This report will present solutions to ethical and sustainable management of those dead due to armed conflict.

While the scale of recent migration and subsequent deaths in places such as the Mediterranean Sea and the United States-Mexico border has been shocking, the death of large numbers of foreign nationals en route to another place or while in another country is nothing new. We do not always see armed actors as migrants, but indeed, the challenges of managing their deaths overseas, the circumstances of their deaths, and the sociopolitical policies that impact whether they are sought and repatriated present some similarities as well as stark contrasts to those communities currently faced with the care of the marked and unmarked graves of the migrant dead. Even many years after the end of a conflict, the bodies of armed actors are discovered by happenstance or even actively sought, and how these remains are managed is a story of nationality and place of remains, a story of where “home” and family are for those remains.

This presentation will examine the distinct circumstances that illustrate the fate of those who take up arms, die, and disappear in a place that is not their home. Some choose to take up arms, later dying in countries that are not their own, while others are conscripted to military service and forced to fight, die, and disappear in a foreign land. Others still are forced to flee one type of violence and, being in an extremely vulnerable position, are recruited into armed conflict in their new “home.” This creates a stark contrast—perhaps no less tragic—with those who die while fleeing their home to escape violence.

Often, at the time of death and burial in armed conflict contexts, identification techniques of the dead and the ability to trace surviving families is limited by resources and the exigencies of war. Sometime afterward; however, there are considerable opportunities to seek out the missing dead, identify them, and return their bodies to their communities and families. This presentation will use concrete cases to illustrate the existing legal, technical, and ethical challenges faced by governments, scientists, communities, and most importantly, aging families in the conflicting borders of managing those who bear arms, die, and disappear in armed conflicts.

## A84 The Role of Civil Society and the State in Transnational Identifications at the United States-Mexico Border

Kate Spradley, PhD\*, Texas State University, San Marcos, TX 78666; Courtney C. Siegert, MA, Texas State University, San Marcos, TX 78666; Mercedes Doretti, MA, Argentine Forensic Anthropology Team, Brooklyn, NY 11233; Robin C. Reineke, PhD, Southwest Center, University of Arizona, Tucson, AZ 85721; Eduardo Canales, BS, South Texas Human Rights Center, Falfurrias, TX 78355; Christine M. Kovic, PhD, University of Houston-Clear Lake, Houston, TX 77058

**Learning Overview:** After attending this presentation, attendees will learn the discordance between state-mandated legal approaches to identification and humanitarian efforts when dealing with transnational identification efforts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by indicating the need for civil society-based approaches to aid in identification efforts across transnational borders.

Forensic anthropologists often work with unidentified human remains with the goal of building a biological profile to facilitate identification and repatriation. While it was once difficult to share missing person's information across state lines, the past 20 years have seen incredible strides with the creation of the National Missing and Unidentified Persons System (NamUs) and the Combined DNA Index Systems (CODIS). NamUs and CODIS both allow data sharing across jurisdictional lines within the United States and work to associate missing persons with unidentified persons, resulting in fewer unsolved cold cases. Although these systems exist through federal funding, there are no state or federal resources that allow for transnational sharing of missing persons information or genetic data.

The continually occurring mass disaster at the United States-Mexico border, with more than 6,000 reported migrant deaths since 2000, remains challenging to forensic practitioners, families of missing migrants, and all agencies working toward positive identification on both sides of the border.<sup>1</sup> Due to the lack of federal- and state-mandated resources for transnational collaboration regarding unidentified human remains found in the United States, civil society plays a large role in facilitating identifications by acting on behalf of families of the missing as well as working directly with forensic practitioners across borders. The purpose of this presentation is to highlight, through data and case studies, the role civil society has played in the identification of missing migrants along the United States-Mexico border with specific reference to Texas.

Data were collected from the Forensic Anthropology Center at Texas State (FACTS) where 287 migrant remains are undergoing anthropological analysis pending identification through coordinated efforts with governmental agencies and civil society. FACTS, through Operation Identification, works with government agencies and civil society organizations, including the Argentine Forensic Anthropology Team (EAAF), the South Texas Human Rights Center, and the Colibrí Center for Human Rights, to facilitate identifications. As required by state law, FACTS submits DNA samples from unidentified human remains for genetic profiling and upload to CODIS. Additionally, FACTS collaborates with the EAAF and Colibrí to compare unidentified genetic profiles with family DNA data that is not in CODIS. In total, FACTS has facilitated 14 genetic associations through the submission of 55 DNA profiles to the EAAF and 19 genetic associations through the submission of 188 DNA samples to CODIS.

Although FACTS follows state laws regarding unidentified human remains, without additional collaboration with civil society organizations, only 16 out of 33 identifications would have been possible. This collaboration has also led to the discovery of burials representing the long-term dead in need of exhumation and identification efforts. Additionally, civil society has been able to raise awareness of the lack of transnational data sharing to policy makers who have the power to provide much-needed change. The identification comparisons will be discussed within a larger framework using specific case study examples and highlighting specific roles that civil society has played in shaping policy for unidentified human remains.

While working within the United States, individual states have the responsibility to facilitate identifications using either local or federal systems. Although our current federal systems facilitate sharing of information across jurisdictional lines, it is not currently possible to share such information on a transnational level without civil society collaboration.

## A85 Empathy and the Identification of Missing Migrants

Cate E. Bird, PhD\*, *International Committee of the Red Cross, Washington, DC 20036*; Jason D.P. Bird, PhD, *Rutgers University, Newark, NJ 07102*; Jose P. Baraybar, MSc, PhD, *International Committee for the Red Cross, Paris, Ile de France 75014, FRANCE*; Derek C. Benedix, PhD, *Nicosia 2039, CYPRUS*

**Learning Overview:** After attending this presentation, attendees will understand the importance of applying an empathetic approach in forensic casework, particularly when attempting to identify missing migrants.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of empathy as a tool for emotional regulation and as an investigative mechanism for identification.

As previous research has demonstrated, assertions of pure objectivity in forensic anthropology are problematic. Forensic practitioners are shaped by their environments, which results in degrees of implicit bias. The lack of acknowledgement of subjectivity is problematic as it can unknowingly guide forensic analyses and interpretations. One aspect of subjectivity that is largely neglected in the forensic sciences is that of emotions, particularly when working with unidentified remains. The prevailing paradigm mandates that forensic practitioners be guided solely by “logic,” but neglects to acknowledge that practitioners are humans who feel emotions, such as anger, fear, disdain, and grief. Strategies to curtail emotion often revolve around desensitization tactics, construction of emotional barriers, and/or the objectification of deceased persons (e.g., not analyzing a human but a bone). The dismissal of one’s emotion may provide the practitioner with a feeling of distance and control, but its efficacy as a mode of objectivity is questionable. It is argued that engaging empathetic processes is one way in which forensic scientists can become more aware of their internal emotional states, better informed of the populations they serve, and more cognizant of novel investigative mechanisms to facilitate identification.

As demonstrated by the Latin American experience beginning in 1983, empathy can lead to *holistic* approaches in forensic science. Empathy refers to a process by which one comes to understand the perspectives of people who are different. Empathy represents a first step in navigating one’s own emotions in order to pursue “mitigated objectivity.” The forensic science community has been slow to understand, embrace, and apply empathetic approaches given the perceived contradiction to scientific “objectivity.” To those unfamiliar with empathy, it is often conflated with sympathy or pity, and viewed as the shedding of detached analyses in favor of unhinged emotion, which is fallacious. In actuality, empathy can contribute to knowledge production and problem-solving through emotional regulation and recognition/interpretation of key features pertinent to the identification process.

This presentation outlines key components of empathy that forensic practitioners should consider in their casework. Components include: acknowledging one’s own involuntary affective responses; recognizing a separation between oneself and others; exposing oneself to the experiences/perspectives of others; cognitively assessing differences/similarities between oneself and others; and regulating one’s emotions. Social science research has demonstrated that effectively engaging empathy provides a mechanism to explore implicit biases and assumptions, and a means to successfully manage one’s own emotional responses (a.k.a. emotional regulation). This process can also provide an overall strategy in the attempt to identify the remains of vulnerable or at-risk groups, such as migrants.

Those who engage in irregular migration represent highly stigmatized and marginalized groups, not only in countries of destination, but also in countries of origin and transit. Migrants are also particularly vulnerable for going missing at various points along their journey and for remaining unidentified even when medicolegal structures are well developed. Drawing on case studies, this presentation demonstrates how an overall lack of empathy toward migrants affects the ability to identify their remains and return them to families. If personal identification is the ultimate objective of analyses, forensic scientists can contribute to this goal and reduce the further devaluing of migrants by becoming familiar with their perspectives in life, by recognizing their group affiliation in death, and by devising effective strategies for their identification (e.g., consultation with community partners).

Applying biocultural profiles for decedents, especially for unknown persons, represents a first step in empathetic engagement. The biocultural approach consists of analyzing material culture, scene context, and biological indicators in a thoughtful manner to develop hypotheses of group affiliation of decedents (e.g., migrants). While employing empathy may elevate the pursuit of justice in clarifying the fate of the missing, it does not decrease objectivity. Rather, the recognition of deceased persons as once-living individuals who belonged to particular communities permits forensic practitioners to better account for mortality trends in certain communities and to investigate appropriate routes for identification.

### Empathy, Identification, Missing Migrants

## A86 Assembling a Forensics of Structural Violence

Adam R. Rosenblatt, PhD\*, Duke University, Durham, NC 27705

**Learning Overview:** After attending this presentation, attendees will recognize ways that forensic science can contribute to making structural violence visible and responding to it, along with some of the challenges that are likely to accompany those efforts.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by identifying specific areas where the ethics and the organizational practice of forensic investigation must adapt to address structural violence.

Beginning with efforts to locate clandestine graves and identify victims of enforced disappearance in Argentina in the 1980s, scientific experts and families of the missing have created a new global paradigm for forensic investigation that is sometimes called “forensic humanitarian action,” a blend of 19<sup>th</sup>- and 20<sup>th</sup>-century ideas of humanitarianism and human rights.<sup>1,2</sup> This presentation argues for complimenting the field’s focus on war crimes, genocides, and “natural” disasters with an integrated, 21<sup>st</sup>-century understanding of structural violence.

Structural violence refers to the differences in people’s well-being or “life chances” that result from “the unequal distribution of power and resources.”<sup>3,4</sup> It is violence that is “built into the structure of society itself.”<sup>5</sup> Critics argue that the human rights movement has long focused too narrowly on direct violence while turning away from the everyday structural violence experienced by the global poor.<sup>6-8</sup>

For forensic scientists, responding to this critique would require moving beyond the traditional definition of “wrongful death”—a claim against a specific perpetrator—to a focus on *preventable* deaths and the living communities impacted by them.<sup>9</sup> Preventable deaths result from disease, poor labor conditions, mass migration, environmental destruction, and the global failure to deter climate change and the unequal distribution of its effects. In many cases, these deaths produce bodies that go missing or wind up in marginalized burial places, their stories never told.

Experts working to identify migrants who die in the United States-Mexico borderlands have called for a forensics of structural violence, and explored its ramifications for the role of individual experts.<sup>9,10</sup> This presentation builds on their work through an interdisciplinary approach combining social anthropology, political theory, and historical perspectives. It further assembles a picture of the forensics of structural violence, as well as ethical and political dilemmas that accompany its necessary development.

A focus on structural violence includes asking what care for the dead—and the chronic disruption of this care—means for the health and well-being of entire communities. It also means questioning what types of historical violence merit forensic investigation: wars and massacres only, or also the forgotten graves produced through generations of exclusion and structural violence?

The forensics of structural violence spark difficult conversations about neutrality and objectivity, and who is present and heard in the spaces where forensic humanitarian organizations chart their directions. These organizations will also need new fundraising solutions to emerge from a humanitarian tradition where “savage inequalities,” though claiming lives every day and disrupting the care of the dead, do not command the same attention as direct violence.<sup>11</sup>

### Human Rights, Structural Violence, Migration

## A87 Beyond Identification: Structural Vulnerability and the Investigation of Migrant Deaths

Angela Soler, PhD\*, New York City Office of the Chief Medical Examiner, New York, NY 10016; Jared S. Beatrice, PhD, The College of New Jersey, Ewing, NJ 08628; Robin C. Reineke, PhD, Southwest Center, University of Arizona, Tucson, AZ 85721; Daniel L. Martinez, PhD, The George Washington University, Washington, DC 20544

**Learning Overview:** After attending this presentation, attendees will learn about structural vulnerabilities affecting undocumented migrants crossing the United States-Mexico border and living in the United States, and how these vulnerabilities impact migrant deaths and death investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by: (1) highlighting the unique perspective and skills of forensic anthropologists that can bring awareness to this continuing humanitarian crisis; and (2) initiating a discussion of the ethical responsibilities of forensic anthropologists working with vulnerable migrant populations.

Nationally, people of color, migrants, transients, and homeless persons are overrepresented in forensic casework, especially in cases of long-term unidentified decedents.<sup>1</sup> Both at the southern border and nationally, undocumented migrants represent a substantial number of these long-term unidentified decedents. However, people of color, and especially undocumented migrants, are immensely underrepresented in local missing persons reports and cases uploaded to national databases. This disparity will intensify as migrants continue to die in large numbers at our southern border and disproportionately within our local communities. As an integral part of the death investigation process, forensic anthropologists are challenged with the identification and repatriation of undocumented individuals, and as a result, we as a discipline are directly and intimately witnessing this humanitarian crisis.

With widely applicable skills in academic, medical examiner/coroner, government, and human rights contexts, forensic anthropologists are in a position that few other forensic practitioners share. Whether attempting to identify unknown remains, contributing skeletal information to the cause and manner of death, or conducting research that will assist in these analyses, we inevitably come into contact with the physical bodies of vulnerable individuals. Many forensic anthropologists also come into contact with distressed and vulnerable families as we communicate with loved ones for the purposes of identification and repatriation. Regardless of the jurisdiction or context in which we work, or the type of analyses in which we participate, as forensic anthropologists we should be aware of the structural vulnerabilities affecting the physical bodies we examine and the families we serve.

This presentation will review structural vulnerabilities in undocumented migrant groups using the three forensic temporal perspectives of trauma as an analytical framework: (1) Antemortem: biological indicators of poverty and physical violence experienced in life and incorporated into the body; (2) Peri-mortem: indicators of structural vulnerability that correlate with the recovery location of deceased migrants and the cause and manner of their deaths; and (3) Postmortem: indicators of structural vulnerability in the unequal treatment of migrant bodies, including incomplete forensic investigation of their deaths, and the burdensome position of family members with a loved one who died while undocumented. These issues will be discussed as they pertain to ethical considerations in research and when handling the remains of vulnerable individuals.

Incorporating knowledge of structural vulnerabilities in undocumented migrants into a forensic context is meaningful for a number of reasons. First, recognizing biological indicators of poverty and physical trauma as additional scientific data can substantially contribute to identification efforts. Additionally, comprehending the stressors affecting families of missing and deceased undocumented migrants may help investigators develop strategies to identify their loved ones and make notification. Undocumented individuals and their families are essentially living “invisibly” in our society and forensic practitioners need to account for this in any efforts to make an identification and when communicating with family members. Some investigative strategies and resources to work through the identification of a probable undocumented migrant will also be presented.

Finally, and most important, there is an ethical responsibility that we must consider in our multidisciplinary role as forensic scientists and anthropologists. Practicing forensic science is to serve the deceased, their families, and ultimately the greater community. As forensic anthropologists, we are deeply involved in various stages of the death investigation process and are in a unique position to share our scientific knowledge and experiences of how this crisis is affecting the greater migrant community. Our service, our research, and our outreach can not only contribute directly to the death investigation process, but also to an awareness of the larger humanitarian crisis that we are witnessing.

The views and opinions expressed in this abstract are the author’s own and do not reflect the opinions of the New York City Office of Chief Medical Examiner or the City of New York.

### Structural Vulnerability, Undocumented Migrants, Death Investigation

## A88 Families of the Missing: Forensic Obligations to Families During the Identification Process

Robin C. Reineke, PhD\*, Southwest Center, University of Arizona, Tucson, AZ 85721; Mirza M. Monterroso, MA, Tucson, AZ 85705; Mercedes Doretti, MA, Argentine Forensic Anthropology Team, Brooklyn, NY 11233; Carmen E. Osorno Solís, Brooklyn, NY 11201; Rachel Daniell, MPhil, Argentine Forensic Anthropology Team (EAAF), Brooklyn, NY 11233; Eduardo Canales, BS, South Texas Human Rights Center, Falfurrias, TX 78355

**Learning Overview:** After attending this presentation, attendees will leave with a useful framework for ethically engaging with families of missing migrants during the forensic identification process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing ethical guidelines tailored toward protecting and respecting families of missing migrants. Adhering to such guidelines will improve rates of identification as well as the social outcomes of the identification process.

Modern international borders pose both unique and familiar problems to the field of forensic anthropology. From the condition of remains upon discovery to bureaucratic and jurisdictional ambiguities, forensic scientists face deep challenges in their work to identify the dead. However, these difficulties pale in comparison to those faced by families of missing migrants. They often live in a different country from where their loved one disappeared, do not speak the same language as forensic investigators, and face safety and security threats due to their status as migrants themselves or as residents of politically unstable countries. All of this is on top of the trauma that any family of a missing person endures. These sociopolitical issues impact the forensic process and should inform the ethical approach of forensic practitioners involved in any stage of the examination and identification process.

The context of extreme vulnerability for most international migrants means that special care must be taken to interact with families in a way that is ethical. There are three stages in the forensic investigation process, during which time special ethical considerations should be considered by forensic practitioners: (1) discovery and reporting, (2) examination and identification, and (3) release of remains. The following guidelines are based on extensive experience working closely with families of Latin American migrants who have disappeared in Mexico or the United States. These guidelines are also informed by the International Committee of the Red Cross (ICRC) Handbook, “Accompanying the Families of Missing Persons.”<sup>1</sup>

During discovery and reporting, forensic practitioners should understand that one of the primary challenges families face in searching for a missing loved one is reporting. Families of missing migrants are often unable to report to United States law enforcement due to local jurisdictional boundaries, fear, language, or a combination of these. Forensic practitioners have a variety of options to support the family reporting process, including working closely with foreign consulates and Non-Governmental Organizations (NGOs), supporting the family in reporting to law enforcement, or taking a forensically relevant missing person report one’s self.

In addition to following established ethical guidelines and laboratory Standard Operating Procedures (SOPs), forensic practitioners can be mindful of practices that can ethically protect the needs of families of missing migrants during the process of examination and identification. As so many migrants are discovered without identification media, or with false documents, the first ethical consideration is to treat remains as unidentified until a strong correlation is made with a missing person’s report submitted by a family. Family must be involved directly or through a third party such as consulate or NGO for an identification to be valid. Other ethical considerations have to do with the language used and imagery collected during examination. Dehumanizing language and hate crimes against Hispanics and Latinos are increasing nationally.<sup>2</sup> Forensic practitioners should consider the impact of the language they use, not only on the family but also on public discourse. Similarly, photographs should be evaluated for their potentially harmful impact on next of kin or public discourse before being shared with the press, on social media, or in public presentations.

Finally, special ethical considerations should be made during the release of remains as either identified or unidentified. In both cases, it is recommended that any personal effects or property are kept separate from the remains and accessible by next of kin. Also in both cases, cremation without consent from family should be avoided at all costs. In the case of identified remains, the notification process is one of the most ethically complicated areas of work, challenged by the fact that most families of missing migrants live very far from the forensic investigation facility. This presentation will include best practices for the ethical notification of families of missing migrants, including examples of translated identification reports that can be made available to next of kin.

### Ethics, Families, Migrants

### A89 Revisiting the Concepts of “Race” and “Ancestry” Regarding Missing Migrants in the United States

Justin R. Maiers, MS\*, University of South Florida, Tampa, FL 33647; Jonathan D. Bethard, PhD, University of South Florida, Tampa, FL 33620-8100; Chaunesey Clemmons, BA, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will understand the complicated history that anthropology has with the concepts of “race” and “ancestry” and how those knotty concepts continue to permeate the forensic identification process at the United States-Mexico border. Attendees will also better understand both the utility and dangers inherent in applying ancestral assessments specifically to missing migrant populations in the United States.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by generating a necessary discussion about the applicability of ancestral assessments to the forensic identification process and what it means regarding an individual’s identity. This presentation will contribute to the discourse by specifically investigating the utility of ancestry assessments on missing migrants.

The use of “ancestry” in the biological profile has its roots in the foundations of physical anthropology. These roots stem from the beliefs that there were true biological differences across various human populations and that certain groups of people were markedly different. The originators of these ideas believed that humans could be grouped into distinct “races,” or even that certain groups should be categorized as separate “species.” This vein of thought reduces individuals into racial typologies and does not adequately represent the true range of human variation. Contemporary anthropologists agree that “race is a social construct,” however this phrase belies the reality that the foundations of much of the current use of “ancestry” in the biological profile can be traced back to a problematic history. Modifying the terminology from “race” to “ancestry” is meaningless with the persistence of remaining underlying issues.

Currently, ancestral assessments utilize a range of different approaches including metric, non-metric, and macromorphoscopic methods. These techniques require an understanding of the range of biological variation and how it is expressed across populations, allowing anthropologists to rely on their experience to ascribe an ancestry estimation to an unidentified individual. In a forensic context, ancestry has historically been divided into discrete categories with varying terminology, such as “European American,” “African American,” etc. This type of categorization does not necessarily represent a decedent’s identity, particularly in instances in which an individual’s ancestry reflects a complex colonial history. Furthermore, there has been little, if any, reflection by forensic anthropologists based in the United States on how “ancestry” estimates are utilized in medicolegal investigations after the anthropological analysis has concluded. Research by scholars outside of anthropology have noted bias in media coverage related to missing persons cases and an unequal emphasis on resources allocated to certain classes of missing people. For example, “Missing White Woman Syndrome” has been described by scholars in criminology and empirical analyses of the Federal Bureau of Investigation (FBI) data have confirmed the reality of this phenomenon.<sup>1</sup>

By extension, the issues with ancestry and identity become magnified when dealing with migrant populations. Consider the example of migrants who perish along the United States-Mexico border and on-going efforts by forensic anthropologists working toward identification. An ancestry categorization as “Hispanic” or “admixed” does not help discern the actual geographic origins of an individual and does little to assist local medicolegal investigators. Treating such a diverse group as a monolith may dramatically reduce the efficacy of any ancestral assessments and has the potential to hinder the identification process. Furthermore, the marginalized and dehumanized status of migrant populations has also played a role in hindering the identification process.<sup>2</sup> Turning to research outside forensic anthropology, scholars in media studies have documented unequal treatment of Latina women who have been victimized by crime or who represent missing persons cases. Ultimately, forensic anthropologists working on migrant identification may need to acknowledge the structural barriers which characterize the medicolegal system in the United States and the reality that not all decedent deaths, and especially those of migrants, receive equal treatment at the conclusion of anthropological analyses.

### A90 Policy, Ethics, and the Use of DNA in Migrant Families

*Sara H. Katsanis, MS\*, Lurie Children's Hospital, Chicago, IL 60611; Diana J. Madden, MA, Chicago, IL 60611; Valedie Oray, Duke University, Durham, NC 27708; Jennifer K. Wagner, JD, PhD, Geisinger, Danville, PA 17822*

**Learning Overview:** After attending this presentation, attendees will understand the ethical implications of the policies informing the use of DNA to: (1) screen for human trafficking; (2) reunify migrant children separated from their families; and (3) verify claimed biological relationships in migration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees on the utility and limitations of DNA testing of families in the context of migration at the United States-Mexico border.

United States border security protocols are turning to DNA as a biometric for processing refugee claims and to screen for human trafficking. Most migrants fleeing their home countries travel without proof of identity, so genetic information is useful for establishing identity and verifying biological relationships. The United States has had the authority to collect DNA from immigrant detainees for the Combined DNA Index System (CODIS) since 2008, primarily to detect immigrants who commit crimes in the United States. Recently, the United States has expanded the uses of biological relationship testing to verify relationship claims in immigration. In 2018, the “zero-tolerance” policy to separate migrant children from the adults accompanying them led to subsequent offers of genetic testing for reunification and use of DNA testing for verifying biological relatives. These discussions sparked controversy in news and social media. Public debate continued into 2019, fueled by a rapid DNA program at the border to perform kinship analysis to verify migrant family claims.

As part of this research into how genomics is used in immigration contexts, this study evaluated how the use of DNA in a politically charged circumstance was covered by news and social media. Systematic searches of newspaper databases and Twitter® were conducted for coverage of DNA testing and migrants for the 2-month period of June and July 2018. For comparison, these search parameters were repeated in May 2019 to capture articles and tweets about the rapid DNA program. This study identified trends, including common topics and miscommunications, as well as significant gaps in discussion of DNA testing and topics covering the legal contexts and ethical implications of using DNA tests as a measure of family relationships. In both news articles and tweets, it was found that a politically conservative or pro-zero-tolerance policy slant strongly corresponded to a pro-DNA testing stance, while a liberal or anti-zero-tolerance policy slant corresponded diversely to pro-, anti-, and neutral stances on DNA testing.

Public discussion surrounding the use of DNA for documenting families demonstrates both the complexity of this application as well as key communication issues in the public sphere, including: (1) lack of transparency on the use of DNA tests (causing speculation); (2) ineffective inclusion of experts in public conversations (causing misinformation to spread); and (3) ill-preparedness of the scientific community to react to public confusion and outcry (causing scientific misunderstandings to go uncorrected). The expanded uses of genetic information beyond crime investigations could result in stigmatization of individuals or entire populations, if applied broadly. Moreover, the geneticization of families undermines the social constructs that underlie human relations and self-identity and could lead to discrimination of non-traditional families or revelations of unintentional family secrets that could endanger individuals.

#### DNA Testing, Immigration, Ethical Implications

### A91 Counting the Uncountable: Certification of Deaths in the Borderlands

Veena D. Singh, MD\*, Midwest Medical Examiner's Office, Ramsey, MN 55303

**Learning Overview:** After attending this presentation, attendees will better understand the Centers for Disease Control and Prevention (CDC) guidelines for certifying disaster-related deaths and how the application of these guidelines allows for a better accounting of deaths occurring during irregular migration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how increased interjurisdictional consistency in investigating and certifying deaths can better inform public health and public safety initiatives related to irregular migration.

During the process of death investigation, Medical Examiners/Coroners (ME/C) routinely collect and report information that may be used for public health surveillance. Death certificate data is used to develop public health and public safety initiatives and inform citizens about patterns and trends in population health. Death certificate data from mass fatality events is used to assess the scope of an event, understand mortality patterns, and evaluate short- and long-term public health impacts. Inconsistencies in certifying a death as disaster-related make it difficult to generate reliable and accurate mortality statistics and to identify the most frequent causes of death associated with disaster events.<sup>1</sup>

Worldwide, it is estimated that, from 2000 to 2019, more than 60,000 people have died during the process of irregular migration. An estimated 6,000 to 7,000 of these migrants have died in the United States as a result of crossing the United States -Mexico border, a death toll similar to Hurricanes Maria and Katrina combined.<sup>2</sup> While alarming, these numbers are minimum estimates only; due to the nature of irregular migration, many of these deaths occur in clandestine fashion and an unknown number of deaths are unreported or undiscovered each year. Moreover, these numbers are a tally only of deaths and disappearances during the process of crossing the physical border and do not reflect persons dying as a result of irregular migration but not in the act of crossing the border (for example, those dying in immigration detention facilities or in hospitals while in the custody of federal law enforcement).

Different government entities and non-governmental organizations may have different methods for counting migrant deaths. There is some evidence that federal data may vary widely from local- and state-level data, hampering policymakers and researchers. Even at the state or local level, ME/C inconsistencies in investigating, certifying, and tracking these deaths make it difficult to accurately count them in a given jurisdiction, much less place deaths occurring at a certain locality within the larger context of irregular migration. Because many of these deaths will fall within the statutory authority of medical examiners and coroners, ME/C data, if comprehensive, can provide the best information about migrant deaths in a given time or place. One way to improve data collection is to standardize the certification of these deaths.

The CDC has published guidelines for the certification of deaths directly and indirectly related to a disaster, whether that disaster is natural, human-induced, or chemical/radiological. This presentation will provide an overview of these guidelines and discuss how they may be adapted to the certification of deaths related to irregular migration. Although the true number of migrant deaths may be impossible to ascertain, better characterization of the known deaths can diminish the magnitude of underreporting of these deaths and allow for improved understanding of the scope of this public health crisis.

## A92 The Detection and Characterization of Human Decomposition Products by Infrared Spectroscopy

Afrin Lopa, MS\*, University of Akron, Chemistry Department, Akron, OH 44325; Liotta N. Dowdy, MA, University of South Florida, Tampa, FL 33620; David S. Perry, PhD, University of Akron, Chemistry Department, Akron, OH 44325; Timothy Matney, PhD, University of Akron, Akron, OH 44325; Linda R. Barrett, PhD, University of Akron, Geosciences, Akron, OH 44325; Erin H. Kimmerle, PhD, University of South Florida, Tampa, FL 33820

**Learning Overview:** After attending this presentation, attendees will understand: (1) how human decomposition products in soil can be detected in the lab with Mid-Infrared (MIR) spectroscopy and in the field with Near-Infrared (NIR) spectroscopy; and (2) how the stage of decomposition, indicative of the Postmortem Interval (PMI), can be estimated from the spectra.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing homicide investigators with a method of detection and characterization of human remains located either on the soil surface or within clandestine burials.

After death, the neutral fats of adipose tissue decompose to fatty acids, both saturated and unsaturated. Over time, the unsaturated fatty acids are converted first to saturated fatty acids and eventually to insoluble salts that are relatively immobile and long lasting. These fatty acids and their salts contain long carbon chains consisting primarily of methylene groups (-CH<sub>2</sub>-) that have characteristic features in the infrared spectrum, both in the MIR and NIR regions. Buried human remains decompose under largely anaerobic conditions, where the decomposition process is relatively slow. Human remains on the ground surface are in aerobic conditions, and therefore decomposition of cadavers on the surface proceeds more quickly.

This study acquired spectra of several different types of soil samples in order to determine how MIR and NIR spectra can be used to detect these fatty acids in the soil: (1) soil with added saturated and unsaturated fatty acids of known concentrations, (2) soil from a mock crime scene using a pig as a proxy for a human cadaver in Ohio, and (3) soil taken from the vicinity of four decomposing human cadavers, on the surface and in burials, at the Facility for Outdoor Research and Training (FORT) in the Institute of Forensic Anthropology and Applied Sciences at University of South Florida. The presence of human remains was successfully detected in the soil samples in both spectral regions, MIR and NIR. In addition, it was demonstrated that fatty acid concentrations varied depending upon the region of the cadaver (e.g., head, pelvis, torso, feet) and the depth and distance from a cadaver that a sample was taken. In the MIR, the spectroscopic signatures of saturated and unsaturated fatty acids are distinguishable, yielding information about the extent of the decomposition and hence about the PMI. Measurements on background soil samples indicate a very small fatty acid background (~3%), not attributable to the presence of a cadaver. This background signal has a characteristic spectral signature that can be distinguished from the burial remains. The characteristic fatty acid peaks in the NIR represent the overtones of the absorptions of the fundamental vibrations in the MIR, and thus are very much less intense. Nonetheless, these weaker NIR peaks have been observed for each cadaver for which MIR peaks were observed. The advantage of the NIR measurement is the possibility of *in situ* measurements in the field. Such field measurements employ a spectroscopic probe that is pushed into the soil and connected to spectrometers on the surface by fiber optics.<sup>1</sup> Thus, these spectroscopic methods can be used in the field for the detection and characterization of clandestine human burials.

### A93 Geographic Information Software (GIS) Application for Building a Nationally Representative Forensic Taphonomy Database

*Katherine E. Weisensee, PhD\**, Clemson University, Clemson, SC 29634; *Blake Lytle, MS*, Clemson University, Barr Hall, Clemson, SC 29634; *Patricia Carbajales, MS*, Clemson University, Geospatial Technology, Clemson, SC 29634; *Anne Shillinglaw, BS*, Clemson University, Clemson, SC 29634

**Learning Overview:** After attending this presentation, attendees will understand the implications of the lack of a robust dataset for examining and improving methods to determine the Postmortem Interval (PMI) in forensic investigations. Attendees will learn about a new application, geoFOR, which will be used to address this gap in the research.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a novel mechanism to collect data about decomposition using a crowdsourced data model. This presentation will introduce a new application, geoFOR, for creating a reference database of decomposition and environmental variables from which improved methods from determining PMI can be developed.

PMI determination is a critical piece of information to determine when human remains are discovered. An accurate determination of PMI can facilitate the identification of an unknown individual and help to reconstruct the events around the time of death. A major weakness with the current state of the research is the lack of a reference dataset with a large number of cases from which research questions regarding factors impacting the rate of decomposition can be addressed.

This presentation will be used to demonstrate an application that can be used by practitioners using crowdsourced data to collect information from scenes where human remains are found. This research utilizes a spatially coded, Geographic Information Systems (GIS) application that is accessible from mobile devices and tablets, among other devices. Forensic investigators working on a case use the app to record basic scoring information on the state of decomposition, upload photos of the state of decomposition, and the GIS software records the location of the discovery. The application will be available for use by investigators from across the country and internationally in order to develop a large reference sample that will be used to create improved models for determining PMI.

Much of the PMI research has focused on a few outdoor research facilities. These are geographically circumscribed areas that have a limited range of environment factors that characterize the variables known to impact the rate of decomposition. The other major source of data for PMI methods are retrospective case studies that are based on small sample sizes and are regionally specific. A review of recently published research articles demonstrates the dependence on small samples for modeling the complex decomposition process.

The decomposition process is influenced by a wide range of factors, both intrinsic to the individual and extrinsic environmental variables. The only way to develop accurate models of this complex system is to have sufficiently large sample sizes. In the absence of a large dataset, a scientific investigation of PMI is severely limited. The small sample sizes and dependence on case studies has limited research in PMI. Previous research has demonstrated that there are multiple factors that impact the rate of decomposition, and we cannot hope to develop a robust and multifaceted model in the absence of a representative and large dataset. In order for the field to move forward and to develop models that are reliable, useful, and with known error rates, a large dataset is necessary and currently missing from the field. The forensic community can work together to construct a reference set to build models of decomposition and improving methods for determining PMI when remains are discovered.

#### GIS, PMI, Database

## A94 Why Hasn't the United Kingdom Got a Human Taphonomy Facility (HTF) Yet?

Anna Williams, PhD\*, University of Huddersfield, Huddersfield, West Yorkshire HD1 3DH, UNITED KINGDOM; Chris Rogers, PhD, University of Wolverhampton, Wolverhampton WV1 1LY, UNITED KINGDOM; John P. Cassella, PhD, Staffordshire University, Stoke on Trent ST4 2DF, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will have gained an understanding of the issues surrounding the complex and controversial campaign to establish an HTF in the United Kingdom. Attendees will learn about the legal situation and the objections that have been raised from different communities and will hear the arguments for and against HTFs, particularly in the United Kingdom, from scientific, ethical, moral, and religious standpoints. Attendees will hear about positive and negative media publicity surrounding the venture and how this has affected public opinion of the venture.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by giving the current United Kingdom perspective on the HTFs that have been so readily established in other countries and by explaining why the United Kingdom has not followed suit yet. This has important implications for forensic science internationally, as the United Kingdom may draw on and learn from the experiences and expertise of the existing facilities in terms of informing forensic cases and engaging the public.

HTFs, or “Body Farms,” are outdoor laboratories where scientific research is conducted on donated human cadavers in order to understand how human decomposition progresses in a variety of conditions. There are currently eight such facilities in the United States, one in Canada, one in Australia, and a “Forensic Cemetery” in mainland Europe.

Currently, in the United Kingdom, empirical decomposition research is conducted using animal analogs (mainly *Sus scrofa*), and university-based Animal Taphonomy Facilities (ATFs). However, concerns have recently been raised about the use of animal remains as human analogs in forensic research.<sup>1-3</sup> There is recognition that HTFs offer the chance to study the effect of certain human conditions and lifestyle choices on decomposition rate and subsequent postmortem interval estimation; something that is not possible to do with animal analogs.<sup>4</sup> This, coupled with the ever-demanding requirements needed of the expert witness in court, including possessing relevant expertise and providing reliable evidence, means that the United Kingdom is falling behind the rest of the world. So, United Kingdom forensic scientists have started to ask the question “Why hasn't the United Kingdom got an HTF yet?”

The possibility of opening an experimental facility is a dramatic and controversial proposal for the United Kingdom, for a variety of reasons. There are objections on scientific grounds, mainly based on concerns about scientific rigor and reproducibility.<sup>5</sup> There is also ethical, moral, and religious opposition, as well as substantial legal obstacles.<sup>6,7</sup> In addition, there is public opinion and perception to consider. There has been a lot in the media recently about this possibility, and it has both garnered support and provoked objections from the public.<sup>8</sup>

This presentation will discuss the current challenges and impediments to the establishment of an HTF in the United Kingdom, the scientific, legal, ethical, and moral objections, and the cogent arguments for and against one in the United Kingdom. It will discuss the risks associated with the creation, delivery, and day-to-day running of a facility. It will show how the United Kingdom situation differs from other countries where HTFs exist, and explore what the United Kingdom can learn from their experiences.

This presentation will also discuss current public opinion in the United Kingdom, based on the results a recent online survey conducted to determine the extent of acceptability of the concept of a HTF among members of the public in the United Kingdom and abroad. This presentation will present an analysis of the respondents' ( $n=600$ ) views toward different aspects of HTF operation and determine the key areas of support and objection toward a HTF being proposed in the United Kingdom.

### Human Taphonomy Facility, United Kingdom, Public Opinion

### A95 Changes in the Cadaver Decomposition Island (CDI) and Soil Chemistry: An 18-Month Time Series for Scavenged and Protected Human Cadavers

*Jacqueline A. Aitkenhead-Peterson, PhD\**, 2474 Texas A&M University Department of Soil and Crop Sciences, College Station, TX 77843; *Haeli Kennedy, Sam Houston State University, Huntsville, TX 77341*; *Jasmine Garcia, Sealy, TX 77474*; *Joan A. Bytheway, PhD, Sam Houston State University, Huntsville, TX 77341*

**Learning Overview:** After attending this presentation, attendees will have a clear understanding of what a surface human CDI looks like with and without scavenging interference and soil chemical composition results obtained throughout the study. Attendees will understand that the CDI is present months after the remains are removed and the concentration of soil nutrients fluctuate during the decomposition process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by bringing awareness to those entities participating in search and rescue efforts to not only focus on looking for the skeletal remains of an individual, but to also look for the CDI and collect soil samples at appropriate depths.

Both the CDI and soil nutrient composition are useful pieces of evidence. Typically, during the late phase of the Early stage of human decomposition, fluids of the body, formed during autolysis, hydrolysis, and by other chemical and bacterial actions, leach into the soil under and around the body, producing a CDI. The fluid contains high concentrations of organic matter and microorganisms, eradicating any vegetation adjacent to and under the body. When the soil pH and nutrients in the upper soil horizons appear to return to a level similar to the original state, translocated nutrients in the soil cause native vegetation, and flora not indigenous to that area, to flourish. In August 2018, five cadavers were placed and the CDIs were monitored monthly for vegetation regrowth. Soil samples were taken to a depth of 40cm (in 10cm increments) after purge, then monthly thereafter for a period of 18 months. This study was conducted at the Applied Anatomical Research Center (AARC) in Huntsville, TX.

The study demonstrated that the CDI is greatest under the trunk, reduced under the head, and further reduced under the limbs. The study documents the timing of the formation of the CDI as well as the timing of the return of vegetation around and within the CDI. After collapse of body cavities and formation of the CDI, caged subjects were removed from their CDI at predetermined intervals of zero, two, and four weeks after purging. Cages remained over the CDIs and daily observation occurred until regrowth within the CDI formed. Most of the CDI for subjects accessible to scavenging had formed under the trunk of the body prior to being moved around by scavengers. However, the CDI of the limbs and head could not be clearly identified after movement of the body by scavenging had smeared the soil. Bodies were pulled away from the major part of the CDI by scavengers, but remained at the periphery throughout the study. The trunks of the bodies that had minimal movement by scavenging prolonged the CDI's soil nutrient composition and evidence of nutrient translocation to deeper depths was observed. In search and rescue efforts for missing individuals presumed dead, a CDI may be detectable a minimum of 12 months after death, even if the body has been displaced from its original location. CDI observation and soil chemistry results will be presented.

#### CDI, Soil Chemistry, Scavenged

## A96 The Importance of Taphonomic History When Conducting Histological and Isotopic Analyses on Bone

Rebecca Reid, MSc\*, Honolulu, HI 96818; Miranda Jans, PhD, SNA, Supporting Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Lesley A. Chesson, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Rebecca J. Wilson-Taylor, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Gregory E. Berg, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853-5530

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how taphonomic histories influence microscopic and isotopic composition of bone.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting how differences in taphonomic history can be observed histologically as well as impact the isotopic composition of bone.

The 1943 Battle of Tarawa resulted in more than 5,000 casualties on Betio Island. The requisite need to bury the casualties immediately after the battle and the post-war repatriation efforts in the late 1940s led to commingling and disassociation of remains. Through a variety of anthropological methods, the Defense POW/MIA Accounting Agency has re-associated recent field recoveries from Betio Island with individuals that were buried at the National Memorial Cemetery of the Pacific (NMCP) in 1949 as “Unknowns.” The Unknowns were disinterred from the NMCP between 2016 and 2017.<sup>1,2</sup> The Unknowns were treated with formaldehyde, while the skeletal elements that remained on Betio Island were not. The re-association of recent field recoveries with disinterred Unknowns allowed for a direct comparison of the same individual skeletal elements with vastly different taphonomic histories. The purpose of this study was two-fold: first, to determine if taphonomic history could be indicated through histology and, second, to determine if taphonomic history degrades isotopic analyses.<sup>3</sup>

A total of 18 skeletal elements, representing nine antimeres or fragment refits from five individuals, were compared histologically using normal and circular polarized light microscopy. Thin sections were prepared following standard histological protocols. The extent of diagenetic alteration of the bone microstructure was scored following the Oxford Histological Index (OHI); intensity of birefringence, extent of cracking, presence of discoloration, and the type of microbial alteration were also recorded.<sup>4</sup> Ten skeletal samples—two per individual, representing antimeres and fragment refits from field and NMCP contexts—were prepared for isotope testing as collagen and bioapatite at California State University, Chico. Collagen was submitted to the Stable Isotope Facility at the University of California, Davis for measurement of carbon and nitrogen isotope values ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ , respectively). Bioapatite was submitted to IsoForensics, Inc. for measurement of  $\delta^{13}\text{C}$  and oxygen ( $\delta^{18}\text{O}$ ) values.

The taphonomic history of the skeletal elements was reflected in characteristic alterations of the bone microstructure. Remains from Betio Island showed a greater extent of diagenetic alteration (bioerosion) in comparison to those treated with formaldehyde. Despite this, the amount (yield) of collagen extracted for isotope testing was consistently higher for elements from Betio Island as opposed to treated bone. Three of the five NMCP samples had collagen yields lower than the accepted 5% threshold, while one of five samples from the NMCP had a bioapatite yield lower than the accepted 25% threshold.<sup>5</sup> Considering all samples, regardless of material yield, mean pairwise differences in collagen  $\delta^{13}\text{C}$ , collagen  $\delta^{15}\text{N}$ , or bioapatite  $\delta^{13}\text{C}$  values were not significant when compared to a theoretical mean of 0. There was a significant difference for bioapatite  $\delta^{18}\text{O}$  values (one-sample *t*-test;  $p=0.0002$ ), with higher  $\delta^{18}\text{O}$  values measured for samples from Betio Island.

This research has implications for biomolecular forensic analyses of chemically altered remains (e.g., embalmed, prepared anatomical materials, etc.). Disinterred samples previously treated with formaldehyde demonstrated well-preserved bone microstructure due to the biocidal effects of the preservative, but overall lower collagen yields. Based on yield data, isotope testing results of 60% of prepared collagen samples could be considered potentially suspect. Conversely, samples from recent Betio Island recoveries demonstrated poor preservation of bone microstructure yet yielded reasonable amounts of both collagen and bioapatite (with one exception) for isotope testing. Disregarding material yields, collagen from disinterred bone was not isotopically distinct from collagen from recent Betio Island-recovered bone when considering either carbon or nitrogen isotopes values, while only  $\delta^{18}\text{O}$  values (and not  $\delta^{13}\text{C}$  values) of bioapatite differed between paired samples. The taphonomic history of a bone, like embalming or burial environment, influences the analytical results derived from that bone and thus should be considered during forensic analyses.

### Taphonomy, Histology, Isotopes

## A97 Prediction of Minimum Postmortem Submersion Interval (PMSI<sub>min</sub>) Based on Eukaryotic Community Succession on Skeletal Remains Recovered From an Aquatic Environment

Sala D. Randall, BS\*, Virginia Commonwealth University, Richmond, VA 23284; Claire M. Cartozzo, MS, Richmond, VA 23220; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will have acquired information on a new method designed to aid in the determination of PMSI<sub>min</sub>, specifically from waterlogged bones.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees how the results obtained from this research may be applied to determine time of death for remains found in cold cases, which may corroborate eyewitness testimony, as well as increase accuracy in the estimation of PMSI in combination with bacterial succession.

Many recent studies were conducted concerning bacterial succession in decomposing animal carrion in terrestrial systems.<sup>1,2</sup> However, not much is known about the microorganisms involved in aquatic decomposition.<sup>3</sup> Dickson et al. presented a study on marine bacterial succession to determine PMSI using partial pig remains; however, this study did not utilize next-generation sequencing technologies.<sup>3</sup> Per research, there are currently no published studies which estimate PMSI based on eukaryotic community succession in aquatic systems. The main goal of this study was to determine the eukaryotic community succession associated with porcine skeletal remains in lentic aquatic environment and to derive a statistical model for PMSI<sub>min</sub> prediction.

Henleys Lake in Crozet, VA, was the location chosen for this research. Fresh pig bones (rib  $N=100$ , scapula  $N=100$ ) were placed in cages (10x10 inch<sup>2</sup>), attached to a floatation device, and submerged using waterproof loggers (to record hourly temperature), and a Yellow Springs, OH Sonde™ (to monitor pH, specific conductivity, dissolved oxygen, salinity, and depth). Every 250 Accumulated Degree Days (ADD), one cage containing five rib and five scapula samples was collected, photographed, and stored at -80°C until processed. Water samples were also collected every 250 ADD and filtered using a cellulose membrane filtration system. DNA extraction was performed using the Invitrogen® ChargeSwitch® gDNA Plant Kit Protocol. Variable region nine (V9) of the 18S rRNA gene was amplified and sequenced using the primers as described by Earth Microbiome Project, including a mammalian blocking primer, and was based on dual-index strategy as described in Kozich et al on MiSeq® FGX sequencing platform.<sup>4</sup> Sequenced data were quality controlled and analyzed via the MiSeq® SOP in Mothur version 1.36.<sup>4</sup> Hierarchical classification of good quality sequences was performed based on SILVA119 database. A phylogenetic approach was utilized for  $\alpha$ - and  $\beta$ -diversity estimation. Analysis of Molecular Variance (AMOVA) was used to test statistical differences in eukaryotic colonization of bone types over ADD.

Preliminary results at the Phylum level (level 2) showed that eukaryotic community associated with rib and scapula samples were similar, characterized by the combined presence of Ciliophora, Ochrophyta, and Peronosporomycetes. Scapula samples showed a difference due to the added presence of Euglenozoa (2.1%). The eukaryotic community changed significantly with ADD in both bone types ( $p < 0.0002$ ). Samples collected at 250 ADD were characterized by the presence of Peronosporomycetes (74.3%) and Dinoflagellata (1.9%, found highest at this time point). The 500 ADD collection was characterized by the presence of Peronosporomycetes (90.4%). Peronosporomycetes abundance declined from 750 ADD through 3,250 ADD, after which an increase was observed (e.g., 51.3% at 4,250 ADD). Collections spanning the 1,000 ADD to 3,250 ADD interval were characterized by Ciliophora (>20%), and the final collection (4,750 ADD) was categorized by the combined presence of Ciliophora (14.7%), Euglenozoa (3.9%), and Peronosporomycetes (6.8%).

In conclusion, this study highlights the eukaryotic community associated with bones in lentic systems and, in the future, this information may be utilized for the development of statistical models for prediction of PMSI<sub>min</sub> either alone or in combination with bacterial community succession.

### A98 Quantifying Missing Migrant Antemortem Data and Their Identification Significance

*Mercedes Doretti, MA\**, Argentine Forensic Anthropology Team, Brooklyn, NY 11233; *Carmen E. Osorno Solís, Brooklyn, NY 11201*; *Karla Hernandez Mares, MA, Argentine Forensic Anthropology Team, Brooklyn, NY 11233*; *Laura Eliz Alexa Sevilla Maldonado, Argentine Forensic Anthropology Team, Brooklyn, NY 11233*; *Rachel Daniell, MPhil, Argentine Forensic Anthropology Team, Brooklyn, NY 11233*

**Learning Overview:** After attending this presentation, attendees will better understand the complexities of identifying remains of missing migrants from poor, primarily rural, underserved communities in the Central America-Mexico-United States migrant corridor, as well as be better informed regarding the probability of obtaining significant antemortem data for achieving identifications in these cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing quantified analysis of antemortem data on missing migrants from the Central America-Mexico-United States migrant corridor that can aid practitioners in the design of effective antemortem data collection tools, help them better understand the value of an antemortem feature coincidence, and inform their assessment of the prevalence of different methods as part of a multidisciplinary identification.

This research project works to further define and illuminate the value of antemortem data in the multidisciplinary forensic investigation process through a case data-based analysis. The research introduced in this presentation seeks to further delineate types of antemortem data useful in forensic investigations into missing migrant cases in the Central America-Mexico-US migration corridor, examining what can be considered significant antemortem data in this regional context by evaluating which types of antemortem data have been forensically significant in supporting identifications for a multi-year, transnational project, the Border Project (Proyecto Frontera).

The Border Project is an initiative that aims to create a transnational mechanism for exchanging forensic information on missing persons and unidentified remains to significantly improve both the identification of missing migrants among unidentified remains in the region and the response of governments to families searching for missing migrant relatives. In this presentation, an analysis of the aggregated dataset from these cases will be presented, encompassing investigations launched since 2010 into missing migrant cases dating from 2000 through to the present. This dataset includes more than 1,300 cases of missing migrants coming from multiple countries of origin in Central America, as well as Mexico, who have gone missing in Mexico and the United States.

When working with cases of human rights violations and missing migrants in Latin America, antemortem data can tend to be limited in terms of formal, recorded documentation, such as medical records, dental records, and fingerprints, due to multiple socioeconomic factors. The vast majority of these cases do not have official medical or dental records, as missing individuals are more likely to have received such care in highly localized circumstances in which no records may be available or are not retained. Thus, antemortem data in the majority of these cases are based on the memories of relatives of the missing person. Nonetheless, such antemortem data have been shown to be highly useful in Border Project missing migrant cases, both in the investigation process and as a tool for exclusions of inconclusive initial genetic matches. This presentation will introduce the context and challenges of reaching identifications in this corridor and will describe each of the antemortem features evaluated in the quantitative analysis. The conclusions provided in this presentation will highlight the antemortem data types that have proven to be most significant in the investigations to date and discuss the evaluation of their level of significance. This presentation will also present differences in antemortem data significance between different countries of missing person case origin in Central America and Mexico, which also may change over time, due to factors such as the local availability of specific dental restorations or the prevalence of tattoos.

A multidisciplinary, integrated approach to the identification of remains is always important, as each context in which a person goes missing—each country, time period, incident, etc.—can affect which elements are more available or more important to prioritize in an investigation. In different circumstances, different factors in reaching an identification may take a lead role in the investigation, including genetics, fingerprints, and antemortem data. Quantifying antemortem data and their forensic significance in reaching identifications for a specific regional context helps to define the leading data factors that can aid in the identification process, thereby allowing more time and resources to be dedicated to those areas of data collection. Moreover, better understandings of the antemortem data that hold the greatest significance in missing migrants case investigations can help to define effective public policy and support establishing protocols and tools that focus on collection of the most impactful information for investigators.

#### Antemortem, Quantification, Missing Migrants

### A99 DNA Identifications of Migrant Remains at the Pima County, AZ, Office of the Medical Examiner (2000–2019)

*Caitlin C.M. Vogelsberg, PhD\**, Pima County Office of the Medical Examiner, Tucson, AZ 85714; *Robin C. Reineke, PhD*, Southwest Center, University of Arizona, Tucson, AZ 85721; *Mirza M. Monterroso, MA*, Tucson, AZ 85705; *Jennifer M. Vollner, PhD*, Pima County Office of the Medical Examiner, Tucson, AZ 85714; *Bruce E. Anderson, PhD*, Pima County Office of the Medical Examiner, Tucson, AZ 85714

**Learning Overview:** After attending this presentation, attendees will understand the methods used by one border medicolegal office to achieve more than 400 genetic identifications for Undocumented Border Crossers (UBCs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a successful model for the facilitation of genetic identifications of missing migrants that is achieved through the rigorous maintenance of data and close inter-agency collaborations.

The Pima County Office of the Medical Examiner (PCOME) implements several methods to aid in the positive identification of the more than 100 unidentified UBCs reported to the Office every year. These methods include fingerprints, visual identifications, and DNA comparisons, among several others. The PCOME has a steady identification rate of approximately 65% of cases, with a trend toward DNA identifications becoming more prevalent over the past eight years. More than 400 individuals have been scientifically identified using DNA analyses since 2000, despite funding issues that resulted in a multi-year backlog of a large proportion of unidentified cases. A 2018 National Institute of Justice (NIJ) Coverdell Award has resulted in the necessary funding to resolve this backlog, with additional identifications expected in the fall of 2019.

Given the circumstances surrounding the majority of unidentified individuals examined at the PCOME, primarily their undocumented and foreign national status, a multitude of resources have been used to aid in their identification. Best efforts are made by the PCOME with local and national law enforcement to establish identifications in the most rapid and cost-effective manner possible, but in many cases DNA analysis becomes the only available option. Behind fingerprints, genetic comparisons are the second-most-frequent method of scientific positive identification used at the PCOME and have accounted for roughly 21% of identifications. As of mid-2019, more than 1,200 samples have been analyzed by Bode Technology™, and an additional 176 are in the beginning stages of analysis; other laboratories, including domestic and international partners, have processed more than 300 PCOME cases. To date, 401 individuals have been scientifically identified using DNA profiles developed by at least four domestic laboratories and through the Mexican Federal Police. The majority of genetic identifications for UBCs (354/401) were established through DNA comparisons at Bode Technology™, while government labs have accounted for slightly more than 10%.

Whether the genetic comparisons take place at a private lab or government lab, the PCOME depends on close partnerships with local law enforcement, Non-Governmental Organizations (NGOs), and foreign consulates to support the collection of missing person information and Family Reference Samples (FRS). Among consulates, the PCOME works most regularly with the Tucson, AZ, office of the Mexican Consulate, which has supported the identification of 325 of the 401 cases, either through funding DNA collection and comparison, providing antemortem data, or completing information needed for case closure and death certificate completion, or all of the above. Similarly, the Guatemalan Consulate has supported 46 such cases, the Honduran Consulate 16, and the Consulate of El Salvador with 10 cases.

In addition to the support from foreign consulates, the PCOME depends on close collaboration with two key NGOs, the Colibrí Center for Human Rights, and the Argentine Forensic Anthropology Team (EAAF). Both NGOs provide families of missing migrants with a safe and secure mechanism to report missing loved ones and to submit DNA for the purposes of comparison against unidentified remains examined at the PCOME. As of the summer of 2019, the Colibrí Center for Human Rights has facilitated 48 genetic identifications and the Argentine Forensic Anthropology Team with 50 in collaboration with the PCOME. All such identifications include multi-agency partnerships, with consulates providing the necessary governmental link to ensure families are able to repatriate remains to their home countries. Some successful identifications included both Colibrí and EAAF, with one NGO collecting family reference samples in a United States state, and the other within the family's country of origin.

The prolonged duration and wide geographic scope of the international crisis that has resulted in the PCOME undertaking the identification of close to 2,000 UBCs has necessitated flexibility and creativity. In this context, the power of the science and technology of DNA can only be realized through international collaboration and public-private partnerships.

#### Undocumented Border Crossers, DNA Identification, Border Issues

### A100 Investigating Unidentified Migrant Remains Across Texas Jurisdictions: An Analysis of Positive Identifications by Operation Identification at Texas State University

Molly A. Kaplan, BA\*, Texas State University, San Marcos, TX; Molly Miranker, MA, Texas State University at San Marcos, San Marcos, TX 78666; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666; Courtney C. Siegert, MA, Texas State University, San Marcos, TX 78666; Chloe P. McDanel, MA, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the positive identifications of unidentified migrants made by Operation Identification (OpID) at Texas State University, the time it takes to make such identifications, and need for centralized investigative efforts in Texas.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing awareness of OpID's investigative activity as well as promoting best practices and strategies for improving identification outcomes of unidentified remains across Texas jurisdictions.

In 2012, Texas surpassed Arizona as the state with the highest rates of migrant death. According to United States Customs and Border Patrol statistics, a total of 1,566 migrant deaths occurred in Texas from 2012 to 2018, though more than 4,000 migrant individuals have died in the state since 1998. Whereas Arizona has the centralized agencies of the Pima County Office of the Medical Examiner (PCOME) and the Maricopa County Office of the Medical Examiner (MCOME) to investigate the deaths of most unidentified migrants recovered from the state's public land, investigations in Texas are county dependent, with most cases being handled by justices of the peace. Because only 14 of the 254 counties in Texas have medical examiner's offices, forensic experts are often not involved in the investigation of unidentified migrant deaths, despite statewide legislation that all unidentified remains undergo inquests and DNA sampling. The need for increased forensic resources and streamlined investigative systems in Texas is urgent.

OpID, founded in 2013, seeks to recover the remains of unidentified migrants found along or near the United States-Mexico border in order to facilitate positive identification and repatriation. To date, OpID has 287 active unidentified remains that have been recovered from ongoing cemetery exhumation efforts or transferred from other medicolegal agencies or law enforcement authorities. Since 2013, OpID has made a total of 35 positive identifications. Despite the much-needed answers that these identifications have given families, the identification process for undocumented migrants still remains challenging, in large part due to the fragmented nature of death investigation in the region. In addition to the difficulty of recovering well-preserved remains from vast expanses of private land, the burial of unidentified migrant remains without proper sampling or documentation greatly hinders their ability to be identified when they are exhumed.

The goal of the current presentation is to examine all of the positive identifications made by OpID in order to shed light on the timing, obstacles, and potential solutions inherent to investigating unidentified migrant death in South Texas. All positive identifications made to date by OpID were analyzed in relation to case demographics, recovery location, and the identification process undertaken, including the timing from recovery to positive identification, the means by which cases were solved (i.e., DNA or fingerprints), and the degree of non-OpID forensic practitioner involvement. For all OpID-positive identifications, the average time from recovery to identification was just over three years (3.3 years), with cases ranging from two months to nearly seven years. OpID cases that had been recovered from exhumation efforts took on average two years longer than cases that had been transferred to OpID from medical examiner or local authorities' offices, though the timing for these transfer cases was also slow (an average of 3.9 years and 1.9 years, respectively). Case studies will be presented to further discuss the timelines of these investigations.

Solving unidentified migrant cases in Texas requires the centralization of postmortem data and extensive coordination between many agencies. While the average time to identify remains is just over three years, there are still more than 200 individuals that have yet to be identified. Data sharing and case coordination between local authorities, forensic institutions, and international stakeholders could aid in the investigation of these cases and shorten the timeline. However, this degree of cooperation needed also requires policies, funding, and educational outreach to ensure compliance with state law. While exhumations of the long-term dead will still be necessary to make positive identifications, future cases should not be interred without proper analyses, sampling, and documentation from forensic practitioners.

### A101 The Application of Geographic Information Systems (GIS) to the Migrant Crisis in South Texas: Modeling Migration in Brooks County, Texas

Courtney C. Siegert, MA\*, Texas State University, San Marcos, TX 78666; Sophia Mavroudas, MA, Texas State University, San Marcos, TX 78666; Devora S. Gleiber, MA, Texas State University, San Marcos, TX 78666; Nicholas P. Herrmann, PhD, Texas State University, San Marcos, TX 78666; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will understand the benefit of applying GIS to evaluate the movement of migrants through the South Texas landscape.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing on search strategies for missing migrants, which will increase recovery rates and aid in optimizing the placement of water stations throughout the landscape.

Current immigration policy and border enforcement strategies have contributed to an ongoing humanitarian crisis at the United States-Mexico border, as people continue to migrate north fleeing poverty and violence. As migration from Central America surged, Texas surpassed Arizona in migrant deaths, resulting in thousands of deaths and unidentified human remains recovered across the South Texas landscape.<sup>1</sup> Much of the current recovery and identification efforts in Texas have centered around Brooks County, where more than 600 presumed migrants have been recovered from 2009 to the present. However, missing persons records largely outnumber unidentified recoveries, indicating that many of the missing have not been found. This mismatch is likely because approximately 96% of Texas is private land, preventing any large-scale searches for migrant remains.<sup>1</sup> Thus, many deceased migrants are found through happenstance. The present research attempts to model migrant movement across Brooks County to better understand where deceased migrants may be found. By incorporating known migrant death locations into the model, this project seeks to improve current search efforts, recovery rates, and the placement of water stations.

Two migration models (Model A and Model B) for Brooks County were generated using ArcGIS® v10.6.1.<sup>2</sup> Cost surface variables include slope, jaggedness, and land use data from the United States Geological Survey (USGS).<sup>3,4</sup> Model A incorporates a cost surface where developed open space is designated as low cost, and all other land use codes are designated as high cost. This surface intends to route migrants through the county by only utilizing open areas, including rural roads and open grassland, and avoiding any moderate to dense vegetation or development. Model A serves as a proxy for easiest movement across the landscape. Model B incorporates a more complex cost surface where cost values are assigned to land use codes based on a theorized compromise between ease of movement and avoidance of detection. Although developed open space is still considered less costly in Model B, shrub/scrub land codes are assigned moderate cost values as it makes moving through the landscape more difficult, while providing camouflage to prevent detection during migration. Two hundred fifty Least Cost Paths (LCPs) were generated from 10 origin points along the southern border of Brooks County to 25 destination points placed along a known pickup road (HWY 285) in the north of the county. Four hundred thirty-seven death locations, obtained from Brooks County Sheriff's Office recovery reports, were then compared to the LCPs from each model.

Near distance analysis of death locations to LCPs suggest Model B more closely approximates how migrants are moving through the landscape in Brooks County when compared to Model A, as indicated by a shorter near distance mean and standard deviation. However, Model A and Model B produce significantly farther distances between death locations and LCPs than when death locations are measured directly to any developed open space code from the original USGS data for the county.

These results suggest that migrant movement across the South Texas landscape is complex, particularly as migrants become dehydrated and disoriented, and that recorded death locations are skewed toward frequently traversed access routes. Continuing research will incorporate hotspot analysis and water station placement to better understand how migrants are interacting with the surrounding landscape. The results of this research can be used by search and recovery teams to develop feasible and efficient strategies that target areas in Brooks County where deaths are more likely to occur. Furthermore, the models that best approximate how migrants are moving through the landscape can be applied to surrounding border counties in an effort to locate and recover more migrant remains.

#### Global Information Systems (GIS), Migrants, Least Cost Path Analysis

## A102 NamUs Location Data: Cluster Analysis of Migrant Deaths at the Texas-Mexico Border From 1990 to 2017

Molly Miranker, MA\*, Texas State University at San Marcos, San Marcos, TX 78666; Alberto Giordano, PhD, Texas State University, Department of Geography, San Marcos, TX 78666

**Learning Overview:** The goal of this presentation is to identify significant spatiotemporal clustering of migrant deaths along the Texas-Mexico border with SaTScan™ software, direct search and recovery efforts based on those clusters, and assess how informative the location data reported on the National Missing and Unidentified Persons System (NamUs) is.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an example of the application of SaTScan™ and ArcGIS® software utilizing Space-Time Scan Statistics (STSS) to detect migrant mortality clusters and assess the accuracy of publicly available locational data from NamUs.

Migrant deaths in Texas drastically increased in 2012, eclipsing the other United States-Mexico border states, and remain high to this day.<sup>1</sup> Local law enforcement, medical examiner's offices and contract pathologists, academic and humanitarian institutions, and United States Customs and Border Patrol (USCBP) face unique challenges in locating and recovering these remains. Specifically, a majority of land in Texas is privately owned (over 95%) and therefore not regularly patrolled by local law enforcement without permission by landowners.<sup>1</sup> Further, there is not systematic collaboration in search and recovery practices because jurisdiction is divided along county lines, of which there are 254 in Texas.<sup>1</sup>

Implementing spatiotemporal analyses of migrant death recovery sites could overcome the challenges to search and recovery efforts ongoing in Texas. STSS can direct efforts by indicating geographic and/or seasonal patterns in death clusters. The goal of this research is to detect significant spatiotemporal clustering of unidentified deceased migrants found along the Texas-Mexico border between 1990 and 2017.

**Methods:** A research area of 31 Texas counties was defined, in which the county was along the border or contained a USCBP check point, constituting ostensibly a second border.<sup>1</sup> NamUs case report data dating from 1990 to 2017 were obtained from these counties where the case notes indicated the unidentified decedent was a probable migrant (i.e., physical description, anthropological analysis, or recovery context).<sup>2</sup> These parameters yielded a total of 659 cases.

Locational data was derived from three different fields within the Circumstances section of each of the reports: (1) auto-generated coordinates through a Google® Maps link, (2) Global Positioning System (GPS) coordinates directly entered by a case manager, or (3) county centroid coordinates based on the location remains were found. All GPS coordinates were converted into decimal degrees for consistency. ArcGIS® 10.6.1 was used to calculate the centroid coordinates.<sup>2</sup> A file was prepared with ArcGIS® 10.6.1 containing case, date found, and location data for analysis in SaTScan™ v.9.6.<sup>2,3</sup>

SaTScan™ performs STSS with a 3D circular window, the base of the window representing the geographic space and the height corresponding to time.<sup>3</sup> SaTScan™ identifies significant spatiotemporal clusters in the Texas border region if, for a specific time period, that area has a higher proportion of migrant cases compared to the remaining geographical areas.<sup>3</sup> The spatial window size was set to not exceed 10% of the study area to ensure smaller cluster phenomena could be detected as well as indicate temporal trends, such as clustering in particular seasons.

**Results/Conclusions:** Significant spatiotemporal clusters were found with Google® Maps and county centroid coordinates, specifically centering near West Texas around El Paso County, Southwest Texas around Maverick county, and South Texas around Brooks county. However, identifying meaningful clusters was contingent on the accuracy of location data available through NamUs. The location data was of mixed scale and therefore cases were not necessarily comparable when trying to identify areas with high mortality incidences. None of the significant clusters' dates corresponded to a season or was narrow enough to be associated with USCBP border securitization activity. No significant clustering was detected using case manager's GPS coordinates, which was likely due to relatively few data being available ( $n=75$ ). The clusters are more likely indicative of documentation behavior by local law enforcement, USCBP, medical examiners, or contract forensic pathologists in the region.

### **A103 Operational and Leadership Assessment During the Puerto Rico Forensic Science Project: How the American Society of Crime Laboratory Directors (ASCLD) Lab Directors, National Association of Attorneys General (NAAG) and Forensic Scientists Assisted the Puerto Rico Laboratory After Hurricane Maria**

*Matthew J. Gamette, MS\*, Idaho State Police Forensic Services, Meridian, ID 83642; Amie Ely, JD\*, National Association of Attorneys General, Washington, DC 20036*

**Learning Overview:** After attending this presentation, attendees will understand the operational and logistical challenges a forensic laboratory may face after a massive natural disaster or significant economic catastrophe. Attendees will be asked to consider the “cracks” or risks in their own laboratories that may be exposed with a significant stressor such as a natural disaster or financial crisis. Attendees will take away some considerations when engaging in benevolent volunteerism as an individual or organization. Attendees will learn about the struggles of an amazing group of colleagues in Puerto Rico and an inspiring group of volunteers from the continental United States that have activated to make a difficult situation better for their colleagues.

**Impact on the Forensic Science Community:** “Labs Helping Labs” is an initiative that needs to continue to grow. Forensics is a unique community where culturally colleagues want to help each other. It is a unique community because forensic science volunteers have a special skills set that must come from the trained experts in the forensic science community. As the number of natural disasters and the amount of political instability increases in the world, forensic scientists must be prepared to immediately deploy the necessary help to bolster the criminal justice services to impacted communities. Critical lessons learned from this project can provide a head start in emergency preparedness and volunteerism efforts all over the world.

In April 2018, ASCLD was asked by the National Association of Attorneys General (NAAG) to provide an operational needs assessment of the forensic science laboratory. The initial needs assessment included an evaluation of facility damage due to Hurricane Maria, instrument damage and other factors inhibiting forensic work, and backlogs existing before and after Hurricane Maria. After discussing the forensic science laboratory critical needs, meetings were held with federal government entities, Puerto Rican government officials, forensic laboratories around the country, and many forensic science instrument and service vendors to coordinate a response. The ASCLD President and the ASCLD Board determined resources the organization could provide and continued to partner with NAAG to determine the best method to provide resources to the Puerto Rico forensic science laboratory.

On-site fact-finding visits were conducted in April and October 2018 by the ASCLD President and the NAAG Director of Center for Ethics and Public Integrity. These visits consisted of visiting with the top leadership of the laboratory, leaders of each laboratory forensic science discipline, grant managers, facility managers, evidence technicians, financial and human resources managers, customers, and stakeholders to understand the scope of issues faced by the laboratory. Immediately evident were problems with the physical facility (e.g., sustainable power, air conditioning, security), broken instrumentation, a lack of personnel, a lack of training resources, and appropriate leadership. The laboratory was in financial crisis due to federal bankruptcy imposed upon the island and also the restructuring of the Puerto Rican government.

ASCLD and NAAG established top priorities, developed a Memorandum Of Understanding (MOU) with the Puerto Rican government, and identified resources to address the most urgent issues. In May 2018, ASCLD provided scholarships for three top Puerto Rico Forensic Science Bureau (FSB) leaders to attend the ASCLD annual symposium in Atlanta, GA. In January 2019, the majority of the ASCLD Board, along with other ASCLD members, traveled to Puerto Rico to provide assistance. ASCLD taught the renowned ASCLD Leadership Academy training at the lab, and approximately 30 FSB leaders graduated. ASCLD brought experts from every forensic science discipline, quality assurance professionals, and laboratory leaders from across the country to directly engage with each technical discipline. Experts were provided a specific mission for approximately the next week to research the issues facing each discipline. Additionally, ASCLD experts were asked to perform a root cause analysis of the existing issues. ASCLD experts provided recommendations for instrument, method, personnel, and process improvement in each discipline. ASCLD appointed a project leader for addressing each forensic science discipline, quality assurance, development of a new Laboratory Information Management System (LIMS), federal grant management, financial management and purchasing, and physical facilities.

ASCLD has continued to work with FSB leaders to make necessary operational improvements at the laboratory. ASCLD experts have continued to provide direct assistance to the laboratory in countless ways. Meetings have continued in-person and via teleconferences to provide expert advice, technical assistance, and information exchange. ASCLD has facilitated donations of instrumentation and equipment, coordinated casework and technical review assistance, provided analyst training, and assisted in identifying potential volunteer and affordable vendors that could provide necessary services. ASCLD will continue to provide essential assistance for the near future as part of a new initiative titled “Labs Helping Labs.”

This presentation—which we propose will be accompanied by sister presentations by our partners at the Forensics Sciences Board (FSB), NAAG, the American Board of Forensic Anthropology, and the American Society for Clinical Pathology—will address, among other things: (1) ASCLD involvement in the Puerto Rico FSB project; (2) operational challenges the laboratory had in recovering from a natural disaster and significant government bankruptcy; (3) challenges a volunteer initiative has in working with the federal government, state or territory government, and potential vendors. Lessons learned for labs helping labs in future emergencies; and (4) lessons learned through this massive humanitarian volunteer effort, including the importance of a robust MOU, establishing connections with government entities and politicians, effective coordination of benevolent donors and avoiding potential political conflicts, addressing funding challenges to support on-site volunteerism, establishing legitimacy with disaster recovery experts and organizations, bolstering leadership and management structure amid political and financial instability, developing trust with laboratory leaders and staff in challenging circumstances, and the considerations of benevolent volunteerism versus paid contract help.

#### **Puerto Rico, Volunteer, Hurricane Recovery**

## A104 Puerto Rico Forensic Science Project: The Puerto Rico Forensic Services Perspective

*Matthew J. Gamette, MS\*, Idaho State Police Forensic Services, Meridian, ID 83642*

**Learning Overview:** After attending this presentation, attendees will understand the operational and logistical challenges a forensic laboratory may face after a massive natural disaster or significant economic catastrophe and key aspects in order to overcome the situation. Attendees will be asked to consider how they might provide assistance in Puerto Rico or other places that might need forensic science assistance. Attendees will be asked to consider disaster planning or recovery models that consider forensic science operations. Attendees will take away thoughts regarding how to accept help effectively in an emergency situation and will learn how critical forensic science operations are to a state or territory criminal justice process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how the critical lessons learned from this project can provide a head start in emergency preparedness and volunteerism efforts all over the world. Practitioners will learn what happens in worst-case scenario situations, and where they may be able to reach out for help. Forensic science leaders who are being asked to focus more on risk mitigation as part of the International Organization for Standardization (ISO) 17025:2017 will learn risk factors they may not be considering in their continuation of operations plans. Right now, the forensic science community is loosely organized for emergency situation response, and planners should consider the increase in natural disasters that impact forensic science service providers each year.

Puerto Rico's Negociado de Ciencias Forenses (in English, Forensic Science Bureau, or "FSB") and Puerto Rico Department of Public Safety (PR DPS) signed a Memorandum Of Understanding (MOU) with the American Society of Crime Laboratory Directors (ASCLD) and National Association of Attorneys General (NAAG) to receive professional volunteer help in recovering from Hurricane Maria. The Puerto Rico FSB has benefited in many ways from the generosity of many volunteer professional forensic scientists, laboratory directors, forensic pathologists, autopsy technicians, attorneys, and other experts from around the continental United States.

**Background of the Puerto Rico Forensic Science Project:** The FSB has experienced severe hardships in the past several years. While most are aware of a series of devastating hurricanes that hit the island, many are not aware of the government financial issues that have led to federally overseen bankruptcy of the island and Puerto Rico government restructuring. The hurricanes did millions of dollars in damage to the FSB facility, eliminated sustainable power and air conditioning to the building, and damaged a majority of the instrumentation and equipment. The Medical Examiner Office (MEO) was overwhelmed with work due to victims from and related to the hurricane, deaths from a high crime rate, and restrictive autopsy laws and policies. In addition, many of the FSB employees left the island in the wake of the hurricanes to take higher paying jobs in laboratories on the continental United States. Due to government restructuring from the bankruptcy, almost overnight FSB went from being an independently operating forensic science laboratory and MEO to being part of the newly established Department of Public Safety. FSB went through several interim Commissioners in rapid succession due to political unrest and an extreme workload. Backlogs that already existed before the hurricane increased, and new operational issues emerged that prevented the lab and MEO from meeting the needs of the criminal justice system on the island. Cases were not being worked, reports were not available for court proceedings, and grieving families could not get access to their deceased loved ones for burial. Political officials from the Puerto Rico Department of Justice, Department of Public Safety, and Governor's Office were looking for solutions to the issues at FSB.

Assistance came initially from ASCLD and NAAG volunteers, and they were able to engage volunteers from several other large forensic science organizations. While initially the FSB staff were a bit skeptical of the staying power of these volunteers, they quickly learned of the determination and resolve they brought to help the situation. They were initially able to assess operational, instrumental, and staffing needs and begin to identify and bring resources to help. They were able to gain the confidence of government officials to help FSB make assurances to those entities, the media, and accrediting bodies that the situation would improve. Efforts were made to identify and train leaders at FSB, and a new permanent Commissioner was identified and confirmed by legislative leadership. While efforts are ongoing to address physical facility, information technology, security, technical, staffing, and other operational issues, the volunteer help of colleagues from all over the United States has been extremely valuable and provides hope to the people of Puerto Rico.

This presentation—which we propose will be accompanied by sister presentations by our partners at ASCLD, NAAG, the American Board of Forensic Anthropology, and the American Society for Clinical Pathology—will address, among other things: (1) forensic science challenges in Puerto Rico before and after Hurricane Maria; (2) leadership and operational challenges the laboratory had in recovering from a natural disaster, government bankruptcy, and government restructuring; (3) challenges and benefits in accepting help from and coordinating with a volunteer initiative; and (4) lessons learned by FSB through this project, including navigating cultural and language barriers, learning to trust entities offering help and setting effective boundaries, managing and coordinating multiple organizations offering various assistance, navigating federal and state government rules and restrictions in an emergency situation, managing political, stakeholder, and public expectations without the resources, working with disaster recovery experts and organizations, and developing a leadership team and management structure amid political and financial instability.

---

### A105 Infrastructure, Organization, and Challenges of the Puerto Rico Medical Examiner System

*Danny A. Milner, Jr., MD, MSc\*, American Society for Clinical Pathology, Chicago, IL 60605*

---

**Learning Overview:** The goals of this presentation are: (1) to describe the current structure and organization of the Puerto Rico Medical Examiner System, (2) to identify challenges in the system and their sources, and (3) to understand the impact of the suggested and implemented solutions for challenges encountered.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how all health systems can be impacted by natural disasters. In the case of Hurricane Maria in Puerto Rico, unmasked ongoing challenges in the medical examiner system that provide an excellent learning opportunity for other health systems are at risk for natural disaster.

The American Society of Clinical Pathology (ASCP), with several supporting and organizing groups, traveled to Puerto Rico on a humanitarian aid mission specifically focused on the challenges of forensic pathology in Puerto Rico. Although Hurricane Maria's path of destruction across Puerto Rico in 2017 caused major headlines for the Puerto Rico Medical Examiner System, the underlying challenges faced by the pathologists and laboratory professionals in Puerto Rico were simply unmasked and not caused by this event. The immediate deaths (direct) caused as a direct result of the hurricane required examination by the Medical Examiners (MEs) and spiked their caseload temporarily. Due to ongoing challenges across the island, additional deaths (indirect) as a result of the hurricane created controversy and challenges as attempts to measure the overall death toll became both subjectively and objectively difficult.

As is seen in many laboratories around the world and in mainland United States, staffing shortages, inefficient external processes, and resource challenges created a "perfect storm" for the ME system to come under fire. Forensic pathologists, those responsible for ascertaining medicolegal deaths, are in short supply nationally, with a significant gap in numbers of pathologists and funding for their services. Puerto Rico, likewise, has a staffing shortage that was quantified and projected by the assessment team. Like the mainland United States, the forensic services of Puerto Rico are a government-funded program and, therefore, the operations are depending on approved budgets, transparency in costing and resource allocation, and matching need with supply for all aspects of the laboratory's function. The leadership of the ME's office has made incredible strides and had documented successes in improving the funding challenges for the laboratory and continue to build out the needed resources.

With the presence of Hurricane Maria, continuous access to power, for example, became a major challenge as refrigeration is a key component of ME functionality, as well as mortuary services throughout the island. The need for temporary storage admixed with communication challenges created disinformation in the public sector. However, the core team, facilities, and processes are clearly prepared to be successful and a series of not-mutually-exclusive solutions are available to propel this system to excellence. In 2014, the ME laboratory was able to obtain the National Association of Medical Examiners (NAME) accreditation. In 2019, NAME extended provisional accreditation for the ME office, yet gaps to meeting the accreditation requirements continue and stem directly from the above challenges and not from a change in the core functionality. However, those gaps, are identifiable and amenable to sustainable changes. The experience of assessing this system, integration and modeling of data, and the presentation of solutions will be discussed.

---

#### **Hurricane, Personnel Capacity, Assessment**

### A106 Decedent Tracking: A Need for an Accurate Headcount in the Medical Examiner's Office

*Jennifer C. Love, PhD\*, Office of the Chief Medical Examiner, Washington, DC 20024*

**Learning Overview:** After attending this presentation, attendees will have an understanding of the need for a strong decedent tracking system, critical factors of a successful tracking system, and the need for supportive standard operating procedures. Failure to properly handle decedent inventory is a problem that many medical examiner offices have faced, including the Puerto Rico Bureau of Forensic Sciences (in Spanish, Negociado de Ciencias Forenses (NCF)).

**Impact on the Forensic Science Community:** This presentation will impact the forensic sciences community by addressing that the difficulties that NCF faced immediately and long after Hurricane Maria are not unique to Puerto Rico or to a mass disaster event. The lessons learned through evaluating the NCF decedent tracking system and developing tools that can assist with decedent handling and storage are informative to medical examiner offices throughout the world.

On September 20, 2017, Hurricane Maria, a Category 5 hurricane, made landfall in Puerto Rico, causing widespread devastation to the island's infrastructure. Initially, the death count from the storm was reported as 65 individuals; a year later, it was corrected to 2,975 individuals. The unfathomable discrepancy is an indication of the breakdown of systems that affected nearly all agencies on the island. The NCF was not immune to the devastation and experienced loss of personnel and resources that jeopardized the laboratory's accreditation and interrupted the forensic science services provided to the Puerto Rican criminal justice system. As the impact of Hurricane Maria accumulated, NCF found itself overwhelmed with decedent inventory. In January of 2019, more than a year after the hurricane, NCF required additional refrigerated trailers from the Federal Emergency Management Agency (FEMA) to handle the decedent inventory.

In 2018, the National Association of Attorneys General (NAAG) received a request from the Puerto Rico Public Safety Secretary for assistance in steadying the NCF. NAAG, in turn, requested the assistance of the American Society of Crime Laboratory Directors (ASCLD), and together these organizations began a multidisciplinary response. One component of the response was to assess the NCF system for decedent tracking and inventory. In order to understand the system, the standard operating procedures governing mortuary operations and decedent identification were reviewed, the facility was toured, and key staff members were interviewed. Decedent processing from receipt to release was mapped.

During the assessment, several obstacles to implementing a strong decedent inventory system were identified. Most notable was the use of three independent electronic data management systems, each with a slightly different purpose. None of the systems served as the master system with complete, accurate, and current information. Furthermore, none of the systems were capable of reporting a list of decedents that were received by NCF but not yet released. Decedent inventories were manually generated by staff visualizing each body bag and writing down the case number on an inventory form. This approach required a significant number of man-hours, placed staff in an uncomfortable work environment (refrigerated coolers) for a lengthy period of time, and was found to be error prone. An additional obstacle was that bodies were not examined until a family member presented to NCF and initiated the identification process. This caused significant delays in the release of the body in many cases. Finally, tentatively identified and unidentified decedents were collectively identified as John and Jane Does, putting at risk critical information needed to facilitate positive identification.

The results of the assessment (audit date April 24, 2019) indicated that NCF's decedent storage capacity, including fixed and temporary storage units, was 295 decedents. NCF was storing 269 bodies. Eighty-four of the bodies were received in 2018 or before. The longest-held body was received in 2010. Forty of the decedents were positively identified and awaiting examination. Fifty-seven of the decedents were classified as Jane or John Doe. Forty of the decedents were ready to be released (positively identified and completed examination). One body had been approved for release in 2015. The identification, examination, or release status of the remaining 48 bodies could not be determined at the time of the assessment.

It became apparent during the assessment that NCF was storing bodies unnecessarily for a lengthy period of time, contributing to the storage space shortage. A centralized data management system that could be used to track the decedent receipt date, identification status, examination completion date, and the ready-for-release date was needed. Until such a data management system can be procured, the assessors developed a spreadsheet to track each decedent and calculate the length of time each body was held at each stage of the process (e.g., length of time between identification and examination). The tool could be used to assist the mortuary operation supervisor in tracking decedents and ensuring unclaimed decedents are released for final disposition in a timely manner following the Puerto Rico statute (25 L.P.R. § 3600).

### A107 Challenges and Lessons Learned From Having an External Expert Step Into the DNA Laboratory

*Ray Wickenheiser, DPS\*, New York State Police Crime Laboratory System, Albany, NY 12226-3000; Mariel Mariel Candelario Gorbea, MSFS\*, Laboratorio Forense de ADN/Serología Negociado de, San Juan, PR 00922*

**Learning Overview:** The goals of this presentation are to: (1) promote the understanding of the challenges faced when hosting an external expert; (2) provide and understand the challenges of the external expert; (3) understand the opportunity of providing outside expertise; and (4) realize the program goals through collaboration.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating both the challenges and rewards discovered through having external experts visit the Puerto Rico Crime laboratory, speak with staff, directly observe lab conditions and resources, and work directly with staff to provide constructive recommendations. Through continued contact, relationship, and trust building, understanding of strengths and opportunities makes the best use of lab and expert time. Outside expertise liaisons provide an objective reservoir of capability, which can be leveraged to break logjams and obtain necessary resources.

On September 19, 2017, Hurricane Maria, a Category 5 hurricane, struck Puerto Rico, devastating the island population, crippling infrastructure, and leaving the vast majority of the island without power for weeks to months. The precarious fiscal situation of the island had already caused the Puerto Rico Crime Lab (Bureau of Forensic Sciences (FSB)) to lose a great number of valuable and highly trained employees, including crime scene investigators, questioned documents examiners, chemists, firearms and tool marks specialists, and digital evidence and DNA analysts. With this economic and environmental crisis at hand, the Department of Justice of Puerto Rico reached out to the American Society of Crime Laboratory Directors (ASCLD) for assistance in rebuilding its forensic capability. ASCLD responded by establishing a Board Meeting on the island to include planning sessions with Puerto Rican Crime Lab authorities to establish a consolidated response, including providing an extensive audit of operations, provision of recommendations, and application for grant funding to outsource backlogged cases and purchase new equipment.

A team of volunteer experts, including those with DNA, quality management, and laboratory operations expertise responded. After a few visits to Puerto Rico by ASCLD and the National Association of Attorneys General (NAAG) members, a Memorandum Of Understanding (MOU) agreement was established. The main goal of this MOU was to implement a laboratory assessment toward identifying the main needs. A team of four individuals visited the Bureau to meet with staff, directly evaluated laboratory infrastructure, equipment, and facilities, as well as laboratory policies, procedures, and metrics. Based on their findings, constructive recommendations were provided by the ASCLD and NAAG team.

Establishing external expert liaisons may represent a challenge. Experts must be welcomed by the host lab, with trust developed through ongoing contact. Through a trusted relationship, a better understanding of the current situation has been gained, along with what areas of the laboratory may need assistance, which can be built upon, and what solutions are a best fit to overcoming challenges of backlogs and resource issues. Recommendations must be tailored to the host lab to ensure they are receptive, that solutions will be embraced, implemented, and provide the assistance they are targeted toward.

Findings and recommendations were discussed with the Puerto Rico staff to ensure such recommendations were fit for implementation. Recently obtained equipment in the Puerto Rico FSB was in the process of validation, and additional recommendations were provided to complete needed validations, as well as to shift staff to the most beneficial components of operations. This was facilitated by a proposal for use of Rapid DNA technology in the morgue unit, freeing up necessary DNA analytical capability. A backlog reduction grant was written with support from external expertise using information provided by Puerto Rican staff. This effort not only enabled a shorter turnaround for the grant application, but also allowed Puerto Rico to apply for more grants by dividing up the work between the external support and the Puerto Rico staff.

The agreement and collaborations between the Puerto Rico FSB, ASCLD, and NAAG are a clear example of how external experts' liaisons with a host lab can provide a valuable viewpoint, adding legitimacy and voice to lab staff. The input and feedback provided have clearly aided the Puerto Rico FSB to identify their areas of need as well as to identify the most appropriate strategies to overcome challenges. In summary, the ASCLD-NAAG Puerto Rican initiative was as rewarding for the external experts as it was for the host lab: labs helping labs with shared expertise.

#### Outside Expert, DNA Lab, Disaster Recovery

### **A108 The American Board of Forensic Anthropology (ABFA) Response to the Puerto Rico Bureau of Forensic Sciences (BFS): Partnering With the National Association of Attorney’s General and the American Society of Crime Laboratory Directors**

*Dana Austin, PhD\*, Tarrant County Medical Examiner’s Office, Fort Worth, TX 76104-4919; MariaTeresa A. Tersigni-Tarrant, PhD\*, Saint Louis University School of Medicine, Saint Louis, MO 63104*

**Learning Overview:** After attending this presentation, attendees will be aware of successful means to organize and implement a forensic anthropology response to assist a medical examiner’s office in the analysis of multiple skeletal cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the organization and performance in a forensic anthropology response to an interagency medicolegal project. Lessons learned from a team of ABFA Diplomate forensic anthropologists assisting death investigation in Puerto Rico will be discussed.

This presentation details the processes of pre-deployment, deployment, and post-deployment as two groups of forensic anthropologists assisted the Puerto Rico BFS with a forensic anthropology case backlog in January and April of 2019. This backlog was, in part, due to the severe illness and resignation of Dr. Edwin Crespo Torres in 2018.

In this situation, where the scope of practice and type of assessment were unknown, the board-certified forensic anthropologists spent considerable time during the pre-deployment period planning for various contingencies and scenarios. The team was provided with an estimated number of skeletal cases requiring analysis; however, the condition of the remains and the laboratory facilities were unknown. The team created a bench notes template that encompassed the wide scope of forensic anthropological analysis: chain of custody, skeletal inventory, biological profile, trauma, postmortem interval, and taphonomy. The template was flexible to allow individual practitioners the freedom to complete analyses using the methods they found appropriate. During this pre-deployment process, a single individual served as the primary point of contact with the team-at-large and as leader of the anthropology team to facilitate communication, completeness, and a cohesive group.

During the first deployment, triage at the Puerto Rico BFS determined priority of casework and division of labor for the team. The six senior anthropologists and two graduate students needed to understand and follow the same processes of documentation with common bench notes, photography, radiography, DNA sampling, and chain of custody for transfer of the cases to the Puerto Rico BFS staff. A single anthropologist focused on ensuring Quality Assurance(QA) and Quality Control (QC) during the implementation and completion of these processes was critical. The QA/QC leader allowed for the rest of the team to concentrate on completing 47 cases, including 17 forensically significant cases, 22 cemetery remains that were not of forensic significance, 7 non-human bone cases, 2 cases comprised of “Other,” and review 14 skeletal case files to assess future needs.

Once the first deployment was completed, summaries and complete case files were provided to the Chief Medical Examiner. An inventory of available equipment, disposable supplies, and reference material was completed for anticipated future anthropology team deployment. Each anthropologist departed with their own bench notes and were provided case report templates and deadlines to complete signed case reports. Case report templates ensured that all reports were uniform in terms of the information that was provided to the Puerto Rico BFS. Once completed, the entire case file and report were reviewed by a single peer reviewer. Peer review provided another QA/QC check to ensure that the notes and case reports were complete, consistent with the template, and that the findings were sound and based on good science.

A second deployment in April 2019 included the same team leader and three new anthropologists. The Puerto Rico BFS staff was prepared for the second team, now comfortable with the processes put in place and enthusiastic because of the amount of work that had been completed on the previous deployment. The mortuary staff pulled numerous skeletal cases and staged them for the anthropologists before the team arrived. The staff also ensured workspace was available throughout the response. This allowed the second team to work more efficiently to complete even more casework, including 34 forensic cases, 17 cemetery remains, 7 non-human bone cases, and 2 cases involving other types of evidence.

This presentation provides knowledge gained during a multidisciplinary team response to a forensic laboratory facing numerous obstacles. The presentation focuses on the anthropology response, showcasing pre-deployment planning, process development, and the flexibility required to successfully perform forensic anthropological analysis in a remote, unknown medicolegal settings. The lessons learned from the response to BFS are applicable to other medical examiner offices facing similar obstacles.

## A109 Assessing Isotope Data Comparability: An Example From the Application of Isotope Testing to Unidentified Human Remains From Past Conflicts

Lesley A. Chesson, MS\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Amelia J. Edwards, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Eric J. Bartelink, PhD, California State University, Chico, Chico, CA 95929-0400; Thuan H. Chau, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Gregory E. Berg, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853-5530

**Learning Overview:** After attending this presentation, attendees will have learned a straightforward method for determining a real interpretative difference that should be used to compare isotope data generated by different laboratories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an example of assessing comparability between isotope datasets from different laboratories; the recommended practice can be easily implemented by research groups collecting and using isotope data to provenance unknown individuals.

Isotope testing has proven to be a useful tool for provenancing unidentified human remains. However, application of the technique requires reference datasets of potential source origins or populations that are sometimes compiled from remains prepared and analyzed at different laboratories. It is critical that scientists assess comparability between datasets, especially when drawing conclusions about an unknown decedent.

Inferences about similarities between a sample and available reference data are questionable when variations in isotope measurement results are not well-defined. To address this, Pestle et al. designed an inter-laboratory comparison to quantify variability in the isotopic analysis of ancient human remains; they found that approximately half the variation was due to differences in sample preparation methods, while the other half was due to differences in analytical techniques.<sup>1</sup> This led to the development of a Minimum Meaningful Difference (MMD) metric. The MMD was calculated by taking the mean pairwise inter-laboratory difference and adding four times the mean of the standard deviation of results from each participating laboratory; differences between laboratories were considered real if they exceed the MMD threshold. While the MMD represents a useful metric for assessing isotope data comparability, it also represents a worst-case scenario due to the number of participants in the inter-laboratory comparison.

A more straightforward method for assessing isotope data comparability focuses on paired samples, whereby a set of samples is prepared and/or analyzed twice to investigate practical differences between two laboratories by calculating a Real Interpretative Difference (RID).<sup>2</sup> To demonstrate this, 30 samples were collected from long bones and split for preparation as collagen and bioapatite at the Defense POW/MIA Accounting Agency (DPAA) Laboratory in Hawaii and California State University (CSU), Chico. Extracts of collagen from both laboratories were submitted to the University of California, Davis for measurement of carbon and nitrogen isotope values, while the bioapatite extracts were submitted to IsoForensics, Inc. for measurement of carbon and oxygen isotope values. Based on collagen yields, nine samples were affected by diagenesis and were not used in subsequent statistical evaluations.

Mean differences in the collagen prepared at the DPAA and CSU, Chico were 0.10‰ for  $\delta^{13}\text{C}$  values and 0.19‰ for  $\delta^{15}\text{N}$  values; while small, these differences were significant when compared to a theoretical mean of 0 (one-sample *t*-test;  $p < 0.001$  for both). There was no significant difference in the  $\delta^{13}\text{C}$  values of the bioapatite extracted at the DPAA and CSU, Chico. In contrast, there was a significant difference in bioapatite  $\delta^{18}\text{O}$  values ( $p < 0.0001$ ), with pairwise differences as large as 1.3‰. RID thresholds were calculated by adding three times the Standard Deviation (SD) of the mean pairwise differences (representing ~99% confidence) to the long-term SD of check standards used during sample analysis. Check standards included bovine liver (SD=0.07 and 0.08 for  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values, respectively) and powdered marble (SD=0.09 and 0.16 for  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  values, respectively). Final RID values were 0.40‰ for collagen  $\delta^{13}\text{C}$  values, 0.74‰ for collagen  $\delta^{15}\text{N}$  values, 1.42‰ for bioapatite  $\delta^{13}\text{C}$  values, and 1.61‰ for bioapatite  $\delta^{18}\text{O}$  values. No pairwise difference exceeded RID thresholds for either collagen  $\delta^{13}\text{C}$  or  $\delta^{15}\text{N}$  values. Likewise, no pairwise difference exceeded the bioapatite RID values for either carbon or oxygen isotope values.

This study demonstrates a method for assessing comparability between isotope datasets, focusing on modern human bone collagen and bone bioapatite. Results show that collagen prepared by the DPAA today can be reliably compared to previously published datasets of collagen prepared by CSU, Chico.<sup>3</sup> Comparison of bone bioapatite prepared at the two laboratories suggests that carbon isotope values are reliable, but the location of preparation has a significant impact on oxygen isotope values. More work is needed to identify and potentially control for this variable as it could have a serious impact on provenance predictions based on the measured  $\delta^{18}\text{O}$  value.

## A110 Using Stable Nitrogen Isotope Ratios From Fly Larvae for Postmortem Interval (PMI) Estimation

Melanie M. Beasley, PhD\*, Purdue University, West Lafayette, IN 47907-2059; Julie Lesnik, PhD, Wayne State University, Detroit, MI 48202; Hayden McKee, MSc, Knoxville, TN 37917; Anielle Duncan, BA, University of Tennessee, Knoxville, TN 37996; Dawnie W. Steadman, PhD, University of Tennessee, Department of Anthropology, Knoxville, TN 37996

**Learning Overview:** After attending this presentation, attendees will understand how changes in stable nitrogen isotope ratios ( $\delta^{15}\text{N}$ ) of some species of flies collected from decomposing human bodies may aid in the estimation of the PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel application of stable isotope analysis of  $\delta^{15}\text{N}$  values of fly larvae residing on decomposing human bodies to use as an alternative to traditional PMI estimation techniques. Furthermore, this study builds on previous research on the application of  $\delta^{15}\text{N}$  ratios of decomposing muscle tissue for PMI estimation. By combining muscle and fly larvae data, seasonal differences in PMI can be estimated from the point of death through the entire skeletonization process as long as larvae are recovered.

One of the most difficult periods to estimate PMI is during initial skeletonization. Imagine recovering a surface scatter of a skeleton in late summer or early fall: Did the skeletonization process happen quickly during a hot humid summer or had a long slow winter decomposition occurred over many months? To test if PMI estimation can be improved during initial skeletonization, the putrefaction process of  $\delta^{15}\text{N}$  ratios in maggots may help. What is happening to nitrogen during decomposition and subsequent consumption by fly larvae? Nitrogen has two stable isotopes with different masses, a heavy ( $^{15}\text{N}$ ) and a light ( $^{14}\text{N}$ ) isotope. In a chemical reaction, the isotopes with different masses will react at different rates, resulting in a preferential selection of one isotope ( $^{14}\text{N}$ ) compared to the other ( $^{15}\text{N}$ ). During decomposition (e.g., putrefaction), the breakdown of amino acids produces a variety of volatile compounds, which preferentially incorporate the light isotope ( $^{14}\text{N}$ ) because it will react faster in a chemical reaction, resulting in an enrichment of the heavy isotope ( $^{15}\text{N}$ ) in the remaining decomposition fluid, which is nutrient rich for fly larvae. The impact to  $\delta^{15}\text{N}$  values as putrefaction progresses would be higher values through time recorded by fly larvae feeding on the nutrient-rich source.

This research was conducted at the Anthropology Research Facility in Knoxville, TN, an outdoor laboratory for the study of human decomposition. A total of 20 donors were enrolled in the study, placed on the surface in two trials with 10 donors each in January (winter) and July (summer) to test differential seasonality effects to the method as a PMI estimator. Blow fly larvae, an early decomposition insect, were present from February through August. Soldier fly larvae, a late stage decomposition insect, were present from June through December. Regardless of whether raw  $\delta^{15}\text{N}$  ratios or  $\Delta^{15}\text{N}$  ( $\Delta^{15}\text{N} = \delta^{15}\text{N}_{\text{Day X larvae}} - \delta^{15}\text{N}_{\text{Day 1 muscle}}$ , with Day 1 as the initial fresh tissue sample to normalize the baseline of different donors), the blow fly larvae did not predict seasonal differences for PMI estimation ( $p=0.61$ ), while soldier fly larvae could be used to predict winter vs. summer placement ( $p=0.00$ ).

The winter trial ( $n=43$ ) had soldier fly larvae arrive after five months of decomposition with a mean  $\delta^{15}\text{N}$  of 27.4‰ (ISD=6.4) and range of 18.0 to 43.2‰. The summer trial ( $n=66$ ) had soldier fly larvae arrive after three weeks of decomposition with a mean  $\delta^{15}\text{N}$  of 18.0‰ (ISD=4.0) and range of 10.7 to 30.0‰; however, there are only four samples above 23.3‰. With a sectioning point of 21.7‰ calculated from the mean  $\delta^{15}\text{N}$  of the soldier fly larvae, the overall accuracy rate for the sample was 79.8%. For conservative PMI estimates, it is recommended that  $\delta^{15}\text{N}$  values from soldier fly larvae be used as general indicators of winter versus summer placement when values are above 24‰ vs. below 19‰, respectively.

This East Tennessee pilot study indicates that the significant influence to  $\delta^{15}\text{N}$  values of soldier fly larvae is time of decomposition prior to arrival of this late stage decomposition insect. The impact to  $\delta^{15}\text{N}$  ratios as putrefaction progresses would be higher values later in decomposition recorded by soldier fly larvae. This initial study indicates there is value in the method as a PMI estimate for recently deceased individuals when soldier fly larvae are present. This relationship does not hold for early stage insect activity, as seen in  $\delta^{15}\text{N}$  values of blow fly larvae.

### Stable Nitrogen Isotope Ratios, Postmortem Interval Estimation, Fly Larvae

## A111 Crossing Borders: International and Multidisciplinary Applications of Isotope Analysis in Forensic Anthropology

Gabriela B. Nardoto\*, University of Brasília, Brasília, Distrito Federal 70910-900, BRAZIL; Luiz Antonio Martinelli, University of São Paulo, Piracicaba 13416000, BRAZIL

**Learning Overview:** The goal of this presentation is for attendees to learn about an integrated tool using isotope data mixed with socio-economic status to be applied forensically for provenance region, in the medicolegal context, but also to add information about unknown persons.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a new proxy for tracking human movements under the worldwide “global supermarket” dietary trend, potentially adding more detailed connections to narrow predictions of a region of origin and in the identification of unknown persons.

Several works have used the multi-isotope approach to track the geographical origin of human remains as well as human movements in forensic anthropology, but only a few studies have used it in association with some socioeconomic status and dietary behavior changes. These studies have demonstrated the progressive substitution of local staples for industrialized processed foods in the developing regions of the world (the so-called nutrition transition process), increasingly recorded in respective rural areas. In this context, a new proxy for tracking human movements under the worldwide “global supermarket” dietary trend was explored.

The spatial distribution of  $\delta^{13}\text{C}$  in contemporary human fingernails, representing the food sources and dietary practices in a region, was associated with the globally well-recognized Human Development Index (HDI) from the United Nations Organization. The  $\delta^{13}\text{C}$  of fingernails from approximately 4,000 Brazilian inhabitants living in rural and urban areas spatially distributed in the territory was analyzed. The HDI at the municipality level was associated with the average  $\delta^{13}\text{C}$  of fingernails for the corresponding municipality. A sub-dataset of approximately 2,000 samples of fingernails from pairwise cities and isolated villages in two different regions of Brazil, the Amazon tropical forest and the Central Brazilian savannas, were analyzed to explore the possibility of using  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  of fingernails to differentiate between urban and village areas and also between males and females living at the same locality.

At the country level, there was a positive spatial correlation between the  $\delta^{13}\text{C}$  and HDI (0.67;  $p < 0.01$ ). The highest  $\delta^{13}\text{C}$  and HDI were found in the Southeast and South Brazilian regions, followed by the Center-West region. The increase in the number of food items derived from  $\text{C}_4$  plant resources and the replacement of food items derived from  $\text{C}_3$  plant resources was associated with higher ultra-processed food purchases as a proportion of overall household food purchases. On the other hand, the  $\delta^{13}\text{C}$  from the North and Northeastern regions had the strongest link to  $\text{C}_3$  food sources, especially in their rural areas. At the regional urban-rural gradient, fingernails from individuals living in agricultural regions were coupled to local carbon and nitrogen isotope composition, while fingernails from individuals living in more urban areas had the most decoupled isotopes signatures from the local ecosystems. However, cases in which the villages were more connected to the urban areas showed a more similar diet to the residents of the urban areas. Also, the  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of inhabitants of villages with high consumer buying power tended to be more decoupled from the local landscape. At the local level, males from the isolated villages had higher  $\delta^{15}\text{N}$  and lower  $\delta^{13}\text{C}$  than females, while in the cities, there was no difference between them, indicating that males are still taking more protein from freshwater fish and bushmeat, indicated by a strong  $\text{C}_3$  signal and high  $\delta^{15}\text{N}$  compared to processed meat. Such differences among country, regional, and local levels resulted in a significant variation in fingernails’ stable isotope ratios according to the information related to both regional food sources and dietary practices but also to the degree of market integration of each region.

This integrated approach proved to be useful as a new tool to be used in human nutrition studies, especially in tracking human movements in forensic anthropology studies in the contemporary world. This integrated tool could then be applied forensically for the provenance region, adding information about missing persons.

### Socio-Economic Status, Isotopes in Fingernails, Human Movements

## A112 Isotopic Analyses of New York City's Unidentified Individuals: Differentiating Migrants From Local Residents in a Multicultural Metropolitan Context

Rhonda L. Quinn\*, Seton Hall University, South Orange, NJ 07079; Helen S. Alesbury, MA, New York City Office of Chief Medical Examiner, New York, NY 10016; Angela Soler, PhD, New York City Office of Chief Medical Examiner, New York, NY 10016; Ligia E. Ceja, BS, New York City Office of Chief Medical Examiner, New York, NY 10016; Linda Godfrey, PhD, Rutgers University, Piscataway, NJ 08854; Jacob B. Setera, Piscataway, NJ 08854

**Learning Overview:** After attending this presentation, attendees will understand how geolocation and dietary isotopic data are used to aid in differentiating migrants from local residents from a sample of long-term unknown individuals in New York City, a large, urban multicultural region with high residential mobility.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving understanding of the complexities of employing geolocation and dietary isotopic methods for decedent identification purposes in a multicultural metropolitan context.

Isotopic analyses of human remains provide geolocation and dietary information to the biological profile, furthering efforts to identify long-term unknown individuals. Geolocation isotopes including oxygen ( $\delta^{18}\text{O}$ ) and strontium ( $^{87}\text{Sr}/^{86}\text{Sr}$ ) and dietary isotopes such as carbon ( $\delta^{13}\text{C}$ ) and nitrogen ( $\delta^{15}\text{N}$ ) are commonly employed to indicate geographic origins and residential mobility of unidentified decedents within the United States and globally.<sup>1-3</sup> Since an individual's isotopic values are derived from ingested food and beverages during life, the homogenization of foods via the "supermarket effect" has potential for blurring regional distinctions for geolocation purposes. Moreover, culturally influenced food traditions pose interpretative complications, especially in multicultural metropolitan regions such as New York City.

In this study, multiple isotopic systems were employed to analyze tissue sets (hair, nail, bone, enamel) of 28 forensic cases of unknown identities in the custody of the New York City Office of Chief Medical Examiner (NYC OCME) to characterize dietary practices and residential histories. Bone and enamel apatite  $\delta^{18}\text{O}$  and  $\delta^{13}\text{C}$  analyses of the 28 individuals and hair  $\delta^{18}\text{O}$  analyses of a subset of 8 individuals were acquired from IsoForensics, Inc. Additional bulk bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values and incremental enamel  $^{87}\text{Sr}/^{86}\text{Sr}$  values via laser ablation were contributed to the case profiles. Hair  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values of 42 living residents of New York City were analyzed and used as a dietary comparative dataset.  $\delta^{18}\text{O}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  values of unidentified remains were compared to published isoscapes based on individuals of known residence and tap water values using established conversion equations.<sup>2,4,5</sup>  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values were incorporated into dietary models of protein consumption and general dietary groups.<sup>6</sup>

Of the 28 NYC OCME forensic cases, enamel analyses yielded average imbibed water  $\delta^{18}\text{O}$  values  $-7.6\text{‰}$ , ranging from  $-12.9\text{‰}$  to  $2.0\text{‰}$ , and  $^{87}\text{Sr}/^{86}\text{Sr}$  values of 0.7128, ranging from 0.7067 to 0.7258. Based on enamel  $\delta^{18}\text{O}$  values alone, 14 individuals resided locally during childhood years. According to combined enamel  $\delta^{18}\text{O}$  and  $^{87}\text{Sr}/^{86}\text{Sr}$  data, only 3 individuals were interpreted as local to NYC during childhood years. Bone apatite  $\delta^{18}\text{O}$  values suggest 19 individuals resided locally during adulthood. From the 8 hair and nail  $\delta^{18}\text{O}$  values, 2 individuals were identified as local residents within months of death. Bone collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values averaged  $-15.9\text{‰}$  and  $10.1\text{‰}$ , respectively, and indicate a range of diets ( $\delta^{13}\text{C}=-19.0$  to  $-12.9\text{‰}$ ;  $\delta^{15}\text{N}=7.3$  to  $11.7\text{‰}$ ). Modern NYC residents have lower  $\delta^{13}\text{C}$  values than the case sample, indicating relatively more  $\text{C}_3$ -based diets. Six individuals have  $\delta^{13}\text{C}$  values higher than  $-13\text{‰}$  and lower than  $-17\text{‰}$ , which is suggestive of non-United States and/or culturally influenced dietary practices.<sup>3</sup>

Two cases are explored in depth, both of which are interpreted to have migrated into the United States. Multiple isotopic data of one individual with an identity confirmed through DNA illustrate overlapping United States and non-United States isoscapes and a  $\text{C}_3$ -based dietary practice, which combined led to a misidentification of the individual's potential residences. Data from a second case, still pending identification, yielded a heavily  $\text{C}_4$ -based dietary practice and an extremely wide range of  $^{87}\text{Sr}/^{86}\text{Sr}$  values visible through laser ablation, which strongly suggest a non-United States residence. These two cases are used to demonstrate methodological limitations and areas of potential for determining whether an individual crossed a border in his/her lifetime.

### Isotopic Analysis, Unidentified/Unknown, Forensic Anthropology

## A113 Isotope Analysis in Modern Colombian Teeth: A Forensic Application

Daniel Castellanos, MA\*, Bogota 57, COLOMBIA; Elizabeth A. DiGangi, PhD, Binghamton University, Binghamton, NY 13902; Jonathan D. Bethard, PhD\*, University of South Florida, Tampa, FL 33620-8100; George D. Kamenov, PhD, University of Florida, Gainesville, FL 32611

**Learning Overview:** After attending this presentation, attendees will have learned the results of isotopic research in Colombia, which aims to evaluate the usefulness of a multi-isotope approach using carbon ( $\delta^{13}\text{C}$ ), oxygen ( $\delta^{18}\text{O}$ ), strontium ( $^{87}\text{Sr}/^{86}\text{Sr}$ ), and lead ( $^{206}\text{Pb}/^{207}\text{Pb}$ ,  $^{208}\text{Pb}/^{204}\text{Pb}$ ) isotopes for the prediction of region-of-origin of skeletal remains in Colombia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing: (1) if Colombian isotopic data differs within the country and between those of other countries; (2) which isotope system can be most useful to determine if an individual is likely to be of Colombian origin; (3) if regional dietary patterns were observed; and (4) if  $\delta^{18}\text{O}$  in enamel bioapatite varies according to altitude as expected.

The application of stable isotopes to human identification is a rapidly expanding field in forensic science due to the valuable information isotopes can impart about the geographic origin and geographic life history of an individual.

Currently, the country of Colombia faces a massive identification crisis because of long-term violence due to socio-political conflict and criminal activity. The government databases estimate that there are currently between 10,000 and 22,000 unidentified persons; therefore, methods that can assist in narrowing identification possibilities are needed.<sup>1</sup>

The sample was composed of modern permanent teeth from Colombia and published Colombian data. The sample included 97 donated teeth of individuals with known demographic information from the cities of Bogota, Cali, and Neiva (approved by the Institutional Review Board of Binghamton University), as well as published data from 61 teeth from the Medellin skeletal collection from individuals with known demographic information.

Overall, carbon isotopes in the tooth enamel carbonate show a diverse range with  $\delta^{13}\text{C}$  values between -14.09‰ to -2.80‰, which falls in the range of reported values from the United States. However, there are significant differences in  $\delta^{13}\text{C}$  values between some Colombian cities (e.g., Cali, Medellin, and Cartagena). Oxygen isotopes in the tooth enamel carbonate show a range of  $\delta^{18}\text{O}$  values between -9.64‰ to -2.74‰; a slight trend in decreasing  $\delta^{18}\text{O}$  values with increasing altitude is observed, in addition to differences between individuals who live in the coast and highlands (e.g., Cartagena vs. Bogota).

Colombian tooth enamel has  $^{87}\text{Sr}/^{86}\text{Sr}$  values between 0.70475 and 0.71839, which fall within the range of reported values from other regions (e.g., Mexico). However, differences between cities are observable (e.g., Cali vs. Bogota). Analysis of the lead isotopic composition is  $^{206}\text{Pb}/^{204}\text{Pb}=17.972$  to  $18.976$ ,  $^{207}\text{Pb}/^{204}\text{Pb}=15.576$  to  $15.683$ , and  $^{208}\text{Pb}/^{204}\text{Pb}=37.819$  to  $38.602$ . Lead isotopic data seems homogeneous; however, slight differences between Colombia, United States, and European values are observed.

This presentation will provide insights about isotope analysis in Colombia and the utility of a multi-isotope approach for determining place-of-origin of an individual. In addition, by generating a Colombian baseline for future place-of-origin predictions, it contributes to the identification and search for missing people in Colombia. The differences found between countries will be useful for forensic purposes on a continental and global scale. This Colombian data will have international applications, such as helping with identifying missing people who die crossing the border or by natural or human-made disasters.

### Isotope Analysis, Colombia, Forensic Anthropology

### A114 Examining Stable Isotope Ratios From Victims of the Internal Armed Conflict in Peru (1980s–2000) to Establish Local or Non-Local Geographic Origins: A Preliminary Analysis of the Victims of the Military Base Los Cabitos, Ayacucho, Peru

Tiffany A. Tung, PhD\*, Vanderbilt University, Anthropology, Nashville, TN 37235; Natasha P. Vang, BS, Vanderbilt University, Anthropology, Nashville, TN 37235-7703; Roberto C. Parra, MA, Lima, PERU; Martha R. Palma Malaga, MG, Ministry of Justice and Human Rights, Lima, PERU

**Learning Overview:** The objective of this presentation is to educate attendees about using stable oxygen carbon and nitrogen isotope analyses as a method for evaluating whether a deceased individual is from the geographic region where a body was disposed. This presentation will also provide attendees with specific information about a case from the Internal Conflict in Peru that left hundreds of unidentified bodies at the Los Cabitos exhumation site in Ayacucho, Peru, the geographical heart of the conflict between the Shining Path and the Peruvian State.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting methods and results that will teach attendees about the benefits and limitations of using stable isotope analysis and missing persons' databases as part of the methodological toolkit for moving closer to identifying unknown persons.

This study applied isotopic analyses to evaluate whether unidentified persons recovered from the Los Cabitos exhumation site in Ayacucho, Peru, were from the local Ayacucho region. Those bodies were disposed there during the Time of Violence in Peru in the 1980s–2000s. This is the first phase of isotopic analysis of the victims' bodies, which will be used to estimate possible geographic origins of the unidentified persons. The oxygen isotope ratios ( $^{18}\text{O}:^{16}\text{O}$ ) in drinking water sources are affected by latitude, temperature, elevation, distance from the coast, and other factors. If a person consumes local water, the oxygen isotope ratio in human tissues should align with local water drinking sources. Carbon isotope ratios ( $^{13}\text{C}:^{12}\text{C}$ ) in humans are determined by the plants consumed (and of the animals that eat those plants), and nitrogen isotope ratios ( $^{15}\text{N}:^{14}\text{N}$ ) from collagen vary depending on protein sources, among other factors (e.g., fertilization of crops). Depending on cultural/ecological contexts, certain ranges of carbon and nitrogen isotope values are expected for particular populations (e.g., a high-altitude, subsistence-based pastoralist from the 1980s in the Andes is likely to have lower carbon isotope ratios due to less access to maize, which grows in lower altitudes, and lower nitrogen isotope ratios because of little-to-no consumption of marine resources).

**Research Goals:** This presentation documents carbon and oxygen isotope ratios from dental carbonates and nitrogen isotope ratios from bone collagen from 45 unidentified persons from the Los Cabitos exhumation site. If outliers are identified based on isotope data, then that likely suggests that those individuals are not from the local Ayacucho region. Those "outlier" individuals can then be compared to the missing persons database of individuals who were imprisoned at Los Cabitos in the 1980s and 1990s.

**Methods:** Two enamel powder samples were taken from each tooth. Chemical preparation of the specimens was conducted at the Vanderbilt Bioarchaeology and Stable Isotope Research Laboratory (BSIRL) and processed at the Yale Analytical and Stable Isotope Center on a Thermo DeltaPlus Advantage (for carbon and nitrogen in collagen) and a Thermo<sup>TM</sup> DeltaPlus<sup>TM</sup> XP (for carbon and oxygen in dental carbonates). Carbon and oxygen isotopes are reported relative to the Vienna Pee Dee Belemnite (VPDB) standard:  $\delta^{13}\text{C} = \left( \left[ \frac{^{13}\text{C}/(^{12}\text{C}_{\text{sample}})}{^{13}\text{C}/(^{12}\text{C}_{\text{standard}})} - 1 \right] \times 1,000 \right)$  and  $\delta^{18}\text{O} = \left( \left[ \frac{^{18}\text{O}/(^{16}\text{O}_{\text{sample}})}{^{18}\text{O}/(^{16}\text{O}_{\text{standard}})} - 1 \right] \times 1,000 \right)$ . Nitrogen isotope ratios are reported relative to Atmospheric Nitrogen (AIR):  $\left( \left[ \frac{^{15}\text{N}/(^{14}\text{N}_{\text{sample}})}{^{15}\text{N}/(^{14}\text{N}_{\text{standard}})} - 1 \right] \times 1,000 \right)$ .

**Results:** Results showed that among the enamel carbonate samples, the mean  $\delta^{18}\text{O}_{\text{PDB}} = -9.0\text{‰}$  (s.d.=1.1) and the mean  $\delta^{13}\text{C}_{\text{PDB}} = -8.2\text{‰}$  (s.d.=1.9);  $N=89$  enamel samples for both isotopes. From the bone collagen samples, the mean  $\delta^{13}\text{C}_{\text{PDB}} = -16.2\text{‰}$  (s.d.=1.9) and the  $\delta^{15}\text{N} = 9.8\text{‰}$  (s.d.=0.5);  $N=12$  bone collagen samples for both isotopes. There are two outliers with both oxygen and carbon isotope values that are more than four times the standard deviation for one individual and four times the standard deviation for oxygen for the other. These isotope data strongly suggest that these two individuals spent their childhood in a distant locale, outside of the Ayacucho region. The bone collagen data suggest that the individuals then moved to Ayacucho, residing there for at least the last five to ten years before death, consuming diets similar to all of the other natal individuals. There are 16 individuals who were born outside of the Department of Ayacucho in the missing persons database for the Los Cabitos military complex.

**Conclusion:** These results can be used to evaluate whether the outliers were one of the non-local people in the missing persons database. Although isotope studies as a sole method do not arrive at positive identifications, these methods do narrow the range of options, which may aid in more focused DNA studies and other identification techniques.

#### Stable Isotopes, Peru, Shining Path Conflict

## A115 Spatial Distributions of Isotope Ratios in Tap Water, Hair, and Teeth From Latin America for Region of Origin Predictions of Unidentified Border Crossers

Saskia Ammer, MSc\*, Munich, Bavaria 80999, GERMANY; Eric J. Bartelink, PhD\*, California State University, Chico, Chico, CA 95929-0400

**Learning Overview:** The goal of this presentation is to introduce recent applications of stable isotopes and “isoscapescapes” for predicting region of origin of unidentified remains cases of Undocumented Border Crossers (UBCs) from the United States-Mexico border. This research provides an overview of the process and implications of building an isoscape from tap water and hair samples and discusses how these reference data provide a framework to predict region-of-origin of deceased migrants from Arizona and South Texas.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the use of reference baseline isotope data to refine predictions of region of origin of unidentified remains of UBCs and to highlight both the limitations and challenges of these approaches.

Each year, hundreds of UBCs are found deceased along the United States-Mexico border, with the highest volume of deaths occurring in Arizona and South Texas. UBCs are among the most difficult individuals to identify due to the lack of antemortem identification records and challenges in obtaining family reference DNA samples. Stable isotope analysis of human tissues represent another line of evidence to provide investigative leads for identification efforts of UBCs from Arizona and South Texas. Previous research on carbon isotopes identified significant dietary differences between the continental United States and Latin America, providing a useful screening tool. The addition of oxygen and strontium isotopes provides a more precise geospatial tool for narrowing region of origin since these isotopes reflect the sources of drinking water and food, respectively. To date, only crude isoscape maps exist for most regions within Latin America due to the lack of baseline reference data, which hinders efforts for predicting region of origin. This presentation adds to the growing baseline data for Latin America by presenting data on regional variation of isotopes in water and hair.

Tap water ( $n=158$ ) and hair ( $n=101$ ) samples were collected from 51 towns and 32 cities throughout Mexico to serve as a reference database for assigning deceased unidentified UBCs to potential regions of origin. Tap water samples were measured for oxygen and hydrogen isotopes, and hair samples were measured for oxygen isotopes. Water ( $\delta^{18}\text{O}$  and  $\delta^2\text{H}$ ) and hair ( $\delta^{18}\text{O}$ ) isoscapes were generated using ArcGIS® based on the spatial distribution of the reference sample using Moran’s  $I$  to quantify spatial autocorrelation (Spatial Statistics Toolbox, ArcGIS® 10.6). The tap water ratio data were defined by Moran’s indices of 0.843 and 0.856 ( $z$ -scores of 7.5 and 7.6 and  $p < 0.000001$  for  $\delta^{18}\text{O}$  and  $\delta^2\text{H}$ , respectively).

Carbon and oxygen isotopes were also measured in tooth enamel bioapatite from deceased UBCs from Pima County, AZ, ( $n=30$ ) and Brooks County, TX ( $n=41$ ). Permission to sample these remains was granted by the Pima County Office of Medical Examiner and Texas State University for the Arizona and Texas samples, respectively. Various lines of evidence indicate that the majority of UBCs found in Arizona derive from Mexico, whereas the majority of UBCs found in South Texas derive from Central America (primarily Guatemala, Honduras, and El Salvador). The mean enamel bioapatite  $\delta^{13}\text{C}$  value is  $-6.4\text{‰}$  ( $\pm 2.3\text{‰}$ , 1 SD; range= $10.2\text{‰}$ ) for the Arizona samples versus  $-5.4\text{‰}$  ( $\pm 3.0\text{‰}$ , 1 SD; range= $13.0\text{‰}$ ) for the South Texas samples, demonstrating a non-significant difference ( $t=1.594$ ,  $df=69$ ,  $p=0.115$ ). The mean enamel bioapatite  $\delta^{18}\text{O}$  value is  $-4.4\text{‰}$  ( $\pm 3.2\text{‰}$ , 1 SD; range= $0.9\text{‰}$ ) for the Arizona samples versus  $-5.5\text{‰}$  ( $\pm 1.2\text{‰}$ , 1 SD; range= $7.2\text{‰}$ ) for the Texas samples, a statistically significant difference ( $t=-3.949$ ,  $df=68$ ,  $p<0.001$ ). However, the differences in  $\delta^{13}\text{C}$  and  $\delta^{18}\text{O}$  between UBCs from Arizona and South Texas are small, and their source populations within Mexico and Central America cannot be determined using the isotope data currently available.

Three case studies from Arizona are used to highlight the application and limitations of the tap water and hair oxygen isotope isoscape based on individuals of known origin (i.e., UBCs who have recently been identified). The isoscape predictions for these cases are consistent with the known origin of these individuals, but include several possibilities within Mexico. The addition of strontium isotope baseline data will aid in refining these predictions in the future.

The ultimate goal is to incorporate the data into a larger network of tap water and human hair isoscapes in order to establish probability densities for the most probable regions of origins for the deceased undocumented migrants.

### A116 Considerations for Isotope Analysis of Human Hair: The Impact of Postmortem Environmental Exposure

Tiffany B. Saul, PhD\*, Forensic Institute for Research and Education, Murfreesboro, TN 37132; Lesley A. Chesson, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Dawnie W. Steadman, PhD, University of Tennessee, Department of Anthropology, Knoxville, TN 37996; Daniel J. Wescott, PhD, Texas State University, San Marcos, TX 78666-4684; Gwyneth W. Gordon, PhD, Arizona State University, Tempe, AZ 85287-1404

**Learning Overview:** After attending this presentation, attendees will appreciate the impact of outdoor exposure upon isotope ratios of human hair over time.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing possible concerns for isotope ratios obtained from human hair exposed to outdoor environments and by encouraging discussion of the impacts of taphonomic processes upon isotope analysis of human remains.

Isotope analysis is a tool anthropologists have adopted from other disciplines, crossing into biochemistry, ecology, and geology to better understand the relationships between people and their environments. As forensic anthropologists use isotope analysis with growing frequency in order to provide additional information about unidentified human remains, it is necessary to assess the limitations of this analysis. While isotope analysis does not provide individual positive identification, predictions about diet and geographic travel prior to death can generate new information in the absence of other leads. Because hair grows at a predictable rate and provides information about the weeks and months prior to death, it has been used in forensic contexts and is particularly useful in determining whether an individual was local to a particular area or possibly traveled from elsewhere. Previous research and predictive geospatial modeling (i.e., isoscapes) were conducted using pristine hair samples from salons, which do not reflect the conditions typical of forensic recoveries. This study addresses how isotope ratios of human hair are impacted by outdoor exposure over time.

Two outdoor laboratories were used: the Anthropology Research Facility in Knoxville, TN, and the Forensic Anthropology Research Facility in San Marcos, TX. Body donors with known residence histories ( $n=46$ ) were enrolled in the study. Hair samples that were collected prior to outdoor placement were compared to hair samples collected at various times throughout the decomposition process, with exposure times ranging from 22 days to 1,140 days (approximately 3 weeks to 3 years) postmortem. All samples were analyzed for carbon ( $\delta^{13}\text{C}$ ), nitrogen ( $\delta^{15}\text{N}$ ), hydrogen ( $\delta^2\text{H}$ ), and oxygen ( $\delta^{18}\text{O}$ ) isotope ratios, and a subset of 18 pairs were analyzed for strontium ( $^{87}\text{Sr}/^{86}\text{Sr}$ ) isotope ratios. No statistically significant differences were observed between pre- and post-exposure samples for  $\delta^{13}\text{C}$  ( $p=0.897$ ) and  $\delta^{18}\text{O}$  ( $p=0.267$ ) values. Significant differences were observed in  $\delta^{15}\text{N}$  ( $p=0.013$ ),  $\delta^2\text{H}$  ( $p<0.001$ ), and  $^{87}\text{Sr}/^{86}\text{Sr}$  ( $p<0.001$ ), though it is important to consider meaningful interpretive differences versus statistically significant differences when comparing values. Additional statistical evaluation using linear growth models revealed that number of days of exposure, location of placement (TN or TX), and placement condition (surface or burial) are variables that impact isotope ratios of human hair.

While this study revealed that postmortem isotope ratios from human hair may be impacted by outdoor exposure, the observed differences did not significantly impact the dietary and geographic travel predictions made from the measured isotope values. With the ever-growing number of unidentified remains of migrants of unknown geographic origin, isotope analysis is an essential tool for the forensic anthropologist. Isotope analysis of hair continues to show promise for providing valuable information that can assist with the identification of unknown human remains, especially as understanding of the effects of taphonomic processes upon isotope ratios continues to grow.

#### Isotope Ratios of Human Hair, Isotope Analysis, Decomposition

## A117 Differentiating Handsaw Tooth Shape Based on the Analysis of the Kerf Floor Contour

Alexandra R. Klales, PhD\*, Washburn University, Topeka, KS 66621; Ashley B. Maxwell, PhD, Washburn University, Topeka, KS 66621; Erin Chapman, PhD, Erie County Medical Examiner's Office, Buffalo, NY 14214

**Learning Overview:** After attending this presentation, attendees will understand if kerf floor contour can be used to accurately predict handsaw tooth shape in dismemberment cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by further validating the work of Symes et al. on saw analyses by indicating whether or not kerf floor shape can be used to reliably predict tooth shape in rip and crosscut handsaws with varying Teeth Per Inch (TPI).<sup>1</sup>

Nearly all dismemberment cases have at least one incomplete cut (a.k.a. false start) available for analysis. The kerf floor and walls contain the most information on class characteristics, including tooth shape: rip vs. crosscut.<sup>1</sup> Rip saws, with flat chiseled teeth at a 90-degree angle, are designed to cut with the grain of wood and produce a U-shaped/concave kerf.<sup>1</sup> Crosscut saws have teeth that are filed usually at 70-degrees with every other tooth being filed on the opposite side. They are designed to cut against the grain of wood and produce a W-shaped/convex kerf.<sup>1</sup> The differences in the contour of the kerf floor are therefore correlated with the differences in tooth design.

This research was designed to answer four questions: (1) Do rip saws always produce a U-shaped kerf floor and do crosscut saws always produce a W-shaped kerf floor? (2) Can kerf floor shape *always* be used to differentiate rip vs. crosscut saws? (3) Does teeth per inch impact visibility of the kerf floor shape? and (4) Does new vs. used blade affect the ability to differentiate saw tooth shape?

Two crosscut and three rip handsaws with alternate set teeth were selected from a local hardware store for the study. Each blade was new and was used by one individual to make 30 consecutive incomplete cuts on dry non-human long bones ( $n=150$  cuts total). Cut order sequence on the bones was randomized and labeled 1–150 prior to beginning, so that the second observer analyzing kerf floor shape did not know which of the five saws or which cut number per saw was being analyzed. Each kerf floor was then blindly analyzed using a digital microscope at 30x magnification. Real-time depth-up composition was used to generate a 3D model of each kerf. Next, the profile function was used to generate a standardized profile contour of each cut along the length of the entire cut. The profile shape was then visually classified by the observer as U-shaped or W-shaped. If any portion of the kerf midline was convex, the cut was classified as a W-shape.

Of the profile contours, 98% ( $n=147/150$ ) matched the expected shape based on tooth type: rip vs. crosscut. Two crosscut saw cuts and one rip saw cut were misidentified. In the case of one of the misidentified crosscut saw cuts, review of the file revealed that depth had not been calculated at the deepest location within the cut by the 3D function of the microscope; therefore an incorrect kerf floor contour was calculated. The other two misidentified cuts were true misidentifications. In all but one case, the entirety of the cut was U-shaped or wide V-shaped for the rip saws ( $n=89$ ). Contrary to expectations, the cuts made by crosscut saws varied along the length of the cut from W-shaped to concave, with the more narrow portions of the cut tending to exhibit the flatter or concave shape. This is likely contributed to blade drift of the alternate set saw. However, at least one portion of the cut exhibited a distinct W-shape for accurate identification. Often, one side of the W was uneven, with the peak extending deeper. This was more pronounced with the lower TPI saw. Profile shape for the 30<sup>th</sup> cut for each saw was compared to the first cut made with each saw. The last cut with each blade was as visible as the first cut for all five saws and, in fact, the misidentified cuts were actually mid-sequence: cut 17/Saw A and cut 10/Saw D. Overall, kerf floor contour can be used to accurately predict handsaw tooth type, and results from this validation correspond to those found by Symes et al.<sup>1</sup> In instances where cuts exhibit both W-shaped and U-shaped sections along the length of the cut, the saw should be classified as a crosscut saw.

### A118 Forensic Fractography of Bone Using Computed Tomography (CT) Scans

*Angi M. Christensen, PhD\*, FBI Laboratory, Quantico, VA 22135; Summer J. Decker, PhD, University of South Florida Department of Radiology, Morsani College of Medicine, Tampa, FL 33606*

---

**Learning Overview:** After attending this presentations, attendees will have learned how to apply principles of bone fractography to fracture surfaces reconstructed from CT scans. Attendees will have also gained a deeper understanding of how 3D models can contribute to skeletal trauma analysis, as well as certain limitations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing additional information on a methodology that can assist in the analysis of fractures from CT scans. As the use of CT expands worldwide, medical examiners (as well as clinicians) will have additional tools for analyzing skeletal fractures using virtual 3D methods in a non-invasive manner.

Fractography is the science of fracture surface morphology and its relationship to crack propagation. This well-established and validated science can be used to assess a material's mechanical properties and determine the underlying mechanisms leading to material failure. Recent studies and case reports have demonstrated the utility of fractography in forensic anthropology for understanding the directionality of impact/force application and fracture propagation on broken bones by assessing features of the fracture surface. Specifically, the presence and orientation of fracture surface features, including bone mirror, arrest ridges, bone hackle, wake features, and cantilever curl, can be used to reliably determine the point of fracture initiation and the direction of crack propagation. However, these previous studies utilized processed bone and directly examined the fracture surface features visually and microscopically. Removal of soft tissue from complete or mostly complete remains may be impractical in some cases, and assessments may be expedited if fracture surfaces could be assessed without maceration.

This study investigated whether the science of fractography can be applied to reconstructed CT scans. As a test of the method, a series of clinical scans of individuals with traumatic lower extremity injuries from patients that presented to a Level 1 Trauma hospital for assessment were obtained under Institutional Review Board (IRB) approval. The scans were performed using a Philips Brilliance 64 slice CT scanner under a standard trauma scan protocol. Relevant images included thin slice data sets of the lower extremities, acquired using bone and soft tissue algorithms. The fracture surfaces were visualized as 3D computational models in the volume rendering software package Mimics® Innovation Suite version 22 and 3-Matics version 14 Materialise. The 3D models were then exported as 3D .pdfs for fractography assessment.

Using this approach, some fractographic surface features were apparent, including bone mirror, arrest ridges, and cantilever curl, which are indicative of crack propagation direction and therefore the direction of impact. Due to resolution limitations, the amount of fracture surface detail visible in the CT scans is notably less than using direct observation of the bone surface, but diagnostic features of crack propagation were still apparent in some cases. As noted in previous bone fractography studies, features were less often identified when cortical area was smaller, and comminuted fractures also made surface visualization and feature identification more challenging. The selection of 3D modeling software may also affect results. When fracture surface features can be visualized and evaluated on CT scans, this may eliminate the need for skeletal processing, and perhaps even be applied in clinical as well as forensic contexts.

#### Fractography, Skeletal Trauma Analysis, Crack Propagation

## A119 The Application of Fractography in Trauma Analysis of Complex Long Bone Fractures

Mariyam I. Isa, MA\*, Michigan State University, East Lansing, MI 48824; Todd W. Fenton, PhD, Michigan State University, East Lansing, MI 48824; Lillian Antonelli, Michigan State University, East Lansing, MI 48823; Patrick E. Vaughan, MS, Michigan State University, East Lansing, MI 48824; Feng Wei, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will have learned about the utility of fractography in identifying point of failure and direction of crack propagation in complex long bone fractures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to a growing body of research on the application of fractography to skeletal trauma analysis. This current study contributes new data from concentrated four-point bending experiments in which fractographic features were compared directly to high-speed video of fracture propagation.

Fractography refers to the study of fracture surface features and the relationship of these features to crack propagation.<sup>1</sup> Fractographic methods have been applied to a variety of materials to interpret the causes of failure. Recently, Christensen et al. proposed a method for applying fractography to the analysis of skeletal trauma in forensic anthropology cases.<sup>2</sup> They described and investigated several fractographic features, including bone mirror, bone hackle, arrest ridges, and cantilever curl, in a sample of human femora that failed in three-point bending experiments. Using these features, they reported low inter- and intra-observer error identifying fracture initiation and estimating fracture propagation in cortical bone.

While these results are promising, there is a need to clarify the strengths and limitations of fractography in skeletal trauma analysis through additional research. In the previous study, each specimen under three-point bending exhibited only one primary fracture. This allowed for a relatively straightforward assessment of one of two complementary fracture surfaces. However, it is of interest to assess whether fractography can help resolve fracture initiation and propagation in more complex cases of skeletal trauma.

The current study investigates the use of fractography in a sample of femora fractured under another set of controlled loading conditions: concentrated four-point bending. Unlike three-point bending, specimens fractured under concentrated four-point bending exhibited complex, “compression wedge” fracture patterns involving multiple fragments.

The goals of this study were: (1) to assess the presence/absence of fractographic features in this sample; and (2) to assess whether these features could be used to interpret fracture propagation. The materials assessed in the current study include six whole, biomechanically fresh human femora failed in concentrated four-point bending experiments as a part of a previous replication study of the work of Martens et al.<sup>3,4</sup> All experiments were filmed with a high-speed camera at 40,000 frames per second (fps) in order to capture fracture initiation and propagation.

The fracture surfaces of each bone fragment were examined macroscopically using oblique lighting and a low power microscope. The presence or absence, anatomical locations, and orientations of four fractographic features were noted: bone mirror, bone hackle, arrest ridges, and cantilever curl. These features were used to interpret the location of initial failure and direction of crack propagation. Finally, fractographic interpretations were compared to the real sequence of fracture events captured on video.

Twenty-eight bone fragments were examined across the six specimens in the study (mean=4.66 fragments per impact). At least one fractographic feature was present on each of the 28 fragments. In each specimen, bone mirror occurred only in the area corresponding to initial failure near the tension surface. As fracture initiated from exactly one location in each experiment, only fragments with a fracture surface corresponding to that location exhibited bone mirror.

Arrest ridges and/or cantilever curl were present where fractures terminated. All six specimens exhibited multiple termination sites; these features were therefore observed in more fragments than bone mirror. Bone hackle was the feature most commonly observed across fragments, although it was subtler in appearance than bone mirror, arrest ridges, and cantilever curl.

In all six specimens, the fractographically inferred direction of fracture matched to the actual fracture propagation direction observed on high-speed video. These results indicate that the fractographic features described by Christensen and colleagues are informative of initial failure and crack propagation even in cases involving complex, compression wedge fractures.<sup>2</sup>

In forensic anthropology, trauma analysis is moving beyond simple descriptions and fracture typologies. Instead, investigators are generating more nuanced interpretations of sequential failure modes, from fracture initiation to fracture termination. Fractography demonstrates promise as one tool to aid in such interpretations. For cases involving complex fractures, reconstructing crack development provides an important foundation for subsequent interpretations, such as bending direction of a long bone in blunt force trauma.

### A120 The Repository of Antemortem Injury Response (REPAIR): An Invaluable Online Resource for Known Age Fractures for Comparison and Research

Carolyn V. Isaac, PhD\*, Michigan State University, East Lansing, MI 48824; Jered B. Cornelison, PhD, Western Michigan University School of Medicine, Kalamazoo, MI 49008; Joseph A. Prahlow, MD, Western Michigan University School of Medicine, Kalamazoo, MI 49007

**Learning Overview:** After attending this presentation, attendees will better understand the Fracture Healing Database, how to contribute samples to the database, and how the database can be accessed and used as a comparative tool in cases involving cranial fracture repair.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a tool for comparison and interpretation of cranial fractures as they relate to time since injury and the influence of age on healing variation.

The genesis of the cranial fracture healing project began as a persistent call for understanding and interpretation of cranial injuries within the context of accidental versus non-accidental trauma. As such, the goals of the project are to simultaneously create a method for human cranial fracture histology, build a database of cases with known injury times, conduct an evaluative intra- and inter-observer study to create a histomorphologic tool for evaluating cranial fracture healing, and provide an interpretive framework for inferring time since injury of cranial fractures.

Searchable and easy-to-use internet-based databases allow forensic practitioners to use and contribute data and conduct research to address specific needs in the medicolegal community. Therefore, a secure web-based data system was created for this project using Occupational Research and Assessment (ORA), since the company has experience with data management for medicolegal purposes. Varying levels of database access are granted dependent on the need of the particular user, including administrator, submitting agency, and forensic professional. Submitting agencies can enter their case information directly into the database, including relevant photographs, radiographs, and documents. Prior to these cases becoming visible to other submitting agencies or forensic professionals, administrators check the submitted data to ensure there is no personal health information or case numbers included prior to publishing.

The database is organized by case, with the accompanying demographic and injury information. Specifically, the data for each case includes information about the decedent's demographics, any medical conditions or medications that could affect bone healing, the injury circumstances, the injured cranial vault bone(s), the type of fracture (linear, depressed, comminuted, diastatic, or other), the time since fracture, surgical interventions related to the injury, when the surgical intervention occurred, and whether there was any insertion of hardware or other material. The database also includes data on each bone sample, including the specimen size, the decalcification agent (EDTA, nitric acid, hydrochloric acid), and the decalcification duration. Other accessible data includes: *in situ* radiography, contact radiography, postmortem examination photographs, and multiple photomicrographs of the four differently stained histologic slides (hematoxylin and eosin, Masson's trichrome, alcian blue hematoxylin/orange G, and Russell-Movat pentachrome). Likely, the most valuable tool in the database is the ability for users to access the photomicrographs that consist of an overall view of the sample, a detail of the fracture, and high magnification views (20X–40X) of the outer table, diploë, and inner table.

The database also provides a search tool for users who would like to find injuries with specific parameters (e.g., age of individual, time since injury, type of fracture). This feature can be used by forensic practitioners to find fractures of known age that may be similar to a case of interest.

Ultimately, this database and the attendant study will provide the tools necessary for understanding how cranial fractures heal in various age cohorts, aid in interpretation of cranial fracture healing rates, and provide a comparative database for investigators to estimate the age of a fracture for cases in which the injury time is unknown.

## A121 Variation in Human Rib Failure Mechanisms in Experimental Anterior-Posterior Loading

Angela L. Harden, MA\*, The Ohio State University, Columbus, OH 43210; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH 43210; Akshara Sreedhar, BS, The Ohio State University, Columbus, OH 43210; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH 43210

**Learning Overview:** After attending this presentation, attendees will have an appreciation for interdisciplinary research in skeletal trauma analysis, specifically in human ribs. Attendees will learn how to interpret failure mechanisms (i.e., tension vs. compression) in human ribs via strain data and high-speed video.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for interdisciplinary analyses of skeletal trauma in ribs. Increased understanding of how ribs fail in an anterior-posterior bending scenario will serve to improve skeletal trauma analyses in forensic anthropology.

Rib fractures are of significant clinical, forensic, and biomechanical interest, yet the biomechanics of rib fractures, specifically the mechanism of failure, is incompletely understood.<sup>1-5</sup> Rib fractures are associated with traumatic events, including accidents and homicides, and a more thorough understanding of the failure mechanism, through validated, experimental trauma research, could lead to increased accuracy in re-creating traumatic events and provide support for scientific testimony.<sup>6</sup> Bone is generally known to be weaker in tension than compression; however, previous studies have found that ribs failed more frequently in compression rather than in tension.<sup>5</sup> This study aims to determine whether the failure mechanism of human ribs, when loaded in precisely the same manner, is predictable.

Sixty-nine human ribs (14 female, 55 male) from 32 Postmortem Human Subjects (PMHS) (11–90 years old, mean=48.3 years) were loaded in an anterior-posterior bending scenario at a dynamic rate of 2m/s. Ribs were each instrumented with four uniaxial strain gauges from Vishay® Micro-Measurement along the longitudinal axis on the cutaneous and pleural surfaces at 30% and 60% of the rib's total curve length. Data directly collected and utilized in this research included: peak strain (microstrain) from strain gauges and time (millisecond). Each experimental test was recorded using a Phantom® VEO 710L high-speed video camera at a minimum of 8,000 frames per second (fps). For a comprehensive description of experimental test details and boundary conditions, see reference.<sup>7</sup>

Strain modes were as anticipated for such a bending scenario; all cutaneous gauges recorded tensile strain (+) and all pleural gauges recorded compressive strain (-). Strain data from the gauges closest to fracture location were used to identify the time of peak strain. Failure mechanism was then determined by quantifying the difference in timing of peak strain between the cutaneous and pleural gauges; whichever gauge reached peak strain earlier revealed the surface on which the bone initially failed and therefore the failure strain mode (tension or compression). Experimental test videos from each impact were viewed frame-by-frame to observe whether the failure initiated on the cutaneous or pleural surface of the bone. In cases where more than one failure occurred, only the initial failure was considered in this analysis. Video data were then compared to strain gauge data to determine whether the data collected from each method were consistent.

The strain gauge data revealed initial failure in tension ( $n=34$ ) occurring more frequently than in compression ( $n=29$ ); however, these data also found simultaneous failure in tension and compression ( $n=6$ ) that was not observed in the high-speed video data. From the corresponding high-speed videos, initial bone failure occurred more frequently in tension than compression ( $n=43$  and  $n=26$ , respectively). The consistency rate of the initial failure mechanism between the strain gauge data and high-speed video was only 47.8%, indicating that even video captured at 8,000–12,000fps may not be enough to elucidate failure strain mode (i.e., mechanism).

Overall, results indicate that a definitive statement regarding whether human ribs subjected to anterior-posterior bending always fail in tension or compression cannot be made. Bones, specifically ribs, are complex structures and likely do not respond to loading like other skeletal elements. Whether utilizing strain data or high-speed video data, ribs failed in either tension, compression, or simultaneously in tension and compression. Previous assumptions regarding the consistency of ribs failing in a specified strain mode may be unfounded. Additionally, results demonstrated that the method in which failure was evaluated affected the determination of failure mechanism. Interdisciplinary experimental research is imperative to further investigate failure mechanisms utilizing a hierarchical model (i.e., from the tissue level up to the individual level) in ribs and other skeletal elements.<sup>5</sup>

## A122 Rib Fractures: An Experimental Approach to Identifying Intrinsic Sources of Variability

Amanda M. Agnew, PhD\*, The Ohio State University, Columbus, OH 43210; Angela L. Harden, MA, The Ohio State University, Columbus, OH 43210; Akshara Sreedhar, BS, The Ohio State University, Columbus, OH 43210; John H. Bolte, PhD, The Ohio State University, Columbus, OH 43210; Yun-Seok Kang, PhD, The Ohio State University, Columbus, OH 43210

**Learning Overview:** After attending this presentation, attendees will have an appreciation for interdisciplinary research in skeletal trauma analysis, specifically in human ribs. Attendees will learn how to conduct experimentally driven biomechanical validation of skeletal trauma for forensic anthropology purposes, and understand the importance of utilizing experimental data to support or challenge current assumptions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for interdisciplinary biomechanical analyses of skeletal trauma in ribs. Increased understanding of intrinsic sources of variability in rib failure mechanisms will serve to improve skeletal trauma analyses in forensic anthropology.

Rib fractures occur frequently in motor vehicle crashes, accidents, and homicides and, therefore, are a high priority for skeletal trauma analysis in forensic anthropology.<sup>1,2</sup> Love and Symes provided strong justification for paying closer attention to rib fractures as they noted that on a large sample of adult ribs, the observable fractures did not necessarily follow predictable patterns.<sup>3</sup> Since these data were collected on forensic case studies, there is no way to know what the actual circumstances were that led to the fractures, and, therefore, details such as fracture mechanism as well as magnitude and direction of force cannot be substantiated. They challenge the forensic anthropology community to consider the influence of bone material and structure in interpreting its mechanical behavior. Others have also emphasized the critical role in understanding biomechanics in order to effectively assess skeletal trauma.<sup>4</sup> Some attempts have been made to induce human rib blunt force trauma in controlled settings, but these generally have included only small sample sizes that cannot satisfy *Daubert* criteria.<sup>5</sup> Nonetheless, more biomechanical experiments are critical to make advances in trauma analysis in forensic anthropology. Therefore, the goal of this study was to identify intrinsic sources of variability on rib response and fracture behavior. Additionally, common assumptions related to fracture outcomes were tested.

Dynamic (1–2m/s) experiments simulating a frontal blunt chest impact conducted in the laboratory on mid-level (5–7) human ribs from donors of all ages (4–108 years) and both sexes form the basis of this work ( $n=347$ ). By creating a repeatable and tightly controlled experiment, all variance observed in how the rib responds to applied loading can be attributed to intrinsic bone properties. Three hundred ninety-one fractures occurred. In general, the most crucial finding from this research was that rib response in a simplified bending scenario may not be predictable. A rib's resistance to loading (measured by peak transmitted force) varied significantly by sex (students *t*-test,  $p<0.005$ ), but was *not* successfully predicted by age (linear regression,  $R^2=7.3\%$ ). Wedge fracture types (23%) were *not* the most common as expected; instead simple fracture types (70%) occurred most frequently. Fracture type did have a significant relationship with age (Kruskal-Wallis,  $p<0.005$ ), but *not* peak transmitted force (Kruskal-Wallis,  $p>0.005$ ). Despite a consistent applied force among tests, the number of fractures that a rib sustained (a measure of injury severity) varied from zero (0.8%), one (81%), two (16.5%), or three (1.7%) and had no relationship with peak transmitted force (Kruskal-Wallis,  $p>0.005$ ). Cross-sectional geometric properties were most influential in determining the rib's resistance to loading. For example, cortical area explained 55% of the variance in force (linear regression,  $p<0.005$ ) and should be employed in interpretation of fractures by forensic anthropologists. This complex, hierarchical approach to finding mechanistic biological explanations for rib response to traumatic loading will be discussed in detail and will help to form a thorough understanding of why and how these injuries occur.

### Blunt Force Trauma, Injury Biomechanics, Rib Fracture

## A123 Histological Age Estimation of the Femur Using Random Forest Regression

Michael W. Kenyhercz, PhD\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96816; Christian Crowder, PhD, Southwestern Institute of Forensic Sciences, Dallas, TX 75207; Victoria M. Dominguez, PhD, Lehman College City University of New York, Bronx, NY 10468

**Learning Overview:** After attending this presentation, attendees will be re-introduced to the histological age estimation method developed by Crowder and Dominguez in 2012, and be introduced to the use of random forest regression to generate age estimates.<sup>1</sup> Additionally, an application to perform these regressions will be presented.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a more flexible statistical approach for histological age estimation than has been previously applied, resulting in a higher quality of forensic practice and reducing errors in histological analysis.

Estimating adult age is a challenging aspect of biological profile construction. Histological methods have been touted as a more accurate approach to adult age estimation because they are based on the continuous turnover of primary by secondary cortical bone and therefore follow a more predictable rate of change. However, research demonstrates that past methods succumb to the same issues affecting gross methods. In 2012, Crowder and Dominguez introduced a method that addressed issues such as subjective variable definitions, difficulty reproducing microscopic field sizes, spatial variation of histological structures, and the statistical significance of histological variables.<sup>1</sup> They employed stepwise linear regression to evaluate the following variables: osteon population density (intact and fragmentary), mean osteonal cross-sectional area, and mean anterior cortical width. Three separate regressions, one each for females, males, and a pooled model, were performed. The female model achieved the highest  $r^2$  at 0.682 (SEE=9.64 years); males had the lowest  $r^2$  at 0.510 (SEE=11.95 years); and the pooled model was in-between with an  $r^2$  of 0.587 (SEE=11.19 years). While this method minimized observer error through improved variable definitions and accounted for a large amount of spatial variation for histological features, it failed to improve a common limitation of adult age estimation—the use of linear regression analysis.

The current study will re-evaluate the variables from the Crowder and Dominguez study using random forest regression.<sup>1</sup> Random forest regression is a flexible, non-linear method utilizing decision trees and aggregated estimates. Essentially, a forest of decision trees, of a user-defined size (typically between 100 and 1,000), is constructed in which random variables are tested at each decision node and individual estimates of age are generated; the number of estimates is equal to the number of decision trees.

The sample includes 236 (120 males, 116 females) femur cross-sections of known-age individuals from three histological collections.<sup>2,3</sup> Histomorphometric data were collected using a transmitted light microscope and a firewire camera. The topographic sampling method was modeled after Iwaniec and colleagues and Stout and Paine.<sup>4,5</sup> Using a Merz counting reticule at 200x magnification (field area=0.2304mm<sup>2</sup>), the method evaluates alternating fields in ten columns from the periosteal to the endosteal cortex at the anterior femur midshaft. This sampling strategy is designed to capture the remodeling variability within the anterior cross-section. Osteon areas and cortical widths were calculated using imaging software.

The current study utilizes the Random Forest package in R to generate three models (female, male, pooled sex) using 800 decision trees. Each tree utilizes separate, bootstrapped training and testing sets to avoid overfitting and to reduce overall bias. Individual estimates are then aggregated by taking the mean of each estimate as the final predicted age. Each individual estimate is retained and can be directly modeled for a Prediction Interval (PI). Random forest regression models, unlike linear regressions, make no normality assumptions, and, as a consequence, PIs cannot be easily generated. Individual age estimates from the model are summarized using quantiles (2.5 and 97.5) to generate a 95% PI. The  $r^2$  values for the resulting models each exceeded those obtained via linear regression reported by Crowder and Dominguez: female=0.796 (MD=3.85 years), male=0.692 (MD=4.56 years), and general model=0.719 (MD=4.17 years).<sup>1</sup> Similar to the results of Crowder and Dominguez, the most important variable in each model is fragmentary osteon population, followed by intact osteon population, cortical thickness, and, lastly, osteon area.

Random forest regression offers a flexible alternative to traditional methods without suffering from the assumptions of linear models. Random forest regression improves estimates and model fits by all available metrics and can be easily implemented with the newly developed application named keRley. This research will benefit the forensic community by generating more accurate age estimates without violating any statistical assumptions.

## A124 Longitudinal Variation in Skeletal and Dental Development

Anna L.M. Rautman, MS\*, Department of Anthropology, Albuquerque, NM 87131-0001; Heather J.H. Edgar, PhD, Department of Anthropology, Albuquerque, NM 87131

**Learning Overview:** The goals of this presentation are to present attendees with a longitudinal comparison of skeletal and dental development, followed by an exploration of preliminary patterns in health, and their potential health implications.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to the awareness that variations in development may be useful in improving the understanding of health histories of the deceased. Further, this presentation will shed light on importance sources of error in juvenile age estimation, including normal variation in the rate of development.

Skeletal and dental development are well known as being useful for the age estimation of juveniles. Complexities in age estimation arise when estimates derived from these two sources of data are dissimilar. Current research on the correlation between the systems has focused on cross-sectional correlations of sample means. In contrast, this presentation will explore the skeletal and dental growth patterns of individuals who were delayed, average, or advanced in their skeletal or dental development at the age of 3 years.

Longitudinal skeletal and dental development was estimated from the radiographs of 150 White (European American) girls who were part the Bolton-Brush Growth Study. Individuals had hand-wrist and lateral cranial radiographs taken at ages 3, 6, 9, and 12 years. Developmental age estimates were calculated using Greulich and Pyle for carpal development, and the London Atlas for dental development.<sup>1,2</sup> The sample was divided into two sets (dental or skeletal) of three subgroups (delayed, average, or advanced) based on development at age 3 years. Repeated measure Analysis of Variance (ANOVA) and Tukey's Honest Significant Difference analyses examined the longitudinal growth patterns of: (1) skeletal development of skeletal subgroups, (2) dental development of skeletal subgroups, (3) dental development between dental subgroups, and (4) skeletal development of dental subgroups.

Information on the girls' health data had been collected by Bolton-Brush researchers via a questionnaire to parents at each visit. The questionnaire included ten specific common childhood diseases, as well as colds and diarrhea. A cumulative count of total illnesses was made for each individual. Mixed linear models were applied to the four models to investigate the significance of disease on development.

The four models demonstrated significant differences between the three subgroups. For models 1 and 3, the pairwise comparison between the subgroups found significant differences between the developmental trajectories. This was not true for models 2 and 4. For model 2, delayed versus average and average versus advanced were significant, while for model 4, only the average versus advanced comparison was significant. This has important implications for the forensic estimation of age, because it suggests a complication in the relationship between the systems that has not been adequately explored.

Individuals who were delayed dentally or skeletally were consistently those who were the sickest between the ages of 1 and 5 years old. However, mixed linear models failed to find any significant effect of illnesses on skeletal or dental development when the three subgroups (delayed, average, or advanced) were compared. Additionally, based on the consistent pairwise significance of the average versus advanced comparison, mixed linear models were applied to only the average and advanced subgroups. Again, no significant effects of illness on development were observed for any of the four models.

These results reflect differences in development of the skeletal and dental systems between those who were at average development at 3 years of age versus those who were advanced at 3 years of age. Although these analyses failed to identify statistically significant effects of health, the case of childhood illnesses affecting the growth patterns of developmental variation is far from closed. Additional approaches to analysis might include primarily focusing on earlier illness events rather than health throughout childhood and approaching variation retrospectively from age 12 rather than predictively from age 3.

### Health, Age Estimation, Growth Patterns

## A125 Subadult Age Estimation Using a Mixed Cumulative Probit and Its Application in KidStats

*Kyra E. Stull, PhD\**, University of Nevada, Reno, Reno, NV 89557; *Michael H. Price, PhD*, Santa Fe Institute, Santa Fe, NM 87501; *Louise K. Corron, PhD*, University of Nevada, Reno, Reno, NV 89557; *Elaine Y. Chu, MA*, University of Nevada, Reno, Reno, NV 89557

**Learning Overview:** After attending this presentation, attendees will be able to better estimate subadult age both methodologically, with the introduction of the mixed cumulative probit, and practically, with the introduction of a freely available graphical user interface, KidStats, and the R package, yada.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community as there is currently no method to build a multivariable, multi-indicator model using both continuous and ordinal data to estimate a continuous variable (i.e., age). Additionally, this presentation will introduce the virtual subadult anthropological database, which contains the largest number of de-identified computed tomography images of individuals ranging in age from birth to 20 years from around the world, housed at the University of Nevada, Reno, and available for research.

To date, positive identification of a subadult is largely dependent on age estimation. There has been a stagnation in the development and validation of age estimation methods, in part due to the lack of available subadult data in skeletal collections. In an effort to advance the forensic anthropological toolkit, as well as better understand growth and development of modern children, a virtual multiregional skeletal collection of approximately 2,500 subadults has been amassed and is housed at the University of Nevada, Reno. The North American sample comes from the University of New Mexico (UNM) Health Sciences Center, Office of the Medical Investigator (OMI) and the Office of the Chief Medical Examiner in Baltimore, MD. The worldwide samples come from Taiwan, France, the Netherlands, South Africa, Angola, Brazil, and Colombia. Supplementing skeletal collections with computed tomography images and full body X-rays has provided a unique opportunity to collect a large number of age indicators—diaphyseal dimensions, epiphyseal fusion, and dental formation—on these individuals to better understand the inherent variability of the age indicators and how it impacts age estimation.

A new algorithm, the mixed cumulative probit, was developed. It is an improved extension of the cumulative probit that handles both ordinal and continuous predictor variables to estimate a single continuous variable, deals with missing data, takes into account correlations among indicators, allows heteroscedasticity in component variables, and provides an estimate of age with 95% confidence intervals. The algorithm is available for forensic anthropologists through the user-friendly graphical user interface KidStats, and also as a separate R package, yada, so it can be employed by other researchers.

This presentation will demonstrate the performance of the mixed cumulative probit using 1,100 North American individuals aged between birth and 20 years, with different variable combinations. Cross-validation was built into model development and was applied to a hold-out sample, offering the most realistic assessment performance. The results indicate narrower confidence intervals than previously provided by any age estimation technique, ranging from 0.1 months to 5 years. The larger confidence intervals are not automatically linked to older individuals, but rather to individuals that had fewer variables input into the algorithm. Results demonstrate that combining all subadult indicators yields a more precise estimate. This study did not see any patterned bias in the age estimates, likely because the model is Bayesian in nature (and therefore has no regression to the mean effect) and because the parametric model used for inference is more flexible than previous models. Comparable performance in the training and test samples suggests there is no over- or under-fitting.

The freely available graphical user interface KidStats allows practitioners to employ this robust method in casework; it yields an age estimate given one of the predictor variables or up to the maximum number of 27 predictor variables. Additionally, the large number of individuals in model development enables the user to choose from a multitude of reference samples to use a global model, a population-specific model, or a model based on any combination of reference samples. If individuals are interested in using this algorithm to develop different estimation methods, it is also available in the yada R package.

The mixed cumulative probit will not only improve subadult age estimation but broaden methodological possibilities for adult age estimation as well. Furthermore, it has a number of applications both within and outside the field, such as paleodemography, economics, and human biology.

---

### Subadult, Age Estimation, Cumulative Probit

## A126 Conditional Independence and Appropriate Number of Stages in Juvenile Dental Age Estimation

Valerie Sgheiza, MA\*, University of Illinois at Urbana-Champaign, Urbana, IL 61801

**Learning Overview:** After attending this presentation, attendees will better understand the importance of testing for conditional independence, as well as how to determine the most appropriate number of stages in age estimation methods.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by challenging an assumption that impacts the correct precision of estimated age intervals.

Juvenile age estimation escapes many of the problems that plague adult age estimation by virtue of the fact that developmental characteristics are more highly correlated to chronological age than are degenerative characteristics. While juvenile age estimation is less prone to issues such as wide age intervals and age mimicry of reference samples, other important challenges are shared. The viability of the conditional independence assumption must be questioned in both juvenile and adult age estimation. This issue is even more pressing in juvenile age estimation where a much larger number of traits are often included in a single estimate.

Conditional independence means that two traits are independent of one another once the effect of chronological age on each trait is accounted for. This assumption allows for the straightforward construction of age intervals when multiple indicators are used. Unfortunately, further testing has revealed that the assumption does not hold for either adult or juvenile age indicators.<sup>1</sup> Assuming independence of related indicators will produce intervals that are too narrow. Furthermore, this raises the possibility of bias, since the number of indicators used may not be large enough to support the central limit theorem, especially when indicators are not independent. This project tests the hypothesis that the permanent dentition within a single quadrant are conditionally independent from one another in development given age.

The data consist of Moorrees, Fanning, and Hunt scores of the lower left quadrant of permanent dentition from panoramic radiographs of 738 female British children between 2 and 25 years of age.<sup>2</sup> Data were generously donated by Helen Liversidge. Ten percent of the sample ( $n=74$ ) was withheld from analysis for cross-validation. Every stage for each tooth was tested for outlying ages using a first derivative test. Lagrange multiplier goodness-of-fit tests were used to determine whether the data fit a cumulative probit model on a straight or log scale. For teeth that did not fit the model with fewer than 1% of the training sample removed as outliers, stages were systematically collapsed until a fit was found. Both staging systems were then tested for conditional independence using the mvord package in R.<sup>3</sup> The collapsed stage system was compared to the original staging system by estimating ages for the withheld portion of the sample via the corresponding cumulative probit models.

All but the third molar fit a log-scale cumulative probit model with outliers removed. For the third molar, stages 0-2 were collapsed, producing a 14-stage model. Variance-covariance matrices of the original and collapsed staging systems produced chi-square values of 763 and 1,296, respectively, when compared to the identity matrix using Bartlett's test. The  $r^2$  between known ages and estimated ages of the withheld sample was 0.9255 for the original staging system and 0.9267 for the collapsed staging system. Slopes were 0.9611 and 0.9595 respectively. When 95% probability regions were constructed for the withheld samples, the actual success rate of true ages falling within the estimated interval was 72.9% for both systems.

In conclusion, the collapsed staging system performed similarly to the original system in accuracy and precision of estimates as well as conditional independence of teeth. This indicates that it is possible to optimize dental staging systems so that only meaningful transitions are recorded. Low success rates indicate that the conditional independence assumption is not supported in either case. Failure of this assumption produces age intervals that are too narrow.

### Juvenile Age Estimation, Dental Development, Conditional Independence

## A127 Dental Morphology as a Key to Understanding the Population History of Latinos

Rebecca L. George, MA\*, University of Nevada, Reno, Reno, NV 89506

**Learning Overview:** After attending this presentation, attendees will better understand the utility of dental morphology in exploring the ancestry of modern Latinos through their population history.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how dental morphology can augment information provided by genetic, cranial, and historical studies, especially as they pertain to groups with diverse population histories resulting in clinal variation, such as Latinos.

The modern Latino population has been established over the past 500 years through genetic drift and gene flow events resulting from European colonization of the New World. Existing variation among Native American, European, and African populations that are parental to Latinos has created a mosaic of genotypic and phenotypic variation that is only beginning to be understood within a forensic anthropological context. As Latinos are among the fastest growing populations within the United States, it is critical that every available tool be utilized to explore their variation so ancestry estimations can continue to improve for existing populations within this country.<sup>1</sup> Genetic studies of Latino populations within the United States show that they generally fall into either a dihybrid or trihybrid pattern of ancestral influence, with levels of parental ancestry varying regionally.<sup>2-5</sup> Regional trends within the United States and Mexico are well-known and have been supported with cranial studies.<sup>6-9</sup> Dental morphology studies exploring this variation, however, are rare, despite moderate to high levels of heritability associated with tooth shape.<sup>10-13</sup> This study examines dental morphology from pre- and post-contact, as well as forensically significant populations, to gain insight into how microevolutionary forces have affected the modern Latino population. The primary goals of this preliminary investigation are: (1) to explore the variation within Native American populations, historic European/American, African/American, and Latino populations, and (2) to see how these populations may have contributed to a modern Latino population.

Samples within this study include: Native American data from Mexico City from the Escuela Nacional de Antropología e Historia (ENAH) and samples from the Christy G. Turner II Database (with permission and access granted by Dr. G. Richard Scott), and a New Mexico sample from the Phoebe A. Hearst Museum of Anthropology; historic European and West African data from the Turner II Database; historic Latino sample from ENAH; historic European American and African American data from the Robert J. Terry Collection; modern European American data from the Texas State University Donated Skeletal Collection and the Documented Skeletal Collection at the Maxwell Museum at the University of New Mexico; and a modern Latino sample from Mexico City at the Universidad Nacional Autónoma de México (UNAM). Morphological data from the Turner II Database were collected according to the published Arizona State University Dental Anthropology System (ASUDAS) standards and data collected for this study were gathered according to the new ASUDAS standards.<sup>14-15</sup> Previously conducted intra-observer error tests found trait agreement at levels of 0.621 or above.<sup>16</sup> Pearson's chi-squares were applied to raw scores for 27 dental morphological traits, with all but two differing significantly ( $p < 0.05$ ) among the samples. The remaining traits were subjected to a Kendall's tau to examine inter-trait correlations; traits with correlation values of 0.4 or higher or those with an uncertain key tooth were removed from future analyses. Additionally, Pearson's chi-squares were conducted to check for sex-correlated traits within the samples. The remaining 19 traits were dichotomized for Mean Measure of Divergence (MMD) and Fuzzy C-Means (FCM) analyses. MMD results show some significant variation among the Native American samples, the historic samples all differ significantly from one another, and the modern Latino sample differs significantly from most samples, except for the New Mexico Native American sample and the historic Latino sample. The FCM analysis shows much overlap among the samples, with only the Texas State sample not falling in the largest cluster with all other samples.

These exploratory results demonstrate there is overlap among the samples through time and space, though some notable differences are present among the modern and pre-contact samples that warrant further analyses. Dental morphology for Latinos, however, does align with genetic and cranial data showing expected influences based on population history with Native American, European, and African ancestries. The continuation of this project will include additional samples and classificatory statistics for application within a forensic setting.

### ASUDAS, Ancestry, Latino

## A128 Cranial Feminization Surgery Methods and Osteological Identification of Post-Operative Individuals

Laura E. Cirillo, MA\*, University of Nevada, Reno, Reno, NV 89557; Jordan C. Deschamps-Braly, MD, Deschamps-Braly Clinic, San Francisco, CA 94108; Kyra E. Stull, PhD, University of Nevada, Reno, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, Reno, NV 89557-0096

**Learning Overview:** After attending this presentation, attendees will understand skeletal alterations that manifest as part of cranial feminization surgery.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing details about cranial feminization surgery in general, and the resulting skeletal and soft tissue modifications specifically. Further, this presentation outlines the alterations that can be expected on the skull of post-operative individuals with variable healing (i.e., bone remodeling and modeling).

The number of transgender individuals in the United States has been estimated between 0.6%, or 1.4 million people, (through the Williams Institute in 2016) and 3% of the population, or 7 million people (by GLAAD in 2017). This group experiences high rates of violence, with 165 trans people murdered in the United States between 2008 and 2016.<sup>1</sup> Therefore, there is a growing need for the forensic community to be able to recognize the signs of cranial feminization surgery to facilitate a positive identification. Considering best practices for sex estimation in forensic anthropology specify observations of the pelvis and cranium, it is especially important for forensic anthropologists, and other individuals involved in constructing a biological profile, to be aware of the signs of surgical cranial feminization.

This presentation begins with a review of craniofacial surgical feminization techniques first developed in the 1980s. An examination is then provided of pre- and post-operative radiographs and Computed Tomography (CT) scans of 18 patients that underwent male-to-female cranial cosmetic surgery. Post-operative radiographs and CT images ranged in generation from 5 to 20 months following surgery. Four anatomical areas are identified on the skull that contribute to the accurate identification of post-operative individuals: (1) reduction of the glabella, (2) shortening of the nasal bones, (3) vertical reduction of the chin, and (4) alteration to the gonial angle (i.e., lateral flaring of the mandible).

In all patients, surgical alteration was made to these four anatomical areas of the skull to varying degrees. In 86% of cases, reduction of the glabella is achieved via osteotomy, in which the glabella is repositioned and the anterior wall of the frontal sinus reconstructed.<sup>2</sup> Most individuals in the sample (94%; 16/17) had at least a small area of anterior wall of the frontal grafted with steel wire. Nasal bone reduction was achieved through removal of the inferior nasal bone below a transverse incision and cartilage augmentation. Reduction of the chin height was achieved via osteotomy and fixation of a reduced mental eminence with titanium hardware in 94% (16/17) of the sample. Mandible alteration typically consisted of burring the outer cortical bone of the most lateral portions of the mandibular body. In 53% of the sample, the reduction resulted in exposure of the trabecular bone.

While the post-operative images range between 5 and 20 months and all patients have functionally healed, no images show complete remodeling of the bone. Patients of cranial feminization surgery continue to show ridges, or “bone scars,” on the frontal bone and mandible even after the bone is inactive. Because the remodeling process may never obliterate evidence of the skeletal procedures, the modifications could provide evidence to facilitate positive identification long after the surgeries were performed.

In addition to skeletal alterations, changes to the soft tissue were documented. These include feminization of the hairline, upper lip augmentation, and reduction of the thyroid cartilage. None of these surgeries were visible on the skeleton and would not necessarily aid in the identification of greatly decomposed individuals.

As these surgeries are increasingly practiced in the modern population, it is imperative that the forensic field can identify and appreciate signs of gender confirmation surgery in skeletal remains.

### A129 A Classification System of Thermal Damage to Human Remains

*Elayne J. Pope, PhD\*, Knoxville, TN 37917-3452; Alison Galloway, PhD\*, University of California, Santa Cruz, CA 95064; Chelsey A. Juarez, PhD\*, California State University, Fresno, Department of Anthropology, Fresno, CA 93740*

**Learning Overview:** This goal of this presentation is to provide a comprehensive and easily interpretable classification system for the degree of thermal damage to human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how a comprehensive classification system will facilitate discussion between researchers and practitioners and provide a realistic assessment of the types and scale of damage seen. Descriptions about the level of damage and the most critical observations that should be made on a fire victim are addressed.

Classification of thermal damage to human remains is lacking the specificity that comes with witnessing multiple fire-related experiments over a wide range of settings. Currently available classifications are relatively gross and are derived from burn situations where calcination and fragmentation were the norm. This presentation outlines a classification based on 12 years of experience with the San Luis Obispo Fire Investigation Strike Team's Forensic Fire Death Investigation Course (FFDIC). The system is based on changes to: (1) soft tissue; (2) exposure of body components (fat, skeletal muscle, internal organs, bone); (3) changes in body position; and (4) skeletal damage from discoloration to calcination.

The classification system utilizes the normal progression of changes to the human body as both fire temperature and duration increase. The ten stages are developed from "minimal burning" to "calcination and fragmentation." Assignment can be made by whole body and by body segment. The classification chart includes lateral images of a body along with descriptions of soft tissue, body position, and skeletal changes.

In this initial study, inter-observer error is assessed between two people with extensive FFDIC experience and between the FFDIC people and a practicing Forensic Anthropologist (FA) who is familiar with burn cases but without as extensive fire progression experience. Twenty-four cases were selected from the FFDIC records from 2010 through 2014. All photographs of the body were placed in a blind sample file. These were assessed by each person separately. FFDIC inter-observer agreement was 75% for exact match and 100% within one stage. Between the FFDIC people and the FA person, 60% of cases were classified as an exact match and 83% within one stage. Difficulties arose in assessing images in which not all the body was visible or where differential burning was significant.

Variation in degree of heat-related changes is due to a number of factors. Bodies often do not exhibit full pugilistic changes due to the surrounding or overlying materials or differential heating. In such circumstances, the arms are most often affected, where muscle mass may be less. Proximity to the major heat source is also different within structural fires. Those areas further from the center of the fire may be less affected than the areas of the body where temperatures are more extreme. Body build is another factor, with thicker muscle and fat layers protecting internal organs and bones. Finally, it is critical that assessment be made either at the scene or from photographs taken at the scene due to the major changes brought about by transportation. Regardless of the factors, a common and comprehensive classification system that abides by the normal progression of changes due to fire is an asset.

#### Fire, Thermal Damage, Classification

## A130 Quantitative Ancient and Forensic DNA Techniques for Maximum DNA Recovery From Thermally Altered Bones and Teeth

*Matthew V. Emery, PhD\**, Arizona State University, Tempe, AZ 85287; *Katelyn L. Bolhofner, PhD*, Arizona State University, Glendale, AZ 85306; *Stevie Winingear, MA*, Arizona State University, Tempe, AZ 85287; *Robert F. Oldt, BS*, Arizona State University, Tempe, AZ 85287; *Sreetharan Kanthaswamy, PhD*, Arizona State University, Glendale, AZ 85306; *Jane E. Buikstra, PhD*, Arizona State University, Tempe, AZ 85287-2402; *Laura C. Fulginiti, PhD*, Forensic Science Center, Phoenix, AZ 85007; *Anne Stone, PhD*, School of Human Evolution & Social Change, Tempe, AZ 85287-2402

**Learning Overview:** The objective of this presentation is to convey the success of obtaining highly degraded DNA from thermally altered skeletal material. Here, the goal is to educate the attendees on the implications of applying ancient DNA methods to traditional forensic cases, and the possibility of reconstructing partial Combined DNA Index System (CODIS) Short Tandem Repeat (STR) profiles using mini-STR multiplexes, as well as reconstruct whole mitochondrial genomes using Next Generation Sequencing (NGS) technologies and bioinformatics pipelines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering the best DNA methods used to test the quality and quantity of DNA in highly burned skeletal remains.

The recovery and analysis of DNA from burned human remains represent some of the most challenging cases in medicolegal investigations. The rapid degeneration of DNA often impedes the ability of forensic examiners to obtain adequate DNA profiles for subsequent genotyping and identification. In this study, the goals were to assess the utility of two different extraction methods used by forensic and ancient DNA researchers to obtain degraded DNA, as well as to establish the effects of heat-induced color change and type/location of element sampled on DNA quality and quantity.

Over a period of two years, this study obtained and documented 62 samples from 26 fire death and cremation cases in collaboration with the Maricopa County Office of the Medical Examiner. Samples were chosen with the goal of obtaining different skeletal tissues showing different levels of burning (levels I–V). After processing the bone to powder, each sample was divided for extraction using either the ancient DNA protocol or the forensic protocol. The total nuclear DNA concentration of these extracts was qualified with an Applied Biosystems® Real-Time Polymerase Chain Reaction (RT-PCR) using the Quantifiler® Trio DNA Quantification Kit, and STR detection was performed using the PowerPlex® ESX 17 Fast Systems STR kit by Promega®. In addition, sample extracts were also converted into double-stranded DNA libraries and enriched for mitochondrial DNA and nuclear Single Nucleotide Polymorphisms (SNPs) for next-generation sequencing.

The results show that average DNA yields recovered from fire-related victims show a progressive decrease in DNA concentration across burn categories I–V. Both extraction protocols work equally well for burn categories I–III; however, highly incinerated remains (categories IV–V) produced better CODIS STR results using the ancient DNA protocol. Overall, the data confirm the difficulties in obtaining DNA from burnt skeletal material using conventional RT-PCR and STR genotyping technologies. Confounding limitations inherent in both ancient and forensic DNA research, such as small sample sizes, intra- and inter-sampling differences in material input, low DNA yields paired with high degrees of DNA degradation, continue to restrict the amount of genetic information gleaned from the most challenging forensic cases. All these factors were recognized in this study. However, integration and adoption of optimized ancient DNA protocols, such as the Dabney DNA extraction protocol, in forensic case analyses may improve the success rate of acquiring adequate STR profiles to identify fire victims in circumstances in which traditional applications have failed.

### Forensic DNA, Ancient DNA, NGS Analysis

### **A131 Assessing DNA Quality and Quantity From Cadaveric Blood Stored on Untreated Blood Cards: The Impact on Short Tandem Repeat (STR) Quality and the Utility of Variably Amplified Markers for the Individual Estimation of Trihybrid Ancestry and Admixture Proportions**

*Frankie L. West, PhD\**, Cullowhee, NC 28723; *Bridget F.B. Algee-Hewitt, PhD*, Stanford University, Stanford, CA 94305

---

**Learning Overview:** After attending this presentation, attendees will have a better understanding of storage options for cadaveric blood samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing detailed information on the quality of DNA provided by storage on blood cards of cadaveric blood samples for STR typing.

Blood cards are widely used for long-term body fluid (e.g., blood, saliva, etc.) storage for DNA analysis. They are especially useful for DNA sample collection at forensic anthropology research centers, given their straightforward handling and sampling protocols, stability in ambient temperatures, small storage footprint, and minimal financial investment. However, little is known about the long-term value of blood cards in forensic anthropological research and forensic genetic casework. This study explores the quantity and quality of DNA extracted from postmortem blood samples, in terms of DNA preservation and STR typing success. Collected as part of a body donation program workflow, these blood samples were taken upon donor intake and stored on FITZCO<sup>®</sup> untreated (non-FTA<sup>®</sup>) blood cards. The study evaluates these cards in terms of DNA preservation and typing success and tests the effect of age of the blood card versus their success in amplification of STRs. As the gold standard in forensic genetics, STRs are used for forensic identification and as potential markers for global ancestry and admixture estimation. Degraded samples, including those stored on blood cards, can result in reduced STR markers sets and, in turn, compromised analyses. This study assesses these blood cards, therefore, with special consideration given to profile matching for positive identification and ancestry estimation for biological profile estimation.

In this study, the degree of DNA degradation is quantified in terms of both the amount and fragment sizes of the individual templates, testing for disagreement in genetically determined and reported sex, and evaluation of the forensic genetic typing potential of the DNA by evaluating Combined DNA Index System (CODIS) profiles generated for each case using evidence of allelic drop/in out, degradation curves, and relative fluorescent units as assessment criteria for 20 blood card samples. This study analyzes the impact of the DNA template on ancestry and admixture estimation, offering insights into the impact of degradation on population identifiability.

While STR profiles were successfully generated for most samples, the results indicate length of storage and time interval between date of death and sample collection have an impact on DNA quantity and quality of DNA, in terms of typing success. There is a statistically significant decrease in Relative Fluorescent Unit (RFU) values with increasing time interval between date of death and collection, indicating degradation in the blood card samples related to the postmortem interval prior to sample collection. The STR profiles generated were used to estimate ancestry and admixture using the software program STRUCTURE, demonstrating utility of the markers beyond individual identification purposes.

---

### A132 Postmortem Submersion Interval (PMSI) Estimation From the Microbiome of Bone in a Freshwater River

Claire M. Cartozzo, MS\*, Richmond, VA 23220; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Jenise Swall, PhD, Virginia Commonwealth University, Richmond, VA 23284; Tal Simmons, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will understand how changes in microbial communities across Accumulated Degree Days (ADD) can be used to predict the long-term PMSI for skeletal remains recovered from a freshwater river.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing proof of concept concerning a novel area of research, the use of microbial succession on skeletal remains submerged in a freshwater river to predict PMSI.

For victims who die in and/or are recovered from water, PMSI estimation has been limited to instances when invertebrates have been found on remains or when the victim was last seen alive, making it applicable in cases of known accidental water deaths only, rather than deposition of homicide and unidentified/unknown victims in water. Since the 2014 National Institute of Justice (NIJ) Forensic Science Technology Working Group highlighted the use of metagenomics to aid investigative leads and the advancement in technologies (i.e., next generation sequencing and bioinformatic pipelines), researchers have explored the use of microorganisms to predict time since death on land and in water, respectively Postmortem Interval (PMI) and PMSI.<sup>1-3</sup> These studies have demonstrated that microorganism colonization of remains occurs in a successional manner, taxa increase over the range of decomposition, and both can be used to predict PMSI. Unfortunately, these studies were conducted over short periods of time, with small sample sizes and repeated disturbance, which are knowledge gaps addressed in this study.

From November 2017 to November 2018, fresh pig (*Sus scrofa*) bones ( $N=125$  rib and  $N=125$  scapula) were submerged in cages that were attached by a rope to the wharf at the Virginia Commonwealth University (VCU) Rice Rivers Center, located on the James River in Charles City, VA. Water quality parameters were continuously and remotely logged using a permanently deployed sonde. Every 250 ADD, calculated using a 0°C threshold, five ribs, five scapulae, and 500mL of water were collected, photographed, and stored at -80°C or 4°C until processed. Water samples were filtered using a cellulose membrane filtration system; bone samples were pulverized using liquid nitrogen in a mortar and pestle. Both filters and bone powder underwent DNA extraction via ChargeSwitch® gDNA Plant Kit. If necessary, samples were purified with the Dneasy® PowerClean Pro Cleanup Kit. Library preparation followed the Kozich et al. protocol.<sup>4</sup> Specifically, 16S recombinant DNA (rDNA) variable region 4 sequencing-by-synthesis was performed on the Illumina® MiSeq® FGx2X. The resulting data was analyzed and visualized using the MiSeq® mothur SOP, mothur version 1.35.9, and R studio.<sup>5</sup>

Preliminary analyses indicated significant differences in bacterial communities among sample types (i.e., rib-scapula-water-mud). For bone types, differences across Accumulated Degree Days (ADD) were present at the phylum-level. Operational Taxonomic Units (OUT) -based beta-diversity (Bray-Curtis) suggested significant differences in ordinated space between ADD for both scapula and rib samples. Meanwhile, alpha-diversity (Shannon) indices demonstrated a curvilinear relationship with ADD. Overall, these results suggest that patterns in bacterial succession can be used to develop a PMSI estimation model.

## A133 The Influence of Water Current on the Rate and Pattern of Decomposition

Natalie Mirosch\*, Keele University, Keele, Staffordshire ST5 5BG, UNITED KINGDOM; Vivienne G. Heaton, PhD, Keele University, Keele, Staffordshire ST5 5BG, UNITED KINGDOM; Jamie K. Pringle, PhD, Keele University, Keele, Staffordshire ST4 6DA, UNITED KINGDOM; Kristopher D. Wisniewski, PhD, Keele University, Stoke-on-Trent, Staffordshire ST5 5BG, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will have an awareness and understanding of how lentic (still) and lotic (moving) water environments affect the rate and pattern of decomposition observed in submerged remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the accuracy of Postmortem Interval (PMI) estimations and furthering current knowledge of how a cadaver moves through the water column, which will prove useful for search and recovery teams in missing persons cases.

Worldwide, there are on average 360,000 water-related deaths recorded each year, making drowning the third-leading cause of death by “unintentional injury.”<sup>1</sup> However, experts believe this figure to be greatly underestimated, as the number of fatalities resulting from natural disasters and the ongoing migrant crisis in the Mediterranean are significantly underreported. Despite these statistics, there is a lack of controlled research investigating the environmental variables that impact the rate and pattern of decomposition in water. The goal of this research was to determine whether water current or turbulent flow influences the pattern and/or rate of decomposition observed in carrion submerged in water.

The duration of the experiment was 79 days in the summer of 2018 and involved the placement of six pigs (*Sus scrofa*), of 30kg average weight, into individual tanks containing 2,000 liters of fresh water. In three of the tanks, two water circulators were placed at opposing sides. This created a current, or turbulent flow, which simulated a lotic (moving) water environment. The three remaining tanks were left to stand still and represent a lentic (still) water environment. Three times a week for the duration of the experiment, decomposition was scored using the Heaton et al. method<sup>2</sup> and both normal and infrared (using a Fluke tiR125 camera) photographs of each pig were taken.<sup>2</sup> In addition, insect activity and the position of each cadaver in the water column were noted. Ambient temperature was recorded hourly by two data loggers onsite; water temperatures were recorded hourly by a data logger in each individual tank. Temperature data were also collected from a local weather station for comparison.

Statistical analyses showed there were no significant differences in the rate of decomposition when comparing the pig carcasses in the lentic water environments with those in the lotic water environments ( $p \leq 0.32$ ). This supports the conclusions made by Heaton et al that decomposition of human remains does not differ significantly among aquatic environments in the United Kingdom.<sup>2</sup> All six cadavers showed similar patterns of decay, although pigs in the lotic water appeared to disarticulate and sink somewhat faster. Water temperatures were significantly warmer than those recorded by both ambient loggers ( $p \leq 0.001$ ) and the weather station ( $p < 0.001$ ) by an average of 3.18°C. This highlights the importance of using the water temperature, rather than ambient when estimating PMI.

When initially placed in water, two of the pigs remained floating while four were immediately submerged. By day 6 (105 ADD), all of the submerged pigs had bloated sufficiently enough to resurface. Knowledge regarding the timing of resurfacing events has implications for search and recovery methods, allowing search personnel to determine where a victim is likely to be positioned in the water column so they can plan accordingly. Floating cadavers were heavily colonized by maggot masses between days 12 (219 ADD) and 25 (474 ADD), which generated enough heat to produce a discernible thermal signature, peaking at 55.6°C on day 24 (454 ADD). These results suggest there is a window of time where thermal imaging could potentially be used as a tool to locate a missing person believed to be in water. By day 30 (590 ADD), all cadavers had begun to sink, which would indicate more appropriate search techniques, such as divers or geophysical methods, would be best utilized.

### Taphonomy, Freshwater Decomposition, Thermal Imaging

### **A134 Macroscopic Analysis and Scanning Electron Microscopy (SEM) of Immature Permanent Molars Immersed in Hydrochloric Acid (HCL, 38%)**

*Christine Jones, PhD\*, Texas A&M University—Central Texas, Killeen, TX 76549; Tammy Bracewell, PhD\*, Texas A&M University—Central Texas, Killeen, TX 76549*

**Learning Overview:** After attending this presentation, attendees will understand the importance of expanding current studies of acid disposal to include immature, incompletely developed permanent teeth. Immature permanent third molars are typical to adolescents or young adults over the age of 15 years, thus studies contributing to current literature regarding acid disposal of dental tissues from this age group are relevant to the forensic sciences.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community in terms of competence by contributing to the comparative body of knowledge regarding immature dental tissues where acid was used in the means of disposing human remains.

In this study, morphological differences in a sample of immature permanent molars before and after immersion in HCL, 38% were evaluated macroscopically and using SEM with the goal of contributing to the body of literature regarding identification of dental tissues partially or nearly completely destroyed using acid. Four intact and non-carious immature, or incompletely developed, permanent third molars were selected as the sample for this study. The teeth used in this study have roots that are not completely formed, where the inferior portion of the root can be characterized by an open apex. The walls of the root are also much thinner than completely developed permanent molars. Incompletely developed permanent third molars are typical of adolescents or young adults over the age of 15 years. The teeth comprising this sample were extracted during the course of normal orthodontic practice and made available for educational purposes. The teeth were sterilized within a week of extraction using an autoclave (121°C, 15lbs psi). Standard odontometric measurements, weight, photographs, and imaging using a Nanoimages SNE-3200M mobile SEM were taken for each tooth before and after immersion in a commercially available formulation of HCL, 38% within brief (1–8 hours), moderate (8–16 hours), and extended (over 16 hours) time intervals. After treatment, the teeth were dried, remeasured, and reimaged using the mobile SEM.

The results of the macroscopic analysis show the sample teeth exposed to acid for a brief duration exhibited transparency in color, gelatinous texture, minor changes in morphology of the crown, such as sharpening of the cusps, reduction in amount of enamel visibly present, and reduction in size of the tooth as measured using standard dental measurements and weight in grams. These changes intensify at the moderate and extended time intervals and are presented with SEM imaging. Microscopic morphological differences in the dental tissues are highlighted.

A dearth of literature exists describing the effects of acid on teeth using SEM imaging. This is especially true concerning adolescent teeth. However, the existing literature does establish acid immersion as a method of body disposal. When suspected human remains are found in acid, limited information is available to assist investigators in determining whether human remains are, in fact, present. Because teeth are the strongest part of the human body, they are more likely than other human substances to be found in a solid state. Teeth represent the most likely human tissue to aid in an investigation where acid is used as a means of body disposal. This research provides academics and practitioners new information regarding time estimates for human remains in acid as well as the ability to identify when HCL was used in the event the acid was strained.

## A135 A Paired Comparison of the Rate and Pattern of Decomposition in Small- and Large-Bodied Human Cadavers

Gretchen R. Dabbs, PhD\*, Southern Illinois University, Carbondale, IL 62901; Christiane I. Baigent, MSc, Southern Illinois University, Carbondale, Carbondale, IL 62901

**Learning Overview:** After attending this presentation, attendees will have learned that differences in body mass of human cadavers can affect the gross morphoscopic observations of the decomposition process.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the first closely paired body weight study using human cadavers to examine the difference in the rate and pattern of decomposition between small- and large-bodied individuals.

Several previous studies have examined the effect of body mass on the rate and pattern of decomposition using both human cadavers and animal proxy samples.<sup>1-9</sup> The results have proven to be inconsistent and categorically diverse. Summarily, inter-cadaver decomposition rate studies categorically suggest: (1) larger individuals decompose faster; (2) there is no difference in the rate or pattern of decomposition between individuals of different sizes; (3) the inter-individual progression of decomposition varies depending on the stage of decomposition observed; or (4) some smaller individuals decompose faster than larger individuals.<sup>1-12</sup> Studies that empirically test body mass as an important variable in human decomposition have largely been conducted using human analogs. Only two of these studies have used human cadavers and considered the longitudinal postmortem intervals that characterize forensic anthropology casework.<sup>1,7</sup> However, these studies diverge in their conclusions. Mann and colleagues suggest larger individuals decompose faster than smaller individuals as a result of the rapid liquefaction of body fats, while Roberts and colleagues demonstrated no correlation of body mass to Kelvin Accumulated Degree Days (ADD) at any observation threshold representing early, middle, and late stage decomposition, although minor differences in the pattern of decomposition were noted.<sup>1,7</sup> In both of these previous studies, individuals were observed independently of the larger project, and data were collated retrospectively.

This study focuses on the paired observation of two individuals at the Complex for Forensic Anthropology Research (CFAR) at Southern Illinois University in Carbondale, IL. The two individuals observed died on the same day (May 17, 2019), were close in age at death (67/68 years old), and were refrigerated in funeral home coolers for the same length of time (seven days) at the same temperature (37°F). They were placed at CFAR on the same day, within 15 minutes of one another. The larger individual is an adult male, 188cm (6'2") in height, weighing 125kg (275lbs), with an estimated Body Mass Index (BMI) of 35.5 at the time of death. The smaller individual is an adult female, 150cm (4'11") in height, weighing 44kg (97lbs), with an estimated BMI of 19.6. Both weights were confirmed by the funeral home contracted to deliver the cadaver. Decomposition was categorically scored using the Megyesi et al. Total Body Score (TBS) system; macroscopic observations not represented in the TBS model were also described.<sup>13</sup> Digital photographs were collected every third day, unless inclement weather interfered with camera use. The decomposition of the two individuals rapidly diverged, with the larger individual advancing more rapidly through the initial stages of decomposition, including color change, bloat, and soft tissue loss throughout the first 23 days post-deposition, suggesting gross decomposition was more rapid. After 23 days of exposure (more than 517 ADD), the advancement of TBS slowed and the two individuals scored nearly identically ( $\leq 1$  TBS point difference) for the next 44 days (until July 29, 2019). Further data will be collected over the course of the next six months. However, in sum, this paired-individual study suggests that larger individuals initially decompose faster than smaller individuals, but as decomposition advances, the differences are marginal. This study also demonstrates the differences in the pattern of decomposition between larger and smaller individuals, which is consistent with previously reported results from varying sources.

### A136 The Differential Rate of Human Decomposition in an Enclosed Vehicle Compared to an Outdoor Environment

West West, BS, Applied Anatomical Research Center, Huntsville, TX 77341; Hannah Cervenka, BS, Sam Houston State University, Huntsville, TX 77341; Haeli Kennedy\*, Sam Houston State University, Huntsville, TX 77341; Joan A. Bytheway, PhD, Sam Houston State University, Huntsville, TX 77341

**Learning Overview:** After attending this presentation, attendees will understand the difference in the postmortem interval between human cadavers decomposing inside a vehicle and control cadavers in similar body positions but located outdoors. Attendees will learn about the factors contributing to the faster rate of decomposition in the control cadavers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting new postmortem interval data, including factors that affected the rate of decomposition between the two environments and the differences in gross appearance throughout the decomposition process.

There is controversy within the literature regarding different rates of decomposition and whether decomposition occurs faster or slower in indoor or outdoor environments. Voss' study, using pig carcasses, showed that carcasses inside a vehicle decomposed faster than the outdoor carcasses due to environmental factors, including higher temperatures in the vehicle.<sup>1</sup> Because decomposition varies between humans and animals, the present study explored if this would be true for human cadavers. This study compared the decomposition rate of two cadavers in a closed vehicle, with two control cadavers in an outdoor surface environment. The cadavers in the vehicle were placed with one in a sitting position in the driver's seat, and one in a loosely flexed position in the trunk. Two control cadavers were placed in similar body positions outdoors. Photos were taken daily until the advanced decomposition stage was reached, then taken weekly thereafter. Physical descriptors for southeast Texas, developed by Bytheway et al. were used to estimate the stage of decomposition for each cadaver.<sup>2</sup> Results showed that the control cadavers (CAD 3 and 4) went through the fresh and early stages of decomposition faster than the experimental cadavers (CAD 1 and 2). CAD 1 was in the driver's seat of the car and CAD 3 was in an upright position in a chair outdoors. For the Fresh stage of decomposition, CAD 3 progressed one day faster than CAD 1. CAD 3 also decomposed faster in the Early stage of decomposition by three days. A similar trend was observed with the trunk control (CAD 4) decomposing faster in the Fresh stage by 1.5 days compared to CAD 2. In the Early stage, CAD 4 decomposed approximately 2.75 days faster than CAD 2. The experimental cadavers remained in the Advanced stage of decomposition for the remainder of the study (365+ days). The control cadavers took approximately 152 days to reach skeletonization.

### Forensic Taphonomy, Human Decomposition, Vehicle

## A137 Location, Location, Location: Environmental Variation and Human Decomposition in Knoxville, Tennessee

William D. Cawley, MA\*, University of Tennessee, Knoxville, TN 37920-2605; Derek A. Boyd, MA, University of Tennessee, Anthropology, Knoxville, TN 37996

**Learning Overview:** After attending this presentation, attendees will better understand how environmental variation affects human decomposition at the University of Tennessee Anthropological Research Facility (ARF) in Knoxville, TN.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating a potential confound affecting research within a single microclimate that involves the estimation of the Postmortem Interval (PMI) using human subjects. Attendees will increase competency in understanding how environmental variation affects the rate of decomposition and increase performance by assisting future research designs of human decomposition studies.

The estimation of the PMI *vis-à-vis* gross evaluation of human decomposition is an essential aspect of medicolegal death investigation. Anthropological research often assumes individuals within the same microclimate will display similar rates of decomposition.<sup>1</sup> Underlying past studies is the assumption that minor variations in location within these microclimates have a negligible effect on the rate of human decomposition and that only large-scale climatic differences affect the estimation of the PMI. The ARF is a major center of human decomposition research and has produced studies involving the determination of PMI using gross human decomposition since the 1980s. Expansions to the ARF, now encompassing an area of approximately three acres, have facilitated projects that incorporate PMI estimation using multiple donors located throughout the property. The ARF land consists of multiple zones that vary by soil type, drainage, elevation, ground foliage, tree density, and use rates, making it a valuable study facility for environmental variation in human decomposition.

Image data from the Daily Photo Collection curated by the Forensic Anthropology Center (FAC) that were collected between 2011 and 2019 were analyzed to determine differences in the rate of human decomposition at the ARF. Using Geographic Information System (GIS) data maintained by the FAC, the ARF was divided into four regions using natural and artificial features of the property that affect watershed and elevation. Photographs of donors ( $n=8$  donors, approximately 24 photos per donor) located in each region were examined to retrospectively assign Total Body Scores (TBS) for the date of placement, on day 5, and on day 15.<sup>2</sup> TBS data were recorded for donors placed in these regions according to season of the placement date (total  $n=128$ , 8 donors scored per region per season) and evaluated using a Bayesian hierarchical linear model in R to characterize variation in decomposition rates between regions and across seasons.<sup>3</sup> A preliminary model using a sub-sample of donors ( $n=24$ ) from across three sectors of the ARF (B, E, and G), areas originally allocated by the FAC for daily operations, were scored at day 15 after surface placement in the late summer (July–August). Results show that the modal parameter values describing the affect of region on TBS score probabilistically differs between regions ( $\beta_B=-1.49$  [95%CrI:-4.97-1.88];  $\beta_E=2.04$  [95%CrI:-2.96-6.89];  $\beta_G=2.44$  [95%CrI: -2.18-7.27]), suggesting the existence of spatially variable environmental differences in the rate of decomposition within the ARF. Macroscopic differences regarding sun exposure proportion, foliage density, and ground-level vegetation are also explored, given the similarity and differences of these factors between areas.

This proof-of-concept study highlights the need for careful selection of areas for donor placements within microclimates (specifically outdoor research facilities) when designing research involving PMI or gross human decomposition. More broadly, the results of this study point toward the existence of environmental heterogeneity in the extrinsic and intrinsic factors long known to affect rates of decomposition.

### A138 A Preliminary Decomposition Study Within the Willamette Valley (WV) of Oregon: Multi-Method Comparison and Sharp Force Trauma Effects

Cheyenne Collins\*, Chico, CA 959264118; Jeanne McLaughlin, PhD, University of Oregon, Eugene, OR 97403-1224; Frances J. White, PhD, University of Oregon, Anthropology, Eugene, OR 97405-1218

**Learning Overview:** After attending this presentation, attendees will understand: (1) how decomposition rates within the WV compare to previous research conducted in the region; (2) how Anderson's and VanLaerhoven's stages of decomposition model compares to Megyesi et al.'s Total Body Scoring (TBS) system in Oregon; and (3) how the increase in the number of open wounds (sharp force trauma) influences decomposition rates within the study environment.<sup>1,2</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing the data available on decomposition, taphonomic variables, and Postmortem Interval (PMI) estimation in an understudied region.

Determining time since death (the PMI) is an essential part of medicolegal death investigations. PMI can give investigators important information about time of death and may help answer questions about the events leading up to death.<sup>3</sup> The purpose of this study was to collect decompositional data from an understudied region (Oregon) and compare multiple scoring methods that are current standards developed in regions such as Tennessee in order to characterize the effects of regional variation on decomposition and taphonomy. Six pig heads were placed on the ground surface in a fenced enclosure and exposed to the natural winter environment of the WV of Oregon for 60 days. Three of these pig heads underwent Sharp Force Trauma (SFT) infliction in order to compare rate of decay with remains that have a singular SFT wound. Stage of decomposition, temperature, precipitation, and preliminary entomological data were collected throughout the 60-day observation period. These data were used to compare Anderson's and VanLaerhoven's stages of decomposition model to Megyesi et al.'s TBS system in the WV; compare and contrast similar studies from different seasons within the WV; and analyze the effects of an increase in the number of open wounds (SFT) on decomposition rates and insect activity.<sup>1,2</sup>

This study found that decomposition in the WV during the cold/wet season (winter) did not closely align with either Anderson and VanLaerhoven or Megyesi et al.<sup>1,2</sup> Analyses of statistical, qualitative, and inter-observer error suggest that neither scoring method is a perfect fit for the WV. Winter decay was found to occur at a slower pace when compared to summer decay and was overall more variable. Partial mummification and rehydration of the remains were observed multiple times during this study. An increase in the number of SFT wounds did not influence the rate of decay. Sub-environmental differences were found to have an effect on decomposition rate, and a considerable amount of small animal and avian scavenging of the remains occurred throughout the study. Scavenging influenced the rate of decay through loss of mass that propelled decomposition forward.

## A139 Evaluating the Application of Multiple Postmortem Interval (PMI) Estimation Methods in Louisiana

Sophia I. Reck, MA\*, Baton Rouge, LA 70806

**Learning Overview:** After attending this presentation, attendees will better understand various methods used to estimate the PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how evaluating the viability of the PMI estimation formulae as they are applied in Louisiana will benefit future PMI estimations in that region.

Forensic anthropologists are often called upon to provide an estimate of the period of time from death until discovery of human remains (i.e., the PMI). PMI estimates are often based on the condition of remains upon discovery (i.e., the observed stage of decomposition); however, since many factors affect the pattern and progression of taphonomic processes, interpretation of the PMI can prove to be difficult. Various formulae have been developed that allow quantitative assessment of PMI; two examples of such formulae are the Total Body Score (TBS) method and the Universal Post-Mortem Interval Formula.<sup>1,2</sup> The process of each method entails associating the stage of decomposition of an individual with a numerical score. For the TBS method, a body was separated into three regions (head and neck, torso, and limbs) that are scored individually, then summed before being entered into an equation.<sup>1</sup> The Universal Post-Mortem Interval Formula requires a numerical decomposition score for the entire body, which is also entered into an equation.<sup>2</sup> Ultimately, an output of PMI in days can be obtained from each formula. Theoretically, formulae of this type would provide methods of PMI estimation that were both standardized and statistically sound.

The goal of the present study was to evaluate the application of these two methods in Louisiana. Both formulae were applied on past casework spanning the years 2006 to 2017 from the Louisiana State University Forensic Anthropology and Computer Enhancement Services (LSU FACES) Laboratory. These analyses were performed in concert with the assessment of qualitative PMI estimation in past casework from Louisiana. Using cases with known PMIs, it was determined how frequently an actual PMI fell within the range of the provided estimate range. Both the quantitative and qualitative methods were evaluated in order to determine the best approach to estimating PMI in Louisiana in the future. Only individuals with both known PMIs and available photographs were considered for the study, and the resulting sample size was  $n=79$ . When testing each formula, cases were excluded based on the requirements of each method. Ultimately, the sample sizes were  $n=49$  for the TBS method and  $n=16$  for the Universal Post-Mortem Interval Formula.<sup>1,2</sup> The formulae had varying degrees of success based on the strength of the correlations. When applying the Universal Post-Mortem Interval Formula, statistically significant results were not observed using Spearman's rho ( $p=0.384$  [ $p<0.1214$ ;  $\alpha=0.05$ ]).<sup>2</sup> However, the TBS method produced a strong correlation ( $p=0.7529$  [ $p<0.001$ ;  $\alpha=0.05$ ]) when retrospectively applied to the casework.<sup>1</sup> When considering the qualitative PMI estimation methods applied at the LSU FACES Lab, the actual PMIs of 69/79 individuals (87%) fell within the range of the PMI estimate provided by the anthropologists. While the TBS method may have the potential for future use in forensic casework, qualitative PMI assessment has also been successful in Louisiana.<sup>1</sup>

## A140 Utilizing Metabolomics Toward Time-Dependent Metabolite Monitoring in Different Postmortem Specimens During Human Decomposition

Katharina M. Höland, MS\*, Knoxville, TN 37919; Shawn R. Campagna, PhD, University of Tennessee, Knoxville, TN 37996-1600; Dawnie W. Steadman, PhD, University of Tennessee, Department of Anthropology, Knoxville, TN 37996; Jennifer M. DeBruyn, PhD, University of Tennessee, Knoxville, TN 37996; Hayden McKee, MSc, Knoxville, TN 37917; Allison R. Mason, BS, University of Tennessee, Knoxville, TN, TN 37996-1937; Amanda May, PhD, University of Tennessee, Knoxville, TN 37996; Thomas Delgado, Knoxville, TN 37918; Sarah Schwing, BA, BS, Knoxville, TN 37996

**Learning Overview:** After attending this presentation, attendees will have a better understanding of how metabolomics of postmortem specimens provide additional knowledge in comparing and contrasting human decomposition processes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing novel aspects of postmortem metabolomics addressing intra- and inter-human metabolic differences in maggots, decomposition fluid, and soil in proximity to human donors across the early and late stages of decomposition.

The ultimate goal of this ongoing study is to reveal drug impacts on human decomposition and the Postmortem Interval (PMI). This presentation examines how metabolomic analyses provide insights into the highly dynamic postmortem biochemical environment. As small-molecule intermediates of human metabolism, metabolites have a multitude of functions, not only in the living human body, but also after death; however, the complexity of factors affecting human decomposition opens up a large, mostly still-unknown area yielding continuous new questions about postmortem metabolic patterns, including molecular signatures or biomarker discovery.

This research is conducted on human donors, obtained through the Body Donation Program of the Forensic Anthropology Center (FAC), in different microenvironments around the three-acre outdoor laboratory known as the Anthropology Research Facility (ARF) in Knoxville, TN. Samples of soil, maggots, and body fluid were obtained and analyzed for metabolites. Soil (10g) obtained from within the Cadaver Decomposition Island (CDI) from ten enrolled donors and control soil (10g), located at least 1m from the donor, were homogenized, flash frozen, and stored in liquid nitrogen until subsequent metabolomic profiling. Decomposition fluid from the body was collected at various anatomical positions around the body. Hourly records of temperature and relative humidity allowed for the calculation of Accumulated Degree Hours (ADH), a metric that combines temperature and time, to determine specific sampling points for soil and decomposition fluid. Maggots were collected at each instar as well as while migrating from the body. Termination of sampling occurred after the body completed active decay as determined by cessation of secretion of body fluid from the trunk.

Metabolites were extracted from 70mg–80mg soil, 30–50mg maggots, and 70–80mg decomposition fluid using a procedure adapted from Lu et al.<sup>1</sup> Analyses were performed by Ultra High-Performance Liquid Chromatography-High-Resolution Mass Spectrometry (UHPLC-HRMS) operating in negative Electrospray Ionization (ESI) with a 2.5 micron reverse-phase Hydro-RP 100, 100mm x 2.00mm Phenomenex® Liquid Chromatography (LC) column. The Exactive™ Plus Orbitrap™ Mass Spectrometer was run in full scan mode with a scan window from 80–1,200m/z.<sup>1</sup> A flow rate of 0.2mL/min was maintained throughout the analysis. On average, 90–120 identified and 1,000s of unidentified metabolites were manually selected based on mass accuracy ( $\pm$  5ppm mass tolerance) and retention times ( $\leq$  2min) using an in-house generated metabolite database.

Donor-, location-, and time-related differences in metabolite signatures were statistically evaluated via Partial Least Squares Discriminant Analyses (PLSDA). Initial results indicate that not only does every cadaver show a unique metabolic signature, but also that each CDI soil is metabolically different from the control soil. Each donor had an individual, time-dependent metabolome based on every sampled ADH throughout the monitored decomposition period. Analyzed maggots and decomposition fluid samples show similar donor- and time-dependent trends, whereas body location seems to impact metabolic patterns.

The current results provide an initial impression of the complexity of the temporal metabolic changes occurring after death in different matrices. Ongoing analyses focus on the identification of possible biochemical biomarkers for decomposition. It is anticipated that with further progression of this study and future toxicological analyses, this study will be able to relate postmortem metabolite signatures to certain peri-mortem drug treatments and answer questions concerning drug-induced decomposition alterations.

## A141 Bacterial Community Succession: Postmortem Interval (PMI) Estimation of Forensic Anthropological Remains

Randi M. Depp, MS\*, University of Akron, Akron, OH 44325; Luis L. Cabo, MS, Mercyhurst University, Erie, PA 16546; Michael Foulk, PhD, Mercyhurst University, Erie, PA 16546

**Learning Overview:** After attending this presentation, attendees will understand the need for uniform data collection and sampling protocols regarding the postmortem microbiome for forensic anthropological cases, the composition of the postmortem microbiome of these cases, and whether the genera *Bacteroides*, *Lactobacillus*, and *Bifidobacterium* are useful groups for estimating PMI.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing standard protocols and best-practice guidelines for data collection and sampling the postmortem microbiome and demonstrating how these protocols can improve future research endeavors and collaboration. In addition, this presentation will identify potential trends of bacterial community composition in sample groups not previously studied.

Decomposing remains are an evolving ecosystem experiencing ecological succession as biological species colonize the remains and modify the biochemical characteristics and resources available. Relative abundance and composition of bacterial communities respond to these environmental shifts, resulting in a succession pattern that has been found to correlate temporally with decomposition. Once refined, these patterns may be useful predictors for the PMI. There is a relative paucity of studies, however, that utilize data from actual forensic cases involving human remains. In addition, existing datasets are based on disparate sample groups, taxonomic levels, and sampling locations. In this study, human remains and the corresponding substrates were sampled from two forensic cases from the Mercyhurst University Forensic Scene Recovery Team (M-FSRT) and one forensic case from the Erie County Coroner's Office. The PMIs ranged from 24 hours to more than five years.

Feasible sampling protocols and best-practice guidelines were outlined for studying bacterial community succession on forensic human remains, both at outdoor scene recoveries and in laboratory settings, for future research endeavors. Two locations on the human remains were dry swabbed: around the oral cavity and around the anus. The corresponding underlying skeletal element was swabbed if no soft tissue was present. For laboratory settings, the substrate sampled was the laboratory table. For outdoor scenes, the soil was considered the substrate and sampled in two locations: at 0m (under the center of the remains) and 5m from that center. Four samples were taken for each sample type and location.

Aerobic culture methods were utilized in order to identify a target group for quantitative Polymerase Chain Reaction (qPCR) analysis. The families Lactobacillaceae, Neisseriaceae, and Enterobacteriaceae were cultured from all human remains. Streptococcaceae were only cultured from human remains with a PMI less than 24 hours. Except for Neisseriaceae, the presence of these bacterial families is consistent with significant groups reported in existing literature. *Lactobacillus* was isolated from all cases and was selected for further analysis. Anaerobic genera *Bacteroides* and *Bifidobacterium* were selected based on reports in existing literature.

Primers identified by Hauther et al. were then used to quantify the three aforementioned genera via real-time qPCR.<sup>1</sup> Bacterial DNA was extracted using the Powersoil<sup>®</sup> DNA Isolation Kit. The concentration of DNA isolated from each sample was determined by Qubit<sup>®</sup> fluorometric quantification. The sample quadruplet with the highest concentration from each sample was chosen for qPCR. DNA samples were diluted to 1:10 or 1:100 based on performance in preliminary testing of the primers. Differences in presence and relative abundances of all three target genera between sample locations and PMI were observed. Due to the limitations of the sample group, any patterns or observations should not be extrapolated.

### A142 The Effects of Scavenging on a Donor From the Western Carolina University Forensic Osteology Research Station (FOREST)

Christine Bailey, MA\*, Western Carolina University, Cullowhee, NC 28723

**Learning Overview:** After attending this presentation, attendees will better understand scavenging patterns at the Western Carolina University FOREST.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that scavenging of soft tissues can impact the rate of human decomposition, as well as the position/location of the remains.

This project presents a case study that complements the mounting research relating to the effects of scavenging on human decomposition. It is pertinent for medicolegal investigators to understand their local scavenger guilds as well as recognize the patterns and results of scavenging. Scavenging affects the ability to accurately estimate the postmortem interval as well as determine peri-mortem trauma from postmortem damage. This study also supports the need for further longitudinal studies relating to geographically specific scavengers.

The purpose of this project was to see if scavenging activity impacts the estimated Accumulated Degree Days (ADD), which is used by anthropologists to estimate the postmortem interval. The method developed by Megyesi and colleagues was used to produce an estimated ADD, which was then compared to the actual ADD.<sup>1</sup> A motion-activated game camera recorded the scavenging activity affecting a 67-year-old female donor over a ten-day period during the summer of 2019. The donor died of natural causes and presented no trauma at the time of placement. The cameras recorded the dates, times, and temperatures during scavenging events.

Over the ten-day period, the game camera was activated ~5,340 times by four different local scavengers: American crows (*Corvus brachyrhynchos*), black vultures (*Coragyps atratus*), turkey vultures (*Cathartes aura*), and North American opossums (*Didelphis virginiana*). The game photos were stitched together into a time-lapse video and reviewed to observe any trends in scavenging activity, as well as the overall impact that the activity had on the remains.

Initial scavenging by American crows occurred within two hours of donor placement. Early on, a pattern of scavenging was consistent over the observation period, with crows and vultures scavenging during the day and opossums at night. By the second day, the cranium and sections of the limbs showed signs of partial skeletonization. This resulted in a high estimated ADD ( $737.9 \pm 388.16$ ) when compared to the actual ADD (36.41), demonstrating the influence that scavenging had on the decomposition process of this individual. Not only were scavengers removing soft tissue directly from the skeletal remains, they were creating openings in the soft tissues that allowed for greater insect access and activity. By the end of ten days, the donor was mostly skeletonized and had been rotated (~45 degrees) and moved approximately one meter from its original location. Again, the estimated ADD ( $4,073.8 \pm 388.16$ ) was much higher than the actual ADD (187). None of this scavenging activity left any evidence on the skeletal remains.

Overall, two important findings were clearly documented in this footage, that: (1) scavenging increased the rate of decomposition, and (2) scavengers altered the placement of the body from its original depositional orientation and location. This project demonstrates the necessity of long-term studies documenting the effects of scavenging on human decomposition as well as revised ADD methods that account for scavenging activity.

## A143 Coyote Pup Scavenging as Distinct From Adult Behavior: The Potential for Reproductive Patterns to Inform the Estimation of Postmortem Interval

Christiane I. Baigent, MSc\*, Southern Illinois University Carbondale, Carbondale, IL 62901; David E. Kintz, Jr., BS\*, Park County Coroners Office, Fairplay, CO 80440; Melissa A. Connor, PhD, Colorado Mesa University, Grand Junction, CO 81501-3122; Gretchen R. Dabbs, PhD, Southern Illinois University, Carbondale, IL 62901

**Learning Overview:** After attending this presentation, attendees will understand juvenile coyote scavengers as behaviorally distinct from adults.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing novel insight into variation in intraspecies behavior and its potential impact on the forensic analysis of human remains.

Coyote (*Canis latrans*) scavenging has received considerable attention in taphonomy and ecology research.<sup>1-3</sup> Scavenging coyotes disrupt outdoor death scenes by consuming and scattering human remains, interfering with search and recovery missions, and reducing the probative potential of osteological analysis and the estimation of Postmortem Interval (PMI). Absent from current coyote scavenger data is consideration of the behavior and pattern of juvenile coyote pup scavenging. Juvenile coyotes present differences in dentition, bite force, body size, musculature, and experience. These variables have the potential to impact the rate, pattern, and presentation of scavenging and impact subsequent analyses of human remains.

The impact of coyote pup scavenging was investigated at Colorado Mesa University's Forensic Investigation Research Station high-altitude satellite facility (FIRS-TB40). FIRS-TB40 is located in the Rocky Mountain Region of Colorado at 9,500 feet Above Mean Sea Level (AMSL). The environment is characterized by steep slopes, alpine forests, open moraine grasslands, dramatic weather shifts, high precipitation, high Ultraviolet (UV) exposure, and heavy annual snowfall. Distinct environments foster distinct adaptive radiations that are expected to have a polyvalent impact on behavior, including scavenging. Baigent et al. described the succession and progression of scavenger guilds among a porcine cohort placed at FIRS-TB40 in the summer of 2018.<sup>4</sup> This study demonstrated cooperative and competitive behavior between canid and avian groups and suggested that adult coyote scavenging at high-altitude diverged appreciably from published norms. A higher resolution model of coyote scavenging is reported with an emphasis placed on juvenile coyotes as progenitors of distinct intragroup scavenger behavior. Four pigs (two exposed/two caged) were placed in the summer of 2018 in a longitudinal transect across a 45° slope, each 30 meters apart. Each sample was monitored by a game camera programmed to collect both time lapse photographs and respond to motion in the environment. Carrion were visited three times weekly for a period of eight weeks, photographed, and decomposition documented using the total body score model.<sup>5</sup> At the terminus of active decomposition, carrion were visited biweekly for six-months, photographed, and game camera data collected and analyzed.

Adult coyotes were the primary agents of tissue removal throughout early decomposition. Adult scavenging was characterized by independent, short interval "eat and retreat" behavior, the movement of osseous tissue upslope, and exclusively nocturnal. Adults made no attempt to disrupt the caged carrion or the centrally located exposed carrion. Juvenile coyotes appeared six-weeks postmortem (consistent with seasonal patterns of gestation and weaning), scavenged nightly across a 45-day window, and diverged from adult behavior significantly. Divergence is categorized as: (1) novel behavior (juveniles were cathemeral and worked individually, or in packs of two to four individuals); (2) tenacity (juveniles were observed digging under and burrowing through cage panels); (3) longer feeding periods (juveniles were observed in scavenging phases that averaged five hours in length); and (4) exploitation of novel resources (juveniles exploited carrion previously ignored by adults). Additionally, unlike adults, juveniles were not dissuaded by desiccated tissue; tissue removal was characterized by longitudinal peeling and did not include skeletal involvement. Juveniles were intermittently observed scavenging under the supervision of one to two adults. Adults did not feed during these phases, suggesting that scavenging presents the opportunity for intergenerational training and that juvenile feeding is prioritized.

Juvenile scavenger patterns are critical to understanding intraspecies variation in behavior that may impact scavenger drive, and the presentation and analysis of postmortem defects. Because coyote reproductive cycles are consistent and predictable, the identification of juvenile scavenging has the potential to be temporally co-related and inform the estimation of PMI. Future study will focus on higher resolution descriptive models of the tissue change associated with juvenile scavenging, as well as impact on patterns of skeletal dispersal in the post-deposition environment.

### High Altitude, Coyote Scavenging, Human Decomposition

## A144 The Patterns of Striped Skunk Scavenging on Human Remains

Alexander J. Smith, BA\*, Colorado Mesa University, Grand Junction, CO 81501; Melissa A. Connor, PhD, Colorado Mesa University, Grand Junction, CO 81501-3122

**Learning Overview:** After attending this presentation, attendees will better understand the patterns of striped skunk scavenging on human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing examples of striped skunk scavenging to assist in distinguishing postmortem scavenging from peri-mortem trauma that may be associated with cause of death.

Striped skunks (*Mephitis mephitis*) are common throughout most of North America. They are nocturnal and generally solitary, often living in burrows created by other animals. Striped skunks are omnivores, predominately subsisting on small vertebrates, insects, eggs, and plant material.<sup>1</sup> Scavenging is a part of their regular diet. However, cases of skunks scavenging human remains are rarely documented. Existing documentation provides a limited description of observed scavenging.

Seven cases of striped skunk scavenging were observed at the Forensic Investigation Research Station (FIRS) in Whitewater, CO, between November 2017 and June 2019. At the FIRS, human remains are laid outside to study decomposition. The outdoor facility is fenced to allow access to small scavengers while excluding larger scavengers. The scavengers observed include skunks, feral cats, mice, and birds. When a body shows evidence of scavenging, donors are documented daily and monitored with game cameras.

Skunk scavenging usually started before the onset of moist decomposition and continued well into moist decomposition. In one case, scavenging continued into mummification. Scavenging was done at night. The duration of scavenging was 29–105 nights with active scavenging 12–48 of those nights. In two cases, the donor was only scavenged once. Skunks did not show preference for any specific donor beyond state of decomposition. Scavenging often occurred on multiple donors on the same night.

Six of the cases occurred in the winter. Skunks were present for all but 12 nights in November and December 2018. Over the two years covered in this study, five of seven donors placed October–December were scavenged by skunks (two in 2017, three in 2018). In cases in which skunks scavenged bodies more than once, the scavenging duration was longer in winter than in spring.

Initial stages of skunk scavenging were often marked by bone exposure in the limbs, primarily the arms, followed by the legs. While bone was exposed in five of the seven cases, only one of those cases showed macroscopic damage to the bone. In this case, the distal radius and ulna were broken, likely in the process of removing the hand. This was the only evidence of disarticulation in any of the skunk scavenging cases. In three cases, skunks preferentially consumed subdermal tissue. Game camera images show a skunk holding the skin back with its paw as it consumed the underlying tissue. This pattern of tissue consumption gave a hollow appearance to the impacted tissue.

In one case, irregular defects, puncture marks, and parallel linear striae were present peripheral to the scavenged areas. This appeared to be related to efforts by the skunk to reposition the limb or climb on top of the donor while scavenging. Skunks were seen climbing on top of the donor in nearly every case, but this single case was the only case where the activity impacted tissue.

Patterns of skunk scavenging thus far appear to be distinct from patterns observed in two cases of feral cat (*Felis catus*) scavenging at the FIRS.<sup>2</sup> Notable differences between the two scavengers are the timing of bone exposure, the type of differential tissue consumption, the prevalence and nature of peripheral defects, and seasonality. Both species preferentially scavenged the limbs and generally avoided involvement of bones. While there is there are only a small number of documented cases for each of these species, noting the impact of these scavengers will expand current understanding of local scavenger communities.

Defects caused by scavengers can be confused with or conceal the impact of peri-mortem trauma. Recognizing and understanding the patterns of scavengers will assist investigators in determining source and timing of tissue damage.

### Skunk Scavenging, Taphonomy, Postmortem Scavenging

## A145 Instars and Stripes: The Scavenging Behavior and Taphonomic Contribution of the Striped Skunk

Rachel E. Smith, BS\*, Marquette, MI 49855; Jane Wankmiller, PhD, Northern Michigan University, Marquette, MI 49855

**Learning Overview:** After attending this presentation, attendees will understand scavenging activities of the American striped skunk (*Mephitis mephitis*) as they relate to human taphonomy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting observations of the scavenging activities of the striped skunk, which may affect trauma and entomological analyses associated with medicolegal investigations.

Scavenging frequently plays a role in the taphonomy of human remains in outdoor contexts. Certain scavengers are known to scatter remains, while others affect a case simply by consuming tissues, which can affect the decomposition sequence and potentially the determination of the postmortem interval. Understanding the type and behavior of scavengers is thus a crucial part of analyzing remains found outdoors.

The research in this presentation was conducted at the Northern Michigan University Forensic Research Outdoor Station (FROST) in Marquette, MI. Common scavengers and carrion feeders of this area include coyotes, bears, gray and red foxes, eagles, gulls, and turkey vultures, though only red foxes and skunks have been observed during data collection activities at FROST. To prevent large scavengers and carrion birds from harming or removing the donor remains at FROST, each body is protected by a large metal mesh cage.

FROST is unique in its location as a forensic research facility, experiencing long, often extremely cold, winters with substantial snow accumulation and several freeze-thaw cycles in a given year. This climatic characteristic markedly affects the decomposition process, but may also affect the scavenging behavior of animals in the area. To better understand the scavenger activity as well as non-scavengers (e.g., songbirds, rodents, deer, etc.), FROST researchers set up trail cameras near recently placed donor remains. The cameras are checked for functionality, and the images are downloaded on a regular basis. The cameras are currently programmed to capture four-image bursts each time they detect motion, 24 hours per day. On several occasions, scavenger activity was noticed on donor remains prior to camera placement, resulting in the setup of a camera in a location that may not have been of interest initially.

Based on previous sightings of foxes and other small mammals in and around the site, many of the animals captured on the trail cameras were unremarkable (e.g., foxes, rabbits, squirrels, and birds), and none have been observed penetrating the cages and scavenging the donor remains. The striped skunk, however, was somewhat surprising, as it represents the overwhelming majority of documented scavenger activity at the site and has repeatedly managed to get inside the protective cages. The skunk appears to be the only recently active scavenger, and trail camera photos demonstrate the consumption of both human tissue and maggot masses when a skunk is present.

Through analysis of the trail camera images and daily observations of the donor remains, FROST researchers have noted two distinct feeding times, as a skunk is often recorded in the late evening and then again in the very early morning, with generally less activity in-between. Skunks also appear to have a preference for scavenging the tissue of the limbs and face, similar to documented observations of raccoons, although there is footage of one skunk consuming tissue from the abdomen of a donor.<sup>1,2</sup> Scavenging of maggot masses is most commonly evidenced by clean-scraped dirt in areas where maggot masses have been observed, indicating that the skunks have scraped up and consumed the maggots. For several months, FROST was frequented by what appeared to be a single skunk, but since mid-July of 2019, four new skunks have been documented. These additional skunks are smaller than the original, suggesting a sharing of knowledge regarding a reliable food source from parent to offspring.

While skunks are known to be carrion feeders and have been observed by researchers during previous taphonomy studies, this is the first instance, per research, of skunks not only representing the primary mammalian scavengers at a site, but also apparently displaying behavior indicating a transfer of knowledge of the human tissue as a food source.<sup>3-5</sup> These observations contribute to the understanding of the ways in which the scavenging activities of the American striped skunk affect human taphonomy.

### Scavenging, Forensic Taphonomy, Skunk

### A146 Out of the Jaws: Identifying Postmortem Alligator (*A. mississippiensis*) Scavenging on the Human Skeleton

Dayanira Lopez, MS\*, Florida Gulf Coast University, Justice Studies, Fort Myers, FL 33965; Heather A. Walsh-Haney, PhD, Florida Gulf Coast University, Fort Myers, FL 33965-6565; Sunil P.A. Hewage, Institute of Forensic Medicine & Toxicology, Colombo 00700, SRI LANKA

**Learning Overview:** After attending this presentation, attendees will understand how to differentiate postmortem change inflicted by American alligator jaws on human skeletal remains from damage made by other scavengers. Attendees will also understand how to easily exclude intentional trauma implicated by a human being, by way of proper identification of the postmortem change caused by alligators.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing clear examples of scoring, punctures, pits, scalloping, and crushing and explain how access to a faunal skeletal collection and zoology methods helped to identify the species (and size) of the scavenger.

The American alligator (*A. mississippiensis*) is one of the two native species of crocodylians living in Florida. Numbering approximately 1.25 million in total, the largest alligator population persists in southwest Florida within the tropical wetlands of the Florida Everglades.<sup>1</sup> With the ability to reach lengths over 12 feet (3.6 meters) and bite force exceeding 2,000psi, alligators create a problem for medicolegal death investigations.<sup>2</sup>

Existing references provide examples of tooth pits, punctures, scoring, and furrows and elaborate on the mechanics of bone crushing but tend to focus on general terrestrial scavenging with few exceptions.<sup>2,3</sup> This study contributes by providing photographic and metric examples of alligator damage to skeletal remains while also providing methods for estimating alligator size using methods borrowed from zoology and applied to forensic casework. No less important, these findings are presented with the permission of the decedent's family.

This case was evaluated by a consulting forensic anthropologist for the medical examiner's office, who was called upon to assist with the death investigation. Time since death analysis revealed the decedent was in an aqueous environment for less than two weeks. Approximately 50% of the skeleton was recovered, and 25% presented with postmortem carnivore scavenging damage. This study crossed interdisciplinary borders by delving into the zoology literature, finding methods for estimating overall size of an alligator based on cranial and dental measurements.<sup>4</sup> Using a comparative specimen from the Human Identity and Trauma Analysis (HITA) Nonhuman Skeletal Collection, this study estimated the length of the specimen from the tip of the snout to the tip of the tail (10ft). Then, the maximum tooth diameters of the HITA alligator were measured. The tooth diameters from the HITA specimen (maximum diameter ranged from 4mm to 14mm) were compared to the pits and punctures (maximum diameter ranged from 3mm to 10mm) on the remains. This comparison of tooth and defect diameters, with published alligator length estimation equations, allowed for the estimation of the size of the scavenger. In addition, comparison to the known specimen assisted in ruling out the possibility that any of the trauma that was evaluated was caused by intentional human force and rather during the postmortem interval.

When remains are found in water for an unknown period of time, several lines of evidence can assist in investigating how the death came to be, but can easily be lost or disappear through interference by carnivorous scavengers, as well as other environmental factors. Results of the methods presented above are twofold: (1) to increase the ability of various investigating agencies in determining the sequence of events leading to the victim's death; and (2) to assist these agencies in bridging the communication gap between them and the family of the decedent. In doing so, the goals of finding justice for the victim and effectively communicating to ensure peace of mind to their surviving loved ones are met.

## A147 Does Donor Skin Color Affect Total Body Scores (TBSs)?

Crystal L. Crabb, BS\*, New Braunfels, TX 78130; Megan F. Veltri, BS\*, Texas State University-San Marcos, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will understand how the discoloration categories used by Megyesi et al. are population specific, making early stage decomposition challenging to estimate in American Black, American Hispanic, and Native American individuals.<sup>1</sup>

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the impact of skin tone on the assessment of the TBS in early decomposition and, therefore, the estimation of the Postmortem Interval (PMI) on People Of Color (POC).

Since its publication, Megyesi et al.'s method of using accumulated degree days and TBS has been widely used by anthropologists studying human decomposition and estimating the PMI.<sup>1</sup> Megyesi et al. advised that this research was preliminary, citing differential environments and temperature as the most important factors for future PMI research.<sup>1</sup> While the ancestral distribution of the Megyesi et al. sample is unknown, many of the coloration terms are specific to White individuals.<sup>1</sup> The purpose of this research is to ascertain if Megyesi et al.'s fresh and early stage discoloration terms, specifically the pink-white and gray to green categories, play a role in accurately estimating the TBS of individuals with darker skin tones.<sup>1</sup>

This study utilized decomposition photographs for 23 POC (9 American Black, 12 American Hispanic, 2 Native American) and 21 American White individuals. The use of photographs to assess TBS has been previously validated.<sup>2,3</sup> Each photograph was scored using the Megyesi et al. scores for the head and neck, torso, and limbs.<sup>1</sup> Discoloration, such as pink-white or gray to green, were included only in the early decomposition stages, and were the focus of this research. However, donor TBS were recorded until the end of the early decomposition stage, marked by post-bloating of the trunk. Deviations from the discoloration, outlined in Megyesi et al., were noted.<sup>1</sup> Additionally, discoloration had to occur on more than half of the body region to be scored as present. Using frequencies, these scores compared White individuals to POC.

In comparing scores for White and POC, several differences were observed. Individuals that were scored fresh (one point) or black-brown (six points) for the head-neck region did not stray from the listed definition. Similarly, points four and five (brown and brown-black/purging of the head-neck) matched the definitions by at least 95% for both POC and White individuals. The categories that strayed the most from scores and definitions were pink-white with skin slip (two points) and gray to green (three points). While 86.7% of White individuals matched the discoloration for the two-point category, only 21.4% of the POC's point scores agreed with the listed definition. Those whose discoloration was scored as gray to green agreed with the definition more than the pink-white discoloration category for both groups (100% for American White, 45.5% for POC). However, POC still did not match either the pink-white or gray to green discoloration definition most of the time they were scored.

A majority of the Megyesi et al. scoring system is inclusive for all individuals.<sup>1</sup> Regardless, the pink-white and gray to green discoloration categories within the early decomposition stage should be altered or based solely on other known and identifiable changes in decomposition. Terms such as "natural skin color" rather than "pink-white" and "color change" rather than "gray to green" may be more appropriate. Utilizing Megyesi et al.'s discoloration terms reduces the effectiveness of the TBS method.<sup>1</sup> As a result, the estimation of the PMI becomes more ambiguous.

## A148 Preliminary Investigations for Documenting Human Skeletal Remains in Obstructed Wooded Environments

*Morgan J. Ferrell, BA\*, Orlando, FL 32817; John J. Schultz, PhD, University of Central Florida, Orlando, FL 32816; Megan L. McCollum, University of Central Florida, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will better understand how Close-Range Photogrammetry (CRP) can be used to record forensic scenes in which there are human skeletal remains in obstructed outdoor environments. This presentation will focus on using CRP data collection methods to record a simulated forensic scenario constructed in an oak hammock environment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing preliminary investigations for using CRP to record scattered skeletal remains that are partially obstructed from view in a wooded environment. Building on previous photogrammetry research documenting skeletal scatters, this research will adapt these methods for obstructed wooded scenes.

Mapping and the comprehensive documentation of crime scenes are essential steps in forensic investigations. However, scenes involving human skeletal remains in wooded environments are very challenging to document. By mapping the spatial distribution of all recovered evidence, including skeletal remains, investigators may be able to recreate the scene and infer post-depositional processes. The purpose of this presentation is to demonstrate how CRP can be utilized to preserve contextual information through the creation of 3D models of forensic crime scenes involving human remains in wooded obstructed environments.

Photogrammetry is a field of study concerned with the use of photographs to obtain reliable measurements and the application of software to create 3D models. In particular, the software used in this study implements a Structure-from-Motion (SfM) algorithm to produce 3D models that allow for additional measurements or observations after the scene has been processed. While 3D modeling using CRP is frequently used to record archaeological sites, it has yet to be widely implemented in forensic settings. There are many advantages to using CRP in forensic scenarios, including recording contextual information as a 3D model that is a true-to-scale representation of the scene. Additionally, simply taking only overhead photos may not be viable for scenes in wooded environments, as individual skeletal elements may be obstructed from view. However, for CRP to become widely used for forensic scenes involving human skeletal remains, guidelines need to be further developed to generate the most accurate imagery.

Multiple iterations of a simulated forensic scene consisting of slightly scattered human skeletal material and clothing were constructed in an oak hammock environment. Data collection occurred in the natural lands of the University of Central Florida, with a ground surface consisting mainly of leaves. Remains were scattered around the bases of a few trees so that individual skeletal elements would be purposefully obstructed from view. Photographs were taken freehand using a Nikon® D7200 camera from five view angles while moving around the scene, with additional parallel overhead shots being taken with the camera attached to an extension pole. Close-up photographs of individual bones and joint surfaces were also taken. Cultural Heritage Imaging calibrated photogrammetric scale bars with coded targets were placed around the scene, and 3D models were processed using Agisoft® MetaShape® Professional.

Preliminary results of the models were very encouraging. The most important advantage of this technique was the ability to view all skeletal elements in one overhead orthophoto generated from the model. Further, the 3D models can be manipulated to view various angles and close-ups of the scene. Two tests were used to determine the accuracy of the models: the Root Mean Square Error (RMSE) and a visual assessment. All models had a RMSE of less than one, which is considered an optimal level of error for an accurate model. When viewing the entire model zoomed out, there are very few visual errors. When zoomed in, minor issues can be noted primarily along the bone edges as well as visual distortion along the interface of the bones with the ground surface.

The main limitations affecting model quality were shadows and constantly changing lighting conditions. These shadows, which are caused by surrounding trees and the photographers themselves, are unavoidable unless photographing while overcast. Additionally, the leaf ground surface proved challenging because moving around the scene during data collection occasionally disturbs the ground surface and, therefore, the model quality. While preliminary, this research generated near high-quality models with minor visual errors. However, further research is still needed to produce models with fewer distortions when zoomed in as well as to develop guidelines for documenting larger obstructed scatters.

### Photogrammetry, Scene Documentation, Forensic Archaeology

### A149 Refining Data Collection Parameters for the Photogrammetric Documentation of Outdoor Skeletal Scatter Scenes: Considering Ground Surfaces

Megan L. McCollum\*, University of Central Florida, Orlando, FL 32816; John J. Schultz, PhD, University of Central Florida, Orlando, FL 32816; Morgan J. Ferrell, BA, Orlando, FL 32817

**Learning Overview:** After attending this presentation, attendees will better understand the applications and limitations of documenting outdoor crime scenes using Close-Range Photogrammetry (CRP). This research focuses specifically on the comparative 3D rendering of different ground surfaces in two simulated outdoor crime scenes containing real human skeletal material.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the utility of CRP and describing how it is advantageous for application in documenting outdoor forensic crime scenes. The effects of different ground surfaces and other environmental factors that affect the 3D documentation process are also discussed.

Forensic archaeologists seek to preserve the context of the entire scene to accurately capture the taphonomic changes and reconstruct events. In archaeology, photogrammetry has been used increasingly to document scenes. However, there has been limited application in the field of forensic science. The purpose of this presentation is to refine CRP methods to use for forensic crime scene reconstructions involving human skeletal material with limited scatter of the bones on two different ground surfaces.

Digital photogrammetry relies on the systematic collection of photographs around a real-world object and computer software utilizing Structure-from-Motion (SfM) algorithms to triangulate 3D coordinates of overlapping points between two or more photographs. This documentation technique allows for the preservation of the entire 3D context and for the virtual manipulation without destroying evidence. Despite these advantages, there has been little research on the applications of CRP to the field of forensic archaeology.

For this research, two simulated crime scenes were constructed using human osteological material and clothing with minimal dispersal of the bones. These scenes were constructed at two sites on the University of Central Florida natural lands. Sites were selected for two different bottom surfaces: a mixed surface dominated by leaves, and a mixed surface dominated by grass. Prior to photography, ground foliage was cleared. Photographs were collected using a Nikon® D7200 camera and a mix of hand-held and extension pole techniques to photograph six different angles around the scene. The first five angles were photographed using the hand-held technique and the sixth angle consisted of overhead shots using the extension pole. These multiple angles have created accurate scenes with better resolution than previous research. Both scenarios were photographed using Cultural Heritage Imaging calibrated photogrammetric scales to create a scaled model. Both models were processed using Agisoft® MetaShape® Professional software. Measures of accuracy used to evaluate the models include the Root Mean Square Error (RMSE) reported by the MetaShape® software as well as visual comparison of the 3D model to the real-world scenario. Visual comparison consists of two evaluations: visual distortion around subject edges, and ground-subject interfacing issues. These are both visual errors that occur in the texture of the model.

This research demonstrates that for spatially limited and less complex scenes, photogrammetry should be integrated into the data collection protocol. Data collection parameters used in this research include both hand-held and extension pole photography techniques, clearing ground vegetation, and a total of six look angles for the models. Using these specifications, both models have final RMSE scores of less than one, indicating that they are models from which accurate measurements can be taken. Overview of the entire 3D model shows high visual and statistical accuracy. Noticeable visual distortion only occurs when the model is zoomed into scenes with highly complex geometry. In this case, the model of the bones on the surface dominated by leaves shows more visual distortion than the surface dominated by grass. Another visual complication present in the model dominated by grass is dappled shadows over the scene that may have influenced the lighting of the resulting model. Overall, CRP provides an accurate model of the positionality and context of skeletal material and should be incorporated as a methodology for the documentation protocol of outdoor forensic crime scenes.

#### Close-Range Photogrammetry, Outdoor Crime Scene, Complex Ground Surface

### A150 Identification of Bone Using an Alternate Light Source (ALS) in Terrestrial Pedestrian Searches

Sara M. Getz, PhD\*, Idaho State University, Pocatello, ID 83209-8005; Christian Petersen, PhD, Idaho State University, Pocatello, ID 83209; Tanyin Watson, Pocatello, ID 83201

**Learning Overview:** After attending this presentation, attendees will understand that conducting an additional nighttime search of an outdoor scene with an ALS is an effective way to find remains that may be missed during typical daylight searches.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing additional evidence that ALS is a valuable addition to the toolkit used in the search for human skeletal remains.

ALS has been shown to be an effective means of detecting bones and teeth in searches of terrestrial outdoor scenes.<sup>1</sup> This presentation describes preliminary results from the first two phases of a three-phase project aimed at testing existing recommendations for using ALS to detect human remains during pedestrian searches. Phase 1 assesses the light and filter combinations possible using the UltraLite™ ALS One, which is a compact and relatively inexpensive ALS kit that includes a four-setting light source (Ultraviolet, 400nm; low and high intensity Blue Merge Technology (BMT™), 450–480nm; Green, 525nm) and three pairs of filter glasses (yellow; amber; red). Dark amber glasses were also evaluated. All combinations were evaluated for use on non-human bone (fresh; sun-bleached; previously buried/soil-stained) and human bone (commercially prepared anatomical specimens; previously buried historic remains).

Specimens were photographed using a digital camera and commercially available lens filters and also subjectively evaluated by three people. High-intensity BMT™ paired with dark amber filter glasses provided the best visualization of fluorescence in bone with organic material present while simultaneously allowing sun-bleached bone, which had limited-to-no fluorescence, to be seen. It was not possible to identically capture what was observed visually using the selected camera filters, however, using the high BMT™, the most comparable camera filter (orange) to the dark amber glasses also produced the best visualizations.<sup>1</sup> These results are consistent with previous success using light in the 450nm range to identify human remains and the manufacturer's recommendation that BMT™ paired with an amber filter is suitable for the detection of most biological evidence.

Phase 2 simulates a scenario in which a day search fails to yield 100% of the remains suspected within a search area. Two test areas of 705 square meters each (23.5 meters by 30 meters) were selected in the semiarid hills of Pocatello, ID, where sagebrush, high desert grasses, and foxtails are the dominant vegetation. Search areas were bounded at one end by a fence marked with flagging tape at 3.5 meter intervals, the other end by reflective markers also placed at 3.5 meter intervals, and on either side by reflectors at 5 meter intervals as guides for bone mapping and search navigation.

A test sample of 35 elements including anatomical, sun-bleached, and stained bones and teeth was distributed in realistic patterns within each area. Remains were partially buried, hidden under sagebrush, obscured with grasses, and inserted into animal burrows with some elements placed in groupings that commonly occur in surface scatters (e.g., mandible and two incisors, two tarsals). Each element was photographed and mapped.

Three-person search teams of student volunteers evaluated each area during the day and at night, for a total of eight searches (four day/night pairs). For the same group of searchers, the average time needed for a day and night search were comparable (Group A: 35, 43 minutes; Group B: 60, 56 minutes, respectively). Between two and ten elements were missed by each group during each day search, however, most were found during each subsequent night search in the same area, resulting in final recovery of 33–35 items (94%–100%) in each search. These preliminary results support integration of ALS into outdoor pedestrian search procedures.

Additional searches are scheduled for Fall 2019 to investigate the effect of increased experience, changing seasonal vegetation, and larger search groups on these results. Phase 3 will evaluate revised search recommendations under more realistic conditions (e.g., no marked search boundaries, mixed search groups of osteologists, law enforcement/medicolegal professionals).

### A151 A Retrospective Study of Forensic Fire Searches and Recoveries at Mercyhurst University: 1983–2019

*Diana L. Messer, MS\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickham, HI 96853; Andrea Ost, MS, University of North Carolina, Chapel Hill, NC; Dennis C. Dirkmaat, PhD, Mercyhurst University, Erie, PA 16506*

**Learning Overview:** After attending this presentation, attendees will better understand the forensic archaeological, taphonomic, and anthropological approaches to fatal fire scenes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining trends in the role of forensic anthropology and archaeology in forensic fire scenes and by providing a set of best practices toward scene processing and human remains recovery for a variety of forensic fire scenes.

A retrospective review of forensic anthropology cases from the Mercyhurst University Forensic Case Data Bank (1983–2019) was performed for fatal fire scene searches and recoveries processed by the Mercyhurst Forensic Scene Recovery Team (M-FSRT). This included fire cases in which a forensic archaeological search and/or recovery was performed, regardless of whether human remains were found.

Data were collected from each fire scene on location (state, county), fire type (structure, vehicle, outdoor, mass disaster, other), seasonality of fire recovery (spring, summer, fall, winter), and manner of fire (accidental vs. intentional). Structure fires were defined as any fire scene that involved burning of all or part of a structure, such as a house or shed. Outdoor fire scenes were defined as any outdoor area where material had been burned, including fire pits. Vehicle fires were defined as any vehicle subjected to fire modification, including fires that occurred as the result of a vehicle crash incident as well as intentional fires to stationary vehicles. Mass disasters were defined as scenes involving a large area and multiple victims, such as plane crashes. Each fire recovery or search was considered one case regardless of the number of victims.

A total of 1,602 forensic anthropology cases conducted between 1983 and 2019 by Mercyhurst University personnel were reviewed. A total of 205 forensic archaeological searches and/or recoveries were conducted over the 37-year period, representing 12.7% of all cases (with 386 total recovered individuals); 36 were categorized as fire searches/recoveries.

From 1983 to 2009, 16% of all searches/recoveries involved fire, while in the past ten years (2010–2019) that number has increased to 18%. More than half of the total fire recovery cases were conducted between 2015 and 2019, with the greatest number of cases occurring in 2017 ( $n=8$ ).

Fire searches/recoveries spanned four states (Nevada, New York, Ohio, and Pennsylvania), with the majority of fire recoveries conducted in Pennsylvania (72.2%). In Pennsylvania, fire recoveries were conducted in 16 of 67 counties, the majority of recoveries from the northwest region of the state. While fire recoveries spanned all seasons, the greatest number of cases occurred in the summer (33.3%), followed by the fall (24.2%).

Of the fire recovery cases included, 36.4% were outdoor fires scenes, 24.2% were structure fires, 18.2% were vehicle fires, and 21.2% were fires as a result of mass disasters. Of the outdoor fire scenes, one case involved a ruptured gas well, and three cases involved burn barrels to either facilitate the burning process or to store burned remains.

In the cases reviewed from Mercyhurst, the majority of fire scene recoveries were related to plane, train, and automobile accidents, accounting for 42.9% of fire scenes. Intentional fires related to the disposal and concealment of a body constituted 34.2% of cases. The manner of fire scene was unknown for 22.9% of cases. The majority of searches/recoveries were conducted in rural areas where large yards and close access to secluded wooded areas allow for prolonged burning, potentially accounting for the large number of intentional fire cases.

Fatal fire scenes present unique challenges to the recovery process. The application of forensic archaeological methods in such cases can be essential to preserving context and association of evidence and human remains. Considering the increasing involvement of forensic anthropologists in fatal fire recoveries and the diversity with which fatal fire scenes may present, it is imperative that forensic anthropologists have sets of best practices for how to approach scenes of this nature. This retrospective review covers a wide variety of fatal fire scenes and archaeological recovery approaches from which recommendations for recovery efforts can be gleaned.

#### Fatal Fires, Archaeology, Forensic Anthropology

## A152 An Evaluation of Mitochondrial DNA Success Rates in a Commingled Assemblage From the Cabanatuan Prisoner of War (POW) Cemetery

Mary S. Megyesi, PhD, Defense POW/MIA Accounting Agency-Central Identification Laboratory, Joint Base Pearl Harbor-Hickam, HI 96853; Diana L. Messer, MS\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Jessica K. Juarez, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Sarah M. Richer, PhD, Aiea, HI 96701; Suni M. Edson, MS, Armed Forces DNA ID Laboratory, Dover Air Force Base, DE 19902

**Learning Overview:** The objective of this presentation is to explore analyses differences in mitochondrial DNA success rates by DNA testing strategy, element type, and taphonomic modifier.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data to aid in better selection skeletal elements for DNA sampling in forensic contexts, particularly when skeletal material is in poor condition and/or commingling is present. This study also examines how various taphonomic alterations may influence DNA success rates.

The Cabanatuan POW Camp was a World War II POW camp located in the Philippines, associated with 2,763 American casualties. Unidentified individuals were eventually interred in the Manila American Cemetery and Memorial (MACM), and historians estimate there are approximately 990 to 1,006 unresolved Cabanatuan individuals.

The Cabanatuan Project, initiated by the Defense POW/MIA Accounting Agency, is a focused effort to identify these unknowns.<sup>2</sup> The remains are commingled and in poor condition.<sup>1</sup> Although each casket presumably designates a single individual, anthropological and DNA analyses have demonstrated as many as seven individuals represented in single casket.<sup>3</sup>

Due to the poor condition of the Cabanatuan remains, many anthropological analyses are not applicable. In addition, the remains were treated with lye and formalin prior to burial at the MACM. Identification of individuals often hinges on DNA results. Selecting skeletal elements likely to yield DNA is crucial to this endeavor. This study examines DNA results to answer two important questions: (1) What elements are most likely to sequence?; and (2) What effect do taphonomic alterations have on DNA success rate?

The DNA results of 20 individual caskets were analyzed. Every element tested for DNA was recorded, and DNA yield was reported as successful if the Armed Forces Medical Examiner System-Armed Forces DNA Identification Laboratory reported a sequence. The type of DNA testing strategy (Sanger or Next Generation Sequencing [NGS]) used for each element was recorded. The presence of commonly observed taphonomic alterations, which included the presence of vivianite (a type of phosphate crystal) and rust staining, were visually assessed, when possible.

A total of 318 sampled elements (404 DNA tests) were included in this study. There were 121 upper limb elements, 112 lower limb elements, 61 teeth, and 19 cranial elements. The remaining elements included a few vertebrae and foot elements. There were a total of 215 Sanger tests and 189 NGS tests. Some elements were sampled more than once, and some samples, after failing to sequence in Sanger, were subsequently tested with NGS ( $n=86$ ). For the purposes of this study, multiple failures of a specific test from a single element were only counted once.

Independence and goodness of fit frequency tests were used to examine differences between DNA success rates of Sanger and NGS. Overall, the difference between successful Sanger and NGS testing for the entire assemblage was slight: Sanger 41.86% (90/215) vs. NGS 41.80% (79/189). However, there were differences in DNA success rates between Sanger and NGS among body regions. NGS had greater success for teeth at 69.70% (23/33) vs. 51.28% (20/39) for teeth in Sanger ( $p<0.001$ ). Sanger had a higher success rate for lower limb elements (60.27%; 44/73) vs. NGS (43.55%; 27/62) ( $p<0.001$ ). There was not a significant difference between NGS and Sanger modalities for upper limb elements ( $p=0.134$ ).

Taphonomic information was collected for available skeletal elements, excluding teeth ( $n=169$ ). Fifty-nine elements were observed with vivianite crystals. Fifty-seven of these elements were tested in NGS and 9/57 (15.78%) sequenced. Only two elements with vivianite were tested in Sanger and neither sequenced. Rust staining was observed on 111 elements. Forty rust-stained elements were tested in Sanger and 55.00% (22/40) successfully sequenced, while only 30.99% (22/71) tested in NGS were successful ( $p<0.05$ ). Forty elements had both vivianite and rust staining; however, taphonomic signatures were assessed independently.

Overall, the Sanger and NGS success rates varied within this Cabanatuan assemblage based on element type. The presence of vivianite was found to indicate poor DNA success in NGS; however, this may be correlated to other underlying factors, such as prior treatment or the waterlogged casket environment. Future studies may further examine this relationship. This information may be useful to other forensic practitioners making DNA sampling decisions for commingled, treated, or waterlogged remains.

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the inconsistent use of grave markers for unidentified migrant remains in South Texas and how the standardized use of grave markers could greatly assist the recovery and identification of remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by promoting best practices for tracking unidentified remains in South Texas cemeteries that will improve future exhumation and investigative efforts and ensure compliance with state laws.

The migrant death toll at the United States-Mexico border is a mass disaster, with the highest numbers of deaths currently in Texas. According to United States Customs and Border Patrol statistics, more than 4,000 people have perished trying to cross the border in Texas since 1998, with more than 1,500 of these deaths occurring since 2012. While the Texas Criminal Code of Procedure (TCCP) mandates that all unidentified remains be investigated, sampled for DNA, and tracked for a minimum of ten years, the degree to which South Texas counties are compliant is inconsistent. Because local authorities often lack the funding or personnel to carry out swift, thorough investigations, the vast majority of unidentified migrants recovered in South Texas are buried in local cemeteries without having been forensically examined or sampled. The way these individuals are buried, including the extent to which their graves and case information are documented, can greatly impact the preservation of evidence and the ability to re-locate burials for future identification.

Exhumation efforts by Operation Identification (OpID) at Texas State University seek to recover the remains of unidentified migrants in order to facilitate identification and repatriation. Having conducted pedestrian survey and large-scale exhumations in partnership with the Forensic Border Coalition across multiple counties in South Texas, OpID has encountered many challenges when locating unidentified migrant burials. Besides incomplete and missing burial records, most graves are unmarked or have markers that are temporary, flimsy, and/or lacking valuable case information. Most burials exhumed by OpID have instead had to be located by other means, such as informant memory recall, Ground Penetrating Radar (GPR) survey, and exploratory excavation, all of which are time- and resource-consuming. Remains that are recovered with grave markers that have dates, locations, funeral homes, or case numbers listed have a much better chance of being identified than those that are buried unmarked.

The present study seeks to examine the use of grave markers related to unidentified migrant remains in three South Texas counties in order to assess the consistency and effectiveness with which grave markers assist investigative efforts in the region. It is the overall goal of the present study to promote the standardized use of permanent grave markers that contain relevant case information that can be easily located and tracked over time.

Grave marker data were collected for all unidentified migrant burials that have been exhumed to date by OpID over the course of four exhumation seasons across three South Texas cemeteries from 2017 through 2019. Grave markers were assessed in each cemetery in terms of their material, legibility, and content of case information. Of the 94 burials exhumed by OpID, only 24 (25.53%) contained grave markers, with only 20 containing case-related information (21.28%). The most common case information listed on grave markers was funeral homes ( $N=11$ ), followed by dates ( $N=9$ ), and death record numbers ( $N=8$ ). While grave markers were found to be present in all three cemeteries, differences in the use of metal or plastic and paper markers and in the types of information they contained were found between the cemeteries. Thus far, three of the four individuals who have been positively identified from these recent exhumation seasons were buried with a grave marker (75%).

It is the position of this presentation that grave markers should become standard practice for unidentified migrant burials in South Texas. Especially in counties that lack access to medical examiners or forensic practitioners, utilizing grave markers is an immediate and relatively inexpensive solution that will greatly aid in the ability to recover and identify remains in the future. Promoting the widespread use of permanent grave markers will also ensure county compliance with state laws regarding the handling of unidentified human remains.

## A154 Assessing Fluctuating Asymmetry in the Crania and Lower Limb Bones of Two Modern Populations

Shelby Garza, MA\*, Texas State University, San Marcos, TX 78666; Emilie Wiedenmeyer, BA, Texas State University, San Marcos, TX 78666-3511; Kari Helgeson, MA, Allen, TX 75002; Kate Spradley, PhD, Texas State University, San Marcos, TX 78666

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of how environmental stress can affect the levels of Fluctuating Asymmetry (FA) in both the cranium and the lower limb bones.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to the ongoing research being conducted involving variables affecting FA and will lead to a better understanding of human variation.

FA, the main focus of this research, occurs when small deviations from perfect symmetry present themselves under conditions of developmental stress. Understanding how environmental stress can affect FA is important in a forensic setting. Individuals that have been exposed to environmental stress during growth and development have the potential to show greater levels of FA in the skeleton. This could reflect the environment of a missing person's childhood, potentially aiding in identification.

Inadequate nutrition, Socioeconomic Status (SES), and climatic changes have been shown to be linked to environmental stressors, which can disrupt developmental homeostasis.<sup>1,2</sup> Skeletal asymmetry in the cranium and long bones can be an indicator of environmental stress that occurred during growth and development.<sup>3</sup> The purpose of this study is to examine a migrant population and a donated skeletal collection to analyze varying degrees of FA between the cranium and lower limb bones from both men and women with different SES. Few studies have compared the prevalence of FA in the cranium and lower limbs of individuals with documented SES.

For this study, a total of 50 individuals were examined with paired long bone and cranial measurements to assess the level of FA. Twenty-seven of the individuals were from the Texas State University Donated Skeletal Collection (TXSTDSC) and 23 were from Operation Identification (OpID), which was representative of the migrant population in this study. This study had three categories of SES: low, middle, and high. The TXSTDSC was separated into one of the three groups using self-reported SES. The OpID population was assumed to be from a low SES because unauthorized immigrants often have significantly lower SES when compared to non-immigrant residents of the United States.<sup>4</sup> Postcranial measurements were collected on all lower limb bones and 3D landmarks were collected from the cranium using a Microscribe® digitizer and 3Skull.<sup>5</sup>

Postcranial measurements were converted to absolute asymmetry percentages and a Mann-Whitney test was used to compare FA between sexes, while a Kruskal-Wallis test was used to compare SES. The results showed that only FA in the fibula was significant when both sex and SES were compared. For the cranium, landmarks were paired and aligned using a Procrustes fit, followed by a Procrustes Analysis of Variance (ANOVA) in MorphoJ to measure left-right asymmetry. The results of the one-way ANOVA showed that there was a significant difference between groups in both the comparison of SES and sex, showing that OpID had lower FA scores than all the TXSTDSC individuals, with a significant difference between OpID and the upper SES TXSTDSC. The results also showed that females had a significantly higher FA scores than males in the cranium.

This research demonstrates that there is a significant difference in FA scores between a donated skeletal collection and a migrant population and between sexes, but not between SES. The present study also suggests that FA is more commonly seen in the cranium when compared to lower limb bones. FA levels represented in this study reflect differences in SES between migrants and high SES TXSTDSC, but not between migrants and the other SES groups in the TXSTDSC. There was also a lack of significant difference between individuals with different SES in the TXSTDSC, possibly suggesting that these individuals experienced similar patterns of environmental stress during childhood, regardless of their self-reported SES. Out of the three long bones examined, only the fibula shows signs of FA. This may suggest a prevalence of FA in non-weight bearing bones, rather than bones that often respond to biomechanical factors.

### A155 Migrants, Crime, and Unidentified Bodies: The Wits Human Identification Unit (HIU) Experience

*Desiré Brits, PhD\*, University of the Witwatersrand, Johannesburg, Gauteng 2193, SOUTH AFRICA; Maryna Steyn, PhD, University of the Witwatersrand, Parktown, Johannesburg 2193, SOUTH AFRICA*

**Learning Overview:** After attending this presentation, attendees will have gained insight into forensic anthropology in South Africa and some of the problems associated with personal identification of the decedents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the advantages of collaborations when attempting to identify the skeletal remains of unknown decedents and will also showcase possible opportunities to gain hands-on experience in forensic anthropology in South Africa.

South Africa is a developing country and home to many documented and undocumented migrants from all over Africa. Unfortunately, crime and violence are rampant. Recent statistics reported that approximately 11% of all deaths in South Africa are due to non-natural causes. The major causes of these non-natural deaths include assault and transport-related accidents. Although murder is not one of the major causes of non-natural deaths, approximately 52 people are murdered in the country every day. This results in a large number of postmortem examinations and forensic anthropological cases. Regrettably, many of these decedents enter the Forensic Pathology Services (FPS) as unknown individuals, and about one in ten in the Gauteng Province will remain unidentified.

To assist with the skeletal analyses of unknown deceased individuals, the HIU, which forms part of the Human Identification and Variation Research Unit (HIVRU) in the School of Anatomical Sciences at the University of the Witwatersrand was established in 2016. This unit works in close collaboration with the FPS located in Johannesburg and assists with forensic anthropological analyses of all cases from the southern cluster mortuaries in the Gauteng Province, which is the most populous region in the country. The mandate of the HIU is to establish a biological profile that can be used by the South African Police Service (SAPS) in conjunction with information provided by the FPS and the International Committee of the Red Cross (ICRC) to make a positive identification. Trauma analyses are also frequently requested, even when the identification is known. By April 2019, approximately 120 cases have been received by the HIU, of which 89 have been completed.

Attesting to the problems in the system, forensic anthropological case analyses during the past two years have included the analyses of numerous cases dating back nearly ten years. The majority of remains examined represented Black adult males. Nearly all cases had dentition present; however, this is often of little use as most South Africans and migrants cannot afford dental care or have perfect teeth and, as such, have no dental records. Many cases exhibit signs of trauma, often with a combination of both antemortem and peri-mortem trauma, suggesting a high-risk lifestyle of many of the victims. Multiple cases of ballistic trauma, including cases of multiple gunshots, are also encountered. These cases are often found at mine sites and are frequently related to “Zama Zamas,” who are mainly illegal migrant gold miners.

Identification of the dead is a basic human right and, despite the difficulties, forensic anthropologists are making every attempt to contribute. Agreements for closer collaboration between FPS, HIU, and the Victim Identification Centre (VIC) of the SAPS have been put in place to aid in the personal identification of unknown and undocumented individuals. Through this collaboration, forensic anthropological case analyses are not only completed for cases from the southern parts of Gauteng, but also from other provinces, such as the Free State, Eastern Cape, and Northern Cape, that do not have their own forensic anthropological services.

Although the identification process has many difficulties, a few success stories keep forensic anthropologists motivated. To date, six cases have been positively identified. Four of these identifications were made through DNA confirmation and two through the use of secondary identifiers, including clothing and tattoos. There are also three more cases that could hopefully be identified. One case is awaiting DNA analysis and two others are waiting for facial approximation. Painstakingly slowly, the unknown and undocumented are being identified.

### A156 A Multidisciplinary Identification Approach of Armed Conflict Victims Exhumed From La Resurrección Cemetery in Granada, Colombia

*Alexandra Semma Tamayo, MS\*, Villavicencio, Meta 500001, COLOMBIA*

**Learning Overview:** This goal of this presentation is to describe the importance of a multidisciplinary approach in the identification of armed conflict victims exhumed from La Resurrección Cemetery in Colombia that were analyzed by the human identification team of the National Institute of Legal Medicine and Forensic Sciences in the Eastern Region of Colombia.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the effort of the Colombian judicial system and medicolegal system to investigate these complex cases from the following perspectives: (1) the recovery of antemortem and contextual information concerning the unidentified victims buried in La Resurrección Cemetery in Granada, Colombia; (2) the exhumation of the cases by the Technical Investigation Corps (CTI) and analyses of these unidentified victims by the medicolegal system; (3) the multidisciplinary approach of the human identification team of the National Institute of Legal Medicine and Forensic Sciences in the Eastern Region of Colombia using the comparison of the contextual information of the deaths and the new information provided by the analyses performed; and (4) the results up to this point and the upcoming challenges.

The phenomenon of missing people in Colombia has been analyzed from different perspectives throughout the years. The recent official numbers given by the National Center for Historical Memory (Centro Nacional de Memoria Histórica [CNMH]) provides an approximate number of 82,998 missing persons from 1958 to 2017; this period corresponds to the origins and growth of the armed conflict as well as the post-conflict phase. During this period, all actors in the armed conflict performed different types of violence against each other, including torture, disappearance, and multiple incidents of combat between these groups and the Colombian army.

The majority of the investigations around combat casualties, especially the victims from the groups outside the law, were focused on cause and manner of death; the identification of the dead was not the main purpose, leaving hundreds of unidentified victims buried in different cemeteries around the Colombian territory. Since 2010, the State Prosecutor's Office, the Ministry of Internal Affairs, and other organizations in Colombia began a characterization of these cemeteries with the objective of achieving a better understanding of the number of unidentified victims buried as No Name (NN), creating strategies to enable an effective recovery, analysis, and identification of these specific cases.

The continuing forensic effort in Colombia must respond to the high number of cases, the lack of antemortem and contextual information, and the small number of specialized forensic teams, which represents an improvement for the victims and their families.

---

### A157 The Detection of Cancerous Lesions in Skeletal Remains Using Visual Methods and Radiographs

Sara Fatula, BS\*, Knoxville, TN 37919

**Learning Overview:** After attending this presentation, attendees will have gained insight into the potential benefits of incorporating medical imaging equipment into standard practice for the detection of potentially individuating lesions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the need for the use of medical imaging equipment in a modern, forensic context to detect the presence of cancer in unknown skeletal remains, contributing to the biological profile and leading to possible identification.

Forensic anthropological literature describes the detection of cancerous lesions on dry bone that originated in soft tissue, later metastasizing to the bone. However, the use of medical imaging equipment to detect these lesions is rarely considered standard practice. Given the mechanisms of cancer metastasis, it is expected that more cancerous lesions would begin inside the bone, thus visible only with the aid of medical imaging equipment. Potentially individuating cancerous lesions may not be detected when employing macroscopic analysis of dry bone. These lesions may be excluded from the biological profile and impede the identification of unknown remains. Rothschild and Rothschild's study analyzed the presence of cancer both macroscopically and radiologically, finding that two-thirds of all cancer cases would be missed with visual inspection alone.<sup>1</sup> However, their study sample may not apply to contemporary, forensic contexts. The objective of this study is to determine if the presence of cancerous lesions in a sample of contemporary skeletons is greater when assessed using radiographs compared to macroscopic examination of dry bone, allowing for more accurate accounts of potentially individuating lesions in unknown remains.

The study sample consisted of 30 individuals with reported cancer from the Bass Donated Skeletal Collection. Elements selected for analysis included: skull, vertebrae, sacrum, clavicles, scapulae, sternum, ribs, humeri, os coxae, and femora. All elements were examined in isolation for the presence of visible lesions following the criteria for differential diagnosis established in the paleopathology literature.<sup>2-4</sup> Each element was also radiographed at the University of Tennessee Student Health Center by a trained radiology technician. Radiographic images were analyzed blindly to ensure no bias in knowing if these individuals exhibited visible lesions. Lesion nature, location, size, and margins were recorded. Following analysis in isolation for each method, the sample was reanalyzed with simultaneous macroscopic and radiographic analysis, with the frequency of lesion presence between the two methods being compared.

Preliminary results indicate that 23% of the sample exhibited lesions only visible on the radiographs; 33% of the sample exhibited lesions macroscopically, but also exhibited additional lesions that were only visible on radiographs. These lesions were primarily lytic in nature, though there were also instances of blastic lesions only visible on radiographs. Of the elements selected, lesions appeared most frequently on the skull, followed by the os coxae. Preliminary results indicate that more than half of lesions in these cases could have been missed if traditional macroscopic analysis alone was employed. This presentation can validate the use of medical imaging equipment in a modern, forensic context to detect the presence of cancer in unknown skeletal remains, contributing to the biological profile and leading to possible identification.

### A158 The Characterization of Peri-Mortem Trauma on World War II (WWII) German Pilots

*Emeline Verna\**, *Faculté Des Sciences Médicales, Marseille, Bouches Du Rhone, FRANCE*; *Laetitia Bouniol, MS, Service Archéologique, Beauvais 60000, FRANCE*; *Emeline Sperandio, MS, Faculté Des Sciences Médicales Et Paramédicales, Marseille 13015, FRANCE*; *Loïc Lalys, PhD, Faculté Des Sciences Médicales Et Paramédicales, Marseille 13015, FRANCE*; *Caroline Costedoat, PhD, Faculté Des Sciences Médicales Et Paramédicales Se, Marseille 13005, FRANCE*; *Michel Signoli, PhD, Faculté Des Sciences Médicales Et Paramédicales, Marseille 13015, FRANCE*; *Jean-marc Femolant, MS, Service Archéologique, Beauvais 60000, FRANCE*

**Learning Overview:** The goal of this presentation is to better understand peri-mortem trauma linked to aircraft crashes during WWII and the consequences of taphonomic damage linked to pilot equipment and coffins.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating peri-mortem trauma within a specific group: WWII pilots. This study helps improve knowledge on skeletal analyses in military contexts and identify a common pattern of trauma.

During WWII in France, temporary burials were established for soldiers while the national military cemetery was being built. In 2018, a temporary cemetery was discovered in Beauvais (Oise, France) during land-use planning work. This area was near the German military airfield used from June 1940 to August 1944. The cemetery was excavated, and 39 coffins were uncovered. At the end of WWII, all the soldiers should have been transferred to the national military cemetery, but some of these were not.

Among these 39 coffins, 23 contained skeletal remains (ranging from a single fragment to several bones), and 16 presented complete individuals. These soldiers were bomber aviators and most of them were buried in their parachute. According to historical records, they fell and died between 1940 and the summer of 1942. Anthropological analyses of each individual included the biological profile and the analysis of pathological and traumatic conditions macroscopic observations.

Among the 16 complete individuals, 7 are well preserved and yielded a complete biological profile. Nine individuals are poorly preserved, and their biological profile was incomplete (most of the time, stature could not be estimated). Postmortem damage (taphonomic alterations) could have been caused by the sediment, the coffin, and/or the military equipment. Fifty-six percent of individuals were wrapped in their parachute and their cortical bone was severely damaged.

Peri-mortem trauma was observed in 14 soldiers (87.5%). Five (31%) had been autopsied and buried without military clothes or equipment. Blunt force peri-mortem trauma was the only type of trauma observed. The most-to-least impacted regions were the lower limb (60%), followed by the skull (56%), the upper limb (35%), the pelvic girdle (25%) and the spine (19%). The thorax was poorly preserved, and it was too difficult to differentiate between peri- and postmortem damage.

Among the types of fractures observed, butterfly, spiral, and segmental fractures were the most recorded on long bones. On the skull, linear fractures were very frequent, but the edges were smooth in several cases, due to subsequent taphonomic damage.

Twenty-three other coffins revealed some bones (from one to several) and almost all coffins with several bones revealed at least one case of blunt force trauma (i.e., one fragment of a butterfly fracture on the femur).

The fracture pattern was very similar in all individuals and is compatible with an air crash combined with a fall from a significant height. Even if that could be contradictory, it is rare to know the exact cause of death of soldiers during WWI and WWII.

This study presents rare cases of bomber aviators buried in the same place who share the same cause of death. In the future, we could compare these results with other soldiers who died during armed conflicts, especially aviators. This study intends to provide a comparative framework for differential diagnosis and possible axes for future research.

#### Forensic Anthropology, World War II, Blunt Force Trauma

## A159 Photogrammetry Using Multiple Camera Systems of Mass Graves in a Humanitarian Context

Sarah F. Skoropa, BA\*, Cranfield University, Shrivenham, Swindon SN6 8LA, UNITED KINGDOM; Roland Wessling, MSc, Cranfield University, Shrivenham, Oxfordshire SN6 8LA, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will understand the potential applications of Structure from Motion (SfM) photogrammetry in humanitarian forensic work of mass graves as an affordable and time-efficient alternative to current contextual recording methods. This presentation also provides an overview of the performance of multiple types of camera systems.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by expanding on current research of SfM photogrammetry, illustrating the potential of multiple camera systems in two types of mass graves. This research broadens the capabilities of humanitarian forensic teams by exploiting already owned or readily available camera systems and computing devices.

Two of the biggest challenges facing international humanitarian forensic efforts is the cost of keeping abreast with the latest forensic techniques and continuously expanding body of forensic knowledge. Recording the context of excavated mass graves is an essential aspect of the forensic anthropological process. The collected records can be used both in analysis and in court to provide evidence that a crime has occurred and give insight into reconstructing the crime.

Current technologies used for contextual recording and processing of mass graves, such as total station units and laser scanners, can be expensive, bulky, and time intensive. SfM photogrammetry represents an inexpensive and easy-to-use alternative for obtaining easy-to-interpret and precise 3D models of multiple types of mass graves.

For many years, SfM photogrammetry has been embraced by archaeologists as a method of preserving and recording cultural heritage at excavation sites. However, it is only in the past few years that the forensic field has seen research of SfM photogrammetry applied to mass graves. Previous research had limited image collection to one camera system while evaluating other variables.<sup>1-3</sup>

This research examines the abilities of multiple camera systems in image collection of two types of mass graves: a large, mechanically dug grave and a long, narrow, hand-dug trench. The images used in the study were collected from the following five camera setups: iPhone® 7 Plus still images, iPhone® 7 Plus stills taken from videos, Canon® D100 still images, Sony® a7ii stills from videos, and a simulated drone using a Canon® G9X with a tall, tilted tripod. The camera systems ranged in cost and degree of automation.

The images were subsequently imported into Agisoft® Metashape® (SfM software) to create the 3D models. Multiple settings within the software were examined. Some settings were determined to be incapable of creating a viable 3D model that provides further recommendations to the field. This research also presents the current limitations of SfM photogrammetry and identifies areas needing more in-depth research and understanding for general international and *Daubert* evidentiary standards to be met. This research also highlights the necessity of properly recording and understanding the variables and settings used by SfM photogrammetry for reproducibility.

## A160 Age-At-Death Estimation Using Dental Cementum Increments: Validation and Limitations

*Benoit Bertrand, PhD\**, University Lille, Lille, Hauts de France F-59000, FRANCE; *Vadim Mesli, MD*, Institut Medico Legal, Lille Cedex, Nord 59037, FRANCE; *Anne A. Becart, DDS, PhD*, Service De Medecine Legale, Lille 59000, FRANCE; *Martine Vercauteren, PhD*, Université Libre de Bruxelles, Faculty of Sciences, Brussels, BELGIUM; *Valéry C. Hédouin, MD, PhD*, Lille, Hauts De France 59037, FRANCE; *Didier Gosset, MD, PhD*, University of Lille, Lille, Hauts de France 59045, FRANCE

**Learning Overview:** After attending this presentation, attendees will understand the potential benefits, limitations, and possible pitfalls of dental cementum annulations when analyzed for age-at-death estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing knowledge of: (1) the potential applications of cementochronology to forensic investigations; (2) specific limitations of this method; and (3) recommendations for critically evaluating and implementing cementum analysis for forensic use.

Age-at-death estimation using dental cementum relies on the attractive principle of yearly deposits that would provide a direct access to chronological age. Dental cementum increments analysis has become a routine method for terrestrial mammalian species, but despite recurrent statements regarding its superior performance in humans, cementochronology remains an under-used method for assessing age-at-death. Demanding histological procedure is surely not the sole reason for disregarding this technique. Protocol discrepancies and inconsistent results lead forensic anthropologists to remain oriented toward classic techniques, more standardized and defined. Yet, frequently used procedures have long been known to yield inaccurate, imprecise, and biased (especially among the elderly) age estimates.<sup>1</sup> Cementochronology is being proposed to broaden the range of methods available; however, any method applied to forensic casework must be proven valid, reproducible, and limitations need to be acknowledged. This work aims to provide a standardized framework to define the method's performance and limits. Compounding the concerns over the precision and accuracy of estimation is the question of applicability of such a method to dental material with different preservation conditions. An additional objective is to evaluate the impact of taphonomical alterations.

The study sample consists of 200 canines from individuals of known age, sex, postmortem, and inhumation intervals from anatomical and anthropological collections, and of 200 canines from archaeological assemblages. Teeth were prepared and analyzed in a standardized procedure to prevent bias. All cross-sections have been assigned an index corresponding to microstructure readability, and the extent of cementum loss has been evaluated using two histological indexes: one exclusively considering microbial action and the other considering other types of physical and chemical alterations. Precision of age estimation was assessed by studying statistical dispersion of annuli counts and accuracy by examining the absolute and relative errors.

Results establish intra-observer consistency and demonstrate that dental cementum analysis achieves a reliable estimation of age at death. Results also demonstrate that cementochronology, like any other method, is characterized by significant limitations. While sex, postmortem, and inhumation intervals do not significantly influence effectiveness, a negative relationship between chronological age and annuli distinctness was observed, and multiple regression analyses demonstrate that these two parameters impact both precision and accuracy. The global accuracy is -4.5 years, but although accuracy for subjects under 60 years of age is excellent, absolute inaccuracy strongly increases for subjects over 60 years of age. This demonstrates that performance of cementochronology cannot be summarized into a single value and that this technique is a two-tier performance method. Furthermore, on subjects with a long Postmortem Interval (PMI), attention should be paid to taphonomy since it paradoxically either increases imprecision or artificially improves precision by limiting the number of usable cross-sections and reducing count dispersion.

To establish guidelines for forensic anthropologists to interpret estimates, threshold values were extracted from 95% confidence intervals. Values far above or below these ranges ought to trigger practitioner or reader doubt.

A user-friendly prediction table computed from regression models is proposed as a means of estimating age at death based on annuli count. This procedure, which represents a compromise between the strong accuracy among the young and the increasing inaccuracy among the elderly, broadens age ranges commonly published in cementochronology but maximizes the likelihood of making an accurate age-at-death estimation.

### A161 Craniofacial Anthropometric Analysis Between the Nose and Nasal Aperture Utilizing 3D Computed Tomography (CT) Scanned Images From Korean Subjects

Joon Yeol Ryu\*, National Forensic Service, Wonju, Kangwon 26460, SOUTH KOREA; Won-Joon Lee, MD, National Forensic Service Seoul Institute, Yangcheon-gu, Seoul 08036, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will understand the correlation between the nose and nasal aperture of the human face and skull and its practical use for craniofacial reconstruction/approximation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the data of the nose and nasal aperture sizes and its correlation in the Korean skull and face. Since all the data set has been collected from the contemporary Korean population subjects, it should be valuable to predict the nose morphology of the modern Korean faces from the unidentified skulls. Also, by the comparison of other ethnicity group data sets, it could provide the anthropological features of Korean faces and skulls.

This study sought to investigate the correlation of morphology and location between the nose and nasal aperture employing major craniofacial landmarks on the human skull and face for the application of a Korean craniofacial reconstruction/approximation. For the study, 100 subjects were selected from the Korean male and female corpus aged between 19 and 49 years whose the bodies arrived in the National Forensic Service (NFS) Seoul Institute for a series of autopsies within 48 hours of their expirations. Postmortem Computed Tomography (PMCT) was employed to acquire 3D head images of the subjects. A total of 32 landmarks were placed on the nose and nasal aperture of each 3D facial and skull image from each subject, and 76 measurements derived from the landmarks were measured in 3D image analysis software (Materialise Mimics).

In frontal, the position values of some bony landmarks on the nasal aperture were related to the position values of some other landmarks on the nose vertically to the transverse plane. In profile, also the position values of some bony landmarks were related to the position values of facial tissue landmarks horizontally to the coronal plane. In 35 out of 76 measurements, the mean values of males were higher than females. In pronasale, subnasal, and right and left alar curvature inferiors, the mean values of 40s of the subjects were higher than 20s of the subjects in both sexes. Overall, 26 out of the 76 measurements showed statistically significant correlations between the corresponding landmarks on the nose and nasal aperture. Simple regression equations were produced from the results.

In conclusion, this study may suggest that the nose and nasal aperture are significantly related with each other in terms of their morphology and location in Korean subjects. The prediction guideline produced as a regression formula could be applicable to the craniofacial reconstruction/ approximation from Korean skulls.

### A162 The Determination and Prevalence of Non-Forensic Specimens in an Unidentified Collection at the Georgia Bureau of Investigation (GBI)

*Christopher M. Goden, BS\*, Baton Rouge, LA 70817-7745; Alice F. Gooding, PhD, Kennesaw State University, Kennesaw, GA 30102*

**Learning Overview:** After attending this presentation, attendees will be exposed to the intricacies of determining the difference between forensic and non-forensic skeletal material and will understand the issues faced by medicolegal professionals before and after such materials have been misclassified.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential for non-forensically significant material to become confused as forensically significant material without proper analysis by a forensic anthropologist. This presentation will aid in the identification of non-forensically significant materials by highlighting common taphonomic changes, craniometric markers, and curatorial differences.

Collections of unidentified remains at medical examiner offices and law enforcement agencies are believed to represent either forensic cases that are pending identification or forensic cases that are deemed to be “cold cases.” In 2016, legislation was passed that allowed for the burial of a large collection of unidentified skeletal remains at the GBI. The unidentified collection at the GBI is comprised of 272 individuals dating back from the 1960s through present day. Prior to interment of the remains, it was decided that a thorough examination of every case was necessary to create a robust case file in the event that a lead on identification of a set of remains arises. Non-forensically significant specimens are often misclassified as forensic in nature. In the state of Georgia, 153 counties use the GBI Medical Examiner’s Office to help identify osseous material. Once at the morgue, remains are first reviewed by a forensic pathologist prior to requesting an anthropological consultation. If anthropological analysis was not available at the time, non-forensically significant materials were often classified as “cold cases.” This misclassification results in a loss of time, resources, and funds during the investigative process.

This study examines the prevalence of non-forensically significant remains present in the unidentified collection at the GBI and hypothesizes that a number of skeletal remains within the “cold case” collection are not of forensic significance and thus can be eliminated from further investigation. For this study, each set of remains had a complete anthropological analysis conducted, including construction of a biological profile through both macroscopic observations and metric analysis, and received taphonomic and trauma analyses. Craniometric landmark data were collected using a MicroScribe® G2x digitizer and 3Skull analysis software. Postcranial element measurements were also recorded. Metric measurements were analyzed using FORDISC® 3.0 and were compared against both the Forensic Data Bank and the Howell’s Data Set.

This study finds that approximately one-tenth ( $n=24$ ) of the entire unidentified collection at the GBI represent non-forensically significant cases. These include remains that are taphonomically distinguished as belonging to historic burials, of anatomical teaching specimen quality, trophy skulls, and other black market materials. This high prevalence means that forensic anthropologists, forensic pathologists, and medicolegal investigators should remain vigilant when osseous materials are examined to ensure materials are classified correctly. It is also urged that remains that have not been analyzed previously receive an anthropological analysis to ensure they are actually forensic in nature.

#### **Taphonomy, Misclassification, Craniometrics**

### A163 Drugs From Dry Bone: How Toxicology Can Add to the Biological Profile

*Lucie Biehler-Gomez\**, Milan 20133, ITALY; *Gaia Giordano, BS*, University of Milan, Milan 20133, ITALY; *Domenico Di Candia, PhD*, University of Milan, Milan 20133, ITALY; *Lorenzo Franceschetti, MD*, University of Milan, Milan 20133, ITALY; *Cristina Cattaneo, PhD*, LABANOF -Sezione di Medicina Legale, Milan 20133, ITALY

**Learning Overview:** By attending this presentation, attendees can expect to discover that drugs may be extracted from dry bones even after a 15-year postmortem interval. A new method using accelerated solvent extraction was successfully applied to samples extracted from well-preserved cadavers during autopsies (serving as a control sample) and cemeterial skeletons buried for at least 15 years.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that drugs may be found in dry bones, including in skeletal remains after a long postmortem interval. In addition, a new effective and low-cost method will be presented to perform toxicological analysis on dry bone.

The anthropological practice is usually limited to macroscopic examination, microscopic observation, and DNA analysis. Indeed, very little literature has investigated the survival of toxicological substances in skeletal forensic material and none in dry bone with a postmortem interval of more than 15 years. The present research shows for the first time the detectability of toxicological substances in known bone material with a 15-year postmortem interval.

In this presentation, samples were extracted from the cranium (compact bone) and ribs (spongy bone) during ten autopsies to serve as a control sample. Samples were collected twice to be submitted to two protocols: the first was directly dried in the oven at 50°C for 24h after separation from soft tissues, thus preserving traces of blood; in the second protocol, samples were macerated until only the bones remained before being dried in the oven at 50°C for 24h, simulating a dry bone situation. All samples were then processed with Accelerated Solvent Extraction (ASE) and the eluates were analyzed using a Q Exactive™ Orbitrap™ mass spectrometer.

Additionally, bone samples were taken from cemeterial skeletons from the Collezione Antropologica LABANOF (CAL) Milano Cemetery Skeletal Collection for toxicological analysis. This collection is a modern and documented osteological collection consisting of unclaimed skeletal remains from the cemeteries of Milan, in agreement with Italian law. In total, 13 cemeterial skeletons with verified or suspected drug addictions, intoxication, or overdose in their associated documentation were selected for toxicological study. Fragments of approximately one gram of bone were extracted from the cranium and ribs and subjected to ASE. Similarly, eluates were analyzed using a Q Exactive™ Orbitrap™ mass spectrometer.

The substances tested included opiates, benzodiazepine, 3,4-Methylenedioxymethamphetamine (MDMA), cocaine, heroin, and antidepressants. The results obtained from the fresh and cemeterial samples show a positivity for chemical substances in the skeletal matrices, demonstrating the possibility of identifying toxicological substances in dry bone, after a postmortem interval of 15 years. In addition, results exhibit the efficiency of the ASE extraction for the purification of drugs and xenobiotic substances in dry bone with various postmortem intervals.

In conclusion, toxicological substances may be found in dry bone, even after a postmortem interval of 15 years. At the anthropological level, the toxicological analysis of chemical substances in bones will provide specific information for the construction of the biological profile for forensic and archeological cases.

## A164 The Detection of Chemical Weapon Nerve Agents in Bone: An Anthropological Approach to Skeletal Toxicology

Katie M. Rubin, PhD\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Bruce A. Goldberger, PhD, University of Florida College of Medicine, Gainesville, FL 32608

**Learning Overview:** After attending this presentation, attendees will understand skeletal toxicological methods and their prospective role in forensic anthropology casework and human rights investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that chemical weapon exposure can be detected from skeletal remains, potentially expanding the ability to collect evidence from atrocities even after prolonged post-incident intervals, and by disseminating anthropologically informed models and methods that improve interpretation of skeletal toxicology results in general.

Forensic anthropologists aid forensic pathologists' determination of Cause Of Death (COD) from skeletonized remains when death is due to physically traumatic causes but cannot provide biological evidence for chemical CODs. Official COD in these cases is often left undetermined. The lack of reliable toxicological tests for skeletal material represents a significant gap in forensic science, especially considering both the opioid epidemic and recent chemical weapon attacks.

Studies show drugs can be detected from skeletal remains, even after years of decomposition.<sup>1,2</sup> Contrary to popular assumption, compounds are most readily detected following acute exposures (e.g., overdoses) rather than chronic abuse.<sup>3</sup> However, the absence of known incorporation mechanisms has hindered application of study results. A model for the incorporation of xenobiotics of forensic interest into the human skeleton, newly proposed as part of this research, suggests drugs and other analytes enter bone via equilibrium-based exchange between vascular fluids, bone interstitial fluid, and the separate water layer bound to each bone crystal.<sup>4</sup> Although most are poor substitutes for bone minerals and rapidly exchange back into vascular fluids, select compounds may adsorb onto mineral surfaces and/or fully substitute into the lattice structure.

Based on their unique chemical properties, Nerve Agent Metabolites (NAMs) may adsorb in relatively elevated quantities. To assess this possibility, methods for the extraction and semi-quantitative detection of NAMs EMPA, iBuMPA, IMPA, CMPA, and PMPA (corresponding to VX, Russian VX, sarin, cyclosarin, and soman) from bone were developed using liquid chromatography/mass spectrometry. A quadrupole time-of-flight mass analyzer was used to identify and evaluate the effects of endogenous bone compounds, while a triple quadrupole was used to achieve lower Limits Of Detection (LODs) of NAMs. Instruments were operated using reversed-phase chromatography and negative electrospray ionization. Bone samples were prepared using rapid demineralization and carbon-based solid-phase extraction. Fortified human femoral bone was used for validation. There were no interferences from the matrix or standards; however, ionization suppression was extremely high, ranging from -11.0% to -87.6% at low analyte concentrations. Citrate was the main source of suppression but could not be fully removed from the samples due to shared chemical properties with NAMs. Mean extraction efficiency was 86.7%–100.5% for low concentration preparations, with Relative Standard Deviations (RSDs) of 2.46%–5.73%. Due to high suppression, this equates to mean total recoveries of 12.8%–77.9%, with moderate RSD values (<20%). LODs were as follows: EMPA=350pg/g, IMPA=20pg/g, iBuMPA=7.5pg/g, CMPA=10pg/g, PMPA=5pg/g. Despite high suppression, these LODs are notably lower than most published for other biomatrices, facilitating detection of trace levels and potentially increasing tolerance for diagenetic loss.<sup>5-9</sup>

The proposed model of xenobiotic incorporation and the validated method were tested using femora from 12 mini pigs exposed percutaneously (high-dose exposure;  $n=6$ ) or intramuscularly (low-dose exposure;  $n=6$ ) to VX *in vivo*. EMPA was not detected in intramuscularly exposed animals. EMPA was detected in 6/6 trabecular samples and 5/6 cortical samples from percutaneously exposed mini pigs; concentrations were highest in animals that died due to their exposure. This is believed to be the first time *in vivo* nerve agent exposure has been detected from bone. Further, detected concentrations and diaphyseal-to-epiphyseal concentration ratios reflected animal exposure history (e.g., dosage level/route and post-exposure survival duration). The results are limited but promising, indicating NAMs interact with bone as a pharmacokinetic compartment and can be extracted from bone postmortem. Importantly, the results suggest toxicological testing of human skeletal remains from mass graves is warranted, although additional studies are needed to maximize testing efficiency.

Further, this research expands the foundation of skeletal toxicology broadly by providing a model for xenobiotic incorporation into bone and specifically by demonstrating a total mineral dissolution sample preparation method with the potential to increase extraction efficiency and lower LODs for multiple drug classes and other analytes. These advances may promote discussions between forensic toxicologists and forensic anthropologists and the resolution of overdose deaths.

## A165 Pore Extractor: A Micro-Computed Tomography (micro-CT) Image Processing Suite for Characterizing 3D Pore Morphometry in Cortical Bone Tissue

Mary E. Cole, PhD\*, Department of Biology, The University of Akron, Akron, OH 44325; Sam D. Stout, PhD, The Ohio State University, Columbus, OH 43210; Amanda M. Agnew, PhD, The Ohio State University, Columbus, OH 43210

**Learning Overview:** This presentation introduces a novel suite of image processing macros for micro-CT images of bone tissue, for application in ImageJ and CT-Analyser. The goals of this presentation are to: (1) visually demonstrate the completely automated extraction of cortical porosity, a predictor of spontaneous fracture risk; and (2) describe a novel structure-strain model for “normal” pore morphometry under low and high strain.

**Impact on the Forensic Science Community:** An eroded and highly porous cortex is a significant predictor of spontaneous fracture risk. Increased porosity can have age-associated (primary osteoporosis) or pathological/drug-associated (secondary osteoporosis) origins. To this end, this presentation develops a structure-strain model for expected changes in pore morphometry over the lifespan. By visualizing the porosity of bone tissue, forensic scientists can better assess a fracture’s traumatic (e.g., forensic) or spontaneous (e.g., osteoporotic) origin.

On grayscale micro-CT images, it seems simple to automatically extract 3D pore networks by binarizing bone (lighter pixels) and pore space (darker pixels). However, small pores and faint trabecular margins are often excluded by a single global threshold for pixel brightness. Additionally, at high resolution, the endosteal boundary separating cortical and trabecular bone is ambiguous and commonly must be manually drawn on numerous image slices. In highly trabecular bones (e.g., femoral neck), it is particularly challenging to distinguish large “trabecularized” cortical pores from adjacent, similarly sized trabecular spaces. A workflow to overcome these challenges was developed using an age series of the matched right-side femoral neck and midshaft fourth rib, with one male and one female per decade from the 20s to the 90s. Whole cross-sections of each femoral neck and rib measuring 10mm long were scanned in a HeliScan™ micro-CT (6.4097µm voxels, 60kV, 80uA, exposure=0.4s).

The resulting image processing suite includes the following modules: (1) Slicewise Brightness/Contrast Adjustment (ImageJ): for each slice, picks the minimum threshold on the pixel brightness histogram that excludes soft tissue and includes bone tissue; (2) Adaptive Thresholding (CT-Analyser): removes mounting fixtures and image noise while isolating faint pores based on local pixel brightness; (3) Segment Merging (ImageJ): merges separately scanned regions of large cross-sections; (4) Marrow Bounding (CT-Analyser): draws the endosteal boundary by morphologically smoothing trabecular struts and cortical pore inclusions, extracting a filled cortical mask and isolated cortical pores; (5) Cortical/Trabecularized Pore Type Differentiation (ImageJ): separates cortical pores from “trabecularized” pores by comparing minimum diameter to marrow distance; (6) RCA/PI (ImageJ): calculates relative cortical area and parabolic index; and (7) Regional Division (ImageJ): divides each slice of the cortical mask into regional halves (rib) or octants (femoral neck).<sup>1,2</sup>

3D pore morphometry was calculated for each regional sub-division and pore type using CT-Analyser. The femoral neck displays an increasing compressive strain along a superior-to-inferior gradient, while the pleural and cutaneous cortices of the rib may display opposing high and low strain. This analysis found that pore networks appear morphologically optimized to resist local mechanical strain. High strain pores are significantly less densely populated, produce lower percentages of porosity, are less convergent with other systems, and are more longitudinally oriented. Such isolated systems would be less vulnerable to the initiation and propagation of microdamage than the dense, broad, and widely convergent pore network permitted in lower strain regions. Age-associated increases in porosity maintain this structure-strain optimization, excepting: (1) significantly lower pore separation due to pore convergence; and (2) superior-anterior coalescence of porosity in the female femoral neck.

This image processing suite fully automates cortical pore extraction from micro-CT images and can be modified for traditional histological cross-sections. This project also describes pore morphometry in high and low strain regions, aiding forensic scientists in identifying age-associated or pathological presentations of porosity that may signify spontaneous fractures.

### Cortical Porosity, Micro-CT, Image Processing

## A166 Resolving Commingling Via Osteometric and Isotopic Data

Kyle A. McCormick, PhD\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853; Gregory E. Berg, PhD, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853-5530; Lesley A. Chesson, MS, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853

**Learning Overview:** The goal of this presentation is to inform attendees of the utility of combined osteometric and isotopic data to resolve commingling.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a framework for incorporating independent lines of evidence into a single cohesive model for predicting correct element matches from commingled assemblages of human remains.

Resolving commingling is an integral part of skeletal analysis, allowing for more complete sets of remains for further analysis. While multiple methods exist for the analysis of commingled assemblages, these methods are employed in isolation, with no obvious or intuitive way to incorporate the results of various methods into a single decision-making criterion. A Bayesian methodology can provide a means for incorporating multiple lines of evidence in one cohesive model. Previous research has shown the utility of such an approach to osteometric reassociation.<sup>1</sup> This study extends a Bayesian approach through the incorporation of limb bone measurements and simulated intra- and inter-individual isotopic data in predicting correct matches from small-scale ( $n=10$ ) commingled assemblages.

To associate elements, simulated bone collagen carbon and nitrogen isotope values ( $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$ , respectively) were combined with linear limb measurements. Isotope values were simulated as random draws from a normal distribution based on the inter-individual and population-level distributional properties of collagen  $\delta^{13}\text{C}$  and  $\delta^{15}\text{N}$  values from a Northeast Asian population.<sup>2,3</sup> Osteometric data came from 883 individuals curated at the Bass Donated Skeletal Collection at the University of Tennessee, Knoxville. These data were applied to the reassociation model described by McCormick, using a commingled assemblage size of 10 individuals and 1,000 simulated commingled assemblages.<sup>1</sup> It was expected that the incorporation of isotopic data would have a significant impact on resolving commingling in non-paired element comparisons (articulating and “other” [non-articulating and non-paired element] comparison types), as these comparisons typically show the lowest correct classification rates from osteometric data alone.<sup>1</sup>

The inclusion of isotopic data increased correct classification across all comparisons (17 comparisons or 17,000 simulated commingled assemblages), for an overall correct classification rate of 92.0%. “Other” element comparisons showed the highest increase in correct classification over limb bone measurements alone, with a correct classification rate of 88.8% using both osteometric and isotopic data as compared to 31.0% for osteometric data alone. Articulating comparisons also showed a dramatic increase in correct classification with the inclusion of isotopic data, with a correct classification rate of 89.9% using both types of data and 43.4% correct classification using only limb bone measurements. Paired elements had the lowest increase in correct classification with the inclusion of isotopic data (97.6% overall; 85.2% osteometric data alone); this is likely due to the already-high correct classification rate of paired elements via limb bone measurements. Overall, isotopic data alone provided a correct classification rate of 84.8%.

Independent lines of evidence (i.e., osteometric and isotopic data) are of obvious importance in forensic science. Such evidence provides convergence and increases confidence in results. This study provides an important early step in objectively combining multiple lines of evidence into a single model, which reduces uncertainty and subjectivity otherwise present when an analyst uses multiple techniques in conjunction to arrive at a decision. These results illustrate the strength of this approach to resolving commingling. When utilizing two independent lines of highly informative evidence, such as with paired element comparisons, this model is both powerful and accurate. Perhaps the most impactful result of this study is the ability to resolve commingling beyond paired elements, an underrepresented aspect of research on the resolution of commingled human remains. These results also confirm the conclusions of Berg et al. as to the value of isotopic data in resolving commingling and highlight the strength of isotope testing in the analysis of human skeletal remains.<sup>2</sup>

### Commingling, Isotopes, Bayesian Modeling

## A167 Rare is Good, Unique is Better: Testing Maxillary Sinus Morphologies for Human Identification

Teresa M. Runge, MS\*, Liverpool John Moores University, Liverpool, Merseyside L3 3AF, UNITED KINGDOM; Joel D. Irish, PhD, John Moores University, Liverpool, Merseyside L3 3AF, UNITED KINGDOM; Matteo Borrini, PhD, Liverpool John Moores University, Liverpool, AE L3 3AF, UNITED KINGDOM

**Learning Overview:** After attending the presentation, attendees will understand the potential of using morphological evaluations of maxillary sinuses for identification purposes. The goal of this study is to quantify morphological uniqueness of maxillary sinuses and to assess their morphology for human identification purposes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insights into the suitability of maxillary sinus morphologies for human identification, observed on X-ray images.

In forensic sciences, many studies are concerned with qualitative analyses of frontal sinuses and their application for identification. Approaches using measurements and volumetric assessments show promising results.<sup>1,2</sup> However, in view of prompt working routines in anthropological case work, utilization of maxillary sinus morphologies offers quicker results, as the features frequently appear on dental overview images. Even if dental comparisons cannot be applied due to, for example, mutilation of the remains, maxillary sinus morphologies can be extracted and compared. However, before techniques can be used to identify remains, the applicability of the procedure needs to be verified as a means of antemortem and postmortem comparison.

A total of 600 maxillary sinuses was sampled on radiographic images from nine population samples dating from Roman times to the 20<sup>th</sup> century. To simulate antemortem and postmortem situations, images were processed twice, for a total of 1,200 sinuses. Individuals were over 20 years of age and showed no pathological changes in the maxillofacial area. Image analyses were performed separately for right and left sinuses. Standardized anteroposterior radiographic images were used for evaluations. Sinus morphologies were extracted using the software SHAPE ver. 1.3, applying Elliptic Fourier Analysis.

Using Analysis of Covariance (ANOVA) statistics, morphological uniqueness between samples as well as individuals was evaluated. Analyses show statistically significant differences for both sides of sinus morphologies between all nine populations ( $p < 0.001$ ). Evaluations by individual show the same trend. Additionally, all individuals have been analyzed divided into modern ( $n=6$ ) and historical ( $n=3$ ) samples to exclude statistical skewing relating to potential evolutionary changes. Results show statistically significant differences for right and left sinus morphologies ( $p < 0.001$ ). Only slight differences can be assessed between the historical samples. Although p-values for the ancient samples are slightly higher, no skewing can be concluded ( $p < 0.05$ ).

To examine suitability of maxillary sinus morphologies for comparison testing, the simulated antemortem and postmortem datasets were assessed using one-way ANOVA. The results indicate total conformity between the two datasets and potentially each antemortem and postmortem morphology pair ( $p=1.000$ ). To evaluate degrees of similarity and difference between individuals in the two datasets, neighbor joining clustering was used. Measuring Euclidean distances, the dendrograms for right and left side morphologies illustrate total morphological accordance for each antemortem and postmortem data pair. Furthermore, they verify sinus morphological uniqueness, as variability between each matching antemortem and postmortem pair is evident. To test for inter- and intra-observer reliability, 18% of the radiographs were reassessed with Kappa statistics. Statistical analysis were performed using IBM® SPSS Statistics v.26 and Past.

This research provides highly encouraging outcomes, demonstrating uniqueness of maxillary sinus morphologies in a simulated environment. Future analyses should involve real life antemortem and postmortem data to verify and further the results.

## A168 A Novel Method to Augment Personal Identification in the Medical Examiner/Coroner Setting

Sharon M. Derrick, PhD\*, Texas A&M University-Corpus Christi, Corpus Christi, TX 78412; Jason M. Wiersema, PhD, Harris County Institute of Forensic Science, Houston, TX 77054; Deborrah C. Pinto, PhD, Harris County Institute of Forensic Science, Houston, TX 77054; Benjamin F. Rentfrow, Texas A&M University-Corpus Christi, Corpus Christi, TX 78412; Blair Sterba-Boatwright, PhD, Texas A&M University-Corpus Christi, Corpus Christi, TX 78412

**Learning Overview:** After attending this presentation, attendees will have been introduced to a new method under development for use in medical examiner and coroner offices to augment personal identification through statistical evaluation of circumstantial evidence. Attendees will be able to assess the potential of this method to improve identification outcomes for individual decedent cases and mass fatality cases when results from DNA and other methods are inconclusive or absent.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing the details of a novel, mathematically based method that can assess the weight of pertinent medicolegal case evidence to quantify the strength of a personal identification.

Medical examiners and coroners in the United States are responsible for the identification of unknown decedents under their jurisdictions. Most unidentified bodies receive a timely identification through fingerprints, dental records, or medical records. Other identifications, such as DNA comparison with a family reference sample, take longer but are still usually successful. However, many decedents remain unidentified for decades when the above-listed methods cannot be used or are inconclusive. The reasons for unsuccessful identifications are not typically due to a lack of investigational effort. The fundamental issue resulting in failure to identify bodies is simply that the arsenal of identification methods is still inadequate. In 2016, the Disaster Victim Identification Subcommittee of the National Institute of Standards and Technology-sponsored Organization of Scientific Area Committees released a Research Need Request for “development of population-level likelihood values for circumstantial evidence to be used in support of human identification.”<sup>1</sup>

A method that quantifies the strength of the evidence collected by investigators (e.g., clothing, geospatial relationships of body location and residence, personal effects), as well as skeletal findings (e.g., demographic profile, anomalies, bony reactions to antemortem trauma or pathological conditions) will be a valuable tool in personal identification. This idea has been posited in the forensic literature but has not yet been operationalized.<sup>2</sup> It is time to develop an instrument that applies statistical weight to the available qualitative evidence, test it, validate it, and apply it to personal identification in death investigations.

A Bayesian model was built to describe a population created from pseudo-data representing a random set of 5,000 medicolegal decedents with certain properties. The goal of the model was to estimate a 95% credible interval from the posterior distribution of the model for the proportion of a population that has a given profile of features. The model was fit using the Bayesian modeling language Stan (<https://mc-stan.org>) and the statistical language R (<https://cran.r-project.org>). The final production version will have a user interface to these programs. The model incorporated six features: sex, age, height, simplified ancestry (European, African, Hispanic, and Asian), presence of a tattoo, and evidence of antemortem fracture. The distributions of height, ancestry, tattoo, and fracture were assumed to be dependent on age and sex, but future testing of the model using real data may result in more relationships between features.

The model generally fit the data well, except for tattoos; a misspecification in the model resulted in a prediction of more tattoos in older people than the population would support. A test of the model on one living individual resulted in a prediction that the proportion of similar individuals in the population was small, between 0.29% and 0.36%. This investigational model forms the framework for an expanded instrument under development that will be tested using data from a sample of 5,000 actual medical examiner cases.

### Identification, Forensic Anthropology, Forensic Pathology

### A169 **Wartime Misidentifications of United States Casualties by the Central Identification Unit (CIU) in Kokura, Japan**

*Alexander F. Christensen, PhD\*, Defense POW/MIA Accounting Agency, Joint Base Pearl Harbor-Hickam, HI 96853*

**Learning Overview:** After attending this presentation, attendees will better understand how the United States military made identifications of war casualties, and prevented misidentifications, during the Korean War.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by examining the certainty about the historical identification of United States war casualties.

The Korea Return Program of the United States Army's Office of the Quartermaster General (OQMG) ran from March 1951, when the first 50 remains were shipped from Japan to San Francisco, CA, until May 1956, when the last of 848 Unknown remains were interred in the National Memorial Cemetery of the Pacific in Honolulu, HI. Over that period, the remains of 28,729 casualties were recovered, identified, and repatriated. How many, if any, of these identifications were in error?

Remains of all casualties who died in Korea were evacuated to the Central Identification Unit (CIU) in Kokura, Japan, for processing and identification. Until July 1951, all casualties were interred in temporary cemeteries in Korea; from that point on, an increasing number were flown directly to Kokura, and by the end of 1951, no remains were buried before analysis. Temporary cemeteries varied in their procedures; at some, remains who did not have a name association (Unknowns) were fingerprinted and had their teeth charted; at others, minimal information was recorded on the interment paperwork. Specialists at the CIU conducted anthropological and odontological analyses; in addition, fingerprints were collected whenever possible for submission to the Federal Bureau of Investigation (FBI).

Following analysis at the CIU, a board of officers at the American Graves Registration Service (AGRS) Zone Headquarters (Zone HQ) in Kokura assessed whether the remains were a satisfactory match to the casualty whose name was associated. If they approved the identification, a copy of the file was sent to the OQMG Memorial Division in Washington, DC, for approval. The vast majority of the time, this approval was rapid. In a sample of 719 identifications made by Zone HQ, approval took a week or less in 17% of cases, and between one and two weeks in 40%. An additional 21% took 15–30 days, 17% 31–90 days, and 5% greater than 90 days. The longer gaps occurred when Memorial Division wanted additional information to support an identification. In some cases, families were queried for civilian medical or dental records; in others, the CIU was asked to reprocess remains to confirm specific aspects of the biological profile.

In the majority of documented cases, these supporting records and analyses confirmed the identification. In a small group of cases, however, the identification was determined to be in error. What do these cases tell us about how errors occurred at Kokura, and who else might have been misidentified?

The most common source of error found in the records is the remains exchange, where two or more individuals were each initially identified as the other. Sometimes these exchanges occurred when the remains were initially recovered and interred, other times when they were exhumed and transported. Most were recognized prior to the identification of the remains by AGRS Zone HQ, whether due to CIU analyses or FBI fingerprint comparisons. Two temporary cemeteries provide an initial idea of how frequent such exchanges may have been. Taegu #1 contained 790 burials and Miryang 1,691; to date, nine remains exchanges have been documented at the former cemetery, and four at the latter. Of these 13, nine appear to have happened during the initial recovery or interment, and four following exhumation.

In a more significant case at Miryang, a field identification based on identification media with consistent age, height, and dental was overturned by a fingerprint mismatch. One year later, a second casualty lost in the same area was identified using the same fingerprints. The casualty originally associated with the remains has still not been identified. In this case, if decomposition had progressed too far for fingerprints to be taken, it is possible that a misidentification would have been approved.

Further study of these records is necessary to determine how frequently significant errors occurred, and whether any misidentifications were actually approved. But preliminary analysis makes it clear that the review process used by the OQMG served its purpose well, and that the vast majority of errors were successfully caught prior to identification and repatriation.

### A170 United States State Laws and Human Skeletal Remains: Are Old Bones Better Protected Than Forensic Cases?

Melinda L. Carter, MD, PhD\*, Alabama College of Osteopathic Medicine, Dothan, AL 36303; Justine Newman, Northeastern University, Boston, MA 02115; Ryan M. Seidemann, MA, Louisiana Department of Justice, Baton Rouge, LA 70802; Sebastian R. Alston, MD, Alabama College of Osteopathic Medicine, Dothan, AL 36303

**Learning Overview:** After attending this presentation, attendees will appreciate that laws across the United States require osteological expertise for handling human skeletal remains found in an archaeological context but rarely for forensic cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how state laws often place jurisdiction for handling forensic skeletal cases in the hands of coroners or medical examiners, who likely have limited experience in human osteology.

The ability to strengthen the field of forensic anthropology by recruiting more students ultimately rests on opportunities for employment. Berryman and Lanfear cite major incidents, such as the September 11 attacks, as the impetus for hiring forensic anthropologists, but it is also noted that these jobs are frequently eliminated or reduced in an economic downturn.<sup>1</sup> Passage of federal law in 1990 generated numerous jobs for human osteologists and influenced the passage of many state-level laws to protect unmarked graves on non-federal lands.<sup>2</sup> The goal of the present study was to review current laws to identify states that recognize osteological expertise as necessary for the recovery and analysis of human skeletal remains. Free online legal databases, such as FindLaw.com, were searched by state for terms including, but not limited to, “skeletal remains,” “anthropologist,” or “unidentified human remains.”

Results indicate that most states have laws protecting archaeological remains. An increasing number of states require a “skeletal analyst” with “a graduate degree in anthropology” to be consulted for both the excavation and scientific study of human remains from an unmarked grave determined to be 100 years old or older. However, only a small number of states, such as Georgia and Louisiana, have laws that recommend consultation with an anthropologist on medicolegal cases with no definition of expertise. Of these, Texas is the only state that requires a forensic anthropologist to hold a doctoral degree. By law in most states, coroners, medical examiners, and law enforcement officers are under no obligation to consult an anthropologist on a case involving human skeletal remains. An ideal situation would be for forensic anthropologists to work with licensed pathologists who understand how this expertise benefits death investigation. Yet in certain states, skeletal cases are handled by individuals with little to no education in human osteology. The discipline of forensic anthropology will be strengthened, and employment opportunities will arise, if modern medicolegal skeletal cases require osteological expertise as do archaeological remains.

#### State Laws, Skeletal Remains, Expertise

## A171 Understanding Current Levels of Forensic Occupational Stress and Wellness: Building a Foundation for Increased Forensic Science Workforce Resiliency

Justin Goldstein, MA\*, Austin, TX 78748-0039; Helen S. Alesbury, MA, New York City Office of Chief Medical Examiner, New York, NY 10016; Jamilla Dick-Quashie, MS, New York City Office of Chief Medical Examiner, New York, NY 10016

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the mental health issues that are affecting specialists employed in the forensic sciences. Understanding the diversity of perspectives on how occupational stressors affect forensic professionals, particularly those who often work in mass fatality contexts, will help attendees not only identify issues in their own offices, but also suggest potentially beneficial interventions. This presentation will emphasize the unique challenges that forensic professionals face and start an important, data-driven dialogue regarding their specific needs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing a gap in current studies of wellness in forensic science training and employment using quantitative and qualitative results from a questionnaire approved for dissemination by the New York City Department of Health and Mental Hygiene Institutional Review Board (Protocol #19-060). Currently, there is a significant lack of research that looks to address or understand the demands of working in medical examiner and coroner offices, let alone doing so in the wake of mass fatality incidents. Mass fatality incidents have become undeniably ingratiated into American culture, and thus it is vital to analyze potential sources of occupational stress and vicarious trauma that forensic professionals are exposed to as part of their daily work. Despite the analytical resources that have been directed toward studies of occupational stress, burnout, and vicarious trauma in emergency personnel following a mass fatality incident, current research either does not consider the experiences of the forensic staff at medical examiner and coroner offices, or does not focus on the specific, long-term effects a mass fatality incident has on forensic staff at medical examiner and coroner offices.<sup>1-7</sup>

This study deployed a 23-question survey to the American Academy of Forensic Sciences (AAFS) membership as well as operational staff at the Clark County Office of the Coroner/Medical Examiner (CCOCME) in Las Vegas, NV, who notably were tasked with processing the deadliest mass shooting to date in American history (October 1, 2017). Survey questions were designed to measure general levels of occupational stress and levels of perceived mental health support. Additionally, questions measuring the potential relationship between elevated levels of occupational stress and frequent contact with human remains and/or frequent contact with next of kin of human decedents were included in the survey. Questions obtaining general demographic information were also included to assess any additional trends. All questions included options to expand on answers to include qualitative data where possible. The survey was generated through the New York City Office of Chief Medical Examiner's Survey Monkey account, and IP address collection was disabled to ensure all participants remained anonymous. The survey was open for a total of six weeks, during which results from 99 individuals (40 from CCOCME and 59 from AAFS) were collected and analyzed.

Results suggest that future studies should consider occupational stress and wellness concerns of forensic professionals at higher, ethnographic resolutions. CCOCME respondents overwhelmingly (75%) reported that they felt contact with human remains and next of kin of decedents had altered their daily life outside of work hours, reporting changes in their interaction with friends and family. Notably, 50% of CCOCME staff and 74% of AAFS reported that they felt common mental health issues were not adequately addressed in occupational, academic, or professional training. Respondents of both survey groups reported feeling worn out from work (61% of AAFS, and 65% of CCOCME), highlighting the potential benefit of further developing wellness programming for the forensic science workforce.

In conclusion, this study finds that forensic professionals do report increased stress levels related to their daily work, as well as specific responses to mass fatality incidents. Additional qualitative responses to some questions also revealed the personal and individualized experiences in fatality management.

### A172 Population Structure, Population Heterogeneity, and Sources of Error in the Forensic Estimation of “Race”

*Heather J.H. Edgar, PhD\*, Albuquerque, NM 87131*

**Learning Overview:** The goals of this presentation are to: (1) summarize the sources of error in race/ancestry estimation; (2) discuss the terminology used to describe such estimates; and (3) describe the underappreciated importance of intra-group variation within socially recognized groups traditionally treated as homogeneous.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with a deeper understanding of how evolutionary history and social forces have interacted to structure phenotypic variation in the United States.

Forensic anthropologists in the United States have traditionally tasked themselves with categorizing unknown human skeletal remains into socially recognized biocultural groups that have conventionally been referred to as “races.” Recognizing that this term carries harmful social connotations, scholars and practitioners are increasingly using alternative terms, such as ancestry or biogeographic ancestry. Regardless of the term used, forensic anthropologists use various probabilistic methods to assign individuals to these socially recognized biocultural groups. These probabilities result from at least two factors: (1) histories of population isolation, movement, and mixture occurring over the past 75,000 years; and (2) political and socioeconomic forces that determine how our society emphasizes or de-emphasizes groups. Though both of these factors shift over time, structured genetic and phenotypic variation exists today in the United States, permitting categorization, with attendant error, in social and forensic contexts.

In this presentation, the term “bioaffinity” is used to reference the socially recognized biocultural groups that derive from this structure. This study examines the sources of error present in estimation of bioaffinity generated from human skeletal remains. These sources include measurement error, mismatch between sample constitution and sample description, error associated with geographic and temporal population structure, and mismatch between the population an individual was ascribed to in life and that indicated by their phenotypic or genetic variants. Further, this presentation will reflect on the terminology used to describe bioaffinity, including the meaning forensic anthropologists hope to convey with each choice of terms and the ways non-forensic anthropologists may actually interpret that terminology.

Finally, this presentation will discuss intra-group variation. This variation has been well studied for bioaffinities that are recognized to derive from a mixture of parental populations, such as Hispanic Americans. However, intra-group variation often goes unexamined in other groups, such as African Americans, European Americans, and Native Americans. For example, using dental morphological characteristics, contemporary European Americans from New York can be discriminated from those from Tennessee with 88% accuracy. This structured intra-group variation means that the sample from which the categorizing discriminant function derives may or may not represent the group from which an unknown individual derives; the degree of the error associated with this mismatch is generally unknown. Similar traits and tests discriminate Hispanic Americans from New Mexico or Florida with at most 81% accuracy, yet the presence of this population structure is generally recognized among forensic and other biological anthropologists. There is to date a dearth of forensically relevant research considering effects of population structure on other markers of bioaffinity, such as craniometric variation, in African and European Americans. Failure to quantify this intra-group variation has important implications for the collection of reference samples and may lead to fewer positive identifications of unknown individuals.

#### **Evolution, Ancestry Estimation, Intra-Group Variation**

## A173 What Are We Really Estimating? An Evaluation of What We Commonly Refer to as Ancestry Estimation

Kate Spradley, PhD\*, Texas State University, San Marcos, TX 78666; Richard Jantz, PhD, University of Tennessee, Knoxville, TN 37996-0720

**Learning Overview:** After attending this presentation, attendees will better understand that the population history of the United States allows for providing estimates beyond what is usually considered ancestry estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting that anthropologists can go beyond ancestry estimation when generating biological profiles.

While it has been stated that it is not possible to sort humans into more categories than continental origins, forensic anthropologists do this all the time, often working within a continent.<sup>1</sup> Forensic anthropologists commonly refer to this practice as ancestry estimation. But is ancestry what we are really estimating? Ousley et al. demonstrated that populations can be sorted by social race categories within the United States, by time period, by ethnic affiliation, and by geographic boundaries.<sup>2</sup> Why then is ancestry estimation the most commonly used terminology? The term “ancestry” was used to replace the word “race” to distance forensic anthropological estimations from a typological and racist past. However, the term ancestry refers to ancestral origins, which could include continental origins or ethnic affiliation. Ancestral categories such as European, African, or Asian are very broad and not especially informative for forensic case work. The purpose of this presentation is to address whether forensic anthropologists are estimating ancestry or something more specific, whether or not such estimations are informative, and how forensic anthropologists should refer to these estimations.

To address questions surrounding what is commonly referred to as ancestry estimation, particularly in the United States, craniometric data, following measurement definitions from Howells, from West Africa (Gold Coast and Cameroon: male=82, female=39), Europe (Germany and the Czech Republic: male=152, female=64), and the United States (American Black: male=213, female=175; and American White: male=282, female=193) were utilized in discriminant function analyses, using the custom import function in *FORDISC*® 3.0, with stepwise variable selection.<sup>3,4</sup> The West African and European groups represent the 19<sup>th</sup> century and American Black and American White groups are separated into 19<sup>th</sup>- and 20<sup>th</sup>-century groups. Analyses were run separately for males and females.

The results for the six female groups indicate the overall classification rate is 67.5%. The West African and European groups have the highest classification rates (97% and 73%) while the 19<sup>th</sup>- and 20<sup>th</sup>-Century American Black and White females range from 46%–68%. For the males, the West African and European groups have the highest classification rates (96% and 88%) while the 19<sup>th</sup>- and 20<sup>th</sup>-century American Black and White males range from 57%–65%. For both the males and the females, the plot of the Mahalanobis distances indicates that the 19<sup>th</sup>- and 20<sup>th</sup>-century American Black groups are intermediate between the European and American White groups and the West African group. The West African group is more dissimilar to the American Black groups, while the European group shows significantly more overlap with the American White groups, for both males and females. When 19<sup>th</sup>- and 20<sup>th</sup>-century American Blacks and American Whites are run separately, classification rates increased (up to 96%), suggesting that morphological differences exist in both groups that provide good classification rates.

The overall discriminant functions suggest that West Africans and Europeans can be differentiated from American Whites and Blacks with high classification rates. While American Blacks and Whites have ancestral origins in West Africa and Europe, they are also uniquely American and both can be assigned group membership to American subpopulations. The population history of the United States includes (but is not limited to) the migration of Europeans and the forced migration of enslaved Africans to the New World, resulting in admixture that shaped population structure. Correspondingly, miscegenation laws, institutional racism, and assortative mating practices have also shaped population structure in the United States to the degree that it is possible to estimate ancestral origins in addition to group membership suggestive of both present-day geography and population substructure. Therefore, an estimation is dependent upon the question asked, and the terminology used is largely context driven. What forensic anthropologists are, or should be, doing is estimating population affinity, a more specific and useful estimation than the more general estimation of ancestry.

### Ancestry, Biological Affinity, Estimation

## A174 The Biogeographic Profile in Forensic Anthropology: An Alternative to Ancestry for Casework Along the United States-Mexico Border

Bridget F.B. Algee-Hewitt, PhD\*, Stanford University, Stanford, CA 94305; Rebecca Vandewalle, MS, University of Illinois, Department of Geography and Geographic Information Science, Urbana, IL 61801; Bruce E. Anderson, PhD, Pima County Office of Medical Examiner, Tucson, AZ 85714

**Learning Overview:** After attending this presentation, attendees will be aware of how the place of origin can be inferred from unknown case variables and how place of origin in Mexico, trihybrid ancestry, case reporting date, and place of recovery on the border are interrelated. This study is relevant to the identification of Hispanics of Mexican origins, especially for Undocumented Border Crossers (UBC) casework from Arizona.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing biogeography as an alternative parameter to single-group ancestry. This presentation shows how novel geospatial and machine learning methods can be used to develop a biogeographic profile for unknown remains recovered along the United States-Mexico border.

Increasing fatalities and shifting demographics of Latin American migrants demand multi-focused research that works to improve rates of positive identification for UBCs.<sup>1-5</sup> Morphogenetic analyses of trihybrid ancestry have distinguished among many bio-cultural groups in Mexico, represented in UBC casework.<sup>6-11</sup> Demographic studies on migration networks have found distinctive transit pathways to “El Norte,” whereby migrants of different origins are associated with particular destinations along the United States-Mexico border at different times.<sup>12</sup> Predictions of individual sending region/origin are argued here to be more valuable for forensic case evaluation than single-group ancestry classifications.

While “ancestry” is an essential component of the biological profile, when defined as a single group category, such as Black, White, or Hispanic, its utility is limited in the border Identification (ID) context, as many UBCs will be classified as the same ancestry. Prior work has advocated for replacing single ancestry with probabilistic estimates of continental ancestry, which, under a trihybrid model, correspond to the relative quantities of European, Indigenous American, and African ancestry. It has shown that these ancestry proportions better account for admixture and the history of colonialism, slavery, and migration in the Americas.<sup>6-9</sup> Expanding this discussion to UBC casework, the present study rejects single ancestry classification in favor of reporting “biogeography”: an identity parameter that reflects the patterned association between ancestry proportions and geographic place of origin. It demonstrates how this “biogeographic profile” can be produced and mobilized in statistical models that predict location of origin from place of recovery. This information on sending region can direct the forensic case investigation by providing probable locations for finding next of kin and by reducing the pool of potential matches from missing persons lists.

Sampling ≈150 cases from the Pima County Office of the Medical Examiner (PCOME) in Arizona, finite-mixture, geospatial, machine learning, and traditional statistical methods are used to: (1) produce biogeographic profiles; (2) investigate the relationships among ancestry composition, geographic location of remains, and case-reporting date; and (3) build models that predict the individual’s documented origin as a microregional category or Geographic Information Systems (GIS) coordinates. Initial geospatial analysis shows global clustering relative to a random distribution (average nearest neighbor ratio=0.53), persisting at a range of scales (5–100km). Visual examination of mapped cases suggests clustering by both sending regions and ancestry, implying preset transit-corridors or routes. Autocorrelation analysis indicates clustering for trihybrid ancestries and latitudes/longitudes. Significant differences exist in ancestry quantities for paired microregions: Southeast cases carry more Indigenous and less European ancestry than North (+32, -27%) and Traditional (+25, -23%) cases. Correlations suggest that quantities of ancestry are structured by space/time. Individuals with more Indigenous ancestry originate in the southeast, more European ancestry in the northwest, and more African ancestry in the northeast. Individuals with higher African ancestry are more commonly recovered in earlier years. European and Indigenous ancestry are inversely related. Indigenous ancestry is a proxy for latitude, as it increases along a north-south axis and changes with the latitude-longitude of the recovery site. Tests of spatial relationships find that the north-south origin location is related to the north-south and east-west recovery location. Bootstrap forest methods confirm the significance of trihybrid ancestry and geo-temporal variables for predicting microregions and coordinates. While logistic regression explains only 38% of the variation and misclassifies 43% of cases, remarkable improvement is gained with more complex machine learning methods. The optimal neural network, fitted using k-fold validation, predicts place of origin with an overall model  $R^2=0.99$ . Latitudes and longitudes are estimated, respectively, with  $R^2=0.99$  and 0.93. Reducing the training sample, using 33% holdout-validation, produces a slightly lower overall model  $R^2=0.75$ .

This study provides a novel framework for producing a biogeographic profile and predicting individual place of origin using both biological and case-context information. It also identifies potential migration pathways that track from place of origin to place of recovery along the border and are related to trihybrid, especially Indigenous, ancestry. This study posits that patterns of spatio-temporal clustering (in case numbers, ancestry composition, reporting year, sex, origin) may reflect evolving motivations, collective knowledge, and barriers to migration. This information provides additional lines of evidence to direct case investigations or support partial identifications. Any new tool that holds the promise of increasing the number of UBC identifications is welcomed and will be put into practice at the PCOME.

## A175 A Geometric Morphometric Approach to Quantify the Impact of Admixture on Craniofacial Form

Joseph T. Hefner, PhD\*, Michigan State University, East Lansing, MI 48824; Amber M. Plemons, MA, Michigan State University, Anthropology, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will be familiarized with the implementation of two-dimensional geometric morphometric methods applied to a large sample of photographs in an attempt to understand how admixture may influence craniofacial form.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing a significant gap in available data for measuring the effect of admixture on ancestry analysis. Geometric morphometric methods for two-dimensional data permit an exploration of the differences in craniofacial morphology between various levels of admixed individuals.

Craniofacial form is under multidimensional selection borne as modular interactions, or functional morphotypic phenotypes. Multidimensional trait analysis can be used to quantify these interactions and, perhaps more importantly, may be used to construct statistical contrasts of the various forms—as *a priori* group designations—to one another in what is generally a high-dimensional shape space.<sup>1</sup> Geometric morphometric methods permit the exploration and quantification of this shape space as a single analytical unit.

This study uses a sample of digitized photographs from Caroline Bond Day's original thesis.<sup>2</sup> Day (1889–1948) was the first African American woman to obtain an advanced degree in anthropology, in any of the four fields.<sup>3</sup> As a Harvard/Radcliffe student, Day was mentored and influenced by E.A. Hooton, who published (and wrote the foreword to) Day's thesis, *A Study of Some Negro-White Families in the United States*.<sup>2</sup> Using a novel combination of sociological and anthropological data, Day examined aspects of biology and sociology within a sample of families having self-identified dual heritage, or admixture. More than 400 family photographs and individual portraits comprising data from 346 families—along with genealogical, physiological, and sociological data—are amassed within Day's thesis. These data are presented through the lens of admixture in the United States and the impact admixture had on sociological and biological aspects of each family. Day's dedication to data collection and her superb data management and reporting provide a dataset for a modern analysis of admixture and the influence of admixture on craniofacial form.

Many of the current research efforts devoted to studies of admixture focus on individuals of Hispanic ancestry and are thus of limited utility. Other works are based on such small sample sizes that the results are questionable, at best. To address these shortcomings, this study selected 197 photographs from Day's thesis with demonstrable head rotation angles between 0 and 10 degrees and that are free of objects (e.g., hair, shadows) obscuring facial landmarks.<sup>4</sup> To standardize pooling, Day's original assessments of “degree of blood quantum from Negro to White” were compressed: (1) 0–25%; (2) 26–50%; (3) 51–75%; and (4) 76–100%. Coordinate data for 24 soft tissue landmarks were collected and analyzed for each group using the geomorph package in R.<sup>5,6</sup>

A generalized Procrustes analysis was used to align and superimpose the landmark data and to calculate mean shape values for each group. These aligned data are used for all subsequent analyses. Multidimensional methods used to explore shape variability within and among various degrees of admixture include thin-plate splines, principal components analysis of the Procrustes landmark data to measure shape variability, and Procrustes Analyses of Variance (ANOVAs) with permutation to evaluate the observed patterns of shape variation and covariation within and among samples.

Several functional regions expressing shape differences were observed in the analysis. American Blacks had broader noses (nasal aperture width), narrower chins (gonial flare), and slightly wider zygomatics (bizygomatic breadth). However, identifying these differences required considerable magnification to visualize the shape differences (mag >x2). In fact, the Procrustes ordinary least squares ANOVA ( $p=0.436$ ;  $z=0.055$ ; permutations=1,000) indicate identifiable shape differences are not statistically significant. Additional explorations incorporating other levels of admixture were also insignificant.

The concept of admixture in the United States reflects historical events, such as forced relocation of Africans and Native Americans to and within the United States.<sup>7</sup> The continuing levels of admixture can reveal fine-scale genetic differences in ancestry, but these differences may not be expressed in skeletal tissues. In fact, the very concept of “admixture” represented in morphological characters is typological and as such is ill-advised as a descriptor for analyses. Larger samples of known individuals of self-reported levels of genetic admixture are needed before any assertions regarding admixture estimation in skeletal remains can be made.

### A176 Craniometrics vs. Single Nucleotide Polymorphism (SNP)s: Is There a Correlation?

Kamar Afra, MA\*, Knoxville, TN 37902; Michelle D. Hamilton, PhD, Texas State University, San Marcos, TX 78666; Bridget F.B. Algee-Hewitt, PhD, Stanford University, Stanford, CA 94305

**Learning Overview:** After attending this presentation, attendees will understand the relationship between craniometrics and specific DNA variations (SNPs) and its value for positive identification purposes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by investigating specific regions of the human genome to determine how they influence the craniofacial skeletal structure in an effort to improve human identification and facial reconstruction efforts for positive identification of the deceased.

In a world where forensic countermeasures are sophisticated tools to deflect, detect, or solve a crime, it is important to consider the human aspect in forensic science. Human identification has long been a leading tool to hold perpetrators accountable, give families closure, and put a face on a skull. This project is a pilot study to merge three disciplines that fall under the human identification umbrella: forensic anthropology, forensic genetics, and forensic art. Current facial research in genetics focuses on data from living individuals where specific SNPs that influence specific regions of the face have been found.<sup>1-3</sup> This study determines if these same regions can be translated to craniometric dimensions (inter-landmark distances) of the underlying skull itself.

The goal of this project is to provide information regarding the correlation of craniometric measurements and SNPs, as well as how these relationships can decrease subjectivity in forensic facial reconstructions and encourage interdisciplinary work within the forensic sciences. This study examined a selection of candidate SNPs currently identified in the literature to determine if there were correlations between inter-landmark distances and those SNPs within the same individual. Craniometric landmark data were collected from 17 documented skulls from the Texas State Donated Skeletal Collection using a 3D MicroScribe® digitizer. Criteria for inclusion in this study included European ancestry, the presence of intact skulls, and the presence of associated donor blood cards collected at the time of body donation. Using these blood samples, DNA from each individual was extracted, amplified, and sequenced through next generation sequencing for the specific chosen SNPs. Afterward, bioinformatics tests were applied to observe the presence or absence of the major or minor alleles in the specific locations on the genome. After determining the presence or absence of an SNP, a set of statistical tests were performed, including: Spearman's correlation between the craniometric measurements and the individual's genetic data variables; two-way hierarchical clustering and Bootstrap Forest modeling between variables that demonstrated significant correlation; a principal component analysis was performed on the craniometric data (inter-landmark measurements) and genetic data (SNP presence/absence) in order to check the homogeneity of each data set; and finally, a pair-wise Procrustes analysis was completed on the correlation of the two data sets as different groups.

The results indicate a correlation in various degrees between the targeted craniofacial regions and the targeted SNPs. There were 11 SNPs that showed significant correlation ( $p < 0.05$ ). However, the correlations were not as expected and showed some interesting results. By group level, there is no significant correlation; however, there is correlation at the individual level. While some SNPs affected the soft tissues only, others showed correlations with the skull (hard tissue), a finding that had not been previously known. These results show that combining craniometric and DNA analyses may provide new tools for forensic anthropological, genetic, and facial artistic approaches to human identification.

#### Forensic Genetics, Forensic Anthropology, Human Identification

## A177 A Call for a Paradigm Shift in the Study of Ancestry

Ann H. Ross, PhD\*, North Carolina State University, Raleigh, NC 27695-7614; Jonathan D. Bethard, PhD\*, University of South Florida, Tampa, FL 33620-8100; Elizabeth A. DiGangi, PhD, Binghamton University, Binghamton, NY 13902

**Learning Overview:** After attending this presentation, attendees will understand the underlying factors responsible for human variation with implications for ancestry estimation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a new paradigm for a better understanding of ancestry.

The estimation of ancestry is a crucial component in human identification but one of the most difficult parameters of the biological profile. Recently, antiquated and over-simplistic views of ancestry based on the trifecta of continental populations from Asia, Europe, and Africa have regained popularity. However, this facile presumption ignores underlying microevolutionary forces such as gene flow, drift, and migrations that are responsible for human diversification. Global population studies demonstrate that human craniofacial morphology fits a neutral evolutionary model because contiguous populations more frequently exchange genes and/or share common ancestry.

There is a need for broad synthesis to better understand the underlying patterns of modern human variation that will inform the estimation of ancestry. The purpose of this study is to explore craniofacial variation in Latin America and test the validity of using the tri-continental approach to ancestry. The sample totals 397 individuals, and samples were separated by biological sex when both were available for analysis (Chile: females  $n=34$ , males  $n=37$ ; Colombia: females  $n=11$ , males  $n=53$ ; Cuba: males  $n=19$ ; Enslaved Africans from Cuba: males  $n=25$ ; Guatemala: males  $n=71$ ; Puerto Rico: males  $n=5$ ; Panama: males  $n=10$ ; Peru: males  $n=7$ ; Spanish: females  $n=58$ , males  $n=67$ ). Sixteen standard Type 1 and Type 2 craniofacial homologous coordinate landmarks were used in the analysis. Coordinate data must first undergo a Generalized Procrustes Analysis (GPA) transformation before subsequent statistical analyses can be performed. The shareware program MorphoJ was used to translate, rotate, and scale all coordinates into a common coordinate system using GPA. Shape is defined as all of the geometric information that remains after the effects of location, scale, and rotational effects are removed. Centroid size is a measure of geometric scale that is mathematically independent of shape. A Principal Component Analysis (PCA) of the covariance matrix was conducted on the GPA-transformed coordinates to reduce dimensionality of the data for subsequent multivariate statistical analyses. Shape and size variation among the groups was examined using a Procrustes Analysis of Variance (ANOVA). Among-group variation was examined using Canonical Variates Analysis (CVA). Mahalanobis distance or generalized distance, which considers the correlations among variables when computing the distance between means, was used to examine group relatedness. An average linkage hierarchical (or agglomerative) cluster analysis was performed using the generalized distance matrix to examine group similarity. Hierarchical clustering begins with every sample in a single cluster, then in each successive iteration, it merges the closest pair of clusters (distances between all pairs and averages all these distances) until all the data are in one cluster. The cluster analysis was performed in JMP® Pro 14.

The Procrustes ANOVA results show significant group variation for shape ( $F(242, 15,785)=6.82, p<.0001$ ) and centroid size ( $F(11,385)=22.35, p<.0001$ ). Ninety-one percent of the total variation is accounted for on the first five canonical variates. The generalized distance results show that all groups are significantly different from one another based on 1,000 permutations ( $p$ -values range from  $0.01<p<.0001$ ), except for Puerto Rico and Peru ( $D=4.14, p$ -value= $0.347$ ). The dendrogram produced from the hierarchical cluster analysis shows two distinct clusters: Chile/Spain. Panama, Cuba, Guatemala, and Colombia branch off the Chile/Spain cluster. The enslaved African sample clusters with Peru, and Puerto Rico is the most dissimilar. These results demonstrate that craniofacial morphology is much more complex than mere proportions of Asian, African, and European continental groups. Notably, these results are consistent with isolation-by-distance of early populations in the region and historical migrations, which underscores the need for a paradigm shift from a three-way continental approach to a population history approach to ancestry.

### Ancestry, Paradigm Shift, Geometric Morphometrics

## A178 Ancestry Estimation, Race Science, and Scientific Racism in Forensic Anthropology

*Donovan M. Adams, MS\*, University of Nevada, Reno, Reno, NV 89557; Marin A. Pilloud, PhD, University of Nevada, Reno, Reno, NV 89557-0096*

**Learning Overview:** After attending this presentation, attendees will understand how forensic anthropological research influences the production of race science and is used in the perpetuation of racist ideologies. Additionally, results from an online survey are presented regarding the views of biological anthropologists on race and ancestry, and professional obligations in response to race science and scientific racism.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the implications of forensic anthropological research and practice in race science and the enforcement of racial hierarchies. Such knowledge, in conjunction with current views in biological anthropology concerning race and ancestry as well as ethical practice, may be used to establish a series of best practices regarding language use, research design, and public engagement.

In forensic anthropology, practitioners differentiate the concepts of biological ancestry and social race to argue that typological views are no longer a valid perspective in the discipline. However, despite these efforts, individuals in a variety of fields continue to assert the existence of biological racial differences with a resulting natural hierarchy. Importantly, for the anthropological community, the research is misused to promote these racist views. To understand this misappropriation, this project examines the literature for instances in which proponents of race science and White supremacists/nationalists utilize forensic anthropological research to justify the existence of biological races. Articles in multiple journals were reviewed, including *Mankind Quarterly*; *The Journal of Social, Political, and Economic Studies*; *American Renaissance*; and *The Occidental Quarterly*.

Two primary ways of misusing research on skeletal human variation were identified. The first is the use of forensic ancestry estimation as evidence for the existence of biological races with clearly delineated differences. The second is the use of phenotypic traits as correlates for racial differences in relation to personality, behavior, and intelligence. Indirectly, research in age and sex estimation, including studies of dental and skeletal development, were used to support various claims of racial differences in intelligence and temperament.

To supplement this review of the literature on race science, results from a recent online survey approved by the Institutional Review Board of the University of Nevada, Reno ( $n=257$ ) are discussed. In this survey of biological anthropologists, there is a consensus regarding the social versus biological dichotomy of race and ancestry. However, there is disagreement as to whether ancestry itself is also a social construct (28.05% agree vs. 49.32% disagree). There is a lack of agreement as to whether the use of categories like African American and European involves the identification of a biological race (21.83% agree) and if forensic anthropology reinforces racial typology (27.95% agree). In fact, scholars are almost evenly split as to whether using categories like African American or White are justified when studying phenotypic variation, with 32.54% agreeing and 35.32% disagreeing.

Questions regarding terminology show some disagreement between respondents. Biological anthropologists suggest geographically based terminology (e.g., European) is preferred over socially based terms (e.g., White) (54.63% vs. 9.73%). There is slightly more disagreement regarding social/nationality-based terms like European American (24.55% agree vs. 42.41% disagree). There is also some debate regarding the use of Hispanic/Latino as an ancestry category with approximately 26% arguing it is a valid category and about 43% arguing it is not.

Nearly half of respondents argued that political correctness is a problem in biological anthropology (46.12%) and about one-quarter of respondents agreed that concerns over the moral and ethical implications of research (e.g., photos, ancestry, terminology) result in the silencing of research. Most anthropologists argue that if misappropriation of research occurs, there is an ethical obligation to intervene (94.87%). Finally, despite these concerns, 71.6% of respondents argued ancestry estimation should remain a component of forensic practice.

The review presented here provides important evidence of continued weaponization of forensic anthropological research to push extremist and harmful ideologies of racial typology. Based on this study, it is critical that forensic anthropologists clearly evaluate what is meant by ancestry and its relation to race. Further, they should be mindful of the terminology used, reference sample construction, and method design. Research should be transparent and forensic anthropologists should engage with the public in discussions of race and biology as well as work to combat the misappropriation of their research.

---

## B1 Complex DNA Mixture Analysis: Massively Parallel Sequencing (MPS) of Rare Single Nucleotide Polymorphisms (SNPs)

Martha Petrovick, PhD\*, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02420; Natalie Damaso, PhD, Oak Ridge Institute for Science and Education/FBI Laboratory, Woodbridge, VA 22191; Tara Boettcher, BS, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02421; Josh Dettman, PhD, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02420; Darrell O. Ricke, PhD, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02421; Philip Fremont-Smith, MS, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02421; Kyleen E. Elwick, PhD, Oak Ridge Institute for Science and Education/FBI Laboratory, Quantico, VA 22135; Mark F. Kavlick, PhD, Quantico, VA 22135; James M. Robertson, PhD, Reserve Support Unit, Quantico, VA 22135; Eric Schwoebel, PhD, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02421

**Learning Overview:** After attending this presentation, attendees will understand how using MPS of rare SNPs allows the matching of more than three references to complex mixtures of DNA, including those obtained from touch DNA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing experimental evidence from two independent laboratories that demonstrates the power of using MPS of rare SNPs for the analysis of complex mixtures.

DNA mixtures from three or more contributors have proven difficult to analyze using the current state-of-the-art method of Short Tandem Repeat (STR) amplification followed by Capillary Electrophoresis (CE). This is due to multiple issues, including the sharing of alleles between different contributors, the production of confounding stutter products during amplification, and the small amount of DNA recovered from some contributors, causing allele drop-out. The discriminatory power of STRs lies in the fact that they are highly polymorphic, even though the individual alleles are not necessarily rare. This feature has enabled forensic scientists to streamline their STR analysis workflow to tens of loci in the genome. In contrast, there are only two alleles at each SNP locus used in this study, and the presence of each minor allele in an individual is relatively uncommon. Therefore, more SNP loci are required to produce a unique individual signature, and many more SNP loci are required for successful mixture analysis.<sup>1</sup> Although the SNP loci used in this study are also affected by allele sharing and drop-out, the drop-in rates for single nucleotides are relatively low, there are no stutter artifacts, and many more loci can be analyzed simultaneously, producing statistical power that enables detection of individual contributors in complex mixtures.

SNP loci were selected based on low fixation index ( $F_{ST}$ ) values and low global minor allele frequencies. In addition, certain SNPs were chosen from the literature for other purposes (biogeographic ancestry, surname and phenotype prediction, identification).<sup>2-7</sup> This panel of 18,147 loci was submitted to Ion Torrent™ AmpliSeq™ White Glove Design service, and primers were successfully designed for 14,934 loci (14,731 amplicons) in a single-tube amplification format. The resulting panel of primers was tested by sequencing DNA from 178 individuals, and 13,917 of these primers (approximately 93%) produced amplicons with adequate sequence coverage at default quality scores. Within the large primer panel containing 13,917 primer pairs, only a subset of loci is appropriate for analysis of DNA mixtures. The panel to be used for mixture analysis was selected from the larger primer panel based on specific criteria ( $F_{ST} \leq 0.08$ , minor allele frequency  $\leq 0.3$ , number of reads within a ten-fold range, strand bias ratio  $> 0.5$ , minor allele ratio for homozygous major loci  $\leq 0.005$ , no Mendelian errors, distance of  $\geq 500,000$  base pairs between loci). Primers meeting these criteria created a mixture panel targeting 2,655 loci, of which 2,311 are used for mixture analysis, while an additional 344 loci were included for identification and biogeographic ancestry prediction.

A custom software platform, IdPrism, was developed with a simple user interface and is composed of modules that identify sequence variants (minor alleles), as well as perform identification, mixture analysis, determine familial relationships, phenotypes, and Bio-Geographic Ancestry (BGA).<sup>8-13</sup>

Two independent laboratories conducted experiments with both controlled, laboratory generated mixtures, and realistic touch samples. A dilution series of single-source samples demonstrated the sensitivity of MPS, where reference profiles can be identified 100% of the time with 20pg of input and 50% of the time with 5pg input. In addition, the minor contributor can be identified at a minor to major ratio of 1:100 for 1<sup>st</sup> degree relatives. Several mixtures were prepared from saliva specimens to simulate complex forensic mixtures (e.g., two- to ten-person mixtures) in various proportions and total template amounts to identify potential limitations of the method. Results from these mixtures demonstrate the ability to resolve up to ten-person mixtures with as low as 1ng total input DNA as well as 1<sup>st</sup> degree relatives. In addition, results from touch samples demonstrated that as many as ten people can be identified in a single mixture, depending of the detection threshold that is applied. Even at a stringent threshold of Probability of Random Man Not Excluded P(RMNE) of  $10 \times 10^{-9}$ , 35 touch samples with four or more individuals were correctly identified as contributors.

### B2 Implementing Hematoxylin Into Casework at the North Carolina State Crime Laboratory

*Lindsey Admire, MS\*, North Carolina State Crime Laboratory, Raleigh, NC 27603; Kristen Crawford, MS, North Carolina State Crime Laboratory, Raleigh, NC 27603; Melanie Carson, BS, Raleigh, NC 27603; Samantha McDonald, BS, East Carolina University, Greenville, NC 27858; David M. Freehling, BS, North Carolina State Crime Laboratory, Raleigh, NC 27603*

**Learning Overview:** After attending this presentation, attendees will understand the growth phases of human hair, the type of hair that may be left behind at a crime scene, and how the presence of telogen hair roots can potentially impact DNA results obtained from hair.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an overview of the internal hematoxylin study performed at the North Carolina State Crime Laboratory and how implementation of the hematoxylin staining technique will ensure that only hair roots with the best potential to develop a DNA profile are sent for DNA analysis.

When a hair root is sent for DNA analysis, the hair examiner has determined that this hair may provide valuable information to the investigators. Hair analysis and DNA analysis complement each other in that DNA may be able to provide a potential identification for the source of a hair that the examiner deemed important. However, sending a hair root for DNA analysis is a destructive test and no further information can be obtained from that root if a profile is not developed. The hair examiners in the trace evidence section noticed over the past several years that hair roots being sent for DNA analysis were not yielding DNA profiles as expected. The recent advancements in the forensic biology section's detection limits prompted the trace evidence hair examiners to begin researching whether changes needed to be made to the current hair root removal protocol to increase the likelihood of developing a DNA profile from a hair root.

Several staining methods for determining the presence of nuclei within a hair root have been tested and published in scientific journals, as well as validated within other crime laboratories. Based on these studies, the trace evidence hair examiners decided to validate the method of hematoxylin staining for use in screening roots in the telogen growth phase for DNA analysis. In this study, more than 700 head hairs from approximately 15 living donors were examined for the presence of telogen roots. Those roots were then stained using hematoxylin and examined for the presence of nuclei. The roots were separated into one of six groups based on the number of nuclei present: Group 0 (0 nuclei), Group 1 (1 to 10 nuclei), Group 2 (11 to 20 nuclei), Group 3 (21 to 30 nuclei), Group 4 (31 to 40 nuclei), and Group 5 (41 or greater nuclei). A set of 64 hair roots, including the negative control group (Group 0) and a positive control group (anagen or catagen growth phase hair roots), were sent for quantitative analysis in the forensic biology section. The quantitative data showed a clear delineation between Groups 1 and 2, where 36% of Group 1 verses 80% of Group 2 passed the quantification cutoff. All samples in Group 0, Group 1, and the positive control group were then amplified along with a representative sample in Groups 2, 3, 4, and 5. After amplification, the delineation between the results of Groups 1 and 2 maintained constant with 27% of Group 1 obtaining DNA profiles verses 89% of Group 2 obtaining DNA profiles. This showed that the cutoff for the minimum number of nuclei required in order to obtain a potential DNA profile at the North Carolina State Crime Laboratory is 11 or more nuclei.

### B3 The “Secondary Burial” in Southern Italy: How Traditional Funerary Practices Affect DNA Preservation in Forensic Human Identification

Ciro Di Nunzio, PhD\*, Magna Graecia University, Catanzaro 88100, ITALY; Michele Di Nunzio\*, Universidad de Barcelona, Barcelona 08036, SPAIN; Aldo Di Nunzio\*, University of Naples Federico II, Naples 80100, ITALY; Pietrantonio Ricci, PhD, University of Catanzaro, Catanzaro, ITALY; Matteo Borrini, PhD\*, Liverpool John Moores University, Liverpool, AE L3 3AF, UNITED KINGDOM

**Learning Overview:** After attending this presentation, attendees will be able to describe how burial practices affect DNA preservation for forensic purposes.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the handling of human remains in South Italian cemeteries may promote the preservation of human bones and, hence, improve the analysis of degraded DNA.

Death represents the definitive transition from life to afterlife, from one social status to another. These transitions are part of different cultures, and it is possible to notice them every time a member belonging to a society dies. Burial rituals are among the few tangible forms of mortuary customs that reflect the belief in the afterlife. These procedures are the result of a complex mix of factors: cultural, philosophical, and practical (e.g., body handling, grave location, and cemetery organization).<sup>1</sup>

In Southern Italian tradition, the deceased person is perceived to be in a transition stage, between life and death, until the burial ceremony takes place. To verify that the transition to the afterlife was successful, from the 18<sup>th</sup> century on, a so-called “secondary burial” has been carried out. During the first stage (as soon as the person dies), cemetery attendants bury the corpse in a sealed wooden coffin. Then, after five to ten years, the morticians exhume the corpse for the definitive allocation. At this stage, the deceased’s relatives take care of the remains. They wash, disinfect, and wrap the human remains in a linen sheet and finally bury the deceased in a stone niche. The whole procedure is performed in compliance with Italian Presidential Decree no. 285, September 19, 1990.

If parentage or any other forensic tests are required, the Judicial Authority allows experts (e.g., forensic geneticists, pathologists, anthropologists) to perform the sampling and analysis. According to the time since death, the remains are recovered from the burial site in different stages of decomposition.

For the present study, four decomposition stages have been recognized: Fresh, Bloated, Advance Decay, and Skeletonized/Mummified.

Although DNA extraction can be conducted in any area of the body, the femoral compact bone represents the best suitable tissue, especially when DNA is degraded due to postmortem phenomena.<sup>2,3</sup>

A review of 150 analyses performed from 2001 to 2018 is presented here to evaluate how the different decomposition stages can affect both the quality and concentration of the DNA extracted from human remains that underwent a “secondary burial.”

As expected, the quality and quantity of extracted DNA decreased with the decomposition process; however, all the Short Tandem Repeat (STR) genetic profiles were adequate for forensic purposes.<sup>4-7</sup> These results demonstrate how the traditional “secondary burial” allows for better preservation of the genetic evidence compared with more modern mortuary customs.

The goal of this study is to evaluate how the handling of human remains in Southern Italian cemeteries positively affects the preservation of human bones and, hence, improves DNA analysis. These results are particularly relevant for the experts involved in exhumations related to parentage tests and identifications of an individual for both recent and cold cases.

#### Forensic Science, DNA Analysis, STRs Identification

## B4 The Student Experience in Participating in a Collaborative Exercise for Methylation-Based Body Fluid Identification

Carly E. Mills, BS\*, The George Washington University, Washington, DC 20007; Yijian Cao, BSc, Arlington, VA 22202; Daniele S. Podini, PhD, Department of Forensic Science, Washington, DC 20007; Hwan Young Lee, PhD, Seoul National University College of Medicine, Seoul 03080, SOUTH KOREA

**Learning Overview:** After attending this presentation, attendees will better understand forensic epigenetics and the potential of using DNA methylation for the identification of biological fluids. Attendees will also gain a better understanding of the student experience in implementing an established Multiplex SNaPshot™ assay and interpreting body fluid identification results via methylation profiles for the purposes of an interlaboratory collaborative exercise.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results from a student evaluation of a novel methylation-based Multiplex SNaPshot™ assay for body fluid identification. The assay has strong potential to be implemented in a general forensic laboratory as a confirmatory test. This would prevent the need to perform time-consuming serological testing to identify semen and offer a confirmatory assay for the identification of saliva for which there is currently not a test commonly used by crime labs in the United States. This assay also has the potential to be automated using equipment well-established in forensic laboratories and to be used for the identification of biological fluid mixtures.

Epigenetics is defined as reversible heritable changes in gene expression that do not alter the DNA sequence itself. Epigenetic changes play an important role in gene expression and can be altered due to a person's age, lifestyle, and environment.<sup>1</sup> DNA methylation, a DNA base modification, is the process by which methyl groups are added to cytosines on the DNA. These sites are termed CpG sites. DNA methylation patterns are established through cell division, giving various cells and tissue types a specific DNA methylation profile, and these patterns have been thoroughly studied and are regarded as a promising tool for forensic science research, including age prediction and body fluid identification.<sup>2</sup> DNA methylation can be quantified to produce methylation profiles via a process known as bisulfite conversion. In this process, un-methylated cytosine residues are converted to uracil, and during Polymerase Chain Reaction (PCR) are then converted to thymine. Following PCR amplification and single-base extension, the resulting amounts of cytosine and thymine correspond to the amount of methylation present at a specific CpG site. Bisulfite conversion is considered the gold standard in assessing DNA methylation, proving to be successful using small amounts of DNA (50–100pg) and result in 80% DNA recovery.<sup>3</sup> The accurate identification of various body fluids using a methylation-based assay will aid forensic investigators in linking evidence and acts of crime where current assays may yield a false-positive or false-negative result.

In this collaborative study, samples from Seoul National University College of Medicine were sent to various labs, including The George Washington University Department of Forensic Science, to be analyzed using an established Multiplex SNaPshot™ assay for body fluid identification.<sup>3</sup> Samples include swabs of unknown tissue source, genomic DNA of known and unknown tissue source, bisulfite-converted DNA of known tissue source, and reference Single Base Extension (SBE) products. Methylation profiles were comprised of a panel of nine CpG sites (cg17610929, cg26763284-138d, cg06379435, cg08792630, cg09765089-231d, cg26079753-7d, cg09652652-2d, cg18069290, and cg09696411). These CpG sites were chosen based on their specificity to blood, semen, and saliva.<sup>2</sup> The panel includes two CpG sites for semen, two for blood, one for saliva, two for vaginal fluid, and two for menstrual blood. Appropriate samples were extracted on the QIAGEN® QIAamp® DNA Investigator Kit, quantified on the Quantifiler® Trio, then processed via bisulfite conversion on the QIAGEN® EpiTect™ Fast DNA Bisulfite Kit, multiplex PCR, and multiplex SNaPshot™. SBE products were then analyzed on the Applied Biosystems® 3500 Genetic Analyzer to produce methylation profiles. Each profile shows peaks for each of the nine CpG sites, indicating methylation status indicative of either semen, saliva, or blood.

All samples produced reliable results using 40ng of input DNA for the bisulfite conversion process. Methylation profiles produced results consistent with blood, semen, and saliva from the corresponding samples. In addition, three genomic DNA samples and three swabs of unknown tissue source produced a methylation profile consistent with blood, semen, and saliva. Observed peak heights for CpG sites cg06379435 and cg08792630, which correspond to blood, and site cg09652652-2d, which corresponds to saliva, were present but lower than expected. Preliminary results indicate the multiplex SNaPshot™ assay for body fluid identification can be successfully performed by analysts familiar with the protocol and carried out using instrumentation that is well-established in general forensic laboratories.

**B5 A Student Experience Evaluating the Ability of a Methylation-Based Age Prediction Model to Be Implemented in the Forensic Laboratory as Part of a Collaborative Study**

*Yijian Cao, BSc\*, Arlington, VA 22202; Carly E. Mills, BS\*, The George Washington University, Washington, DC 20007; Hwan Young Lee, PhD, Seoul National University College of Medicine, Seoul 03080, SOUTH KOREA; Daniele S. Podini, PhD, Department of Forensic Science, Washington, DC 20007*

---

**Learning Overview:** After attending this presentation, attendees will better understand the students' experience in practicing a multiplex SNaPshot™ assay and a Methylation-Sensitive Restriction Enzyme (MSRE) Polymerase Chain Reaction (PCR) assay for methylation-based age prediction. Attendees will understand the advantages and the disadvantages of these two methods in forensic applications for methylation analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the results from practicing and evaluating a multiplex SNaPshot™ assay as well as a preliminary test of an MSRE PCR method for methylation-based age prediction. Both procedures have a strong potential to be implemented in a general forensic laboratory. These DNA methylation-based age prediction methods would provide useful information to narrow the search for suspects when the profile from evidence samples does not match any of the reference samples or any profile in the available database.

DNA methylation analysis is reported to be a promising tool for age prediction for forensic applications. DNA methylation is a form of epigenetic regulation of gene expression that widely occurs on the CpG sites of the genome. As age-associated DNA methylation is tissue specific, most age prediction models developed are specific to the type of body fluid tested. This study focuses on the prediction for blood samples, the most commonly found body fluid at the crime scene. The commonly used methods to detect differential DNA methylation at a CpG site of interest are bisulfite-based approaches and MSRE PCR analysis. Bisulfite conversion-based approaches, including pyrosequencing, SNaPshot™-based Single Base Extension (SBE), and massively parallel sequencing, are the most commonly used in forensic research to date. Age prediction models have been proposed using methylation status obtained from bisulfite-conversion approaches, including a multiplex SNaPshot™ assay for blood samples based on the methylation status of five CpG sites from ELOVL2, FHL2, KLF4, C1orf132, and TRIM59 genes developed by Lee et al.<sup>1</sup> The alternative method for methylation analysis is MSRE PCR analysis. This approach utilizes the differential cleavage ability of MSRE depending on the methylation status of the CpG site of interest. The MSRE approach depends on specific recognition sites that flank the CpG site. Compared to bisulfite conversion, MSRE requires less DNA input, which could be a huge advantage for forensic investigations with a limited amount of sample.

This study aims to evaluate bisulfite-based SNaPshot™ assay and MSRE PCR analysis in successfully estimating the age of an individual. For bisulfite-based approach, the study practiced with the age prediction model developed by Lee et al. as a part of a collaborative study to demonstrate its accuracy in age prediction and ability to be implemented in general forensic laboratories.<sup>1</sup> This method was tested on familial samples of the children versus their corresponding parents. Preliminary results show that this model correctly grouped the samples into the corresponding age group. A sample of a 2.5-year-old was also tested, and the age prediction was 2.28. For MSRE PCR analysis, five age-associated CpG sites that can be recognized and cleaved by the methylation sensitive restriction enzyme HhaI were selected to develop an age prediction model. These sites are reported to have strong correlation between their methylation status and age in blood samples. This study demonstrates an effective procedure for MSRE-based analysis consisting of DNA extraction, quantification, MSRE digestion, PCR amplification, and capillary electrophoresis. The preliminary results show that the methylation status at locus cg23500537 is significantly different between child and adult samples.

**DNA Methylation, Age Prediction, Bisulfite Conversion and MSRE**

## B6 A Comparison of InnoQuant® and Quantifiler® Trio as Quantification/Degradation Methods for Predicting Next Generation Sequencing (NGS) Success

Jessica M. McLamb, MS, Oak Ridge Institute for Science and Education/FBI Laboratory, Stafford, VA 22554; Natalie Damaso, PhD, Oak Ridge Institute for Science and Education/FBI Laboratory, Woodbridge, VA 22191; James M. Robertson, PhD\*, Reserve Support Unit, Quantico, VA 22135

**Learning Overview:** After attending this presentation, attendees will better understand the relationship between DNA quantification/degradation for forensic-type samples and NGS library yield as it relates to NGS success in obtaining a full profile of Short Tandem Repeat (STR) loci.

**Impact on the Forensic Science Community:** The results in this presentation will impact the forensic science community by providing information from DNA quantification/degradation that will streamline analysis by helping the analyst to decide to pursue STR or mitochondrial DNA (mtDNA) analysis.

DNA quantification kits can not only provide information on the amount of DNA in a sample, but also on the state of its degradation. Studies have been reported on the accuracy and reproducibility of the InnoQuant® and Quantifiler® Trio quantification methods in comparison with other commercially available DNA quantification kits capable of degradation estimation.<sup>1,2</sup> The Degradation Index (DI) is a ratio of a short and long fluorescent fragment with degraded DNA giving ratios >1. However, there has not been a report on an evaluation of the DI in conjunction with NGS library preparation success rates. This research on DNA quantification will give biologists a better assessment for how challenging samples will perform when subjected to library preparation, the first step for NGS processing. In addition, knowing the DI helps the analyst predict the success of obtaining a full STR profile by conventional Capillary Electrophoresis (CE), but it is not known if this is true for NGS as well.<sup>3</sup> Analysts can use this information to decide whether to pursue mitochondrial DNA (mtDNA) sequencing, which would be more successful in providing information on the source of the sample than STR analysis.

In this work, DNA from samples of blood (5µL homogenized whole blood; treated with either sonication or Ultraviolet (UV) irradiation in an attempt to artificially degrade the DNA; n, 24), bone (50mg homogenized powder; n, 12), and hairs (1cm fragments cut from root end; n, 12) from three donors each was extracted following standard procedures and the DNA was subjected to quantification and degradation analysis in duplicate using the InnoQuant® (IQ) and Quantifiler® Trio (QT) quantification kits. Library preparation, amplification, and indexing was performed using the MiSeq™ FGx Forensic Genomics System with Ing DNA and Primer Mix B multiplex. After purification, libraries were quantified using the PowerSeq™ Quant MS System. From 90 libraries, 30 were selected to be normalized, pooled, and sequenced on the MiSeq™ FGx instrument with the MiSeq™ ForenSeq™ Sequencing Kit. Sequencing data was analyzed using the ForenSeq™ Universal Analysis Software (UAS) to produce autosomal STR profiles using the manufacturer's default settings (analytical threshold, 4.5% and interpretation threshold, 7.6%).

No correlation was observed between the library yield and the level of the DI in the ranges obtained for both kits. Blood DI values ranged from 0.72–1.8 (IQ) and 0.80–1.7 (QT); bone DI ranged from 2.5–15.9 (IQ) and 1.8–6.8 (QT); and hair DI ranged from 0.76–4.74 (IQ) and 0.76–4.57 (QT). Linear regression analysis was performed to determine whether a relationship existed between the reported DI for both kits and NGS library yields. Results showed weak linear relationships for all sample types from both kits ( $R^2$ : 0.0487 [IQ] and 0.1175 [QT] for blood; 0.2167 [IQ] and 0.0926 [QT] for bone; and 0.2176 [IQ] and 0.0495 [QT] for hair).

The amount of DNA used to prepare the library strongly influenced both the library yields and NGS success. Average library yields ranged from 145,000pM (1.0ng), 4,700pM (67–90pg), 3,000pM (1–28pg) and 2,400pM (<1pg). The sequencing success was judged by the percentage of STR loci (n, 28) reported by the NGS analysis software. For example, 99–100% of the STR loci were reported when 1.0ng was used to prepare the libraries from blood and 82% from bone. However, with decreased input, fewer loci were reported (80pg bone: 35–96%; 30pg hair: 71–93%; 8pg hair: 4%).

In summary, this study demonstrated that NGS STR genotyping success appears to be influenced more by the amount of DNA used to prepare the library than by the degradation state of the DNA. The two quantification kits behaved similarly with respect to the DI.

### B7 Further Evaluation of a Dry Vacuuming Technique for Recovery of DNA From Handwritten Documents

Christian Hopkins, BS, John Jay College of Criminal Justice, New York, NY 10019; Patrick McLaughlin, BS, John Jay College of Criminal Justice, New York, NY; Mechthild K. Prinz, PhD\*, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** After attending this presentation, attendees will know more about a non-destructive method of vacuum swabbing large surface areas of handwritten notes and will have learned how it affects the workflow for paper evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing validation data on a method that allows the investigator to process paper evidence for DNA prior to latent print and questioned document examination. This will increase success rates and reduce contamination events for DNA recovered from handwritten documents.

In a previous presentation, a non-destructive homemade vacuum method for collecting biological material from handwritten documents was introduced.<sup>1</sup> The method had yielded >70% of useful DNA profiles and did not negatively affect friction ridge detail and indented writing. Based on these results, it should be possible to reverse the current forensic laboratory practice of first processing paper for indented writing, then for latent prints, and only collect DNA as the last step from areas with visible prints. Aside from the risk of contamination and loss of DNA, this workflow has the disadvantage of not including any DNA evidence deposited during the writing process and the writer's hand scraping across the page. The previous work had been performed on standard white copy paper.<sup>1</sup> Prior to casework implementation, the method needed to be tested under different conditions (e.g., on different paper substrates). Accordingly, this small validation study was designed to cover other paper types, such as notebook paper, bank deposit slips, magazine pages, and manila envelopes.

Paper substrates were made DNA free by Ultraviolet (UV) exposure in an Air Science UV-Box™. Male volunteers consenting to be part of the study were asked to write a standard text and deposit left-hand fingerprints on each piece of paper. The same set of eight volunteers was used for all paper types. The writing samples were suspended using adjustable magnetic clamps and then vacuumed using a Carolina® 9-inch glass pipette containing a moistened cotton Puritan® swab with a vacuum hose attached to the narrow end of the pipette. DNA was extracted using a lysis buffer with 5% Chelex®, 10% Tween® 20, and Proteinase K followed by concentrating the extract with DNA Fastflow Millipore® Microcon membrane filter units.<sup>2</sup> All recovered samples were quantified using Quantifiler® Trio and typed with AmpFℓSTR® Identifiler® Plus, both from Thermo Fisher Scientific™ Applied Biosystems®. Fingerprints were developed with 1,2 Indanedione in a petroleum ether zinc chloride solution.

The quantity of recovered DNA varied from donor to donor, but showed a trend that can be explained by the different sizes and surface properties of the tested paper types. Copy and notebook paper had the same size, but copy paper is rougher and yielded more DNA. Deposit slips with their smooth surface and small size had a very low DNA yield. The vacuum did not work well on manila envelopes as these were too thick to allow for air to pass through and the vacuum had less suction. Magazine paper is very thin and was difficult to handle. Fingerprints were successfully detected on copy paper, deposit slips and manila envelopes, but not on magazine paper. Friction ridge detail quality was not affected by the vacuum collection process.

### B8 Eye and Skin Color Identity Single Nucleotide Polymorphisms (SNPs) Screening Using Polymerase Chain Reaction (PCR) High Resolution Melt (HRM) Assays

Lakin Prescott\*, Towson, MD 21286; Farah Narmouq\*, Towson University, Towson, MD 21252; Kelly M. Elkins, PhD, Towson University, Towson, MD 21252

**Learning Overview:** After attending this presentation, attendees will understand the advantages of using a single-step assay to screen eye and skin color phenotypic characteristics for unknown samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing screening tools that can be used post-PCR, and potentially within a quantitation assay, to determine phenotypic traits of eye and skin color, potentially eliminating the need for additional post-PCR assays. The screening assays can also be used to check sequencing results that are difficult to interpret.

Determining phenotypic characteristics can be extremely beneficial in forensic investigations, providing information to aid in identifying unknown suspects or missing persons or in corroborating eyewitness testimony.<sup>1,2</sup> This tool, commonly called Forensic DNA Phenotyping (FDP), can also aid in forensic facial reconstruction by providing phenotypic traits or pigment-related features of unidentified skeletal remains that would previously not be known.<sup>1-3</sup> SNPs are the key to FDP and are used to predict eye and skin color using SNPs that have been previously linked to phenotypic gene expression.

One forward and two reverse PCR primers were designed for each of six SNPs. Each SNP has a major and minor allele, and was differentiated by the two reverse primers, one with a GC-clamp to shift the melt temperature higher and one without. Proper PCR amplification was checked using several DNA standards including 2800M, K562, 9948 that were previously sequenced using the Verogen ForenSeq™ DNA Signature Prep Kit using Primer Set B on the MiSeq® FGx through Massively Parallel Sequencing (MPS). The targeted SNPs included rs12913832 (HERC2 gene), rs12203592 (IRF4 gene), rs12896399 (SLC24A4 gene), rs16891982 (SLC45A2 gene), rs1426654 (SLC24A5 gene), and rs885479 (MC1R gene). Following PCR, an HRM assay was performed using a Rotor-Gene® Q real-time PCR instrument. The QIAGEN® ScreenClust® software was used to identify allele(s) present based on their differing melting temperatures and clustering. After the primers were optimized for accurate identification of the SNPs for the standards, buccal swabs were collected from volunteer donors as approved by the Towson University Institutional Review Board. Following DNA extraction and quantitation, each sample was analyzed with the optimized primer sets for each SNP, and the results were used to make phenotypic predictions of eye and skin color using decision tree models for each. The allele(s) present at the six SNPs was confirmed for each donor using Sanger sequencing. PCR HRM assays can be used as preliminary screening tools to determine eye and skin color and are much more cost-effective than MPS. PCR HRM can also be used to determine allele calls when the number of MPS reads at the SNP does not clearly support a determination of heterozygote or homozygote.

#### Forensic Science, SNPs, DNA Typing

### **B9 Assessing Potential Inhibitory Effects of Personal Lubricant on the Ability to Detect Biomarkers Consistent With Semen, Saliva, and Vaginal Fluid**

*Catherine O. Brown, MSFS\*, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Heather E. McKiernan, PhD, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Phillip Danielson, PhD, University of Denver, Denver, CO 80210; Kevin M. Legg, PhD, Center for Forensic Science Research and Education, Willow Grove, PA 19090*

**Learning Overview:** After attending this presentation, attendees will have gained an understanding of the effects of personal lubricant on the ability to detect and identify protein biomarkers using protein mass spectrometry for the analysis of sexual assault evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an in-depth scientific evaluation describing the adverse effects of lubricant on serological identification and how modified procedures using advanced instrumental techniques can mitigate deleterious effects.

Sexual assault evidence remains one of the most commonly encountered types of evidence. This has prompted extensive research and development in advancing confirmatory serological techniques in order to complement the sensitivity obtained with modern genetic testing. Protein mass spectrometry has been demonstrated as an attractive alternative to traditional testing methodologies, allowing for the confirmatory identification of trace levels of fluid-specific biomarkers. In order to further evaluate the implementation of protein mass spectrometry in relation to sexual assault kit workflow testing, an extensive study has been conducted to evaluate the effects of lubricants on the ability to detect target biomarkers. Lubricants have the potential to inhibit protease activity, displace hydrophobic markers during Solid Phase Extraction (SPE), and suppress ion detection during mass spectrometry analysis.

A previously established assay containing protein biomarkers consistent with seminal fluid (semenogelin 1, semenogelin 2, prostate specific antigen, prostatic acid phosphatase, and epididymal secretory protein), saliva ( $\alpha$ -amylase, statherin, submaxillary gland androgen-regulated protein 3B, and cystatin-SA), and vaginal fluid (small proline rich protein 3, cornulin, neutrophil gelatinase, Ly6/PLAUR, suprabasin, perioplakin, and involucrin) was utilized during the course of this research. Lubricant types assessed included water-based with glycerin, water-based without glycerin, silicon-based, hybrid silicon, and natural oil-based lubricants. Three studies were performed for the completion of this research: (1) determining the ability to detect vaginal fluid biomarkers from vaginal swabs fortified with lubricant; (2) establish the effect of lubricant types on the ability to detect biomarkers of seminal fluid and saliva; and (3) assess the ability to identify biomarkers on pre-lubricated condoms.

Vaginal swabs free of semen or saliva were collected, solubilized, and pooled to create a single-source matrix. The extract volume was normalized and applied to clean cotton-tipped swabs prior to fortification with lubricant and/or seminal fluid and saliva. For the first portion of this research, vaginal swabs were enriched with 1 $\mu$ L, 5 $\mu$ L, or 15 $\mu$ L of lubricant. Samples for the second portion of this study were prepared in a similar manner, with swabs fortified with lubricant and either 1 $\mu$ L of seminal fluid or 10 $\mu$ L of saliva. Last, for the third portion of this study, prepared swabs were moistened and used to sample the external and internal portions of a pre-lubricated condom. This sample set was designed to simulate an authentic vaginal swab recovered from an individual who had been assaulted with a barrier form of contraception.

Swabs were solubilized and protein material was separated from cellular material through centrifugation. Samples were then pre-treated prior to enzymatic digestion using SPE with Waters<sup>®</sup> Oasis<sup>™</sup> HLB 1cc vac cartridges as an additional cleanup to reduce lubricant impact. An Agilent<sup>®</sup> AssayMAP Bravo automation platform was employed for tryptic protein digestion and micro-SPE clean-up. An Agilent<sup>®</sup> 6495 triple quadrupole mass spectrometer coupled to a 1290 series liquid chromatograph was utilized for this study. Data was interpreted according to three criteria: (1) the overall Peak Area Response (PAR) of the target biomarker; (2) biomarker PAR in relation to internal standard; and (3) PAR of digestion control protein. PAR response was dependent on the type of lubricant assessed, with greater effects observed on hydrophobic biomarkers. Water-based lubricants had little-to-no effect on biomarker detection. As hypothesized, increased lubricant volumes resulted in greater PAR loss. Select hydrophobic biomarkers experienced a >80% decrease in PAR with silicon and natural oil lubricants; however, this issue was resolved with additional sample preparation procedures. Furthermore, select hydrophilic biomarkers exhibited ion enhancement in the presence of silicon-based lubricants, the effects of which were also decreased with the additional sample pre-treatment.

In conclusion, lubricant type does affect the ability to accurately identify protein biomarkers. A sample preparation method was developed in order to eliminate a majority of the deleterious effects observed on the consistency of biomarker detection.

### B10 Developing a Forensically Relevant Single-Cell Interpretation Strategy for Human Identification

Amanda J. Gonzalez, MS\*, Cherry Hill, NJ 08003; Harish Swaminathan, PhD, Boston University School of Medicine, Boston, MA 02118; Ken Duffy, PhD, Maynooth, IRELAND; Catherine M. Gricak, PhD, Rutgers University, Camden, NJ 08102

**Learning Overview:** After attending this presentation, attendees will better understand how confounding signal (i.e., allelic drop-out, stutter, and allelic drop-in) adversely affects mixture interpretation of bulk-processed samples and how the characterization of signal garnered from single cells is an important step toward the development of single-cell inference systems.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential of single-cell systems to improve mixture interpretation.

Biological evidence submitted to the forensic DNA laboratory contains cells from an unknown number of contributors in unknown proportions, resulting in interleaved mixture profiles, which are difficult to interpret, affecting match statistics or inclusion/exclusion decisions reported to the trier-of-fact.

Given the complexities associated with bulk-mixture interpretation, recent efforts have focused on introducing single-cell systems into the forensic laboratory in order to de-convolve the mixture signal by separating cells at the front end of processing. However, low-template and single-cell signal are often obfuscated by the presence of elevated stutter; false negative detection of alleles, known as allelic drop-out; and false positive detection of alleles, commonly referred to as allelic drop-in.

In this study, 1,845 single-cell profiles were analyzed, 556 of which were acquired from single-source, single-cell samples (laboratory conditions: Globalfiler™ amplification, 30 Polymerase Chain Reaction (PCR) cycles, 25-second injection on ABI® 3500 Genetic Analyzer). The data from all 556 samples was evaluated to determine the distributions associated with allelic drop-out, stutter, and allelic drop-in. The data was statistically assessed to determine whether confounding signal observed in the Electropherograms (EPGs) of single cells was significantly different from artifactual signal acquired from bulk-processed samples. The results demonstrate that, in contrast to bulk-processed samples, allelic drop-out is likely cell dependent. Stutter was again found to be locus dependent. In addition, the propensity of single-cell samples to exhibit elevated stutter ratios was observed. Notably, the stutter percentages for the single-cell samples ranged from 0% to 241% as predicted by the stochastic model described by Duffy et al.<sup>1</sup> Further, the frequency of allelic drop-in was consistent with that of bulk-processed samples (i.e., 0.04%) and cell independent, suggesting that its detection is mainly driven by laboratory parameters and conditions rather than sample condition or total DNA concentration. The presence of cell-dependent drop-out rates and high levels of stutter suggest that if a full evaluation of multiple single-cell signal is desired, new probabilistic constructs that do not rely on assumptions of cell-independence for drop-out are likely required. Since probabilistic inference relies heavily on models that adequately represent the system in question, this study forms the foundation from which these inference systems can be developed.

To further explore the viability of single-cell pipelines for forensic DNA casework, a protocol was developed to desorb buccal cells from cotton-tipped applicators. To measure its efficacy, hemocytometry was used to determine the percent of cells recovered. The 52% recovery of buccal cells was consistent with previous work wherein 54% of DNA was recovered from cotton swabs.<sup>2</sup> These results demonstrate that a single-cell strategy for forensic mixture interpretation is a viable alternative to bulk-mixture interpretation strategies that can lead to signal that is too low or highly masked by other contributors in the DNA mixture.

*This project was supported by the Jan S. Bashinski Criminalistics Graduate Thesis Grant from the Forensic Sciences Foundation.*

### B11 High-Throughput and Simultaneous Analysis of 12 Cannabinoids in Hemp Oil Using Liquid Chromatography With Ultraviolet (LC-UV) Detection

Liguo Song, PhD\*, Western Illinois University, Macomb, IL 61455; Shashi B. Pathipaka, MS, Western Illinois University, Macomb, IL 61455; James D. Leese, BS, Western Illinois University, Macomb, IL 61455; Madison Chao, BS, Western Illinois University, Macomb, IL 61455; Tranellie Collins, BS, Illinois State Police, Springfield, IL 62702; John P. Westein, BS, Illinois State Police Research & Development Lab, Springfield, IL 62702

**Learning Overview:** After attending this presentation, attendees will better understand the strategy to achieve high-throughput and simultaneous analysis of cannabinoids and appreciate a validated LC-UV method for the analysis of 12 cannabinoids in hemp oil.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by first introducing three fast LC separations of 12 cannabinoids that can be used with either UV or Mass Spectrometric (MS) detection. This presentation will further impact the forensic science community by introducing a validated LC-UV method for high-throughput and simultaneous analysis of 12 cannabinoids in hemp oil, which can be routinely used by cannabis testing labs.

In recent years, the use of products of *Cannabis sativa* L. for medicinal purposes has been in a rapid growth, although their preparation procedure has not been clearly standardized and their quality has not been well regulated. To analyze the therapeutic components (i.e., cannabinoids) in products of *Cannabis sativa* L., LC-UV has been frequently used because LC-UV is commonly available and usually appropriate for routine analysis by the cannabis growers and commercial suppliers. In the literature, a few validated LC-UV methods have been described. However, so far, all validated LC-UV methods only focused on the quantification of 11 or fewer cannabinoids. Therefore, a method able to simultaneously analyze more cannabinoids in a shorter run time is still in high demand because more and more cannabinoids have been isolated and many of them have shown medicinal properties.

In this study, the LC separation of 12 cannabinoids, namely Cannabichromene (CBC), Cannabidiolic Acid (CBDA), Cannabidiol (CBD), Cannabidivarinic Acid (CBDVA), Cannabidivarin (CBDV), Cannabigerolic Acid (CBGA), Cannabigerol (CBG), Cannabinol (CBN), Delta-8 Tetrahydrocannabinol ( $\Delta^8$ -THC), Delta-9 Tetrahydrocannabinolic Acid A ( $\Delta^9$ -THCA A), Delta-9 Tetrahydrocannabinol ( $\Delta^9$ -THC), and Tetrahydrocannabivarin (THCV), has been systematically optimized using a Phenomenex® Luna® Omega 3 $\mu$ m Polar C18 150mm  $\times$  4.6mm column with regard to the effects of the type of organic solvent (i.e., methanol and acetonitrile), the content of the organic solvent, and the pH of the mobile phase. The optimization has resulted in three LC conditions at 1.0mL/minute able to separate the 12 cannabinoids: (1) a mobile phase consisting of water and methanol, both containing 0.1% formic acid (pH 2.69), with a gradient elution at 75% methanol for the first 3 minutes and then linearly increase to 100% methanol at 12.5 minutes; (2) a mobile phase consisting of water and 90% (v/v) acetonitrile in water, both containing 0.1% formic acid and 20mM ammonium formate (pH 3.69), with an isocratic elution at 75% acetonitrile for 14 minutes; and (3) a mobile phase consisting of water and 90% (v/v) acetonitrile in water, both containing 0.03% formic acid and 20mM ammonium formate (pH 4.20), with an isocratic elution at 75% acetonitrile for 14 minutes.

In order to demonstrate the effectiveness of the achieved LC separations, an LC-UV method is further validated for the high-throughput and simultaneous analysis of 12 cannabinoids. The method used the mobile phase at pH 3.69, which resulted in significant improvement in throughput compared to other validated LC-UV methods published so far. The method used flurbiprofen as the internal standard. The linear calibration range of all the cannabinoids were between 0.1 to 25ppm with  $R^2 \geq 0.9993$ . The Limit of Quantitation (LOQ) ( $S/N=10$ ) of the cannabinoids was between 17.8 and 74.2ppb. The validation used a hemp oil containing 3.2wt% CBD and no other cannabinoids, which was reported by the vendor with a certificate of analysis, as the matrix to prepare control samples: the hemp oil was first extracted using Liquid-Liquid Extraction (LLE) with methanol; cannabinoids were then spiked into the extract at both 0.5ppm and 5ppm levels. Afterward, the recovery, precision (%RSD), and accuracy (%Error) of the control samples were assessed, and the results met the requirements by the International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17025 and American Society for Testing and Materials (ASTM) E2549-14 guidelines.

#### Cannabis, Cannabinoids, LC-UV

## B12 Cannabinoid Content in Commercially Available Oils

Tiffany M. Matyja\*, Fort Myers, FL 33913; Kenyon M. Evans-Nguyen, PhD, Tampa, FL 33606; John Struss, PhD, University of Tampa, Tampa, FL 33606

**Learning Overview:** After attending this presentation, attendees will better understand a method used to analyze the Cannabidiol (CBD) content in seven commercially available oils.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a quantitative analysis of commercially available cannabinoid products using Gas Chromatography (GC) and Mass Spectrometry (MS).

CBD is a non-psychoactive component found in *Cannabis sativa* (hemp), typically extracted from the plant via supercritical CO<sub>2</sub> extraction.<sup>1</sup> The Farm Bill of 2018 saw the legalization of CBD derived from hemp with less than 0.3% THC content by dry weight in the United States. CBD can now be purchased in tincture, oil, capsule, topical, and edible forms from local stores, in addition to online. In Florida, the sale of hemp products, which includes CBD oils, was recently legalized with SB 1020. SB 1020 mandates that all CBD products be tested by an independent laboratory and have this analysis available on the product packaging, but many of the samples obtained lacked this information. However, many of these products contain Tetrahydrocannabinol (THC), a schedule I drug under the Drug Enforcement Administration (DEA), which poses the question of how hemp products are regulated. In addition, there is no Food and Drug Administration (FDA) regulation for most of the manufacturers of these products, and no way to know if the manufacturers' claims of THC and CBD concentrations are legitimate. This project looks at seven commercially available CBD tinctures and analyzes the advertised CBD concentration compared to the concentration found via GC analysis.

An extracted solid CBD sample was obtained from Extract Labs™ and determined to be of pure quality by Botanacor, a third-party lab, and in-house via melting point analysis (66.5–67.3°C) and GC-MS. A seven-point calibration curve was made with this standard in a solvent of 9:1 hexane: 2-propanol. Initial quantitation on seven CBD tinctures was performed based on this curve. Tinctures were obtained from Tampa Bay, FL, area shops and online. Matrices were Extra Virgin Olive Oil (EVOO), glycerin, and Medium-Chain Triglycerides (MCT) (coconut oil). The glycerin samples were diluted in 2-propanol, and EVOO and MCT were diluted in the 9:1 hexane:2-propanol solution. The samples were then run on Thermo Scientific™ Trace GC Ultra GC/Flame Ionization Detector (FID) with dichloromethane as the wash solvent to minimize carryover. After quantitation, the calculated concentrations of each tincture were compared to the advertised concentration. The lab analysis data was also reviewed, if available from the manufacturer of the tincture.

Initial data suggest that five of the samples have a lower CBD concentration than advertised, and two of the samples have a higher CBD concentration than advertised. It is also suggested that some of the samples also contain THC. The initial data suggests that the manufacturers' advertisement of THC-free CBD tinctures is not accurate, both with the THC-free claim and the concentration advertised. Current work is focused on revising the quantitation method to better assess precision and robustness. Additionally, a separate MS-based method is being developed to quantitate the trace amounts of THC in the oils.

### **B13 The Detection and Identification of Synthetic Cathinones by Portable Nano-Liquid Chromatography (Nano-LC) With Dual Wavelength Ultraviolet (UV) Detection**

*Marisa C. May, BS\*, Alexandria, VA 22304; David C. Pavone, BS, Washington, DC 20008-3413; Ira S. Lurie, PhD, The George Washington University, Washington, DC 20007*

**Learning Overview:** After attending this presentation, attendees will understand how different synthetic cathinones can be screened for and identified by portable nano-LC with dual wavelength UV detection.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the first portable nano-LC with UV detection that can be used in the field or laboratory for the screening or identification of emerging drugs, specifically synthetic cathinones. This is a valuable technique because, unlike other portable devices, it is both lightweight and highly amenable to mixtures. In terms of identification, the proposed technology presents a low-cost option to meeting the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG) guidelines.

Emerging drugs have been created to avoid controlled substances laws. These drugs, also known as “designer drugs,” are created by slightly altering the chemical structure of a current controlled substance. Since these drugs are not regulated by controlled substances laws, they can be purchased over the internet and in local smoke shops. Synthetic cathinones are an example of designer drugs. They are a group of amphetamine compounds derived from the active stimulant (cathinone) of the khat plant. These drugs imitate the effects of controlled stimulant drugs, such as methamphetamine, Methylenedioxymethamphetamine (MDMA), and cocaine. The desirable effects of synthetic cathinones felt by users include increased alertness, euphoria, increased sociability, and improved attention span.

The most commonly used field test for the preliminary identification of seized drugs are color tests, which lack specificity. Portable instruments employed, including Raman, Infrared (IR) spectroscopy, Ion Mobility Spectrometry (IMS), and Gas Chromatography/Mass Spectrometry (GC/MS), can be used for the on-site identification of seized drugs but have limitations in the identification of synthetic cathinones. Portable Raman and IR spectroscopy are problematic for the identification of mixtures. Portable IMS, which can separate mixtures based on their mobility in a buffer gas, lacks specificity. GC/MS can both separate and identify mixtures of seized drugs, but is limited for the identification of synthetic cathinones due to indistinguishable mass spectra and retention times of certain positional isomers.

SWGDRUG guidelines specify for drug identification that when a category A test is unavailable, alternatively acceptable are two procedures from category B and a third from category C. The category B tests include two retention times using uncorrelated separation systems, while the category C is of lower specificity.

The portable nano-LC instrument employed in this investigation is the first of its kind; weighing only 16 pounds, it can easily be transported between the laboratory and the field. The instrument’s software can be run on a laptop or tablet connected through built-in Wi-Fi and has a rechargeable battery that can be used for 10+ hours. Because of its size, the instrument uses a fraction of the solvents and produces a fraction of the waste of conventional laboratory LC systems. The nano-LC can be equipped with different tandem columns in series with on-column LED UV detection at two wavelengths. This instrument is ideal for the screening of seized drugs because it can give two uncorrelated retention times and peak area or peak height ratios (dependent on absorbance ratios) that are proportional to the drug’s extinction coefficient at both wavelengths. In addition, based on the multitude of identification points, it could meet SWGDRUG guidelines for drug identification. The present study employs two capillary columns in series (C8 and biphenyl) and dual UV detectors (255nm and 275nm) for the screening and/or identification of different synthetic cathinones, including in the presence of adulterants. These drugs are identified by the ratios of the relative retention times for both capillaries and by their peak height or peak area ratios determined by dual wavelength detection.

#### **Portable Nano-LC, Emerging Drugs, Synthetic Cathinones**

### B14 Retrofitting Massively Parallel Sequencing (MPS) for HLA-DQA1 and Polymarker (PM) in Forensic Casework

Audrey V. Hoyle, BS\*, The George Washington University, Washington, DC 20052; Erin Weaver, BS\*, Washington, DC 20002; Fabio Oldoni, PhD, The George Washington University, Washington, DC 20007; Robert Lagacé, BS, Thermo Fisher Scientific, South San Francisco, CA 94080; Daniele S. Podini, PhD, Department of Forensic Science, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will be able to understand the potential use of MPS in forensic casework where no original biological evidence remains, but HLA-DQA1 and PM forensic analysis results are present.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternative method to approach cold cases and cases in which biological evidence, originally processed with the AmpliType® PM+DQA1 PCR Amplification and Typing Kit, is no longer available.

The objective of this research is to retrofit MPS to establish the genetic profile of an alleged suspect in a cold case, where the sole remaining evidence for comparison are results from the AmpliType® PM+DQA1 Kit. The AmpliType® PM+DQA1 Kit simultaneously amplified six loci: HLA Class II Histocompatibility Antigen gene coding for the DQ Alpha 1 Chain (HLA-DQA1), Low-Density Lipoprotein Receptor (LDLR), Glycophorin A (GYPA), Hemoglobin G Gammaglobin (HBGG), Group-specific Component vitamin D Binding Protein (GC), and D7S8.<sup>1</sup> The methodology was based on a reverse dot blot assay, which utilized an allele-specific oligonucleotide probe, immobilized on a nylon membrane, to hybridize with the complementary DNA sequence.<sup>1</sup> Following hybridization, a colorimetric assay indicated the presence of the corresponding allele.<sup>1</sup> The AmpliType® PM+DQA1 PCR Kit was one of the first Polymerase Chain Reaction (PCR) -based DNA typing kits. It emerged in the early 1990s as a popular technique that provided improved sensitivity compared to Restriction Fragment Length Polymorphism (RFLP) assays, although it had a lower power of discrimination. The assay was soon replaced by Short Tandem Repeat (STR) -based assays in the mid to late 1990s. This presentation aims to communicate the development of an MPS assay to type the six original loci and depict the results of preliminary testing on reference samples.

Primer and probe sequences were obtained from the literature.<sup>2,3</sup> Primers were synthesized for compatibility with the Ion AmpliSeq™ targeted sequencing technology in collaboration with Thermo Fisher Scientific™. Additional primers were designed for redundancy. Initially, samples of known genotypes were amplified in a singleplex reaction using conventional PCR with AmpliTaq Gold® DNA Polymerase. Successful amplification was verified utilizing agarose gel electrophoresis. PCR products were subsequently pooled and processed with the Ion AmpliSeq™ manual library preparation protocol. The barcoded samples were later templated and sequenced on the Ion Chef™ and Ion S5™ platform using the Ion S5™ Precision ID Chef & Sequencing Kit. In parallel, primers were pooled and samples were processed with the automated library preparation Precision ID DL8 kit and sequenced as described above. The sequenced samples were analyzed using Integrated Genome Viewer (IGV) software through localization of probe sequences for each marker to determine the genotype of each sample and compared to known references for verification. The most challenging region to type was GYPA due to the similarities between GYPA, Glycophorin B (GYPB), and Glycophorin E (GYPE). GYPA, GYPB, and GYPE are all sialoglycoproteins found on the human erythrocyte membrane, and they help determine the MNS blood groups. There is 95% homology among them.<sup>4</sup>

Preliminary results indicate that this MPS-based assay is able to effectively type the loci targeted in the original AmpliType® PM+DQA1 PCR Amplification and Typing Kit. Results from the manual library preparation are consistent with the results obtained utilizing an automated approach. As expected, sequencing the HLA-DQA1 region is more discriminating than the original assay as it allows for detection of microvariants indiscernible to the probe hybridization-based methodology.

#### HLA-DQA1 Polymarker, Massively Parallel Sequencing, Cold Case

### **B15 A Method Development for Analyzing 17 Benzodiazepines and Metabolites Used in Crimes Using Solid Phase Extraction-Tandem Mass Spectrometry**

*Vadoud Niri, PhD\**, State University of New York Oswego, Oswego, NY 13126; *Kimberly E. LaGatta, BS*, State University of New York Oswego, Blossvale, NY 13308; *Michaela Gysbers*, State University of New York Oswego, Oswego, NY 13126; *Taylor Maslin*, State University of New York Oswego, Oswego, NY 13126; *Shokouh Haddadi, PhD*, State University of New York Oswego, Oswego, NY 13126

**Learning Overview:** The goal of this presentation is to explain the results of a research project on developing an analytical method for detection, identification, and quantification of drugs used in crimes, at very low concentrations, using Solid Phase Extraction coupled to Liquid Chromatography/Tandem Mass Spectrometry (SPE-LC/MS/MS), which can be used in analyzing these drugs in biological samples, such as urine and blood.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a newly developed analytical method for detection, identification, and quantification of drugs used in crimes at very low concentrations in biological samples such as urine and blood. Victims of Drug Facilitated Crimes (DFCs) often report the crime hours or even days after they have happened, which adds to the challenge of detecting the drugs in the biological samples by the currently used analytical methods in forensic toxicology laboratories. The developed method can help detect the drugs at lower concentrations than possible with the current methods, which can extend the time the drugs can be detected in victims' urine or blood samples, giving them a better chance to prove the case.

Benzodiazepines are a class of antianxiety drugs, including drugs such as flunitrazepam, alprazolam, and diazepam. They are also known as predator or date-rape drugs used in DFCs—crimes that include robbery, the maltreatment of the elderly and children, as well as rape and other sexual assaults. Identification of these drugs, or their metabolites, in biological specimens such as the urine, blood, saliva, and hair of victims is commonly proof of exposure to the drug.

Like other psychoactive drugs used in DFCs, benzodiazepines are highly potent and have short half-lives. The combination of potency and short half-life makes the time window for when the drug is still detectable in biological samples very small. Victims of DFCs usually experience short-term memory loss and often report the crime days after they have happened, which adds to the challenge of detecting the drugs in the biological samples by the currently used analytical methods in forensic toxicology laboratories. The goal of the current project is to develop a method for detection, identification, and quantification of 17 benzodiazepines at sub-ppb concentrations in aqueous solutions and apply it to the analysis of these drugs and their metabolites in biological samples such as urine and blood.

In this study, an SPE-LC/MS/MS method was successfully optimized. A Supel™-Select HLB 54183-U 200mg cartridge was selected for SPE. Washing and conditioning of the packing was completed using 12mL of methanol and 2mL of ultra-pure water, respectively. After sample introduction, the analytes of interest were eluted using 5mL of a 50:50 mixture of methanol and acetonitrile. The elutant was evaporated using rotary evaporation and, upon dryness, was reconstituted using 1mL of 0.01M ammonium acetate. The reconstituted sample was then subjected to LC using C18 HPLC column (particle size: 1.9µm and length: 20cm) with gradient elution with a mixture of acetonitrile and 0.01M ammonium acetate buffer solution. The elution started with 100% 0.01-M ammonium acetate and was gradually decreased to 10%, while acetonitrile was increased to 90% and held for half a minute. Then 0.01-M ammonium acetate was increased back to 100% and held for four minutes. For MS detection, a Selected Ion Monitoring (SIM) method was started at minute 3.00 of analysis until minute 8.00. Using the optimized SPE and LC/MS/MS method, this study determined the Limits Of Detection (LODs) for 17 analytes to be in the range of 0.01 to 1.8ng/ml. The optimized method was applied to analyze the drugs in the spiked urine samples and will be applied to spiked blood samples.

### B16 “Free Range” Gunshot Primer Residue: A Study on Multiple Transfers of Gunshot Primer Residue

*Christopher P. Chany, MS\*, Texas Department of Public Safety, Austin, TX 78752; Thomas R. White, BS, Texas Department of Public Safety, Austin, TX 78752; Stephanie A. Freiwald, BS, Texas Department of Public Safety, Austin, TX 78752*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the number of times Gunshot primer Residue (GSR) can transfer from one surface to the next.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing practitioners insight into the dynamics of GSR particle transfers from one surface to a second surface to a third surface. This presentation describes the methods used to test this theory of transfer of GSR.

GSR is produced by a firearm when it is discharged. The primer for centerfire cartridges is mainly composed of lead styphnate, barium nitrate, and antimony sulfide. The residue from the primer explosion escapes from openings in the gun and can be deposited on a person’s hands and clothing. These particles can be collected and analyzed using automated scanning electron microscopy/energy dispersive X-ray spectroscopy. Characteristic GSR particles have a molten appearance and contain barium, antimony, and lead. There have been several studies that examine the transfer of GSR to the interior of police cars from a person who has gunshot residue on their person. There have not been studies conducted that try to determine the number of times GSR particles could transfer from one surface to another.

This presentation will detail the results of two studies on the potential transfer of GSR. The first study involves the transfer of GSR from a GSR-contaminated area to a clean subject who enters the area, then subsequently transfers the gunshot residue particles to other surfaces outside the contaminated area. One of the analysts of the Trace Evidence section of the laboratory attended firearm familiarization training given by the Firearms and Toolmarks section of the laboratory. This analyst does not handle firearms at all. At the end of the training, the analyst was asked to stub her clothing, her cubicle chair, the driver seat of her car, and any chairs that she might have sat in at her home in the same clothing she had worn to the training.

The second study deals with the potential transfer of GSR from a victim’s clothing to a person’s hands that touch the victim. The Firearms and Toolmarks section re-created a shooting victim’s clothing. An analyst who had no GSR on their hands handled the shooting victim’s clothing. Their hands were then stubbed to analyze for GSR.

All of the above stubs were analyzed using scanning electron microscopy energy dispersing X-ray spectroscopy instrumentation using standard laboratory procedures for the analysis of GSR.

This research takes a novel approach by investigating the likelihood of multiple transfers of GSR particles between surfaces.

### **B17 Ambient Ionization Mass Spectrometry (AMS): A New Forensic Tool for Adhesive Tape Evidence Discrimination**

*Maureen E. Oliva, BS\*, San Antonio, TX 78230; Yinglei Pu, BS, Texas Tech Department of Chemistry & Biochemistry, Lubbock, TX 79409; Dong Zhang, BS, Texas Tech Department of Chemistry & Biochemistry, Lubbock, TX 79409; Gerardo Gamez, PhD, Texas Tech University, Lubbock, TX 79409*

**Learning Overview:** After attending this presentation, attendees will be better informed about AMS techniques for the analysis of tape evidence. In particular, the methodology will explore analyzing different types of adhesive tapes to identify discriminating mass spectral properties. AMS techniques were utilized in new ways to aid forensic investigations in exploiting novel evidence items, such as tape.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an additional technique for analyzing forensic adhesive tape evidence. This technique was optimized to distinguish the manufacturer of the tape samples. This new technique is able to provide data in real time that has the potential to expedite a forensic investigation. Additionally, this technique could be optimized for other sample types. The optimization of the different types of AMS sources could lead to a wider applicability of this methodology as a tool in discriminating other evidence types commonly encountered in the crime scene.

Adhesive tapes are often found at crime scenes, and these tapes supply numerous investigative leads, if treated properly. Trace evidence (hair, fibers, etc.) are often found on tapes, along with DNA and fingerprints. Physical tear matches can also be performed to link a piece of tape to the original roll it came from. There is also one other way that forensic professionals analyze adhesive tapes, and that is via chemical analysis. Chemical analysis of adhesive tapes is where the adhesive and/or backside layer of the tape are analyzed to get its chemical composition. The chemical information is used to differentiate the tapes by type and/or brand, which is important because it allows investigators to make connections between suspects and the tape evidence. Several chemical analysis techniques, including Fourier Transform Infrared (FTIR), Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS), Isotope Ratio Mass Spectroscopy (IRMS), Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS), Nuclear Magnetic Resonance (NMR), and Energy-Dispersive X-Ray Spectroscopy (EDX), have been shown to yield different accuracy in distinguishing tape brands, but, while they offer several advantages, they may require intensive sample preparation, complex instrumentation with limited accessibility, or are destructive in nature. AMS is a relatively new, easy-to-use, cost-effective, and portable technique that allows direct desorption/ionization from sample substrates with little-to-no sample preparation to yield chemical analysis in real-time.

The purpose of this study was to develop and evaluate different AMS approaches, such as direct desorption Flowing Atmospheric Pressure Afterglow (FAPA), and Laser-assisted Desorption (LD) AMS for analyses capabilities of adhesive tapes. With these different approaches, multiple different tape types were analyzed, including silver duct tape and black electrical tape. There were numerous manufacturers of each tape tested to be able to distinguish and categorize the types of tape, and the brands of each tape. Data were analyzed using Principle Component Analysis (PCA) and the Partial Least Squares (PLS) method in order to find the covariance and correlations that lead to the discrimination of tapes by manufacturer. This technique captured an array of structural information for each tape under study, thereby highlighting promising results of ambient ionization techniques as a forensic tool.

#### **Adhesive Tape, Ambient Ionization, Manufacturer**

### B18 Supplementary Viewing Techniques of Gunshot Residue (GSR) Utilizing Infrared (IR) and Fluorescence

*Christopher L. Ardell, BS\*, Huntington, WV 25701; Zachary E. Weitzel, BS, Georgia Bureau of Investigation, Decatur, GA 30034; Charles A. Smith, BS, Georgia Bureau of Investigation, Decatur, GA 30034; Amanda L. Bazzanini, MS, Georgia Bureau of Investigation, Decatur, GA 30034*

**Learning Overview:** The goal of this presentation is to inform attendees about the use of IR and fluorescent photography as a method for visualizing GSR on dark, patterned, or contaminated clothing.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating techniques capable of visualizing GSR on normally difficult-to-work-with evidence in a rapid and non-destructive manner.

While muzzle-to-target analysis is a crucial component of forensic investigation into firearms-related incidents, a number of obstacles can impede the ability of traditional techniques to observe depositions of GSR at an acceptable level. Microscopic examination for the purpose of documenting GSR deposition patterns is difficult to perform on evidence comprised of darker or patterned fabrics, and environmental contaminants can affect both the microscopic examinations and follow-up chemical testing. For these reasons, development of a supplementary non-destructive technique for GSR visualization is desirable.

Previous studies have demonstrated that GSRs possess both IR and fluorescent properties, allowing for the visualization of deposition patterns on a variety of substrates, though no definitive methodology has currently been established. This study evaluates the ability of the Foster and Freeman Crime-lite® 82S series of light sources, as well as the Foster and Freeman DCS® 5 workstation, for the purpose of visualizing GSRs across a number of variables.

In order to establish that GSR deposition patterns observed utilizing IR mimicked expected results derived from more easily observed lighter fabrics, dark fabrics were shot in triplicate over a selection of fixed distances and calibers. These results were compared to a light fabric control shot with the related caliber at each distance. Testing was then expanded to incorporate a variety of ammunition manufacturers and fabric types to discern the effects, if any, each of these variables had on visualization with IR. Obtained samples were also subjected to fluorescent testing utilizing a green light source (490–560nm) coupled with a deep-red filter (571nm) in order to serve as an additional method for GSR visualization and as a comparison point for obtained IR images. Final testing involved the application of a selection of commonly encountered environmental contaminants to fired targets in order to document their potential interference in the visualization process.

The results of this study indicate that visualization of GSR on dark fabrics utilizing IR in ideal conditions is widely successful across most tested calibers and manufacturers, while fabric composition, weave, and pattern differentially affected IR visualization. Green fluorescent visualization was tested with varying outcomes observed across multiple calibers, manufacturers, and target materials. Contaminants were also demonstrated to have varied effects on visualization as certain environmental contaminants were able to be eliminated nearly completely while others completely obscured GSR patterns. Future avenues for investigation can involve testing the effects of different fluorescent wavelengths and additional contaminants or utilize a more comprehensive list of distinct ammunition types and manufacturers.

#### Gunshot Residue, Infrared, Fluorescence

### B19 The Development of a Rapid, Reliable Detection Method for Synthetic Cathinones

*Mario O. Vendrell-Dones, BS\**, Florida International University, Miami, FL 33199; *Chiara Deriu, MS*, Florida International University, Miami, FL 33199; *Ling Wang, MS*, Florida International University, Miami, FL 33139; *Bruce R. McCord, PhD*, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will understand the principles of Surface-Enhanced Raman Spectroscopy (SERS), how the application of SERS is used to rapidly detect synthetic cathinones, and how selected bands can be utilized as markers of these substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the application of SERS to the detection of synthetic cathinones, such as 3,4-methylenedioxy-5-methylethcathinone and 4-methylethcathinone.

Effectively examining synthetic cathinones will contribute to the prevention of their proliferation and to the assistance of victims suffering from overdose, irreversible health damage, or even death. Improvements in the control of these compounds will also aid toxicologists and forensic scientists in detecting and limiting their effect on society. Furthermore, being able to detect these synthetic drugs will provide critical assistance in understanding the effects of these substances on the human body.

Currently, countless structural variations of new synthetic cathinones (“bath salts”) appear in drug markets. However, the research into their specific toxicological effects in humans is lacking. Manufacturers synthesize these new synthetic cathinones in various ways, and many of these drugs are sold as mixtures containing additives. Variations in the purity of these drugs and, thus, the presence of additives at unknown concentrations, can cause overdoses. These mixtures cause problems for both policing and health agencies. Therefore, there is a need for a screening method that can assist authorities in identifying these drugs in a more rapid, sensitive, and inexpensive way.

Since the drugs studied in this proposal are structurally similar, SERS is uniquely suited as a screening procedure. Due to its molecular specificity and sensitivity, SERS constitutes an ideal platform to detect and differentiate synthetic cathinone analogs. SERS utilizes nanometallic surfaces to amplify the Raman signal of analytes, providing qualitative and quantitative information. The oscillations of the conduction electrons of these nanometallic structures causes the accumulation of photonic energy and results in Localized Surface Plasmon Resonances (LSPRs). LSPRs are responsible for the signal enhancement that allow adsorbed molecules to be detected, even at low concentration levels. LSPRs can also produce signal enhancements such that single molecule signals can be detected. This provides a flexible method to detect newly developed compounds and keep them off the streets.

The synthetic cathinones 3,4-methylenedioxy-5-methylethcathinone and 4-methylethcathinone have been analyzed with both traditional Raman spectroscopy and SERS. The methods for their detection have been optimized by varying pH, incubation time, nanoparticle size and composition, aggregating agents, and laser wavelength. Density Functional Theory (DFT) calculations have been used to assign the vibrational modes of major bands for each of the selected synthetic cathinones, providing a sound spectroscopic interpretation of the experimental Raman and SERS spectra. Further validation of this work will be completed with the ultimate aim of detecting these drugs and their analogs in biological matrices, starting with oral fluid.

#### Synthetic Cathinones, Surface-Enhanced Raman Spectroscopy, Density Functional Theory

### B20 A Validation Study of the Synthetic Cannabinoid 5-Fluoro PB-22

*Trista Gray, BS\*, Birmingham, AL 35204; Erin Shonsey, PhD, Alabama Department of Forensic Sciences, Hoover, AL 35244*

**Learning Overview:** The goal of this presentation is to educate attendees on the growing problem of synthetic cannabinoids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how dangerous and prominent synthetic cannabinoids are becoming as well as by providing a method by which 5-fluoro PB-22 can be identified in samples using Gas Chromatography/Mass Spectrometry (GC/MS) analysis.

**Background/Introduction:** The first synthetic cannabinoid was developed in the late 1980s by chemist John W. Huffman in an effort to understand the two cannabinoid receptors (CB<sub>1</sub> and CB<sub>2</sub>). The cannabinoid receptors are not only involved in the high experienced by marijuana users, but also in the control of appetite, pain, and sleep. While the development of synthetic cannabinoids led to a greater understanding of the cannabinoid receptors, it also precipitated an entirely new drug market. Clandestine chemists hijacked scientific research, using published scientific articles to synthesize cannabinoids for distribution in the gray market. Products containing synthetic cannabinoids were marketed as Spice, herbal blends, or incense. The products are labeled “to be used as incense” and “not for human consumption” in an effort to circumvent drug laws and regulations. Spice products can contain more than a dozen synthetic cannabinoids of varying concentrations.

**Objective:** The focus of this project is to develop and validate a method for the analysis of the synthetic cannabinoid 5-fluoro PB-22, which first appeared in 2014. 5-fluoro PB-22 has high affinities for both cannabinoid receptors, which is significant because  $\Delta^9$ -Tetrahydrocannabinol (THC) is only a partial agonist for both of the cannabinoid receptors.

**Methods:** This validation includes studies determining the Limit Of Detection (LOD), the accuracy of identification, and specificity of the assay. In addition, a GC/MS program has been developed to differentiate between 5-fluoro PB-22 and 13 of its isomers. The isomers of 5-fluoro PB-22 that were examined included five hydroxyquinoline isomers, five hydroxyisoquinoline isomers, and three N-(fluoropentyl) isomers. Finally, casework was simulated using previously confiscated samples submitted by law enforcement to the Alabama Department of Forensic Sciences.

**Results:** The LOD for 5-fluoro PB-22 is 20 $\mu$ g/mL using the developed method. The method provided reproducible results over the course of three different days. Two different isomers, 5-fluoro PB-22 4-hydroxyquinoline isomer and 5-fluoro PB-22 5-hydroxyquinoline isomer, are the only isomers that resulted in interference with the target drug. 5-fluoro PB-22 5-hydroxyquinoline interfered with library matches as well as ion ratios. 5-fluoro PB-22 4-hydroxyquinoline isomer had a retention time interference with the target drug. Additionally, three additional synthetic cannabinoids (JWH 081, AKB48 N-(4-fluorobenzyl) analog, and 5-fluoro THJ) were also found to interfere with the library matches to the target drug as well as ion ratios. The method was able to identify 5-fluoro PB-22 in ten simulated case samples with concentrations of the drug ranging from 75 $\mu$ g/mL to 500 $\mu$ g/mL.

**Conclusion/Discussion:** The LOD falls within an acceptable range for the purpose of the assay. The developed method has provided reliable and reproducible results in the analysis of the target drug. The method has also provided reliable results in identifying the drug in simulated case samples. Of the 145 synthetic cannabinoids tested, two isomers of 5-fluoro PB-22 have caused interference with the analyte. Currently, separation of 5-fluoro PB-22 from the two interfering isomers has not been achieved, but work is ongoing.

#### Synthetic Cannabinoid, Clandestine Chemistry, Spice

## B21 Metabolism of Furanylfentanyl in Fresh Human Hepatocytes: Detection and Confirmation of Furan Ring-Opened Carboxylic Acid Metabolite

Tatsuyuki Kanamori\*, Kashiwa, Chiba 277-0882, JAPAN; Yuki Okada, MS, National Research Institute of Police Science, Kashiwa 277-0882, JAPAN; Hiroki Segawa, PhD, National Research Institute of Police Science, Kashiwa 277-0882, JAPAN; Tadashi Yamamuro, PhD, Kashiwa, JAPAN; Kenji Kuwayama, PhD, Kashiwa, JAPAN; Kenji Tsujikawa, PhD, Kashiwa, JAPAN; Yuko Togawa Iwata, PhD, Kashiwa, JAPAN

**Learning Overview:** After attending this presentation, attendees will have gained a deeper knowledge regarding the metabolism of furanylfentanyl, an analog of fentanyl that has a furan-2-carbonyl group instead of the propionyl group found in fentanyl. Furanylfentanyl has been available in the United States and Europe since at least 2015 and has been detected in more than 18 countries.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the metabolic pathways of furanylfentanyl definitively determined using authentic standards of its metabolites.

In the present study, the metabolism of furanylfentanyl was investigated using fresh human hepatocytes. Four metabolites of furanylfentanyl were definitively identified in the culture medium of hepatocytes incubated with furanylfentanyl by comparing the analytical data with chemically synthesized authentic standards.

**Methods:** The authentic standards of furanylfentanyl and its five putative metabolites (nor-furanylfentanyl, 4'-hydroxy-furanylfentanyl,  $\beta$ -hydroxy-furanylfentanyl, 4'-hydroxy-3'-methoxy-furanylfentanyl, and furan ring-opened carboxylic acid metabolite) were synthesized in the laboratory. Fresh human hepatocytes (seeded in a 24-well plate at  $2.1 \times 10^5$  cells/cm<sup>2</sup>) were incubated with 10 $\mu$ M furanylfentanyl at 37°C and 5% CO<sub>2</sub>, and the culture medium was sampled 48h after addition of the drug. The medium was treated with  $\beta$ -glucuronidase/aryl sulfatase, followed by deproteinization by the addition of acetonitrile. After centrifugation, the supernatant was dried under a stream of nitrogen and reconstituted with the initial mobile phase used in liquid chromatography. Metabolites in the samples were analyzed via liquid chromatography-triple stage quadrupole mass spectrometry.

**Results:** 4'-Hydroxy-furanylfentanyl ([M+H]<sup>+</sup>;  $m/z$  391),  $\beta$ -hydroxy-furanylfentanyl ( $m/z$  391), 4'-hydroxy-3'-methoxy-furanylfentanyl ( $m/z$  421), and furan ring-opened carboxylic acid metabolites ( $m/z$  409) were detected on the Extracted Ion Chromatograms (EICs) of their protonated molecules. Furan ring-opened carboxylic acid metabolite was considered the main metabolite of furanylfentanyl owing to its extremely strong peak intensity. The other three metabolite peaks were minimally detected in the EICs. In the case of fentanyl, the desphenethylated metabolite, nor-fentanyl, was the main metabolite found *in vivo* and *in vitro* in the previous study; however, the desphenethylated metabolite of furanylfentanyl, nor-furanylfentanyl, was not detected in the culture media at all. To date, two studies on the metabolism of furanylfentanyl have been published.<sup>1,2</sup> Both studies reported that the dihydrodiol metabolite ([M+H]<sup>+</sup>;  $m/z$  409, identical to the furan ring-opened carboxylic acid metabolite) is formed from furanylfentanyl and the presence of the furan ring-opened carboxylic acid metabolite was ruled out. However, the dihydrodiol metabolite was not identified with authentic standards in those studies. In the present study, the metabolite with a molecular weight of 408 ([M+H]<sup>+</sup>;  $m/z$  409) was definitively identified as a furan ring-opened carboxylic acid metabolite by comparing the analytical data with authentic standards. Several studies have reported the formation of furan ring-opened carboxylic acid metabolites. For example, loop diuretic furosemide and  $\alpha_1$ -blocker prazosin are known to form furan ring-opened carboxylic acid metabolites. Therefore, these facts support the results obtained in this study.

### Furanylfentanyl, Metabolism, Hepatocyte

### **B22 An Analysis of Smokeless Powders, Smokeless Powder Residues, and Pyrolysis Products by Gas Chromatography/Mass Spectrometry (GC/MS)**

*Emily C. Lennert, BS\*, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816; Candice Bridge, PhD, National Center for Forensic Science University of Central Florida, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will understand the analysis and classification of smokeless powders and post-burn smokeless powder residues, as well as how the pyrolysis products generated in the residues are related to the compounds present in the unburned samples through GC/MS.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the pyrolysis products generated through the burning of smokeless powders may be related to the intact smokeless powder. The research presented herein may aid in providing a link between a suspect and a crime scene and may be applied to analyses such as organic gunshot residue analysis or analysis of debris after an explosive event.

Following an explosive event, such as the detonation of an improvised explosive device or discharge of a firearm, intact or partially burned smokeless powder particles and burned smokeless powder residues may be recovered. Therefore, to best simulate possible real-world evidence, intact and burned samples were analyzed. Intact smokeless powders were extracted for GC/MS analysis through a simple extraction procedure set forth by the National Center for Forensic Science, using Dichloromethane (DCM) and an internal standard of undecane. Smokeless powders were burned to generate smokeless powder residues. The residues were extracted from foil with approximately 2mL DCM, followed by evaporation and reconstitution in 250 $\mu$ L DCM with an *n*-tetracosane internal standard. Additionally, standards of common smokeless powder compounds, such as nitroglycerin and ethyl centralite, were burned in the presence of Nitrocellulose (NC) to generate pyrolysis products for each compound individually that could be compared with the residue of actual smokeless powder samples. An individual sample of NC pyrolysis products alone was also generated to determine pyrolysis products of NC that may be observed in all samples. The pyrolysis product residues were extracted in DCM. All extracts were analyzed via GC/MS to allow for identification of smokeless powder compounds and pyrolysis products present from each compound and in the smokeless powder residue. GC/MS parameters were optimized for each sample type prior to analysis.

Organic compounds of interest were easily identified in smokeless powders, smokeless powder residues, and individual compound pyrolysis products. The residue composition may then be related to the intact smokeless powder composition. Pyrolysis product peaks were identified in the smokeless powder residue extracts using the data gathered from the individual compound pyrolysis products. Additionally, Pearson correlation coefficients were calculated between the smokeless powders and smokeless powder residues, as well as the smokeless powder residues and pyrolysis samples to determine the similarity in their resulting patterns.

GC/MS is a standard method for analysis that is widely available to investigators. Thus, analysis and characterization of smokeless powders and smokeless powder residues via GC/MS may be beneficial to the forensic community. Additionally, the ability to characterize smokeless powder residues and relate the residues to an original powder composition may be helpful in determining the brand or origin of a suspect sample and provide a link for investigators between a suspect and crime scene.

#### **Smokeless Powder, Explosives, Organic Gunshot Residue**

### B23 An Analysis of Test Exemplar Techniques in Relation to Footwear Examinations

*Ismail M. Sebetan, MD, PhD\**, National University, La Jolla, CA 92037-1011; *Paul Stein, PhD\**, National University, La Jolla, CA 92037; *Amy Laabs, MFS\**, Lakewood Police Department, Lakewood, CO 80226

**Learning Overview:** This presentation will determine the best practices for obtaining the most detail in the test exemplars. This in turn will lead to developing potential for more accurate and detailed footwear impression examinations. The main objective of this study was to compare one technique to another to determine the one with the most reliability.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that acquired characteristics observed in the outsole of four pairs (eight shoes) of athletic shoes can be used to differentiate wear in a common sole design and will provide the best practices for obtaining the most detail in the test exemplars. This in turn will lead to developing potential for more accurate and detailed footwear impression examinations.

The Adidas® Superstar athletic shoes (size 4½) were worn by the same female subject (50 years old) over a period long enough to cause noticeable and unique wear, cuts, and stone-hold characteristics on the outsoles. These randomly acquired characteristics were studied and compared to the characteristics observed in the scanned outsole of each shoe. After collecting the shoes, six techniques were used for obtaining test exemplars. These were: Kiwi® polish, magnetic powder, TreadPrint®, Speedball® Ink and Inkless Shoe Print, WD40® with magnetic powder, and bichromatic powder. The outsoles of each shoe were then photographed and documented after using each of the six techniques. They were then re-examined to locate the visible randomly acquired characteristics.

A total of 48 test exemplars were created and the collected data statistically analyzed using chi-square and the Analysis of Variance (ANOVA) test. Significance was determined by p values <0.05. A comparison of these randomly acquired characteristics revealed that, although the numbers varied, the results were consistent. They also indicated that any of the methods were as good as the others for defining the acquired characteristics developed in the similar sole pattern. The resulting exemplars were suitable for footwear examination.

Footwear examiners will use any and all information available to provide a complete examination of the evidence presented to them. Photographic documentation of the footwear impression evidence on scene alongside the documentation of the outsole of the known shoe and a highly detailed test exemplar have been the best form of evidence utilized in a comparison. This project relied heavily on the ability to properly document the outsole and obtain detailed test exemplars. The methods utilized captured the randomly acquired characteristics of the outsoles extremely well compared to the scanned outsole. However, it was surprising to find that the observed number of randomly acquired characteristics in each outsole was comparable.

In conclusion, further research should be performed in order to aid with the investigation of footwear and possibly tire tread examinations related to crime scenes.

#### Patterned Evidence, Footwear Evidence, Test Exemplars

### B24 Magneto-Archimedes Levitation (MagLev) Separation of Drugs

*Joe Bozenko, MSc\**, Dulles, VA 20166-9509; *Christoffer K. Abrahamsson, PhD*, Harvard University, Cambridge, MA 02138; *Michael J. Fink, PhD*, Harvard University, Cambridge, MA 02138; *Amit Nargarkar, PhD*, Harvard University, Cambridge, MA 02138; *Dan Preston, PhD*, Harvard University, Cambridge, MA 02138; *Shencheng Ge, PhD*, Harvard University, Cambridge, MA 02138; *George Whitesides, PhD*, Harvard University, Cambridge, MA 02138

**Learning Overview:** This presentation will inform the attendees on the process of MagLev and the application to separation of drugs of abuse. Attendees will identify the benefits associated with the use of MagLev to recover analytes sufficient for spectrophotometric analyses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community as this novel technique avails analysis of low-concentration drugs, in particular fentanyl and fentanyl-related substances.

Currently, forensic drug chemists face a challenge in identifying controlled substances in complex mixtures containing multiple drugs, adulterants, diluents, and other drug-related substances. Many forensic drug labs have formed a great deal of reliance upon chromatographic separations and identification, such as Gas Chromatography/Mass Spectrometry (GC/MS), which has relegated spectrophotometric techniques, such as infrared or Raman, to a minor role in day-to-day analysis with certain classes of drugs. In light of the complex mixtures typically encountered, the rise in fentanyl and fentanyl-related substances, particularly at low concentrations, necessitates the availability of additional separation techniques. Higher potency of this class of drugs, at times, dictates lower concentration in samples recovered by law enforcement and submitted to forensic labs. This method would enable recovery suitable for spectrophotometric evaluation for low-concentration drugs.

MagLev affords separation of hydrophilic drugs and related substances with little effort. The MagLev device is composed of like-facing NdFeB magnets mounted in 3D-printed brackets that are positioned above and below a polycarbonate cuvette. With the use of a non-polar solvent mixture of tetrachloroethylene and hexanes providing a solution of a gadolinium complex, hydrochloride salts of drugs and other water-soluble-related substances remain suspended within the cuvette in a vertical column. In the time span of 5 minutes to 30 minutes, these substances levitate according to their densities, which affords separation into discreet crystal masses in a restorative process. These crystal masses were then recovered via Pasteur-pipette while still under magnetic forces using a specially designed access port through the top of the device chassis. These crystal masses are then transferred to laboratory filter paper and dried of residual paramagnetic solution with acetone and vacuum dried in preparation for spectrophotometric examination via infrared or Raman spectrophotometry. These crystal masses were then successfully characterized via Fourier Transform Infrared (FTIR). Experimental separations were performed on methamphetamine HCl, cocaine HCl, heroin HCl, fentanyl HCl, acetylfentanyl HCl, and benzylfentanyl HCl. In addition to these reference materials, the technique was applied to commonly encountered mixtures with adulterants and diluents. One such example is a mixture composed of 1.3% fentanyl HCl, 2.6% heroin HCl, and 96.1% lactose. Due to the differing densities of each substance, the crystal masses of each levitated to a different height presenting separation. These were then recovered using a Pasteur-pipette for spectrophotometric characterization. MagLev provides a resilient separation of hydrochloride salts of drugs and most respective adulterants and diluents based upon their densities while suspended in non-polar solvents. This technique is amenable for a great many commonly encountered drugs of abuse, requires no electricity, is low cost save for modest solvent purchases, and has a very small bench footprint.

### B25 An Investigation Into the Use of Amino Acid Ratios to Distinguish Between the Hairs of Similar Individuals

Allison M. Macri\*, University of New Haven, West Haven, CT 06516; Alyssa L. Marsico, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will gain an understanding of how amino acid concentration ratios of hair proteins can be used to distinguish between the hairs of demographically similar individuals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternate method of hair analysis for when DNA is not present in a hair sample and for when different hair samples appear similar under a microscope.

Hair is a very important piece of trace evidence to forensic scientists because it is commonly found at crime scenes and can be a vital piece of evidence in a criminal case. Currently, forensic hair analysis is performed by both Microscopic Hair Comparison (MHC) and DNA analysis, but they are not always reliable. For example, MHC is very subjective and is not supported with statistical analysis. On the other hand, DNA analysis can be problematic if there is not enough undamaged nuclear DNA to sample from or if the nucleated cells within a hair follicular tag are not intact or are not present. Therefore, a new technique of analyzing hair, such as proteomic analysis, must be developed to replace MHC and DNA analysis for instances in which no beneficial results can be obtained from those methods. In this study, amino acid analysis was investigated as a new method to analyze hair proteins.<sup>1,2</sup> Human hair is made up of several proteins, such as keratin, and these proteins can have slight genetic variations in the form of Genetically Variant Peptides (GVPs). These GVPs contribute to an individual's genetic variation because they can alter amino acid sequences.<sup>3</sup> This means that the amount of amino acids can vary in people's hair based on their genetics.

First, hair samples were washed with deionized water and methanol. Then, the hair proteins were broken down into their corresponding amino acids via acid hydrolysis with hydrochloric acid. After digestion of the hair proteins, norvaline, an amino acid not synthesized by humans, was added to the hair samples as an internal standard. The amino acids were then derivatized with N,O-Bis(trimethylsilyl)trifluoroacetamide and identified using gas chromatography/mass spectrometry. The amino acids present in hair were quantified relative to norvaline, and the values were used to construct amino acid ratios. The amino acid ratios of various hair samples from individuals of common demographics and from monozygotic twins are compared to distinguish one hair sample from many others.

Hair samples were obtained on various days and from various areas of the head. The aim was to show that people's amino acid ratios do not change based on when the hair samples were taken or where the hair samples were taken from the head. Initial results suggest that amino acid ratios of hair proteins do not change over a short period of time and do not change among different areas of the head. Next, hair samples were taken from two people who have similar demographics. The goal was to use amino acid ratios to distinguish between the persons' hairs. Preliminary data supports the hypothesis that hair amino acid analysis can be used to distinguish between demographically similar individuals. For example, one person's proline/valine ratio was three times higher ( $5.46 \pm 1.68$ ) than the same ratio in the other person's hair ( $1.84 \pm 0.27$ ). Differences were also observed for the phenylalanine/leucine ratio, with one person's ratio being seven times higher ( $0.51 \pm 0.07$ ) than the other person's ratio ( $0.07 \pm 0.02$ ). Other ratios that were different between the hairs include aspartic acid/threonine, serine/leucine, tyrosine/valine, and several others. However, a larger population must be investigated further, including multiple individuals with similar demographics as these two people, as well as comparing the hair amino acid profiles of monozygotic twins.

In conclusion, hair amino acid analysis has the potential to enhance the current identification methods of individuals. Although it is not an individualizing technique, it could help provide law enforcement with a person's demographics based on hair found at a crime scene. This could help to narrow a suspect pool or rule out specific individuals.

### B26 A Comparison of Area of Origin Determination of Impact Spatter From Vertical and Horizontal Surfaces

Alexis P. Johnson, BA\*, Stockton, CA 95207; Michael J. Van Stratton, BS, Kansas Bureau of Investigation, Topeka, KS 66604; Melissa M. Bailey, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** After attending this presentation, attendees will understand the value of using spatter stains on both horizontal and vertical surface stains when determining the area of origin from an impact event.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by expanding the amount of evidence that can be utilized in the field, as well as defining limitations of the method when applied to stains on a horizontal surface.

Traditionally, determining the area of origin of an impact event has utilized stains deposited on vertical surfaces. Recent research has determined that impact stains found on a horizontal surface in front of an event may be useful in the determination of area of origin, but its use is more limited.<sup>1</sup> To date, there has been no direct comparison of the calculations of the area of origin made from stains on both the vertical and horizontal surfaces surrounding the same event.

This experiment compares the area of origin determination from stains on vertical and horizontal targets, from the same event, to determine whether including measurements calculated from both surfaces provides similar results. To produce a consistent impact pattern, a ring stand was attached to a leveled horizontal surface and a five-pound weight was used to strike a 1.2 milliliters (mL) pool of defibrinated sheep's blood from a height of six inches. "Walls" were constructed from uncoated butcher paper and placed ten inches from the center of the blood pool. A butcher paper "floor" extended approximately ten feet in front of the blood pool. Impact events were conducted at four heights representative of four body positions: standing (5 foot 8.8 inches), sitting (3 feet 6 and a half inches), kneeling (1 foot 6 and a half inches), and lying prone (6 and a half inches). A total of 120 patterns were created with ten events per height. Individual stains on each wall and floor pattern were selected to be measured. Only well-defined ellipses that indicated the appropriate directionality from the impact site were selected. Based on previous research, elliptical stains that were only within one meter of the impact site on the horizontal surface were used for area of convergence and area of origin determination.<sup>1</sup> The length and width of each was measured using a digital microscope. A Leica® Bosch GLM 35 laser measuring device was used to measure from the leading edge of each stain to the chosen area of convergence. The area of origin was calculated using a trigonometric formula. Results from a previous study, as well as this experiment suggest that current methods of impact determination used on vertical surfaces can be applied to horizontal surfaces within limitations.<sup>1</sup> The area of origin calculated from horizontal surfaces is similar when subjects that are in a lying prone position or kneeling on all fours to that calculated from vertical surfaces. However, as height increases (sitting or standing), finding suitable stains becomes increasingly more difficult and results are less accurate. Thus, calculating the area of origin from both horizontal and vertical surfaces may be useful in some cases, but caution should be used if a sufficient number of suitable bloodstains are not present.

### B27 An Analysis of Organic and Inorganic Gunshot Residues (OGSR and IGSR) Via Electrochemical Methods With Screen-Printed Carbon Electrodes and Nanoparticle Modifications

Colby E. Ott, MS\*, Shippensburg, PA 17257; Pedro Calderón-Arce, MS, University of Costa Rica, San Jose 11501-2060, COSTA RICA; Korina Menking-Hoggatt, MS, Morgantown, WV 26501; Courtney H. Vander Pyl, MS, Department of Forensic and Investigative Science, Morgantown, WV 26506; Ana L. Alvarado-Gómez, PhD, University of Costa Rica, San Jose 11501-2060, COSTA RICA; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will be able to understand the use of alternative analytical tools to detect Gunshot Residues (GSR) and to explain the advantages associated with electrochemical methods to improve detection capability, uncertainty, and speed of analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community through the implementation of a rapid and comprehensive voltammetric GSR method for the dual detection of IGSR and OGSR. Practitioners will find a simple yet powerful technique that could offer timely investigative leads and speed up forensic investigations.

Following the discharge of a firearm, the compounds present in the propellant and primer, as well as residues from the cartridge and bullet, are expelled from the firearm under high pressure and heat. These compounds, globally termed GSRs, are then deposited in the vicinity of the shooting, including the hands and clothing of individuals. The detection of GSR can be a critical piece of evidence during a shooting incident and can provide valuable leads to investigators. However, the current analysis methods either lack sensitivity (as in color testing), take hours per sample (as in using Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy (SEM/EDS)), or are limited to detection of only the inorganic or the organic markers.

Electrochemistry improves upon these weaknesses by offering the simultaneous analysis of both IGSR and OGSR signatures, reducing run times to a few minutes per sample, offering qualitative and quantitative information, and providing lab-based and portable field testing. In this study, the analysis of OGSR and IGSR was performed using both Square-Wave Voltammetry (SWV) and differential pulse voltammetry in acetate buffer pH 4.5. A pre-concentration potential was applied before the analysis of the sample to improve the signal. The electroanalytical method was performed first using disposable carbon electrodes for the analysis of inorganics (lead, antimony, and copper) and organics (2,4-Dinitrotoluene [DNT], Diphenylamine [DPA], Nitroglycerin [NG], Methyl Centralite [MC], and Ethyl Centralite [EC]). The use of gold nanomaterials for the modification of electrode surfaces was investigated for the deposition of gold (Au) onto the working electrode (Screen-Printed Carbon Electrodes [SPCE]/Au). The use of bismuth films was also explored. Comparison of the performance of bare carbon, bismuth film, and gold surface working electrodes is presented in this study.

The following limits of detection were determined through statistical analysis of calibration curves as three times the standard deviation in the y-intercept divided by the mean in  $\mu\text{g/mL}$ : 0.09 (lead), 0.25 (antimony), 0.04 (copper), 1.28 (DNT), 1.17 (DPA), 0.52 (NG), 0.68 (EC), and 5.34 (MC). Analysis of GSR via gold deposition onto the SPCE working electrode resulted in improved limits of detection (in  $\mu\text{g/mL}$ ) of 0.012 (lead), 0.011 (antimony), 0.013 (NG), and 0.007 (DNT). The limit of quantitation for the organic compounds using the SPCE/Au was below  $0.050\mu\text{g/mL}$  with the relative standard deviation for repeatability and reproducibility below 2%.

A validation set of 180 samples collected from the hands of shooters ( $n=80$ , diverse ammunition and firearm) and non-shooters ( $n=100$ ) were run to assess the performance of the method, with overall accuracy better than 84%. Accuracy was estimated based on the number of true positives, true negatives, false positives, and false negatives.

This work demonstrated the ability of simultaneous detection of both OGSR and IGSR using electrochemical methods. Excellent improvements in sensitivity were shown for OGSR when utilizing a gold surface on the carbon working electrode. The sensitivity for OGSR is highly desirable due to the higher informative value of these compounds in associating a suspect to a shooting incident.

#### Gunshot Residue, Electrochemistry, Screen-Printed Carbon Electrodes

### **B28 The Utilization of Classical Forensic Methods in the Study and Preservation of Human History and Cultures, the Conservation and Restoration of Objects of Art and Artifacts, as Well as the Detection of Art Fraud and Counterfeiting**

*Nicholas Petraco, MS\*, Petraco Consulting, Massapequa Park, NY 11762-3549; Mary Eng, BS, New York City Police Laboratory, Jamaica, NY 11432*

**Learning Overview:** The goal of this presentation is to further advance the utilization of well-established forensic science analytical methods and techniques in the study of historic preservation and art conservation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by assisting attendees to acquire the knowledge, skills, and ability to apply classical forensic science methods and techniques to the disciplines of historic preservation and art conservation.

Edmond Locard, a founding father of forensic trace evidence analysis, noted in 1929 that whenever a person commits a crime, there is always a mutual transfer of trace evidential materials between the people, places, and things involved in the crime. Locard established in his work, research, and writings that these traces can be effectively used to not only describe the people, places, and things involved in an event, but the incident itself. In other words, transferred trace evidence can be used to reconstruct the crime.

It turns out that the application of Dr. Locard's principle of mutual exchange, classical forensic science investigative rationale, well-established forensic scientific methodologies, and laboratory tools can be successfully applied in many other scientific endeavors. Relics such as fragments of textiles, minute pieces of stone, ceramic, pottery, glass, metal, and wood or any artifact of historical interest found at archeological studies of ancient sites can be documented, studied, analyzed, identified, and compared employing forensic methods and procedures.

Additionally, art-oriented scientific disciplines, such as historic preservation, scientific authentication, preservation and conservation of historically significant buildings, monuments, statuary, fine and decorative arts, can all benefit by applying the forensic approach to identity, individualization, and reconstruction.

Typically, preservation, conservation, and authentication projects start with an in-depth study of the subject's history and ownership of the artifact or object of art that is under study. In the case of a piece of fine art, provenance is often of prominent importance. Next, features, such as an artist's style and technique, are crucial to their endorsement. Other essential aspects, including the chemical analyses of the materials available during an artist's lifetime, are vital in determining the authenticity of a work. In many cases, less-scientific forms of proof, such as an artist's signature, the identification of a fingerprint, the advice of experts, or the opinion of a connoisseur, are the sole evidence of proof. These forms of evidence often lead to confusion and misidentification.

When questions remain concerning the methods and materials used to produce the work or the authorship of the work, the trace evidence embedded within the work remains a vital, untapped, valuable, gold mine of data and unbiased proof to acquire information concerning these artifacts, articles, and works and to determine the work's creation and creator.

This study presents real-life examples in which the Locardian principal, forensic investigative logic, and well-established forensic methodology can apply to the disciplines of historic preservation, fine and decorative art restoration and research studies, as well as conservation and restoration case studies. A number of studies of vital historical note, including the restoration of the original Statue of Liberty in 1983, the authentication of the missing 9/11 American flag, the identity of the American flag draped around the shoulders of the 1980 gold medal-winning USA Hockey team's goaltender, a research study of the dust in Napoleon's origin dress uniform, as well as several works of decorative and fine arts paintings, including the long-suspected last work of Jackson Pollock, are presented and fully elucidated.

---

#### **Forensic Science, Historic Preservation, Art Conservation**

### **B29 The Chemical Composition of Gunshot Residue (GSR) of Commonly Encountered Samples in Shooting Events in Kosovo by an Optimized and Validated Scanning Electron Microscopy With Energy Dispersive X-Ray Spectroscopy (SEM/EDS) Method**

*Milazim Tahirukaj\**, Kosovo Agency on Forensic, Pristina, WA 10000, KOSOVO; *Blerim Olluri, PhD\**, Bill Clinton, Prishtina 10000, KOSOVO; *Andriana Surleva\**, University of Chemical Technology and Metallurgy, Sofia, BULGARIA

**Learning Overview:** The goals of this presentation, based on the presented results and discussions, are to gain knowledge about the state-of-the-art in the field of GSR analysis and applied classification in different countries, to increase awareness of the forensic scientist regarding the chemical composition of ammunition encountered in shooting events in the Republic of Kosovo, to initiate GSR database development in Kosovo, and to initiate discussion on the classification of GSR particles currently applied in Kosovo.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by exerting a positive effect by describing the current state of GSR analysis in the Republic of Kosovo and the capabilities of the legal science lab in the optimization and validation of the SEM/EDS method, as well as by critically summarizing the findings on the chemical composition of GSR samples commonly encountered in Kosovo. This initiated preliminary study on the GSR database in Kosovo could provide additional information to forensic scientists worldwide.

This work is focused on optimization and validation of the SEM/EDS method for inorganic GSR analysis in samples commonly encountered in shooting events in the Republic of Kosovo. The effect of accelerating voltage (12.5–30kV), working distance (8–14.2mm), spot size (3.5–8), acquisition time (1–30sec), and detector resolution (Amper time 0.12, resolution 179.88, Amper time 3.84, resolution 128.32) were optimized to obtain accurate and reliable GSR identification and composition data. The partially optimized method was validated according to the requirements of the American Society for Testing and Materials (ASTM) 1588-08. The repeatability and within lab reproducibility for Lead, Antimony, and Barium (PbSbBa) particles of 0.5 $\mu$ m diameter was 8% Relative Standard Deviation (RSD). The RSD of 100 total PbSbBa particles was 2% in a 4-week study by two operators. The trueness was estimated by bias and sensitivity. Mean sensitivity of the 4-week study was 95% (SD 2) and bias was -5% (SD 2), no false positive was detected, the number of false negatives was between 3 and 7, and the number of true positives was between 96 and 100. The partially modified ASTM 1588-08 method was proved fit for purpose.

Chemical composition of GSRs found in shooting events in Kosovo was determined by the validated SEM/EDS method. Both characteristic three component particles and consistent two components particles were considered. A survey on the chemical composition of particles from shooting events encountered in Kosovo in the past three years was presented.

The results have shown that recently non-toxic ammunition has been used in the Republic of Kosovo. The use of lead-free ammunition has spread worldwide; however, the classification of particles as GSR is still not widely agreed upon. On one hand, the ASTM standard applied in Kosovo states that PbSbBa has spherical morphology to classify particles as a GSR. On the other hand, the European Network of Forensic Science Institutes (ENFSI) standard applied in the European Union (EU) additionally included as characteristic for GSR the particles containing the phases of Gadolinium (Gd), Titanium (Ti), and zinc (Zn) or the phases of Gallium (Ga), Copper (Cu), and Tin (Sn). Currently, ASTM qualification is applied in Kosovo. However, careful study of samples from shooting events in Kosovo revealed the increasing number of cases in which lead-free ammunition was used. This fact requires reexamination of the standards in GSR forensic standards used in the Republic of Kosovo. Moreover, some non-routine elements were also detected in the studied samples. The comparison between GSR composition and chemical composition of cases or cartridges could provide additional information to forensic scientists.

### B30 The Effect of pH on Presumptive Forensic Serological Testing

*Ariel B. Smart, BS\*, Wilmington, DE 19801-7100; Kimberlee Sue Moran, MSc, Rutgers University-Camden, Camden, NJ 08102; Ja'Neisha Hutley, MS, Philadelphia, PA 19102; Stephanie L. Murphy, PhD, Rutgers University, New Jersey Agricultural Experiment Station New Brunswick, NJ 08901*

**Learning Overview:** After attending this presentation, attendees will better understand how and if soil pH affects blood and semen stains. In addition, this presentation will investigate whether the length of time that semen or blood is exposed to soil affects presumptive test results.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing more detailed information on presumptive testing for blood and semen and if a negative result obtained after presumptively testing buried material could be the result of a false negative.

When clothing is found buried at a crime scene, a presumptive test will be conducted to determine whether biological evidence in the form of blood or semen stains is present. If the result is positive, evidence is sent for a confirmatory test, followed by DNA analysis. If the result is negative, in most instances, testing ceases. Presumptive serological testing is a cost- and time-effective way to determine if suspected biological fluid is present. However, presumptive testing is known to produce false positive results with some substances. What is less known is whether false negatives exist. This research attempts to answer the question: "If blood or semen was present on clothing exposed to soil, could the pH of the surrounding soil and the length of exposure cause a false negative result?"

Two hundred fifty 2cm<sup>2</sup> fabric swatches were prepared: 108 swatches were stained with 50μL of human blood and 108 swatches with 100μL of human semen. The presumptive tests chosen for this project were Acid Phosphatase for seminal fluid and Kastle-Meyer test for blood. To determine if soil pH would affect presumptive testing, acidic, neutral, and alkaline soil was prepared. Approximately 145g of each soil type was placed in its own plastic container, resulting in 66 containers of acidic soil, 66 containers of neutral soil, and 66 containers of alkaline soil. After the stains had dried in ambient conditions, each fabric swatch was placed into its own container and surrounded with soil. Positive controls (stained fabric left unburied) and negative controls (fabric buried but not stained) were also prepared. Soil containers were stored in the lab in darkness at 70°F. Fabric was left exposed to soil over the following intervals: 3 days, 7 days, 11 days, 30 days, 45 days, and 60 days. Five replicates of each fluid sample at each exposure time in each soil type was prepared, as well as a negative and positive control. Once a sample reached its designated exposure time, the fabric was removed from the container and any loose soil was cleaned off. Presumptive testing was conducted according to manufacturer's guidelines. Presumptive testing was also conducted on a positive and negative control.

Results show that soil pH does, indeed, impact serological screening results as does the duration of exposure. Blood stains in the neutral soil appeared more deteriorated when compared to stains from other soils, even when exposure time was greater. The reaction time and intensity of the results for both the Kastle-Meyer test and Acid Phosphatase test for neutral soil samples changed after the 11-day exposure period. The intensity of the result of the Kastle-Meyer test directly compared to the intensity of the blood stain. The Acid Phosphatase test result was in the last acceptable time range for color change (i.e., 60 seconds). Forensic serologists should be aware that buried evidence can impact screening tests. It is important for analysts interpreting screening test results on buried evidence to exercise caution when determining whether or not a weak result is a true negative.

#### Presumptive Testing, Serology, Soil pH

### B31 Analyzing Gamma-Hydroxybutyrate (GHB) by Fourier Transform Infrared Spectroscopy (FTIR) With Minimal Sample Preparation

Anna Stuteville\*, Huntington, WV 25705; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701; Samantha M. Leach, MS, Washington, DC 22191; Morgan M. Levitas, MFS, DC Department of Forensic Sciences, Washington, DC 20024; Luke C. Short, PhD, DC Department of Forensic Sciences, Washington, DC

**Learning Overview:** After attending this presentation, attendees will understand how to detect the Schedule 1 controlled substance GHB and distinguish it from the non-scheduled Gamma-Butyrolactone (GBL) using FTIR.

**Impact on the Forensic Science Community:** Due to different legal classifications of GHB and GBL, it is imperative that forensic chemists have the tools to distinguish between the two substances. This presentation will impact the forensic science community by demonstrating one such tool, FTIR, to allow for such a distinction.

Typically, forensic drug laboratories often rely on Gas Chromatography/Mass Spectrometry (GC/MS) instrumentation for the separation and detection of controlled substances. However, GHB converts within the high-temperature injection port to the non-scheduled GBL. Due to different legal classifications of these substances, it is imperative that forensic chemists have the tools to distinguishing between the two substances.

One commonly used traditional method of analysis includes derivatization of GHB followed by GC/MS, stabilizing GHB from dehydration cyclization to GBL.<sup>1-3</sup> Derivatization is a somewhat lengthy process and requires the use of a toxic chemical—N,O-Bistrifluoroacetamide (BSTFA). Alternatively, GHB analysis can be performed by liquid-liquid extraction, requiring a firm grasp of solubility of GHB in sample matrix versus extraction liquid.<sup>4</sup> Unfortunately, this approach is complicated by the limited solubility of GHB and often yields too little recovered product to perform a confirmation. Finally, both <sup>1</sup>H and <sup>13</sup>C Nuclear Magnetic Resonance (NMR) have been reported for the identification of GHB in forensic analysis; however, many forensic laboratories do not have access to this instrumentation.<sup>5</sup>

The DC Department of Forensic Sciences Forensic Chemistry Unit currently uses the BSTFA derivatizing agent to confirm detection of GHB by GC/MS. Therefore, it was important to investigate if another method could be implemented to support routine casework, or at least provide another orthogonal method for confirmation. This research project focused on demonstrating the FTIR method using samples in pure liquid matrices. A consequence of this research was the demonstration of a more rapid and safer preparation method, as well as an efficient detection method for GHB and GBL using FTIR.

A validation of the sample preparation and analytical detection was performed as part of this research project. The validation was based off a previously validated cocaine method (for base vs. salt form) in determining selectivity, matrix effects, precision, limit of detection, and robustness for GHB and GBL. The analysis proved successful in this work, except for complications found in some complex matrices. The different solvents used to study matrix effects were: (1) ethanol, (2) methanol, (3) water, and (4) glycerin. It was discovered that when GHB is mixed in these matrices, the broad hydroxyl peak around 3,300 cm<sup>-1</sup> provided a challenge in resolution of characteristic functional groups within the spectrum. This effect can be addressed; however, by systematically removing the matrix via nitrogen evaporation. This process was demonstrated with water in the present study, to be expanded upon in future studies to the other matrices. Further, future research will focus on addressing sugar-saturated solutions, as GHB is often knowingly or unknowingly consumed in sugary drinks, such as juice, mixed alcoholic drinks, or sodas.

### B32 Presumptive Test Compatibility With Efficient DNA Collection Swabs

Bruce Budowle, PhD\*, University of North Texas Health Science Center, Fort Worth, TX 76107

**Learning Overview:** After attending this presentation, attendees will be better informed regarding the fact that the collection of stains at crime scenes and preservation of the integrity of the collected biology evidence after collection are critical components impacting the success of downstream chemical and molecular biology assays. While an important part of the evaluation of biological evidence, presumptive tests and whether there are any inhibitory effects associated with the swabs used to collect evidence have rarely been validated. Over the past few years, there have been advances in the collection tools (i.e., swabs; notably the advent of nylon swabs that presumably should be inert regarding downstream assays). However, the glues, process residuals during manufacturing, and any additives (especially those intended to preserve DNA) may impact performance of chemical or enzymatic presumptive tests. Therefore, swabs should be evaluated for presumptive tests compatibility, just as the rest of the tests in the laboratory workflow.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an understanding that all aspects of forensic biological analyses require validation. In particular, the development of superior performance synthetic swabs requires consideration that the additives or manufacturing components may impact presumptive test results. Therefore, these swabs, if used for sample collection, should be validated for the intended use.

Swabs should be tested to determine if there are any effects from the swabs on downstream presumptive tests. Based on the demonstrated success of DNA collection and DNA yield in the studies by Comte et al. and Sherier et al., the COPAN® Italia 4N6FLOQSwabs™ were selected to develop an effective test system.<sup>1,2</sup> These swabs are similar except that some versions contain an anti-microbial reagent. Thus, a controlled experiment between swab types can be performed for this initial test design. If the process is effective, then it could be used for more comprehensive testing among a variety of swabs, if needed. Blood, semen, and saliva stains on glass slides were prepared. The concentrations were neat and diluted (up to 1:99). The stains were allowed to dry overnight (minimum) before testing. Standard presumptive tests for each stain type (blood: leuco malachite green, saliva: RSID saliva; semen: acid phosphatase) were employed. These three presumptive tests were selected because they span the range of chemical (peroxidase-like catalytic activity of hemoglobin), enzymatic activity (acid phosphatase), and antibody-based (amylase detection) assays. The results were compiled as positive/negative and with an arbitrarily designed 1-4 scale. Preliminary testing supports that 4N6FLOQSwabs™ are inert with regard to these presumptive tests.

### **B33 A Comparison of DNA Typing Success in Compromised Blood and Touch Samples Based on Sampling Swab Composition**

*Ciara Rhodes, Mechanicsville, VA 23111; Memunatu J. Koroma, BS, Virginia Commonwealth University Department of Forensic Science, Richmond, VA 23284-3079; Brittany C. Hudson, MS, Virginia Commonwealth University, Richmond, VA 23284; Nubaha Islam, BS, Virginia Commonwealth University Department of Forensic Science, Richmond, VA 23284; Haris Mukic, BS, Virginia Commonwealth University Department of Forensic Science, Richmond, VA 23284; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, Richmond, VA 23284; Robert A. Bever, PhD, Bode Cellmark Forensics, Lorton, VA 22079; Sarah J. Seashols Williams, PhD\*, Virginia Commonwealth University, Richmond, VA 23284-3079*

**Learning Overview:** After attending this presentation, attendees will understand the impact of time and temperature on DNA analysis of samples using both cotton and a proprietary swab designed to minimize degradation of forensic samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an opportunity to evaluate a novel sampling product for forensic DNA evidence and promote more research about and awareness of preventing DNA degradation at sampling and during storage.

Sample collection at the crime scene can introduce variations in DNA recovery, both based upon the substrate or material used as well as the storage conditions after collection. Both the substrate and the body fluid deposited on the evidence can harbor microbial populations, which can be co-collected onto the swab and degrade the sample even during drying and storage, and before DNA extraction can be performed. The purpose of this study was to evaluate and compare standard cotton swab collection with the Bode BioSafe™ swab, which includes both a desiccant at the swab head as well as proprietary bacteriostatic compounds included to prevent degradation of the sample.

Venous blood samples were collected from five donors into sodium heparin tubes, and contact samples from ten donors were deposited onto both porous (cotton fabric for both blood and touch) and non-porous (linoleum flooring and computer keyboards, respectively) surfaces and allowed to dry. The samples were then swabbed with a standard cotton swab or the BioSafe™ swab and stored at room temperature, 37°C or 55°C for 30, 90, or 180 days. After the elapsed time, DNA was isolated and quantified from all samples, and DNA profiles developed from select samples.

DNA yields varied from 80–190ng and 10–200ng for blood samples deposited on linoleum and cotton, respectively, regardless of swab method used. While no trends were observed in comparing the DNA yields of samples extracted from blood collected with either swab type, degradation indices tended to be lower for BioSafe™ as compared to cotton swabs. Contact DNA samples yielded between 0.1–1.5ng and 0.5–5ng on T-shirt and keyboard samples, respectively, with higher yields found with samples swabbed using the BioSafe™ swabs on both substrates, and lower indications of degradation with the BioSafe™ swabs. Because touch or contact samples are known to harbor higher bacterial loads than blood in addition to the free DNase enzymes known to inhabit keratinized epithelium, the bacteriostatic, desiccating, and enzyme-inhibiting capability of the BioSafe™ swabs may prove to result in better DNA profile outcomes than the standard swabbing procedure.

#### **Swab, Touch, LCN DNA**

### **B34 A Comparison of DNA Profiles Recovered From Cotton Versus Nylon-Flocked Swabs From Postcoital Cervicovaginal Samples**

*Kathleen M. Maguire, BS\*, Whitehall, PA 18052; Janine Kishbaugh, MS, Cedar Crest College, Allentown, PA 18104; Jillian Conte, PhD, Keystone College, La Plume, PA 18440; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104*

**Learning Overview:** The goal of this presentation is to illustrate the differences observed in DNA recovery efficiencies between traditionally used cotton-tipped swabs and newer nylon-flocked swabs from postcoital cervicovaginal samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information that could potentially improve the standard practices and tools used as part of a sexual assault kit.

Cotton-tipped swabs are routinely used as a method of collecting biological material by medical personnel and forensic investigators. Standard practices include collecting vaginal swab samples from a female victim as part of a sexual assault kit. Swabs used to collect biological material should be able to maximize the cellular material collected, then elute intact cells for DNA extraction and profiling. A swab with a higher extraction and recovery efficiency can lead to more DNA available for genotyping. The differences in swab morphology between cotton-tipped swabs (considered wound swabs) and the hydrophilic open fiber structure of the flocked swabs may account for the higher rates of sample elution from flocked swabs.<sup>1</sup> This study aims to compare male profiles obtained from vaginal samples taken with cotton-tipped swabs and nylon-flocked swabs.

Following Institutional Review Board (IRB) approval, sets of four vaginal swabs were collected from sexually active, heterosexual participant couples. The couples varied in age, menstrual cycle, and birth control methods. Swabs were collected over three distinct postcoital time intervals, with the cotton and the nylon-flocked swabs being inserted concurrently following the National Institutes of Justice (NIJ) recommendations for sample collection.<sup>2</sup> Control swabs of the vaginal cavity were taken after a sexual abstinence period of at least seven days and collected immediately prior to intercourse. Vaginal swabs were collected after 72, 120, and 168 hours postcoitus with ejaculation. Each collection was based on a separate act of intercourse. Cheek swabs of the male and female participants were collected to obtain reference profiles. The reference swabs were extracted using a 5% Chelex<sup>®</sup> method. The vaginal swabs were extracted using QIAamp<sup>®</sup> DNA Investigator Kit. Both reference profiles and vaginal swab extractions were amplified using the PowerPlex<sup>®</sup> Y23 System. For one 72-hour sampling period, the profile obtained from the cotton swab showed 3 of 22 (13.6%) alleles, while the profile obtained from the nylon swab showed 12 of 22 (54.5%) alleles. This same couple also completed the 120-hour sampling period, with the cotton profile returning 2 of 22 (0.9%) alleles and the nylon profile having 13 of 22 (59%) alleles present. For a second 72-hour sampling period by different participants, the cotton profile returned 16 of 22 (72.7%) alleles, while the nylon profile had all 22 alleles present. The 72-hour sampling period by a third couple returned full profiles (22 of 22 alleles, 100%) for both the cotton and the nylon swabs.

These results provide data that could be used to improve the collection methods used in a sexual assault kit. The improvement of the swabs used in postcoital vaginal sampling could have positive downstream implications when attempting to obtain a DNA profile.

#### **Sexual Assault Collection, Nylon-Flocked Swabs, Cotton Swabs**

### **B35 Direct Polymerase Chain Reaction (PCR) Using MicroFLOQ® Direct Swabs With a Modified QIAGEN® Investigator 24plex GO! Protocol From Decomposing Human Remains for Disaster Victim Identification (DVI) Applications**

*Coral K. Loockerman, MS, Austin, TX 78759; Sheree R. Hughes, PhD, University of Queensland, Brisbane, Queensland, AUSTRALIA; Rachel M. Houston, PhD\*, Sam Houston State University, Huntsville, TX 77340*

**Learning Overview:** After attending this presentation, attendees will understand the performance of a direct PCR workflow for DVI samples using the microFLOQ® direct swabs in conjunction with the QIAGEN® Investigator 24plex GO! kit. This project compared a direct and traditional workflow for processing decomposing human remains.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an alternate workflow for processing DVI samples. DVI relies on rapid identification of decomposing human remains, often in remote areas without access to storage facilities. Collection of biological material using swabs may prove easier, more efficient, and more amenable to storage in harsh conditions. MicroFLOQ® direct swabs have been identified as a potential alternative for more rapid collection and processing of DNA in forensic and DVI situations.

4N6FLOQSwabs™ Genetics and microFLOQ® direct swabs were used to collect DNA from red muscle via an incision in the arm or leg of a decomposing human cadaver. Traditional DNA processing with the Genetics swabs was compared to a direct amplification strategy using the microFLOQ® swab coupled with the Investigator 24plex QS GO! Kit. Additionally, both swab types were evaluated for their ability to store DNA for up to three months. The direct amplification strategy was optimized by pre-treating the swab (washing, vortexing, lysis) prior to amplification and slightly modifying the cycling parameters. As an alternate method, the microFLOQ® swabs were used to sub-sample DNA stored on the Genetics swabs.

Results indicate that both swab types were able to store DNA at room temperature. Short Tandem Repeat (STR) success rates of traditional and direct PCR methods were comparable but were highly dependent on the stage of decomposition and the sample location. Up to day ten, full profiles were obtained using both processing methods with samples taken from the leg for up to three months of storage at room temperature. Full profiles were obtained from day 13 and day 20 using traditional methods, while partial profiles were obtained on day 13 using microFLOQ® swabs and subsampling. The Quality Sensor (QS) markers were used to assess sample quality. Interestingly, the QS markers indicated that even after pre-washing the microFLOQ® swabs, there was still inhibition present in the amplification for microFLOQ® swabs that were dried overnight. However, when the microFLOQ™ swabs were processed within hours of swabbing or used to sub-sample, there was less-to-no inhibition indicated by the QS markers and profile completeness improved.

Overall, microFLOQ® swabs in conjunction with the GO! Kit facilitated direct processing in the laboratory from decomposing remains.

### B36 Criminalists at the Crime Scene: Where Do They Come From and Where Can They Go?

*Rebecca E. Bucht, PhD\**, National Bureau of Investigation Forensic Laboratory, Vantaa 01301, FINLAND; *Michelle D. Miranda, PhD\**, Farmingdale State College, State University of New York, Farmingdale, NY 11746; *Claude Roux, PhD\**, University of Technology Sydney, Broadway, NSW 2007, AUSTRALIA; *Sheila Willis, PhD\**, National Institute of Standards and Technology, Gaithersburg, MD 20899

**Learning Overview:** After attending this presentation, attendees will better understand the myriad ways organizations recruit crime scene investigators, with emphasis on the variation in required education, training, and experience. The goal of this presentation is to encourage attendees to address what is needed to be a successful crime scene investigator and what educational and career paths are necessary to ensure a sustainable solution to crime scene staffing.

**Impact on the Forensic Science Community:** Crime scene investigation and reconstruction are scientific endeavors requiring individuals educated and trained in the principles of criminalistics, as well as the fundamentals of critical thinking and reasoning. This presentation will impact the forensic science community by explaining that the technical “bag and tag” approach is not sustainable for the complexity of today’s cases and the increased momentum toward robustness and accountability in forensic science endeavors. Panelists from the United States, Europe, and Australia will share their experiences with these different solutions, and provide opinions on what the critical elements for success are and what still needs to be improved on a system scale in order to ensure that forensic science is used to its full potential at the crime scene.

Attendees will be encouraged to provide their own experiences and concerns in an effort to facilitate discussion and broaden the scope of the presentation topic.

Crime scene work is arguably the most critical part of the forensic science process. The changing crime and security environment, including increased traceability (e.g., more varied trace sources, larger volume of traces, pace, blurring of physical and digital lives, etc.), continue to add complexity to crime scene work. Developments in quality assurance and accreditation within the discipline of crime scene investigation have increased the pressure on these actors to reflect on how to validate their standard operating procedures and how to demonstrate the competence of their staff.

Some jurisdictions follow a testing lab model based on the “bag and tag” approach (i.e., the scene investigator collect traces, perhaps triaging the packaged items, and then sends “test tubes” to a forensic laboratory that is increasingly disconnected from the forensic science problems). In this model, crime scene investigation is often undertaken by sworn officers and the scientific education, training, and experience of these individuals can be quite diverse.

In some jurisdictions, there has been a push for civilian scientists at the crime scene, with science graduates being recruited. This alone does not necessarily solve the problem—a science graduate does not necessarily translate to an effective examiner. Only a few of these individuals manage to find a path of appropriate career progression, perhaps because the culture remains that to progress you must be a sworn member of law enforcement.

In other jurisdictions, generally those with an integrated lab/forensic service within police agencies, the situation has been more seamless, and there is less obvious distinction between sworn and unsworn members of the crime scene investigation unit. An example of this is the Australian Federal Police (AFP) who now apply a problem-oriented/consultancy model within their organization. Crime scene investigation is undertaken by sworn and unsworn employees, and there are ample opportunities for people to move from one space to the other.

The critical point is to have staff with the appropriate education, skills, and abilities to do the job properly. If the crime scene poses a scientific problem, then appropriately trained scientists are necessary to provide the solutions.

The feature of sworn vs. unsworn crime scene staff may seem to be of importance mainly for law enforcement organizations, but it can also have wider implications on the staffing and oversight of crime scene units under diverse management models. How can law enforcement attract, screen for, and retain critically thinking scientists for crime scene work? Is the strategy to recruit scientists and educate/train them to operate in the context of police work or to recruit police officers and educate/train them to be scientists? How can these strategies be successful? What positions can sworn or unsworn criminalists apply for when they want to or need to move on from operational crime scene work? What role can and should the forensic laboratory play in this framework?

---

#### Crime Scene, Competence, Career Path

### B37 The Utilization of Sex Hormone Antibodies for Screening and Separation of Trace Biological Mixtures

*Kristin Jones, BS\*, Richmond, VA 23222; Susan Greenspoon, PhD, Department of Forensic Science, Richmond, VA 23219; Christopher J. Ehrhardt, PhD, Virginia Commonwealth University, Richmond, VA 23284*

**Learning Overview:** After attending this presentation, attendees will understand: (1) how to optimize staining of epithelial skin cells with antibodies; (2) how to assess binding efficiency of antibody probes; and (3) if pairing antibodies to different molecular targets enhances the signal intensity or facilitates more distinct staining patterns for male versus female epithelial cells.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the novel application of fluorescently labeled antibodies targeting testosterone, Dihydrotestosterone (DHT), and estradiol molecules to selectively stain epithelial skin cells in trace biological mixtures. Using these antibodies to screen for male epithelial cells is an innovative concept that will benefit forensic biology units tackling touch/trace mixtures. Screening for the presence of male cells and separating them from female cells could eventually be applied to casework samples in order to simplify complex touch/trace mixtures or eliminate these mixtures altogether prior to forensic DNA analysis.

In recent years with the increased sensitivity of DNA analysis instrumentation and Short Tandem Repeat (STR) typing kits, evidence submitted to forensic laboratories for DNA analysis has shifted such that a large proportion consists of “touch” or trace evidence. Moreover, touch or trace DNA mixtures constitute one of the most difficult types of evidence to successfully profile and interpret. If male cells can be differentiated by antibody staining from female cells, this could be exploited to separate out contributors in a touch or trace mixture and increase the success rate of profile interpretation. Testosterone, the primary male sex hormone responsible for producing male phenotypes, is a potential antibody target due to its abundance in males at approximately ten times that of females in blood serum levels and its long-term stability in biological samples.

In this study, skin epithelial cells were used to model touch or trace mixture evidence, which constitutes half of the casework evidence items submitted for DNA analysis. For the optimization of antibody staining, male and female skin epithelial samples from the same donors were incubated and hybridized with fluorescently labeled anti-testosterone, anti-DHT, and anti-estradiol antibody probes separately, each at varying concentrations. Antibody binding efficiency was assessed by analyzing stained single-source male, female, and control epithelial skin cells through flow cytometry to determine if the staining was specific to either cell population compared to the unstained control. The objective was to maximize probe binding to male cell populations and the selective labeling of male and female cells. Once an optimal staining condition was established, it was tested across several individuals from each sex. If an improved signal was observed, as demonstrated by an increased median fluorescence and separation between male and female samples, then the testing moved forward to Fluorescence Activated Cell Sorting (FACS) analysis.

The results for testosterone labeling showed an increased median fluorescence for male cell populations compared to female. Staining with anti-DHT probes resulted in only a slight shift in median fluorescence from unstained to stained cells and showed no separation in median fluorescence between male and female cell populations. The results for estradiol antibody probes showed an increased median fluorescence separation between male and female cell populations. When testosterone and DHT antibodies were used simultaneously, the median fluorescence increased between unstained and stained cell populations. However, there was not a large separation in median fluorescence between male and female cell populations. Overall, these results suggest that antibody probes targeting testosterone and estradiol may be used to differentially label contributor cell populations in touch or trace mixture samples. This can potentially be used to presumptively screen evidence samples for the presence of either cell population or as the basis for separating cell populations based on fluorescence prior to DNA profiling.

### B38 Classification of Body Fluid Source in Dried Samples Using a Panel of MicroRNAs (miRNAs)

*Ciara Rhodes\**, Mechanicsville, VA 23111; *Annabelle C. Campbell, BSc*, Richmond, VA 23220; *Carolyn Lewis, BS*, Virginia Commonwealth University, Richmond, VA 23284; *Tracey Dawson Cruz, PhD*, Virginia Commonwealth University, Richmond, VA 23284; *Edward Boone, PhD*, Richmond, VA 23284; *Sarah J. Seashols Williams, PhD*, Virginia Commonwealth University, Richmond, VA 23284-3079

**Learning Overview:** After attending this presentation, attendees will understand how miRNAs can be of significant value for body fluid identification in forensic casework. Attendees will understand that specific miRNA markers can distinguish different body fluids, and that miRNAs may be a better molecular-based method for the identification of body fluids than the use of current serological tests, which are based on enzymatic activity and are often prone to false positives.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the evidence for miRNAs as molecular markers for body fluid identification continues to build strength.

MiRNAs are small non-coding RNAs, 18–25 nucleotides in length, that have been identified and evaluated as potential markers for the identification of forensically relevant body fluids. There is significant interest in the use of miRNAs for forensic casework because of their short length and high resistance to degradation. They have also been shown to co-extract and be detectable in DNA extracts, which could make the use of miRNAs a more streamlined and easily implementable molecular body fluid identification method than other described methods.

Candidate miRNAs were identified through high-throughput sequencing of the miRNome and quantitative Polymerase Chain Reaction (qPCR) panel analyses of differential expression patterns in venous and menstrual blood, vaginal secretions, saliva, feces, urine, perspiration, and semen. Candidate miRNAs were identified and subsequently further validated using population sample sets from each biological fluid, ultimately identifying seven miRNAs to identify blood, semen, menstrual secretions, saliva, feces, and urine. This panel of miRNAs includes a pair of endogenous reference markers that provide normalization of miRNA expression without evaluation of the RNA quality or known input quantity. miRNA expression is detected using Reverse-Transcription quantitative PCR (RT-qPCR) to identify and differentiate dried body fluids of a volume and type as may be collected from the scene of a crime.

Each of the seven miRNA markers in the miRNA panel was analyzed in 50 samples of blood, saliva, vaginal fluid, urine, and semen samples and, together with previous data, were used to construct a classification regression tree that provides likely sample classification based on its relative expression of each candidate. Identification of the biological fluids was found to be reliable across population samples of mixed ages, ethnicities, and gender, with 80–100% of the unknown samples classified correctly, depending on the body fluid in question.

In conclusion, the classification tree developed in this work demonstrated high accuracy in identifying the biological source of unknown samples. This complements previous research confirming consistent miRNA expression in compromised samples, and a low limit of detection of  $10^4$ – $10^5$  copies. Consequently, the miRNA panel can provide robust, accurate identification of six biological fluids, with demonstrated utility for implementation into forensic casework.

#### Body Fluid Identification, MiRNA, MicroRNA

### B39 A Determination of the Optimal Method for the Detection of Vaginal Fluid

Melissa Rogers\*, North Wales, PA 19454; Lawrence Quarino, PhD, Cedar Crest College, Allentown, PA 18104; Amrita Lal-Paterson, MSFS, Division of Forensic Science, Wilmington, DE 19801; Janine Kishbaugh, MS, Cedar Crest College, Allentown, PA 18104

**Learning Overview:** The goal of this presentation is to demonstrate the methods that have proven to differentiate vaginal fluid from other body fluids, such as saliva and urine.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the foundation for a potential confirmatory test for vaginal fluid, and so provide context for sexual assault investigations.

With the advent of DNA and the potential to be corrupted by bias, many people, including forensic scientists, have forgotten the importance of applying context to the evidence of a particular case. DNA may be present at a crime scene, but without context, that DNA evidence may be interpreted incorrectly. Identifying the body fluid from which the DNA came can provide information of how the DNA came to be there. Forensic science literature presents a number of tests to confirm the presence of various bodily fluids; however, such a test for vaginal fluid is still needed.

A confirmatory test for vaginal fluid will provide critical context for forensic casework, especially in sexual assault cases where no semen is present. In this study, different methods were examined to detect and confirm the presence of vaginal fluid on “used” condoms donated by women of different ages and then tested over periods of time. Following Institutional Review Board (IRB) approval, multiple samples were obtained from more than 20 volunteers. After extensive validation, a tandem method is proposed that provided robust results over all demographic groups tested.

The first method utilizes the Periodic Acid-Schiff (PAS) reagent to stain glycogen present in vaginal epithelial cells in a histochemical reaction.<sup>1</sup> The reagent proved to be an improvement over Lugol’s iodine, which was more commonly used in forensic labs.<sup>2</sup> Of 20 vaginal fluid samples tested on women ranging in age from 24–82 years, all produced positive results with no false positives observed with corresponding saliva and urine dried stains. These visual results were bolstered by using cellSens software with an Olympus® Polarized Light Microscope to photograph the stained slides and measure the Red, Green, Blue (RGB) values of each photo.

The second method utilizes real-time Polymerase Chain Reaction (PCR) to amplify genetic sites in three bacteria typically associated with the vaginal cavity: *L. crispatus*, *L. iners*, and *L. gasseri*.<sup>3</sup> This method also proved effective; while some of the bacteria were also present in saliva and urine, more amplified product was observed in vaginal fluid samples, as well as used condom samples.

Not only do these results bring to light more effective detection methods for vaginal fluid, but they also provide the foundation for a potential confirmatory test that could be used in serology laboratories Utilizing and validating these methods is vital for aiding in sexual assault investigations. The detection of vaginal fluid in cases could provide the context needed to solve these heinous crimes.

### **B40 Forensic Body Fluid Identification Using Microbiome Signature Attribution Through 18S Recombinant DNA (rDNA) High-Throughput Sequencing**

Alyssa Daniels\*, Henrico, VA 23228; Ines Benaissa, BS, Richmond, VA 23222; Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Richmond, VA 23284-3079; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284; Denise Wohlfahrt, BS, Virginia Commonwealth University, Richmond, VA 23284; Kathleen D. Brim, BS, Richmond, VA 23221-3013; Eric A. Abshier, MS, Worldwide Counter Threat Solutions, Fredericksburg, VA 22401; Francys S. Nogales, BS, Virginia Commonwealth University, Richmond, VA 23223; Haris Mukic, BS, Virginia Commonwealth University Dept of Forensic Science, Richmond, VA 23284; Angela L. Brand, MS, Richmond, VA 23220

**Learning Overview:** After attending this presentation, attendees will have a better understand of eukaryotic communities associated with forensically relevant human body fluids.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by developing an improved method for the accurate identification of body fluids as an alternative to current serological techniques. While the human microbiome has been used for identification purposes in the past, high-throughput sequencing has allowed for a more detailed and rapid analysis of microbial communities.

The conception of the Human Microbiome Project advanced the understanding of bacterial communities in the human body, and previous research has established that unique microbial signatures can help distinguish each body fluid. While these signatures have been developed for the prokaryotic microbiome, the next step is the examination of the eukaryotic microbiome. Eukaryotic signatures could provide a greater specificity and statistical weight when discerning between body fluids. These microbial markers can be implemented to develop a confirmatory assay for body fluid identification that works in tandem with other DNA-based methods in the forensic workflow.

Using an approved Institutional Review Board (IRB) protocol, 100 samples each of urine, feces, saliva, vaginal fluid, menstrual blood, and semen were collected. The semen and urine samples were first collected in a container, then dried onto sterile cotton swabs at room temperature. Saliva, vaginal fluid, menstrual blood, and feces were collected onto cotton swabs and dried at room temperature. DNA was isolated and quantified using DNA extraction methods commonly used by the forensic community. The V9 region of the 18S rDNA was amplified using dual-index strategy as described by Kozich et al.<sup>1</sup> Amplified products were purified, quantified, and pooled in equimolar concentration for paired-end sequencing on the MiSeq® FGx sequencing platform. The sequences will be analyzed using mothur version 1.39.4, and R version 3.4.0.<sup>2,3</sup> Ensemble subspace classification methods will be developed for the identification of body fluid samples in a single test either alone or in combination with bacterial signatures associated with these body fluids.

The 18S rDNA amplification resulted in two amplification products for most of the body fluid samples. Only those fragments of the target size were gel extracted and purified. For the same samples, microbial signatures based on 16S rDNA sequencing showed that except for female intimate samples (menstrual secretions, vaginal secretions, and female urine), the bacterial structure was significantly different between different body fluids. Most probably, an ensemble subspace classification method developed based on combined bacterial and eukaryotic community structure data will be able to differentiate even female intimate samples.

In conclusion, this study will highlight eukaryotic community structure associated with a large number of human biological samples and will develop a method that will be able to identify all forensically relevant biological samples in a single test.

### **B41 Integration of Microchip Electrophoresis and a Validated Messenger RNA (mRNA) Panel as a Novel Approach to Forensic Body Fluid Identification**

*Tiffany R. Layne, MS\*, University of Virginia, Charlottesville, VA 22904; Rachel I. Fleming, PhD, Private Bag 92-021, Auckland, NEW ZEALAND; Dion Sheppard, MS, Institute of Environmental Science and Research, Sandringham 1025, NEW ZEALAND; Andrew Sarman, MS, Institute of Environmental Science and Research, Sandringham 1025, NEW ZEALAND; John Bone, BS, Institute of Environmental Science and Research, Sandringham 1025, NEW ZEALAND; James P. Landers, PhD, University of Virginia, Charlottesville, VA 22904*

**Learning Overview:** After attending this presentation, attendees will better understand a simple method for microchip electrophoretic separations, the use of a novel mRNA panel for differentiation body fluids, and how the integration of these two scientific advances applies directly to forensic body fluid identification. This information will present a novel alternative to current methods used in forensic laboratories and literature.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a simple, yet specific, alternative method for body fluid identification that can be easily integrated into the forensic workflow, is automated to minimize user intervention, and can produce genetic profiles from mixture samples that are comparable to those generated from commercial genetic analyzers.

This research aims to develop a microfluidic approach to forensic body fluid Identification (bfID) using an mRNA panel coupled with electrophoretic separation on a centrifugally driven microfluidic device. The Institute of Environmental Science and Research (ESR) has developed a method for detection and differentiation of body fluids in an unknown sample. The approach is based on amplifying mRNA targets specific to individual body fluids, then electrophoretically separating the amplicons. Traditionally, a commercial genetic analyzer is used for separation of fragments by capillary electrophoresis. However, electrophoretic separation can instead be carried out on a microfluidic device to decrease required assay time, cost, and user intervention relative to use of a commercial instrument.

Genetic material (mRNA) was extracted from various samples containing either a single fluid (blood, semen, saliva, vaginal fluid, or menstrual blood) or a mixture, amplified, then separated by size using either a commercial genetic analyzer (3500xl or 3130xl), or a novel microfluidic device was developed for separation of the mRNA targets. Sample injection time and channel temperature for the microfluidic approach were optimized for improved DNA fragment resolution with on-disc microfluidic electrophoresis. To determine the optimal sample injection time for an on-disc electrophoresis, different electrokinetic sample injection times prior to separation were evaluated to determine the minimal amount of time needed to produce acceptable peak heights (above 1,000 Relative Fluorescence Units [RFU]). This study also evaluated whether heating of the separation domain/polymer was necessary for sufficient peak resolution and separation, with the temperature adjusted via an embedded Peltier thermoelectric device. Analysis of the resulting electropherograms indicated that heating of the separation channel did not have a large impact on the resolution or separation of the peaks in the electropherograms. To determine detection sensitivity of the on-disc platform, two single-source samples for each body fluid were diluted to various extents (1:2, 1:6, 1:10, or 1:14) prior to injection and electrophoresis. This demonstrated an on-disc platform sensitivity that was comparable to current bfID techniques. The fluorescence signal from all peaks was detectable through 2X and 4X dilution for the majority of the body fluids, although, some drop-out was observed.

In conclusion, this study has provided evidence for an on-disc microfluidic separation of a novel mRNA body fluid panel as an alternative to current bfID techniques that demonstrates detection of individualized targets for all five body fluids, detection of all peaks for mixture fluid samples, and rapid separation times (~8 minutes). This on-disc separation provides genetic profiles that are comparable to “gold standard” genetic analyzers used in forensic laboratories, based on peak heights and ratios. In addition, the on-disc platform was able to consistently separate all peaks in the mixture samples and show detection of highly diluted amplified samples. The next steps will be to optimize amplification of the mRNA targets on-disc and integrate the amplification and separation domains to allow for full automation after lysis of a sample for a “sample in-answer out” device.

#### **Microchip Separation, Body Fluid Identification, Mixture Analysis**

### **B42 Advances in the Development of Portable Surface-Enhanced Raman Spectroscopy (SERS) for Rapid, Sensitive, Confirmatory Identification of Human Body Fluids**

*Miranda L. Shaine, BS, Allston, MA 02134; Richard S. Andino, PhD, Boston University, Photonics Center, Boston, MA 02215; Ranjith Premasiri, PhD, Boston University, Boston, MA 02215; Harrison Ingraham, BS, Boston University, Photonics Center, Boston, MA 02215; Amy N. Brodeur, MFS, Boston University School of Medicine, Boston, MA 02118; Lawrence Ziegler, PhD\*, Boston University, Boston, MA 02215*

**Learning Overview:** After attending this presentation, attendees will have learned that SERS has the attributes to become a transformative technology that can robustly detect and identify trace amounts of human body fluids in minutes employing an easy-to-use single platform that offers unprecedented sensitivity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting how recent advances in the use of a SERS-based methodology for rapid confirmatory identification of dried blood, semen, saliva, vaginal fluid, menstrual blood, and urine from a single portable platform is ready to be employed by forensic scientists at crime scenes and in forensics labs. No such capabilities currently exist in the forensic science community.

Body fluids, such as blood, semen, vaginal fluid, and saliva are among the most important forensic evidence collected at crime scenes. An ideal detection and identification platform for these fluids is confirmatory, rapid, sensitive, highly specific, portable, and easy-to-use, providing crime scene investigators with maximal time for subsequent law enforcement activities. Furthermore, non-destructive and/or highly sensitive techniques are desirable for forensic identification because they leave sufficient amounts of trace biological evidence for other detection platforms, in particular for DNA testing. This presentation demonstrates how recent advances in the development of SERS-based procedures allows SERS to satisfy these forensic attributes in a portable single-platform instrument.

In a new sample preparation protocol, SERS spectra of dried blood, semen, saliva, vaginal fluid, urine, and menstrual blood have been readily obtained using a simple 50% acetic acid (HAc) extraction step. This results in larger signals, and better differentiation, than water or saline extraction. Perhaps most significantly, this novel methodology allows the blood identification signature to be dominated by the SERS spectrum of hemoglobin and minimizes variable background non-specific protein contributions. Identification of unknown body stains are accomplished by unique statistically based identification procedures resulting in analytical sensitivity and specificity >95% for all body fluid classification analyses when combined with this new sample preparation protocol.

High sensitivities have been routinely achieved with this SERS identification and detection procedure. For example, SERS spectra with excellent signal-to-noise of human blood diluted by  $10^4$  in water can be readily obtained. A dramatic and practical demonstration of SERS sensitivity is further illustrated by spreading a solution of 10 $\mu$ L of blood in 1mL of water over a 1 sq. ft. piece of glass, rubbing a swab with 50% HAc over a 1 sq. in. area, then touching the swab to the SERS chip, resulting in a strong SERS blood spectrum. By using a subtraction methodology, this study has been able to provide confirmatory identification of dried blood stains after they have been presumptively identified by luminol emission.

In another key advancement for practical and routine use of this technology, cotton swabs have been developed for the acquisition of SERS spectra of body fluids via two approaches for this forensics application. In one, the cotton swab is dipped in 50% HAc, lightly rubbed on the dried body fluid stain, then touched to the SERS substrate, and a SERS spectrum is obtained. In the second method, a solution of gold (Au) nanoparticles is pipetted onto the cotton swab, the swab is dipped in the HAc solution, then contacted with the suspected body fluid stain before the swab is directly placed at the focus of the Raman instrument for signal acquisition. High-quality SERS spectra are obtained with both approaches for easy and rapid practical use.

In addition, this presentation shows that the signature of these body fluids is unaffected by the surfaces they are found on. For example, SERS spectra of (1 $\mu$ L) dried blood on nine different materials have been acquired by the Au particle-covered swab technique and result in identical blood SERS spectra. Finally, a number of lab synthesized and commercial Au and silver (Ag) substrates as well as portable Raman instruments capable of rapid SERS use were tested, and an optimized choice for this forensic purpose will be described.

In conclusion, a portable SERS-based methodology has been developed offering a single-platform for confirmatory identification of human body fluids at crime scenes and in forensic lab settings with higher sensitivity and specificity and faster than techniques currently commercially available to crime scene forensic investigators.

#### **SERS, Body Fluids, Identification**

### B43 A Comparison of Short Tandem Repeat (STR) Allelic Recovery Post-Ultraviolet (UV) Damage Utilizing the PreCR<sup>®</sup> Repair Method: Singleplex Versus Multiplex Polymerase Chain Reaction (PCR) Amplification

Morgan Barrett, BS\*, East Haven, CT 06512; David San Pietro, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will gain an understanding of how UV, hydrolytic, and oxidative damage affects the Deoxyribonucleic Acid (DNA) sequence and therefore the STR profile, how the PreCR<sup>®</sup> Repair Mix functions to repair those damages, and whether or not singleplex amplification may be more efficient in STR allele recovery than the multiplex method.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of the nature of the multiplex amplification method and how it relates to UV DNA damage and the PreCR<sup>®</sup> repair process.

DNA is subject to many environmental factors that cause various types of deleterious damage to the molecule, including oxidative, hydrolytic, and UV light-induced.<sup>1</sup> This is a major issue in forensic DNA profiling as forensic samples are often found in a damaged or degraded state. The damage inflicted on biological samples results in a degraded DNA template to be used in PCR amplification and ultimately causes the loss of STR peak signals in forensic DNA profiling.<sup>2</sup> The PreCR<sup>®</sup> Repair Mix by New England BioLabs<sup>®</sup> is composed of enzymes used in the cellular mechanisms of DNA repair.<sup>3</sup> Studies have shown the ability of this mix to repair most types of DNA damage prior to PCR amplification of the core STR loci.<sup>4</sup> However, this repair process does not always result in complete STR profile recovery. Standard STR analysis kits are designed as multiplex PCR amplification reactions, consisting of forward and reverse primers for multiple STR loci. The purpose of this study was to determine whether or not singleplex amplification reactions post-UV damage repaired with PreCR<sup>®</sup> would result in greater STR allele recovery with the idea that singleplex reactions would allow for less competition between individual STR loci primers and primer binding sites, allowing for more efficient amplification.

As larger STR markers tend to be more susceptible to environmental damages, as observed by the “ski slope effect,” this study focused on three STR loci of differing lengths, all with simple, tetrameric repeats for the singleplex amplifications: TH01, D18S51, and CSF1PO.<sup>5,6</sup> Primer sequences for these loci were obtained from STRbase and all forward primers were developed to include a 6-FAM fluorescent tag.<sup>6</sup> Multiplex and singleplex amplifications were performed in triplicate under three different conditions; No Damage, No Repair (NDNR), Damage, No Repair (DNR), and Damage, Repair (DR). Additionally, two damaging events were performed as the consistency of UV damage to a particular sequence is unknown.<sup>2</sup>

Many observations were made with the data obtained in this study. These include the interpretations of any differences in peak height percent recovery post-PreCR<sup>®</sup> repair within each locus between multiplex and singleplex amplifications, any consistencies or inconsistencies between the two damage events, any allele size shift, alterations in peak height ratios, or introduction or disappearance of non-specific peaks, and differences in peak height percent recoveries post-repair between shorter and longer loci and homozygous and heterozygous loci. Further studies that focus on more STR loci, both heterozygous and homozygous, as well as a larger sample size and more damage events are warranted.

### **B44 A Comparison of Genotyping Success of Cotton and FLOQ™ Swabs on Casings Using Direct Polymerase Chain Reaction (PCR)**

Natalia Czado, MS\*, Fayetteville State University, Fayetteville, NC 28303; Stephen D. Towery, Fayetteville State University, Fayetteville, NC 28301; Yolonda B. Miller, Fayetteville, NC 28304

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the differences in genotyping success rates of different swab materials in direct PCR reactions used to obtain DNA from brass casings.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by assisting labs in the determination of how best to obtain and analyze DNA from brass casings and similar substrates.

Often, casings recovered from crime scenes involving firearms will have potential touch DNA evidence of the perpetrator or owner deposited on them. Traditional methods of DNA processing are time-consuming and expensive and rarely generate successful and reliable profiles from touch DNA samples.<sup>1-3</sup> One method to overcome this obstacle is to subject the substrate or swab directly to an amplification reaction, through a process known as direct PCR. Direct PCR has been shown to successfully yield DNA profiles from casings.<sup>4</sup> However, genotyping efficiency among different swab types on unfired casings using direct PCR has not been examined.

In this study, swabs composed of different materials were compared to determine which performed better when direct PCR was used on mock 9mm brass firearm cartridge samples. For the study, 15 9mm brass cartridges were sterilized under ultraviolet light for a minimum of 24 hours. After sterilization, 1µL of female control DNA (9947A diluted to 1ng/µL) was added to each cartridge case and allowed to dry. One set of five cartridges was swabbed using COPAN® microFLOQ™ Direct swabs, following the manufacturer's collection protocol. The second group of five cartridges were swabbed using COPAN® 4N6FLOQSwabs™, according to the manufacturer's protocol. The final five cartridges were swabbed using traditional cotton-tipped applicators following the same protocol as the 4N6FLOQSwab™ samples. The entire swab portion of the microFLOQ™ Direct swabs, and 3mm cuttings of the 4N6FLOQSwabs™ and cotton applicators were added to PCR reactions. All samples were amplified using the Identifier™ Plus PCR Amplification Kit and genotyped on the 310 Genetic Analyzer using GeneMapper™ V 3.2.1 software. None of the samples resulted in complete DNA profiles. Most samples recovered no allele peaks, with only six samples successfully detecting 3–9% of concordant alleles.

Though microFLOQ™ Direct swabs were expected to outperform the other swab types, their small surface area may not have recovered enough DNA to overcome copper inhibition. This study suggests that swab type is not the most important factor in determining genotyping efficiency from these types of samples. Instead, future studies should examine ways to decrease copper inhibition in order to increase the amount of DNA recovered and amplified from brass casings before determining if a difference in genotyping success exists among different swab materials.

### **B45 A Comparison of the Overall Quality and Quantity of DNA Evidence From Fingerprints Collected From Various Substrates Found at Simulated Crime Scenes**

*Sulekha Coticone, PhD\**, Florida Gulf Coast University, Fort Myers, FL 33965; *Lora Bailey Van Houten, MS\**, California Department of Justice, Fresno, CA 93740-0001

**Learning Overview:** The goal of this presentation is to discuss the effect of the type of substrate on the amount of DNA recovered from fingerprints. Following this presentation, attendees will better understand how the surface texture and characteristics can affect the DNA recovery from various substrates

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing to a growing body of knowledge regarding the utility of DNA recovered from fingerprints from different substrates.

Latent fingerprints are biometric features representing one of the most common evidence types that can be used for human identification at a crime scene.<sup>1</sup> The selection of an enhancement technique for visualization of fingerprints depends on a number of factors, including the type of substrate and the location or environment of the fingerprint.<sup>2</sup> The most common method of enhancement is the use of various types of powders (e.g., aluminum powder, black magnetic powder, black granular powder, etc.).<sup>3</sup> The powders function by attaching to the components of sweat released by the fingertips, which reveals details of ridge elements, thereby enhancing the visualization of the fingerprints.

This research study was conducted to determine the effects of fingerprint powders on the collection and subsequent analysis of the DNA lifted from different substrates. For collection, fingerprints were placed on six different substrates (steel, aluminum, unpainted wood, painted wood, glass, and faux leather) for a total of 144 fingerprints and left for four different time periods (1 hour, 24 hours, 1 week, and 1 month). Subsequently, half of the fingerprints were dusted with fingerprinting powder and the others left bare. All 144 samples were collected from their respective time periods and the DNA extracted and quantitated using real-time quantitative Polymerase Chain Reaction (qPCR) with subsequent short Tandem Repeat (STR) analysis. It was found that though the fingerprint powder did not interfere with the subsequent analysis, there was a difference in the amount of DNA recovered from different substrates after one month. The qPCR degradation ratio varied from 1.6 (steel) to 7.25 (unpainted wood) and correlated with the percent degradation by the relative DNA absorbance measured at 260nm. To assess the quality of DNA recovered, the extracted DNA was amplified, followed by capillary electrophoresis, and the results correlated with the qPCR results.

The results of this study will aid crime scene analysts by providing information regarding the most desirable locations to retrieve DNA from fingerprints at a given crime scene.

### B46 An Internal Validation of the ANDE® 6C Rapid DNA Analysis System for Forensic Samples

Krista A. Herrera, BS\*, Huntington, WV 25703; Brandy L. Plean, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406-3001; Ashley N. Henderson, BS, Barboursville, WV 25504-1450; Amy McGuckian, MSFS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406-3001; Kelly Beatty, MSFS, Marshall University Forensic Science Center, Huntington, WV 25701; Julie Conover Sikorsky, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406

**Learning Overview:** After attending this presentation, attendees will understand the results of the internal validation studies and suitable sample types for the ANDE® 6C Rapid DNA Analysis System.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a thorough validation of a commercially available Rapid DNA system so laboratories can better evaluate their options when considering the implementation of this technology.

In forensic DNA analysis, highly variable regions known as short tandem repeats are tested to generate a DNA profile. The traditional processing of DNA samples is performed in a series of five steps: extraction, quantification, amplification, capillary electrophoresis, and data analysis. While there have been some technological advancements, the traditional DNA lab process can take two or more days to complete. The implementation of Rapid DNA technology in the forensic DNA laboratory has the potential to significantly reduce the time needed to process and generate a DNA profile.

Rapid DNA is the term used to describe the generation of a DNA profile, without human intervention, in less than two hours.<sup>1</sup> Rapid DNA is being incorporated into law enforcement booking stations as well as accredited forensic DNA laboratories.<sup>1</sup> Other applications that can benefit from the use of Rapid DNA include: human trafficking, disaster victim identification, immigration, military applications, and homeland security.<sup>2</sup> Although only recently accepted by the Combined DNA Index System (CODIS) in 2018, Rapid DNA instrumentation first became available as a commercial product in the early 2010s. Due to the wide availability of Rapid DNA instrumentation and the multitude of potential applications, there is a need for forensic DNA laboratories to develop a Rapid DNA infrastructure to ensure proper handling and processing of forensic DNA samples for CODIS entry. A strong foundation will not only continue to expand the CODIS database, but potentially lead to the generation of investigative leads in a timelier manner.

An internal validation of the ANDE® 6C Rapid DNA Analysis System was performed at the Palm Beach County Sheriff's Office to demonstrate reliability and robustness of the instrument. The ANDE® 6C Rapid DNA Analysis System is a fully automated instrument, capable of generating a DNA profile in less than two hours with minimal human intervention. The system uses the FlexPlex27 multiplex assay that includes 23 autosomal loci (D3S1358, D1S1656, D2S441, D10S1248, D13S317, Penta E, D16S539, D18S51, D2S1338, CSF1PO, D6S1043, TH01, vWA, D21S11, D7S820, D5S818, TPOX, D8S1179, D12S391, D19S433, SE33, D22S1045, and FGA), three Y-chromosomal loci (DYS391, DYS576, and DYS570), and amelogenin.<sup>3</sup> The ANDE® 6C Rapid DNA Analysis System is approved for use at the National DNA Index System (NDIS) by an accredited forensic DNA laboratory for reference sample buccal swabs.<sup>1</sup>

A series of studies were conducted on the Arrestee Chip (A-Chip) to define the performance and limitations of the instrument by evaluating contamination, sensitivity, reproducibility, repeatability, National Institute of Standards and Technology (NIST) traceability, mixtures, and known/mock sample types. All samples run on the ANDE® were processed via the laboratory's conventional typing methods and compared for concordance. Samples processed on the A-Chip include buccal samples from a variety of donors, collected at different timeframes, ranging from fresh to approximately eight years of age.

The results indicate that this technology has the potential to expedite the processing of select DNA samples resulting in a faster turnaround of preliminary associations to aid investigations.

McCord, PhD*, Florida International University, Miami, FL 33199; *Kevin Lothridge, MSc*, National Forensic Science Technology Center, Florida International University, Largo, FL 33777

**Learning Overview:** After attending this presentation, attendees will better understand how a microwave can be used to help extract DNA for Rapid DNA analyses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees how the use of a microwave to extract DNA can greatly increase the speed of extractions and has the potential to also inactivate downstream Polymerase Chain Reaction (PCR) inhibitors.

The goal of this project is to develop a quick microwave-based extraction technique as a front end for rapid DNA analysis. The recent development of rapid and microfluidic technology has made it possible to perform field-able analysis of saliva samples from suspects.<sup>1</sup> However, when confronted with forensic samples such as blood, semen, and touch DNA, these same instruments often perform less well. Currently available instruments can perform DNA typing from extraction through genotyping in fewer than 90 minutes and this newly developed ultra-rapid DNA system can yield genotypes in fewer than 15 minutes.<sup>2,3</sup>

The problem is that the processes these instruments use to isolate DNA are slow and inefficient when utilized with samples other than saliva and may not be fast enough nor effective enough for certain sample types and critical time-sensitive intelligence applications. Results from studies involving crime scene samples indicate the need to mitigate issues with sensitivity and PCR inhibition and to improve the speed of rapid DNA systems. Furthermore, processing difficult samples in remote locations is important for rapid on-site intelligence applications. Thus, there is a need to develop a rapid and efficient front end for processing difficult samples in remote locations. This project will develop microwave DNA extraction methods as a front end to a variety of commercial- and laboratory-based rapid Short Tandem Repeat (STR) genotyping systems to improve the speed and quality of results for rapid genotyping of challenging forensic samples.

The importance of effective forensic DNA extraction methods was reviewed by Lee and Shewale, and while there are many effective procedures, several are time-consuming, use hazardous chemicals, unstable chemistries, and/or are generally not amenable to field deployment.<sup>4</sup>

Microwave DNA extraction methods were first published for gram positive bacteria in 1991 and for eukaryotic organisms in 1993.<sup>5,6</sup> Microwave extraction has been applied to paraffin-embedded tissues, sludge, cyanobacteria, spores human disease vectors, bone, serum, and blood resulting in DNA suitable for both Polymerase Chain Reaction (PCR) and Massively Parallel Sequencing (MPS) applications.<sup>7-16</sup> In a study comparing chemical, enzymatic, and microwave extractions, results showed that the microwave method outperformed the other two methods in both the quality and quantity of recovered DNA.<sup>16</sup> This study concluded that the microwave-based procedure is easy, rapid and cost-effective for high-yield isolation of analytical-quality DNA.<sup>17</sup>

Three different microwaves have been successfully used for DNA extraction in the laboratory. In the first study, a dramatic increase in DNA isolation speed was demonstrated using a conventional 400W microwave oven on eukaryotes, including plants, fungi, snake and protists.<sup>6</sup> In a second study, a microwave DNA isolation method was successfully applied to human forensic samples: blood, saliva, semen, fingernails, and hair, in collaboration with Ted Pella Inc using a computer-driven microwave: Ted Pella Inc., Model 3440 at 800W.<sup>18</sup> Two eight-second pulses at full power with an intermittent rest of 20 seconds could be used to isolate DNA from 16 samples in 400µl of extraction buffer simultaneously while only slightly raising the temperature (4–6°C) in less than one minute, resulting in comparable quality and quantity to conventional methods.<sup>18</sup>

A third study tested the compatibility of microwave-extracted DNA with direct rapid PCR. Replicate 15µl saliva samples were microwave extracted, then amplified directly with a rapid two-step PCR protocol for amplification of a seven locus multiplex. Direct STR amplification and detection were achieved in 13 minutes from microwave-extracted saliva samples.

Microwave DNA extraction can increase the speed of extraction and DNA yield, resulting in high-quality DNA suitable for direct rapid PCR protocols. The system has been applied to a variety of single-source human saliva, blood, and epithelial samples. The protocols will be tested on samples deposited on different substrates, samples spiked with inhibitors, and mixtures. Furthermore, a set of mini STRs has been developed for rapid direct PCR of the microwave extracts with amplification in less than nine minutes.

The inclusion of the microwave digestion at the front end of the analytical stream may help to mitigate PCR inhibition, improve the lysing of cells, and increase the overall yield of input DNA for rapid DNA analysis. These positive effects should greatly improve overall speed and success rates using a rapid DNA processing stream for both laboratory and commercial systems.

### **B48 Considerations for Database Searching With Siblings**

*Lisa Sansom, BS\*, University of North Texas Center for Human Identification, Fort Worth, TX 76107; Melody Josserand, MS, University of North Texas Center for Human Identification, Fort Worth, TX 76107; Michael D. Coble, PhD, University of North Texas Health Science Center, Fort Worth, TX 76107-2690*

---

**Learning Overview:** After attending this presentation, attendees will be aware of the varying statistical results observed in kinship calculations when associations to a missing person found in the Combined DNA Index System (CODIS) include a single parent and sibling assembled into a pedigree tree and how these variations affect the outcomes of database searches.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and legal communities by highlighting the chance of missing an identification of a missing person when including a sibling reference into a pedigree search in CODIS. Recommendations to address this situation will be provided.

Since the release of CODIS v6.0 in 2008, missing persons searches performed in the software utilize pedigree trees to search for missing family members in the Unidentified Human (Remains) index of the database. First-order relatives are requested to optimize searching of CODIS, including siblings. Typically, the addition of a sibling to a single parent in a pedigree tree is beneficial for calculating kinship statistics such as a Likelihood Ratio (LR) when a genetic association is found in CODIS, as opposed to a parent alone. However, situations have been observed in which the addition of a sibling to a pedigree tree with a single parent (biological father or mother) has substantially reduced the statistical value of a genetic association compared to using the parent alone. This is attributable to the manner in which alleles are passed from parents to their offspring. Because it is possible that even full siblings may share two, one, or (especially) zero alleles in common, the statistical weight of a CODIS association can be negatively affected by the inclusion of the sibling data. The effect of allele sharing between siblings on statistical calculations can therefore mean that a valid association within the CODIS database may be missed due to search threshold requirements.

It is also possible that the submission of a sample purported to be from a full sibling is actually from a half-sibling. The information regarding the half-sibling relationship may be known, but not included in the submitted case information, or the true relationship is not known to the reference sample donor at all. In some scenarios observed, this is not the case. The addition of a full sibling to a pedigree tree has decreased the LR on more than one observed occasion, sometimes so low that the results are not above the lab threshold for reporting. This leads to the possibility that the addition of a full sibling to a pedigree tree in CODIS may actually depress the kinship LR just enough so that it does not meet the level required for reporting, resulting in a true association that is missed during a search of a large database.

Recommended solutions to address this situation will be presented. These solutions may include ignoring the submitted sibling reference sample when searching in the CODIS database. Sometimes, “less may be more” when calculating kinship LRs in missing persons cases wherein family reference samples include a single parent and sibling.

---

### **B49 Internal Validation of the Applied Biosystems™ RapidHIT™ ID System Using ACE and INTEL Cartridges**

Ashley N. Henderson, BS\*, Barbourville, WV 25504-1450; Brandy L. Plean, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406-3001; Krista A. Herrera, BS, Huntington, WV 25703; Amy McGuckian, MSFS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406-3001; Kelly Beatty, MSFS, Marshall University Forensic Science Center, Huntington, WV 25701; Julie Conover Sikorsky, MS, Palm Beach County Sheriff's Office, West Palm Beach, FL 33406

**Learning Overview:** After attending this presentation, attendees will have an understanding of the studies performed and results from the validation of the Applied Biosystems™ RapidHIT™ ID System for processing both reference standards and crime scene evidence for forensic casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees that this validation will provide a budding resource that can process DNA samples more expediently than conventional processing methods.

Rapid DNA is the accelerated processing of crime scene or reference samples to develop a DNA profile without human intervention in less than two hours. The addition of Rapid DNA technology to a DNA laboratory can significantly advance the workflow, as conventional DNA processing currently requires a minimum of two days to complete, from sample intake through data analysis.

Other areas in law enforcement, such as booking stations, can also benefit from integrating this technology. As the implementation of Rapid DNA expands, the development of a Rapid DNA infrastructure among agencies is critical to ensure the responsible handling and processing of samples for DNA analysis. An established Rapid DNA network will not only continue to supply the CODIS database with DNA profiles, but also expedite the processing of time-sensitive DNA samples and casework.

The Applied Biosystems™ RapidHIT™ ID System is a fully automated instrument capable of taking human DNA samples from sample to profile in approximately 90 minutes.<sup>1</sup> The RapidHIT™ ID System utilizes Short Tandem Repeat (STR) -based identification and review through an incorporated expert system. The instrument accepts two types of sample cartridges: the ACE Cartridge, which is used for single-source reference samples, and the INTEL Cartridge, which is designed for lower template, crime scene evidence samples. Both cartridges use the GlobalFiler™ Express STR typing chemistry for amplification.

The integrated software, RapidLINK™ v1.0, is capable of producing electropherogram results for analyst review using GeneMarker™ HID STR Human Identity Software.<sup>2</sup> The RapidLINK™ software has the capability to link multiple RapidHIT™ ID systems across a shared network, allowing multiple data sites to be managed from one location. This network of instruments allows the user to share and review results in real time and equips the user with a databasing function for samples that are not eligible for CODIS upload.

The validation study conducted for the RapidHIT™ ID System consisted of a contamination assessment, sensitivity, reproducibility, repeatability, National Institute of Standards and Technology (NIST) traceability, mixtures, and known/mock sample types for both the ACE and INTEL Cartridges. All of the validation samples were processed with the accredited laboratory's conventional DNA analysis methods and compared for consistency.

After assessing the RapidHIT™ ID analysis results in tandem with the results generated from traditional forensic DNA methods, it was determined that the instrument is capable of obtaining concordant DNA profiles. Therefore it was concluded that the RapidHIT™ ID System is a reliable tool for the expeditious processing of reference and crime scene samples, allowing for quick inclusions and exclusions with the potential to further criminal investigations.

### B50 Performance of Microhaplotype and Short Tandem Repeat (STR) Biomarkers in Mixture Detection and Deconvolution

Fabio Oldoni, PhD\*, The George Washington University, Washington, DC 20007; Drew A. Bader, Washington, DC 20007; Chiara Fantinato, Vicenza, ITALY; Sharon C. Wootton, PhD, South San Francisco, CA 94080; Robert Lagacé, BS, Thermo Fisher Scientific, South San Francisco, CA 94080; Ryo Hasegawa, BS, Foster City, CA 94404; Joseph P. Chang, BS, Thermo Fisher Scientific, South San Francisco, CA 94080; Daniele S. Podini, PhD, Department of Forensic Science, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will understand the use of different biomarkers for mixture detection and deconvolution.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing microhaplotype markers as a supplemental tool to conventional STR typing analysis.

Microhaplotypes (microhaps) are emerging biomarkers defined by two or more closely linked Single Nucleotide Polymorphisms (SNPs) in <300bp displaying multiple allelic combinations.<sup>1</sup> The presence of multiple SNPs within the same locus augments the information over a stand-alone SNP locus. The multi-allelic nature of microhaps, although less polymorphic than STRs, makes these markers a promising versatile toolset as it offers certain advantages over STRs. These are absence of stutter, same-size alleles within a locus, low mutation rate, and ancestry informative alleles. Microhap multiplex assays can reach the same power of discrimination of STRs and also be used for different forensic applications, including human identification, mixture deconvolution, relationship testing, and ancestry prediction.<sup>2</sup> Unlike the standard Sanger sequencing methodology, which does not determine the *cis/trans* relationship among individual SNPs, Massively Parallel Sequencing (MPS) allows determining the parental SNP haplotypes by clonal sequencing of individual amplicons originating from each individual strand, thus distinguishing each parental allele at a locus. This study evaluated the mixture performance of a 74 microhap locus-assay on the Thermo Fisher Scientific™ Ion Torrent S5™ system and compared the results to standard sized-based STR and sequenced-based STR analysis.<sup>3,4</sup>

The detection limit of the bioassay was tested in triplicate using a 2ng to 25pg range of input DNA. The performance of the microhap panel was evaluated in parallel with the GlobalFiler™ kit on Capillary Electrophoresis (CE) on the ABI® 3500 Genetic Analyzer and the Precision ID GlobalFiler™ NGS STR Panel v2 on the S5™ platform. To simulate casework-like DNA samples, a large series of two- to five-person mixtures was simulated at 1-10ng input DNA and at different contribution ratios. Examples of the tested ratios included 10:1 to 40:1 for two-person mixtures, 5:5:1 and 10:5:1 for three-person, 20:5:1:1 for four-person mixtures, and 5:5:1:1:1 for five-person mixtures. For genotyping of microhap loci, Microhaplotyper Plugin v8.1 was used while STR sequence data and CE STR data were analyzed with Converge and GeneMapper® ID-X software, respectively.

The 74-locus panel was found to be sensitive to approximately 50pg input DNA (equivalent of eight diploid cells). Overall the deconvolution and interpretation of CE-based STR mixtures was challenging for imbalanced and high order mixtures. However, sequencing data demonstrates that the deconvolution of these latter can be enhanced by MPS. This approach allows detecting additional minor alleles masked by stutter with conventional CE but distinguishable by sequence and displaying repeat pattern variation or due to the presence of microvariants. It is worth noting that both sequencing of microhap and STR mixtures displayed imbalanced coverage between different loci in all mixtures tested using an input amount of 1–10ng DNA. For microhaps and, in particular, for two-person mixtures, a full minor profile was reported at 1:10 ratio with minimal allele and locus dropout at 20:1, and more significant locus dropout at 40:1 ratio at both 1ng and 10ng DNA inputs. At the same input DNA amount for three- to five-person mixtures, full microhap profiles could be reported for the minor DNA contributors at all tested mixture ratios with the exception of some microhap loci that underperformed.

These findings suggest that microhap biomarkers can enhance the deconvolution of mixed DNA samples and complement both conventional size-based and sequence-based analysis of STRs.

**B51 Optimization Parameters of Fragmentary Voltage and Collision Energy for the Identification and Separation of 1,3,5-Triamino-2,4,6-Trinitrobenzene (TATB) From Other Explosives With Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS)**

*Blerim Olluri, PhD\**, Bill Clinton, Prishtina 10000, KOSOVO; *Milazim Tahirukaj\**, Kosovo Agency on Forensics, Pristina, WA 10000, KOSOVO; *Xhemajl Ademaj, PhD\**, Kosovo Agency for Forensics, Prishtina, Kosova 10000, KOSOVO; *Herolind Krasniqi\**, Kosovo Agency on Forensics, Pristina 10000, KOSOVO

**Learning Overview:** After attending this presentation, attendees will better understand the development and optimization of the parameters for the creation of a new method for the identification and separation of organic explosives.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the current capabilities of the Kosovo legal science lab in the development of new methods for the identification and separation of organic explosives by chromatographic methods and the impact on the identification of source(s) explosives and interconnections to identify terrorists.

Explosives are classified in several ways, based on different criteria. Thus, explosives are divided into high and low explosives based on the type and speed of the action. Explosives are also classified according to their chemical structure. The most important group is that of organic compounds containing the nitro (NO<sub>2</sub>) group. They are further subdivided based on the site where NO<sub>2</sub> is attached to the atomic structure. Nitrogen compounds contain C-NO<sub>2</sub> groups, a group of C-O-NO<sub>2</sub> nitrate ethers, and C-N-NO<sub>2</sub> nitrite nitriles.

There are different methods for identifying and separating organic explosives, especially 1,3,5-triamino-2,4,6-trinitrobenzene (TATB), but recently, double-mass spectrometric detector chromatography has begun to accommodate numerous scientific researches by forensic scientists to find appropriate parameters for the identification and separation of organic explosives in low concentrations in picograms (pg) or even in femtograms (fg).

Therefore, considering the needs, reasonable work has begun to create optimal parameters for Collision Energy (CE) and Fragmentary Voltage (FV) for identifying and dividing TATB from other explosives by using LC/MS/MS with the Atmospheric Pressure Chemical Ionization (APCI) model, Zorbox<sup>®</sup> SB-C18 column 600 bar 3 x 50mm 3.5µm and mobile phase methanol/isopropanol/water (1:3:6), as well as 0.1% chloroform.

In studying this, optimal CE and FV values have been established for the identification and separation of TATB from other explosives, the change of fractional energy values greatly influences the fragmentation of the molecule under study, the fragmentation fractions molecule at all levels, and this facilitates the identification of the molecule of the unknown explosive, and all fractions comply with the preliminary knowledge of the TATB structure and knowledge of its potential fragmentation, in addition to the excellent division achieved with this technique and the limit of detection down to fg.

At the end of this study, optimized parameters for identification and separation of organic explosives with LC/MS/MS result in the following conclusions. This study analyzed the following organic explosive samples: 3,4,8,9,12,13-Hexaoxa-1,6-diazabicyclo(4.4.4)tetradecane (HMTD), 1,3,5,7-Tetranitro-1,3,5,7-tetrazocane (HMX), RDX, TATB, 1,2-dinitroxyethane (EGDN), 1,3,5-Trinitrobenzene (1,3,5-TNB), 1,3-Dinitrobenzene (1,3-DNB), *N*-Methyl-*N*-(2,4,6-trinitrophenyl)nitramide (TETRYL), 4-amino-2,6-dinitrotoluene (4A-DNT), Nitrobenzene (NB), Nitroglycerin (NG), 2-amino-2,6-dinitrotoluene (2A-DNT), 2,4,6-Trinitrotoluene (TNT), 2,6-Dinitrotoluene (2,6-DNT), 2,4-Dinitrotoluene (2,4-DNT), 1,3,5-Trinitro-2-[2-(2,4,6-trinitrophenyl)ethenyl]benzene (HNS), 2-Nitrotoluene (2-NT), 4-Nitrotoluene (4-NT), 2,2-Bis[(nitrooxy)methyl]propane-1,3-diy dinitrate (PETN), 3-Nitrotoluene (3-NT), 3,3-Dimethyl-1,2-dioxacyclopropane (TATP), and CARBAMITE. This work allowed the creation of methods for the identification and separation of explosives doing the optimization of parameters on LC and MS/MS.

During the study, methods for specific explosives were created: HMX, RDX, TATB, TETRYL, TNT, 2,6-DNT, HNS, PETN, and CARBAMITE. These were named: (1) EKSPLOSIVES-MMI-APCI.m, and (2) EKSPLOSIVES \_2-6-2-4\_DNT\_MMI-APCI.m.

Parameter optimization for both methods was accomplished as follows: flow of mobile phase was 0.5mL/minute, temperature of column was 35°C, and the length of column was 3x50mm, the diameter was 3.5µm, the Ionization source Multimode (MMI), ionization model (APCI), and volume of sample injected was 20µm. Mobile phase was suitable for both above methods.

Optimization of parameters was conducted as FV and CE for the explosives listed above to identify and separate explosives in a trace amount at the fg level.

### B52 Forensic Fiber Analysis by Thermal Desorption/Pyrolysis Direct Analysis in Real Time Mass Spectrometry (TD/Py-DART®-MS)

Mengliang Zhang, PhD\*, Middle Tennessee State University, Murfreesboro, TN 37132; Jared Frazier, Middle Tennessee State University, Murfreesboro, TN 37132; Virginia Benefield, Middle Tennessee State University, Murfreesboro, TN 37132

**Learning Overview:** After attending this presentation, attendees will better understand an alternative method for fiber analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting how TD/Py-DART®-MS could be used to analyze the polymer backbone of the fiber and other chemical residues from different fiber treatments during manufacturing.

The DART®-MS and TD/Py system can be used to distinguish among different types of fibers and provide orthogonal information for fiber identification. This research is a pioneer for gradient heating controlled Py-DART®-MS, which will hold great potential across a broad range of topics in the analytical chemistry area and impact the forensic science community, especially within forensic fiber analysis.

The forensic examiner should perform a combination of methods to characterize the fiber evidence in order to provide a complete and specific description of the item and rigorously assess its uniqueness and value as evidence.<sup>1-3</sup> The identification or the comparison of fibers requires an examiner to perform at least two of the analytical techniques for each of the following categories: generic class, physical characteristics, and color. Morphological comparison of fiber evidence by microscopic techniques is required in forensic case work since it can offer characteristic information of fibers in all three categories. Additional analysis is required for each category and, ideally, orthogonal techniques should be used (inorganic/organic, spectroscopy/chromatography/mass spectrometry, etc.) to provide the most discriminating information.<sup>4-6</sup> Ambient MS methods such as DART®-MS can be an alternative method for fiber analysis. The objectives of this research were: (1) to evaluate the potential of DART®-MS for fiber analysis, and (2) to classify fiber samples based on their types by using DART®-MS technique and chemometrics.

The pyrolysis device, IonRocket®, was coupled with DART®-MS to assist the analysis. The IonRocket® system is an ideal unit for the analysis of polymers with which the samples can be heated up to 600°C with accurate temperature gradient control for DART®-MS analysis. The temperature was increased at the rate of 100°C per minute, so data with three dimensions consisting of  $m/z$ , time (=temperature), and intensity was generated, which further enhanced the discriminating power comparing with sole DART®-MS analysis when chemometrics was applied. TD/Py-DART®-MS was used to analyze fiber evidence efficiently and effectively because it provided an objective evaluation for a greater variety of characteristics of fiber evidence than the optical microscopic method and eliminates the need for complicated sample preparation procedures necessary for other MS-based instrumental analyses. A wide array of information related to the physical properties (e.g., melting point, sublimation point, and degradation temperature) and chemical composition of fiber evidence was achieved from TD/Py-DART®-MS analysis.<sup>7</sup> The versatility of the analysis can increase the discriminating power (specificity) and improve the accuracy of results for fiber evidence while still providing timely results for investigators. Principal component analysis was successfully applied to classify the fibers based on the materials of textile fibers.

## B53 Preservation of Trace Compounds From Headspace Analysis in Adsorbent Capillaries

Megan Harries, BS, National Institute of Standards and Technology, Boulder, CO 80305; Kavita M. Jeerage, PhD\*, National Institute of Standards and Technology, Boulder, CO 80305

**Learning Overview:** After attending this presentation, attendees will better understand the stability of gasoline-derived compounds captured by dynamic headspace sampling with alumina as the adsorbent. This presentation considers evidence stability as a function of storage conditions and storage interval to address situations in which evidence must be preserved prior to analysis (hours to days) or for re-analysis (weeks to months).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing experimental and statistical methods to quantify the distribution of compounds captured by an adsorbent. These methods may support archival of forensic samples collected by headspace methods, including fire debris extracts, by providing quantitative evaluation of chromatogram reproducibility.

Headspace vapors are collected to extract trace compounds from complex solid matrices (e.g., fire debris) or in other situations where the solid or liquid under investigation cannot be directly analyzed. Static headspace sampling is appropriate for volatile compounds; headspace concentration must be employed for low-volatility compounds. The National Institute of Standards and Technology (NIST) has developed a dynamic headspace sampling method that utilizes alumina Porous Layer Open Tubular (PLOT) capillaries to concentrate headspace vapors. In this method, an inert carrier gas sweeps headspace vapors through the capillary, which can be cooled if needed, depending on the volatility or stability of the analyte(s), to promote adsorption. The capillaries can be eluted with solvent and analyzed by any analytical technique, typically Gas Chromatography with Mass Spectrometry (GC/MS).

PLOT dynamic headspace sampling was originally developed to identify compounds in the headspace of low-volatility explosives and has been successfully applied to the detection of gravesoil, among many other applications.<sup>1,2</sup> PLOT dynamic headspace sampling can be performed in the field with a portable briefcase-sized unit. The method detection limit has been determined for diesel fuel, and explosives- and gravesoil-related compounds have been detected inside a simulated shipping container.<sup>3,4</sup>

This report investigates the distribution of compounds recovered from alumina capillaries after storage in heat-sealed polyester/polyethylene laminate evidence bags. To generate large populations of nominally identical samples, individual headspace vials containing a known liquid sample were sampled with individual capillaries. The liquid sample was 50% weathered gasoline, which contains a variety of volatile compounds ranging from C<sub>7</sub> (e.g., toluene) to C<sub>11</sub> (e.g., methylnaphthalene). The headspace vial was equilibrated in an oven at 60°C, and the cryostat containing the “trap” portion of the capillary was cooled to 0°C. Headspace vials were purged with carrier gas at 0.6mL/min, and the total collection volume was 1.5mL. Capillaries were heat sealed in evidence bags and randomly assigned to room temperature storage or refrigeration and to various storage intervals.

GC/MS analysis included total ion chromatograms and selected ion monitoring (*m/z*) for alkanes (57, 71, 85, 99), cycloalkanes (55, 69, 83), aromatics (91, 105, 119), indanes (117, 118, 131, 132), and polynuclear aromatics (128, 142, 156). Principal component analysis was applied to probe differences between time points and among samples from the same time point. The analyses investigated variations in the carbon number, carbon class, and total mass of retained compounds. Individual compounds were also monitored. These statistical methods quantitatively demonstrate the reproducibility of the collection method; however, after six weeks, room temperature storage leads to the loss of low molecular weight compounds. Furthermore, the samples lost compounds in a divergent manner. The methods described here can be used to evaluate any adsorbent material stored for any time period and should be applied to situations in which vapor samples must be collected in a field setting and preserved until analysis.

## B54 The Sensitivity of Fingermark Color Contrast Between Sexes

Mallory R. Einfalt, BS\*, University of New Haven, West Haven, CT 06516; Josep De Alcaraz-Fossoul, PhD, University of New Haven, West Haven, CT 06516; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will be familiar with the use of image color contrast as a tool to distinguish latent fingermark aging patterns of males and females in a monitored, indoor environment.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the robustness and sensitivity of using color contrast as a potential age estimation model for latent fingermarks.

For decades, latent fingermark identifications have been routinely performed to link perpetrators and victims to crime scenes and pieces of evidence. However, a reliable and validated method for determining the time of deposition of a latent fingermark has yet to be standardized. This valuable piece of information could help corroborate witness statements and possibly exclude individuals from being present during the occurrence of a crime. Researchers have started to address this matter by investigating the degradation patterns of latent fingermarks in various environments.

Prior research has identified four morphometric parameters that could be used to quantify visual changes that occur during the aging process of latent fingermarks, one of which is the color contrast between the ridges and furrows after enhancement with a powder.<sup>1-6</sup> The methods used to analyze the morphometric parameters were inexpensive, readily available, and easy to perform, which is crucial for implementation into routine forensic casework. Previous results showed that the environmental factors of substrate type (glass vs. plastic), secretion type (eccrine-rich vs. sebaceous-rich), and natural lighting condition (light, penumbra, vs. dark) influenced latent fingermark degradation differently.<sup>1-6</sup> To better understand the observed trends, additional factors must be examined in combination with the aforementioned environmental conditions, including human factors such as biological sex. The purpose of the present study was to determine whether latent fingermarks from males and females have distinct aging processes that lead to significant differences in changes to the color contrast parameter over time.

The current experiment involved aging a total of 756 sebaceous-rich latent fingermarks from seven males and seven females over a period of three months. Inclusion and exclusion criteria were used to minimize exogenous factors and other sources of human variation. The impressions were deposited in triplicate on glass and plastic substrates using a controlled amount of pressure and contact time. These were stored in complete darkness in an environment in which the temperature and humidity were continuously monitored. At nine discrete times, random impressions on glass and plastic for each individual were enhanced with titanium-dioxide powder, photographed, edited, and analyzed using digital imaging software. The image color contrast data in grayscale was collected from histograms that display the distribution of every pixel color making up a photograph. Darker pixels were represented by low color values (with zero being pure black), while lighter pixels were represented by high color values (with 255 being pure white).

Preliminary data revealed an increasing trend in the mean pixel color value of the images over the nine aging periods and a decreasing trend in the amplitude pixel color value. The mean is the average of all pixel colors contributing to the color in the image while the amplitude is a measure of how many different colors are making up the image. The trends in these values were observed in the impressions on both the glass and plastic substrates with no observable differences between the males and females. As the latent fingermarks aged, the powder appeared to be more dispersed throughout the impressions. This shifted the histograms toward the lighter pixel colors causing a higher mean value, a lower amplitude value, and a more concentrated distribution in the histogram (Figure 1).

Figure 1. Examples of a fresh (left) and a three-month-old (right) enhanced latent fingermark on glass from a single male and their representative histograms. The ridges are shown in white.

The results of this study suggest that male and female latent fingerprints have similar aging patterns and comparable trends in changes to the image color contrast over time. From a practical perspective, an age estimation model based on color contrast could therefore be robust enough to include impressions from both biological sexes but sensitive enough to detect degradation over time. This study contributes to the current knowledge base regarding visual aging parameters of latent fingerprints and provides a foundation for future research on the influence of other human factors.

### Biological Sex, Aging, Color Contrast

### B55 Data Fusion From Spectroscopic Techniques for the Discrimination of Colored Automotive Paint Mixtures

*Morgan N. Carpenter, BS\*, Sam Houston State University, Huntsville, TX 77340; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX 77340*

**Learning Overview:** After attending this presentation, attendees will be better informed regarding the importance of how to combine analytical data from two different spectroscopic methods when applied in the context of automotive paint examinations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, in particular trace evidence examiners, by exploring the potential to properly carry out data fusion to obtain data sets of discriminating features in light of addressing interpretive aspects (i.e., source attribution questions) following comparative examinations of paint specimens.

Paint evidence examinations are conducted following an analytical sequence that typically starts with microscopical examinations, followed by methods of instrumental analysis. While comparing sets of questioned and reference items, data obtained from the various techniques are usually evaluated sequentially, in the sense that when differences are noted between compared sets, there is no need to proceed with further testing. In cases in which the forensic scientist cannot differentiate the compared sets, a subsequent method of the adopted sequence is applied. When the compared sets are indistinguishable at the end of the chosen sequence, an overall evaluation of the data is made to address the question of a common source. The rarity factor of the different features measured with the various methods in a population of interest is of utmost importance to address the “source” question: estimating the chances to observe another coated object in the relevant population that exhibits the same properties as those observed within the questioned specimens as a function, for example, the observed microscopic features *and* infrared profile *and* elemental profile. The present study focuses on the method of combining data obtained from different techniques, where the measured features are typically known to be dependent. The confined scope of this study is to investigate whether the method of combining data from two analytical techniques may affect the outcomes of data analysis for grouping or classification purposes. The way to combine data from different methods is considered critical. These measurements are not carried out on the same area of the specimen simultaneously; hence, it is hypothesized that this process has a greater variability than if measurements using multiple methods would be collected simultaneously.

Automotive repair paint samples collected from auto body shops were mixed at known proportions. Three sets of mixtures were created from the following pairs of base colors: yellow and blue; yellow and red; and blue and green. Proportions at 70%:30%, 50%:50%, and 30%:70% by weight were prepared. Reflectance visible Microspectrophotometry (MSP) (spectral range 400–700nm) and micro Raman spectroscopy using a near-infrared laser source at 785nm (spectral range 2,000–250cm<sup>-1</sup>) were used. Seven replicates of the base color paint and the three mixtures were collected for both techniques. These two methods were selected because of the assumed dependencies between the collected data since both techniques inform about the colorant components. Raman spectroscopy allowed identifying the monoclinic polymorph of bismuth vanadate (BiVO<sub>4</sub>) or C.I. Pigment Yellow 184 for the yellow base paint, the blue phthalocyanine or C.I. Pigment Blue 15 for the blue base paint, the green phthalocyanine or C.I. Pigment Green 36 for the green base paint, and the Diketo-Pyrrolo-Pyrrol (DPP) or C.I. Pigment Red 254 for the red base paint. The classic data analysis procedure of Principal Components Analysis (PCA) followed by Linear Discriminant Analysis (LDA) was used. LDA was conducted on a derived data set consisting of the three principal components that cover about 95% of the total variance of each data set. Data analysis was carried out on the MSP data set, the Raman data set, and a combination of data from these two methods when measurements 1 to *m* of sample 1 to *n* using MSP are combined sequentially side-by-side with measurements 1 to *m* of sample 1 to *n* using Raman. Four additional data sets were created by randomly pairing MSP and Raman data. For LDA, the data sets were randomly split in training sets of four samples and in testing sets of the three remaining samples.

Overall, the accuracies of the PCA-LDA models vary between the side-by-side combinations and those obtained randomly. Low accuracy values were observed; MSP was not sensitive to the color nuances resulting from mixing the paint components, and the pigments detected using Raman underwent known selective resonance effects that would enhance Raman bands from one particular pigment, irrespective of the mixed proportions.

#### Trace Evidence, Automotive Paint, Data Fusion

### B56 Forensic Discrimination of Concrete Pieces From Different Sources Using Inductively Coupled Plasma/Mass Spectrometry (ICP/MS)

Masaaki Kasamatsu\*, National Research Institute of Police Science, Kashiwa, Chiba 277-0882, JAPAN; Yasuhiro Suzuki, National Research Institute of Police Science, Kashiwa, Chiba 277-0882, JAPAN

**Learning Overview:** After attending this presentation, attendees will understand what type of elements are in the acid-soluble components of concrete and the variation in their concentrations when they are from different sources. Attendees will also be shown how to calculate indicators of discrimination based on the concentration of those elements and how to use those indicators to identify differences in concrete.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a new method of discriminating concrete based on elemental profiles of concrete pieces as physical evidence.

Because concrete is a familiar material used for building structures and block walls, concrete fragments produced in relation to crimes can be important physical evidence. Criminal investigators sometimes have to evaluate the similarity of fragmented concrete samples in order to determine whether they derive from the same origin. Generally, such samples are examined to identify whether they match certain physical structures. In that process, subjective observation should be minimized, because the results may vary from one inspector to another. For those reasons, the forensic discrimination of concrete should refer to objective indicators measured during instrumental analyses, to which end a method focusing on contained trace elements can be effective.

In this study, the components of cement and concrete that are soluble in nitric acid were subjected to ICP/MS. Indices expressed as the ratios of concentrations for selected elements were calculated from the results, and discrimination was performed based on the difference between the intra-sample and inter-sample variations of those indices.

The qualitative analysis of an acid-soluble fraction prepared from a cement sample confirmed that the fraction contained copper (Cu), zinc (Zn), rubidium (Rb), strontium (Sr), zirconium (Zr), barium (Ba), lanthanum (La), cerium (Ce), neodymium (Nd), and lead (Pb). Because the same elements also appeared in another cement sample in the experiment, those elements were used as indicators and quantified. La was selected as the normalizing element due to its relatively high signal intensity and small deviation within the sample. Once differences in the normalized values were detected between the samples, discrimination was performed using those values as indicators.

To discriminate samples, a range of the average value  $\pm 2 SD$  was first calculated for each sample, and ranges between two samples were compared. If the ranges did not overlap, then a sufficient difference between them was identified that, in turn, suggested the possibility of discriminating the samples. If the ranges overlapped, however, then no sufficient difference between the samples was recognized, which suggested that distinguishing them would prove difficult. The discrimination of two samples of interest was performed for all combinations.

When only one indicator was used, many pairs of samples could not be distinguished, and although the discrimination power between the samples was insufficient, it could be improved by combining all nine indicators. If multiple indicators did not overlap the range of  $\pm 2 SD$ , then the samples were considered to be distinguishable. Of 28 pairs from eight concrete pieces, 26 pairs (about 93%) could be differentiated. By combining indices in that way, the discrimination power improved significantly. Nevertheless, it remained difficult to identify differences in concrete blocks purchased from the same retailer, because commercially available concrete blocks are liable to be produced at the same time. Indeed, when analyzing three concrete blocks from the same batch, the samples were not distinguishable from each other. That result indicates not only that the method can be used to distinguish samples, but also that samples from the same origin could be the same.

Because cement can be nearly homogeneous when making concrete, focusing on cement as an acid-soluble component is appropriate for forensically discriminating concrete. Furthermore, because the method used involved comparing ratios, it stands as an excellent approach that does not require determining the dilution ratio of the sample during pretreatment for acid decomposition.

#### Concrete, Forensic Discrimination, ICP/MS

### B57 Black and White Foils as Packaging Material in Murder Cases

*Cornelia I. Blaga, Utrecht 3562 KW, NETHERLANDS; Peter de Joode, Rotterdam, Zuid Holland 3085NP, NETHERLANDS; Cees Vooijs, Den Haag, Zuid Holland 2497GB, NETHERLANDS; Zita Y. van Zanten, Netherlands Forensic Institute, The Hague 2497GB, NETHERLANDS; Willem Wiarda, MS, The Hague 2497 GB, NETHERLANDS; Gerard J.Q. van der Peijl, PhD\*, The Hague 2490 AA, NETHERLANDS*

**Learning Overview:** The goal of this presentation is to address the possibilities of highly discriminating multi-technique investigations to obtain information on the background variation for black and white foils that were used in two separate murders. This method has a wider application, however.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by devising and executing a plan for newly encountered materials to make in-depth comparison investigations, obtain information on the meaning of any matches found, and interpret and report this to the courts.

In two separate murder investigations in the Netherlands, bodies were wrapped in polyethylene foils and deposited in canals. The foils were black on one side and white on the other side. Primarily, this type of black-white foil is used in the agricultural sector to control the heat (e.g., as cover on the inside of greenhouses or over the soils where plants are developing).

The secondary use of these foils in the Netherlands is in the illegal cultivation of hemp (e.g., in apartments or in attics, where the black-white foils are used to suppress the heat signature of the plant growth lights so as to hinder detection by investigating authorities).

In the two separate investigations, results for the reference foils in each investigation matched with results for the foils wrapped around the victims in visual investigation (visual aspects such as color, morphology, and layer structure) and chemical composition (Fourier Transform Infrared [FTIR] and Isotope Ratio Mass Spectrometry [IRMS]) characteristics. Although both crimes were apparently drug related, no other tactical link between the two crimes was found.

Since the background variation (variation in these characteristics for visually similar black-white foils, unrelated to these crimes) for the black-white foils was unknown at the time of analysis, 36 reference samples were collected from different sources (foil producers, agricultural applications, and police seizures from illegal hemp growth locations) and information was collected on production, applications, and the distribution network for the primary use in agriculture. Contacts with producers and distributors were established for this project.

Visual and FTIR characteristics were determined for the 36 reference samples. Nineteen reference samples clearly differed in visual aspects, especially in thickness and/or layer structure, from the casework foil samples. IRMS and Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) characteristics were also determined for the remaining 17 reference samples that did not clearly differ in visual aspects. For IRMS both H and C isotope ratios were measured for the combined foil layers while LA-ICP/MS measurements (42 isotopes ranging from Li7 to U238) were made separately for the black and white layer.

For one of the casework investigations, LA-ICP/MS characteristics were also determined for the casework samples and found to match for the two black-white foils to be compared. Using the combined characteristics (visual, layer structure, IRMS, LA-ICP/MS), two of the reference samples could not be discriminated from the matching casework samples in this investigation.

For the other casework investigation, no LA-ICP/MS analysis was performed on the samples, but even then none of the reference samples matched the casework samples in the combination of the other characteristics.

This presentation will discuss how these results can be used in the interpretation and reporting of the observed matches for the two casework investigations.

#### Black and White Foil, IRMS, LA-ICP/MS

### B58 The Use of Laser-Induced Breakdown Spectroscopy (LIBS) for the Identification of Bullet Holes

Noah Scarpelli\*, Falmouth, ME 04105; Brooke W. Kamrath, PhD, University of New Haven, West Haven, CT 06516; Virginia M. Maxwell, DPhil, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will understand the value of LIBS for the identification of key elements present in bullet wipe.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a novel methodology for the identification of bullet holes. It is a rapid and relatively non-destructive analytical method that increases the level of confirmation of bullet wipe identification, thus potentially providing a valuable tool for shooting reconstructions.

Firearms are used in the majority of murder cases and a large percentage of other violent crimes. For many of the investigations related to these events, a shooting reconstruction is completed using trajectory determination. Without first identifying what is and is not a bullet hole at the scene, the reconstruction will not be as forthcoming. In cases where the hole is not obviously from the passage of a bullet, such as if there is an intermediary target, it could be overlooked and left out of the reconstruction. To date, bullet hole identification has been primarily accomplished through chemical tests, such as the sodium rhodizonate and Griess tests. While these tests are efficient in identifying individual chemical elements and functional groups commonly attributed to Gunshot Residue (GSR) and other components present in the bullet wipe (e.g., copper and nickel from a jacketed bullet), they have significant drawbacks. Some of these include the amount of time required to mix and apply the chemicals, the narrow identification of the chemical components of the suspected bullet hole, and the application of chemicals directly to the item of evidence. With the growing backlog of forensic laboratories, a rapid method for bullet hole identification would be of value for the forensic community. This technique must increase throughput and the level of confirmation while also decreasing the destruction of the evidence in question.

In this study, LIBS was evaluated as an elemental analysis method for the identification of bullet wipe. Five common clothing fabrics (T-shirt jersey, sweatshirt jersey, nylon, denim, and fleece) were chosen. These fabrics were shot with two calibers of full copper jacketed ammunition (.22 and .380) at three angles (10°, 45°, and 90°). Five replicates of each sample were analyzed using LIBS from each of the cardinal directions. The resulting bullet holes were analyzed, and the LIBS spectra were examined for the elements lead (Pb), barium (Ba), antimony (Sb), copper (Cu), and nickel (Ni).

Results indicate that this methodology is promising for the identification of these elements using the major non-interfering emission lines for the five elements, which resulted in the analysis of a total of 18 spectral peaks. Pb peaks were completely absent in the control spectra of the fabrics but were present more than 91.33% of the time in the experimental samples. The Ba peaks were absent from four of the five controls (it was detected in nylon) and were present in all the experimental samples. Sb had one peak without spectral interferences, which proved useful for the identification of this element in 96.00% of the samples shot with the .380. However, Sb was not detected on the bullet holes produced with the .22. Cu was able to be identified in more than 98.33% and absent in the controls. Ni was able to be identified in 38.50% of the samples compared to all of the controls, excluding nylon, analyzed at one peak on the spectra and was present in 98.50% of the samples compared to absence in the controls at the other peak examined. There were no observable trends in elements detected based on the bullet's incident angle.

Based upon results obtained in this preliminary study, it was concluded that LIBS has the potential to be a useful method for the identification of bullet holes in fabrics. Future research will include examination of additional calibers and types of ammunition, alternative target materials, determining the capability of LIBS for analyzing bullet holes through bunched or layered materials, and the use of LIBS in conjunction with commonly used colorimetric chemical testing.

#### LIBS, Gunshot Residue, Shooting Reconstruction

### **B59 A Characterization of Nylanthrene Dyes in the Differentiation of Macroscopically Similar Black Fibers Using Light Microscopy and Visible Microspectrophotometry (MSP)**

*Andra Lewis, MS\*, The Woodlands, TX 77382; Christopher S. Palenik, PhD, Microtrace, Elgin, IL 60123-4755; Skip Palenik, BS, Microtrace, Elgin, IL 60123-4755; Patrick Buzzini, PhD, Sam Houston State University, Huntsville, TX 77340*

**Learning Overview:** After attending this presentation, attendees will better understand the unusual nylanthrene dyes used in the coloration of black polyamide fibers and the abilities of the classical analytical methods of light microscopy and visible MSP to characterize and differentiate them.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, and, in particular, trace evidence examiners, by discussing the strengths and limitations of the classical analytical sequence of both microscopy and MSP in the examination of fiber samples that appear macroscopically indistinguishable.

While microscopical and instrumental analysis methods can be used to determine the composition of textile fibers recovered in casework, discrimination in the context of comparative examinations is typically valued by examining the color of a fiber. This is just as important when the bulk composition of a fiber is relatively homogenous, as it is with nylon, acrylic, and other man-made fibers, as it is when the bulk composition of a fiber is heterogenous, as it is with cotton, wool, and other natural fibers. However, these types of analyses often come with more than a few difficulties, including very small sample sizes, the need for non-destructive techniques, and the enormous complexity of both archaic and modern dye compositions. Fiber examinations start by means of light microscopy methods. The determination of whether the fibers are natural (e.g., cotton or wool) or man-made (e.g., viscose, polyester, acrylics, or nylons) is initially made. Man-made fibers usually display a large number of morphological features (i.e., width, cross-sectional shape, presence of delustrant particles, or particular surface striations). Polarized light microscopy is used to study optical properties of man-made fibers. Color, dichroism, and fluorescence are important features used during comparative examinations. It is then suggested that either visible MSP followed by Thin Layer Chromatography (TLC) be used if Ultraviolet/Visible (UV/Vis) MSP is not available. While MSP is concerned with the measurement of the color of fiber specimens, typically resulting from dye mixtures, TLC procedures offer the potential to determine the dye class and the number of components of a given mixture. However, what about fiber samples that macroscopically appear identical after examination using tried-and-true methods?

In this project, a reference collection containing 14 black swatches on a shade card was dyed with known concentrations of four known nylanthrene dyes: nylanthrene black GLWC, nylanthrene rubine SBLF, nylanthrene navy LFWG, and nylanthrene orange SLF. These understudied nylanthrene dyes are no longer being used and have since been discontinued, but they are still susceptible to being recovered in casework at the present time. These dyes were typically used for the dyeing of polyamide 6 or 66 and were known for their favorable migration properties, which provided both excellent coverage as well as stain resistance. These fabric swatches appeared macroscopically similar to each other, and each fabric swatch was dyed with either one, two, or three of the four potential dyes with a total dye concentration of 4% in each swatch. Several fibers were isolated from each swatch and characterized microscopically using bright field illumination and Polarizing Light Microscopy (PLM). Cross-comparisons were carried out using the analytical sequence of comparison microscopy and visible MSP. Pairwise comparisons were performed in which a value of one, two, or three was assigned to each compared pair, based on the difficulty of differentiation, with a value of three assigned to those pairs that were easily differentiated, and a value of one assigned to those pairs that were not able to be differentiated. Out of 91 pairs of fibers, 90% or 82 of the pairs could be differentiated. However, 10% or nine pairs could not be differentiated using either comparison microscopy and/or MSP. Of the nine pairs that could not be differentiated, almost half, (44% or four pairs) differed in their concentrations of only navy and black dye concentrations, while 22% or two pairs differed in their concentrations of only black and orange dye concentrations. The remaining 34% or three pairs differed in their concentrations of orange and navy, in their concentrations of black, navy, and orange, and in their concentrations of black, navy, and rubine.

### **B60 The Forensic Analysis of Skin-Safe Stamp Pad Inks**

*Swetha Rajagopal, MS, John Jay College of Criminal Justice, New York, NY 10019; Thomas Kubic, JD, PhD, Northport, NY 11768; John Lombardi, PhD, New York, NY 10031; Michelle D. Miranda, PhD\*, Farmingdale State College, State University of New York, Farmingdale, NY 11746*

---

**Learning Overview:** After attending this presentation, attendees will be informed about the potential role of skin-safe stamp pad inks in forensic scenarios, the significant interrogative information that can be obtained from the analysis of these inks, the various analytical methods that can be employed to determine chemical composition, and the results from the analysis of a selection of skin-safe inks currently available on the market.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing analysts with key elementary methods of analysis for skin-safe stamp pad inks. The methods aim to provide results that can improve investigatory efforts for forensic cases involving ink traces of this nature.

Skin-safe stamp pad inks are currently being used at locations such as family entertainment centers, music festivals, adult entertainment, and other venues with the purpose of stamping individuals that visit the location. This is done in an attempt to identify attendees and monitor the number and activity of visitors. The stamps may be customized for the venue, and the stamp pads may be composed of skin-safe inks specifically marketed toward venues that stamp their patrons. The ink composition may be proprietary and that very nature of the inks can effectively render their chemical composition specific to a manufacturer. The detection, analysis, and identification of the chemical composition of these inks could play a significant role in providing crucial investigatory information in forensic cases.

The goal of this research was to scientifically evaluate these inks by documenting the physical and optical properties of the inks both macroscopically and microscopically and to identify the chemical properties of the ink components spectroscopically. The application of Ultraviolet/Visible (UV/Vis) spectroscopy and Fourier Transform Infrared (FTIR) spectroscopy to the analysis of skin-safe stamp pad inks sold for temporary marking purposes has been explored.

Results from this study indicated that each step of the analysis and each technique used by itself was powerful enough to approach closer and closer to a full discrimination of the ink samples and, through successive analytical methods, all of the analyzed samples were successfully discriminated from one another. Furthermore, the identity of the components in the ink samples can be ascertained through the comparison to known standards, such as those found in a spectral library.

The spectral results from this research can be used as reference for potential skin-safe stamp pad ink that may be encountered in a forensic context. The combination of the methods used in the study created a unique array of results that a forensic analyst may use to comment on the nature of the ink traces that may be found on skin. From an investigatory standpoint, such information may be useful in source attribution, determining the movements or locations of an individual, and ultimately aiding in the identification of an individual.

#### **Ink, Microscopy, Spectroscopy**

### **B61 A Novel Approach to the Identification of Beetles That Colonize Remains: A Chemometric Processing of Direct Analysis in Real-Time Mass Spectrometry (DART®-HRMS) -Derived Chemical Signatures of Carrion Insects**

Amy M. Osborne, BS\*, State University of New York at Albany, Albany, NY 12222; Justine E. Giffen, BS, State University of New York at Albany, Albany, NY 12222; Jennifer Rosati, PhD, John Jay College of Criminal Justice, New York, NY 10019; Rabi A. Musah, PhD, State University of New York at Albany, Albany, NY 12222

**Learning Overview:** After attending this presentation, attendees will better understand the use of DART®-HRMS in the generation of unique insect species-specific metabolome profiles and how statistical analysis can be applied to these profiles to enable insect species identification that is useful for Postmortem Interval (PMI) determination.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the use of metabolome profiles as unique chemical fingerprints that enable differentiation between species of insects. Attendees will also learn about the application of statistical analysis for processing of insect chemical profiles for differentiation and classification, as well as about methods for handling specimens.

**Hypothesis:** Statistical analysis can be applied to unique metabolome profiles generated by DART®-HRMS of insect-ethanol suspensions in order to accomplish species identification.

**Synopsis:** One of the most important aspects of a death investigation is estimation of time since death, also known as PMI. This can be difficult to assess for remains that have advanced to such a state of decay that traditional methods for determining PMI are no longer applicable. In such cases, carrion insects found on or near the body can assist forensic investigators in accomplishing this task, as there is a well-established correlation between a given stage of decomposition and the insect species that colonize the remains. Since the timeline associated with insect progression through various life stages is well established, knowledge of the species of the retrieved entomological evidence can be used to calculate PMI. For this reason, accurate species identification is critical. However, this process is challenging because different insect species are often morphologically similar at a given life stage. Thus, species identification often requires an experienced entomologist to make a positive identification based on the gross physical features of the adult after rearing the insects to maturity, a time-consuming process. Furthermore, the insects most likely to be found colonizing remains that are in the advanced stages of decay are beetles. Yet, there is a limited amount of research on methods that can be used to quickly identify beetle species.

**Methods and Results:** It is demonstrated here that chemometric processing of DART®-HRMS data acquired from analysis of insects can be used to rapidly accomplish species identification. Five individual dried insect specimens were obtained for each of 18 species of necrophagous insects belonging to the Diptera and Coleoptera orders, such as *Muscidae spp.*, *Necropilia americana*, *Creophilus maxillosus*, and *Nicrophorus tomentosus*. In order to mimic field collection practices, the dried specimens were suspended in aqueous ethanol prior to analysis by DART®-HRMS. The optimal conditions for insect rehydration prior to mass spectral analysis were also investigated. While it was determined that species-specific DART®-HRMS chemical fingerprints could be acquired using dried, non-hydrated samples, consistent results were obtained when dried samples were suspended in aqueous ethanol for at least 24 hours. Suspending the samples for more than 24 hours was found to confer no added advantage, nor was an advantage seen in rehydrating the insects with steam prior to placing them in suspension. The results showed that the ethanol suspensions of each species exhibited a unique chemical fingerprint and that these fingerprints were consistent for members of the same species but different between species. The application of Kernel Discriminate Analysis (KDA) to the data revealed that clear differentiation was possible between insect species based on the chemical fingerprints generated by DART®-HRMS analysis of insect-ethanol suspensions. Furthermore, the separation occurs even between insects belonging to members of the same family, such as the Silphidae family.

**Conclusion:** At the scene of death investigations, insects present on remains are often underutilized as evidence due to the cost, time, and other resources needed to extract the useful information provided by the specimens. The use of DART®-MS and statistical analysis to differentiate between species of insects can circumvent some of these challenges, thereby increasing the value of entomological evidence.

**Forensic Entomology, DART®-HRMS, Chemometrics**

### **B62 A Novel Approach for the Collection and Characterization of Inorganic Gunshot Residue (IGSR) Standards**

*Korina Menking-Hoggatt, MS\*, Morgantown, WV 26501; Edward M. Pollock, Sacramento County District Attorney Crime Lab, Sacramento, CA 95820; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506*

**Learning Overview:** After attending this presentation, attendees will be aware of a novel collection and characterization for authentic IGSR originating from the primer of ammunition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community, which does not have access to an IGSR standard that can be consumed, by attempting to develop one to help advance the discipline of IGSR analysis.

The detection of gunshot residue (GSR) is an important form of trace evidence because it can provide investigative leads, enhance reconstruction, protect citizens from violent criminals, and assist in intelligence operations. Although current methods of Scanning Electron Microscopy/Electron Dispersive X-ray Spectroscopy (SEM/EDS) analysis are scientifically valid, they are time-consuming, typically requiring hours of analysis per sample. Furthermore, studies into new types of rapid instrumentation are slowed by the lack of GSR standard reference materials. A synthetic GSR standard is available for SEM/EDS analysis, but there is no option for a standard that can be manipulated, digested, or deposited onto a substrate. Also, researchers must have firearms and a ballistics lab to test a new method, which can be impossible without access to the proper resources.

A research group at West Virginia University in collaboration with the Sacramento District Attorney's Office—Laboratory of Forensic Services developed a novel method for the collection and characterization of IGSR particles. Ammunition consisting of only a primer and cartridge case was discharged in a controlled environment and suspended in an organic solvent. Then, the particles were collected, stored, and analyzed by three different analytical techniques to characterize the particle's morphology, distribution, and composition of the IGSR standard.

An Inductively Coupled Plasma/Mass Spectrometry (ICP/MS) digestion method was developed and validated for qualitative and quantitative characterization of the IGSR particle suspension. During the preliminary study, the elemental concentration was monitored over three months and an Analysis of Variance (ANOVA) statistical analysis determined the stability of important IGSR markers (e.g., Lead [Pb], Barium [Ba], and Antimony [Sb]) during the time stored. Ruggedness testing was performed to determine the main effects of the digestion method and examined six factors (digestion temperature, digestion time, the time between sample preparation and digestion, the time between digestion and analysis, acid concentration, and analyte concentration) at two levels for 38 different elements. After determining the main effects, the method was validated for the 38 analytes and figures of merit—selectivity, precision, and trueness—were determined.

Since morphology is also a critical aspect of GSR evidence analysis, the standard was assessed to determine if the collection process preserved the spherical morphology and elemental composition typical of GSR particles. The standard was spiked on GSR stubs at multiple time intervals and analyzed by SEM/EDS during the preliminary three-month study. The analysis indicated no degradation of either was observed. To test the homogeneity and reproducibility of the particle deposition, small amounts were spiked onto GSR stubs, and the particles were mapped and counted using an automated GSR recipe and following the American Society for Testing and Materials (ASTM) E1588-17 standard procedure.

Last, laser-induced breakdown spectroscopy was used to test the practical application of the primer standard. The standard was spiked onto GSR stubs and used in a Box-Behnken optimization design and also as a daily Quality Control (QC) sample. The optimized parameters were applied to a micro-chemical mapping method for the detection of IGSR.

A standard such as the one developed can be a powerful tool to greatly enhance the study and interpretation of GSR evidence. For the first time, the forensic community would have access to an IGSR standard of known elemental concentration and number of particles. This study developed a micron-size particle IGSR standard that mimics residues from leaded and non-toxic modern ammunition. The standard is anticipated to strengthen not only future research but also the understanding of the transfer and persistence of GSR by providing ground truth of the number of particles present before activities. A standard can also improve analysis in crime laboratories by providing an option for monitoring the performance of another method of GSR detection besides SEM/EDS analysis. A material such as this can enhance the evidential value of GSR in the long run because the nature of the trace evidence can be evaluated with greater certainty, GSR examiners can provide a clear record of instrument performance, and the community can validate new instrumentation without the challenge of collecting authentic GSR samples.

#### **Gunshot Residue, Standard Development, SEM/EDS**

### B63 Explosive Residue Transfer From Various Explosive Ordinance Disposal (EOD) Render Safe Procedures (RSPs)

*Joseph Stein\*, Richmond, VA 23220*

**Learning Overview:** After attending this presentation, attendees will understand various RSPs used by bomb technicians in the EOD field and how these procedures can potentially transfer explosive residue onto Improvised Explosive Devices (IEDs). Attendees will also learn what specific compounds are found in these residues.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about residues left by some RSPs and how this can affect forensic analysis of IEDs. Examiners will now be aware that residues found on IEDs may have originated from the RSPs and not from the main charge of the device if it was initiated and consumed. This will help them with the interpretation of their results that can ultimately affect the outcome of a case.

Before an IED is sent to a laboratory for analysis, it needs to be rendered safe if it did not already explode or initiate, which can lead to potential contamination of the evidence if residue analysis is important. RSPs include utilizing a Percussion-Actuated Non-electric (PAN) disrupter or a fluid-filled bottle disrupter. PAN disrupters utilize shotgun rounds to propel liquid or solid projectiles that disrupt the electrical fuzing system or break open the container. The fluid-filled bottle disrupter utilizes a plastic bottle that is filled with water and a detonation cord used to disrupt soft containers, such as backpacks.

While the goal of these disrupters is to render the device safe without having it initiate, occasionally the procedure will fail and the IED will detonate. If this occurs, only the residue on the IED fragments can be chemically analyzed to ascertain the identity of the explosive. However, since these RSPs also use explosives, they too can impart residue on the IED. Smokeless powder is used in the PAN disrupter ammunition, which can also be found as a main charge in IEDs. Compounds of analytical interest in smokeless powders include Nitroglycerin (NG), Diphenylamine (DPA), Ethyl Centralite (EC), and Methyl Centralite (MC). The bottle disrupter utilizes a Pentaerythritol Tetranitrate (PETN) -filled detonation cord, another explosive that may be used in IEDs.

Before any testing was conducted, analysis of the bulk powder used in the shotgun ammunition and detonation cord was conducted to determine the explosives and stabilizers present in each. The powders were then burned onto the various substrates to determine if the compounds would decompose after deflagration. To test whether RSPs impart residue on IEDs, the disrupters were fired onto inert containers used in IED construction, such as pipes and backpacks. These were later analyzed for post-blast residue. The PAN disrupter was loaded with two different rounds. A blank was used to shoot a water column at a Polyvinylchloride (PVC) pipe, while a birdshot cartridge was used to target a steel pipe. The water from the bottle disrupter was imparted onto a backpack. All the tests were performed in triplicate.

Instrumentation used in the analysis of the residues included a Gas Chromatograph/Mass Spectrometer (GC/MS), a Liquid Chromatograph/Mass Spectrometer (LC/MS), and a Gas Chromatograph with an Electron Capture Detector (GC/ECD). Analysis of the smokeless powder from both of the shotgun ammunitions used in the PAN disrupter showed the presence of NG, DPA, and EC. Only PETN was identified in the detonation cord used in the bottle disrupter. The residue from the smokeless powder and PETN showed no decomposition of the analytes after they were burned. Two of the three steel pipes rendered safe with the birdshot had detectable amounts of NG and EC. No DPA was detected on any of the steel pipes. None of the PVC pipes had detectable amounts of NG, EC, or DPA. Trace amounts of PETN were detected on two out of the three backpacks. Overall, finding such residue in casework should not rule out the possibility that an individual used a particular explosive in the construction of the IED, but examiners should be aware of residues left by disrupters, especially if the device initiates during the RSP.

---

#### Explosives Residue, Render Safe Procedure, Improvised Explosive Device

### B64 Paper-Based Electrochemical Detection of Drugs of Abuse in Sweat

*Rosa L. Cromartie, BS\*, Florida International University, Miami, FL 33199; Bruce R. McCord, PhD, Florida International University, Miami, FL 33199*

**Learning Overview:** After attending this presentation, attendees will understand how drugs of abuse can be detected using a paper-based electrochemical sensing method. As paper-based microfluidics is becoming a rapidly developing field, printed electronics is also growing swiftly, especially in the sense of wearable technology. By combining these fields, fluidic samples can be used as substrates for detecting analyte concentrations using voltammetric techniques. This electrochemical drug-detecting sensor is designed for drugs such as opioids to be detected in sweat.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that sweat can be used for detecting the presence of abused drugs through the merger of two practical applications, electrochemistry and paper microfluidics. The design and developmental validations of this sensing method will involve opioid detection in biological fluids, such as sweat.

The use of biological fluids for detecting drugs of abuse has increased rapidly; however, these fluids are typically tested for drug abuse over a short time period. Sweat testing for drugs can take place over a longer time span. Current drug testing using sweat has mainly been used in clinical applications; however, it is uncommon in drug-of-abuse testing. There have been many studies that have facilitated testing procedures for detecting drugs through sweat patch testing. However, the results from the sweat patches were limited due to their varying volumes of perspiration collected onto the sweat patches and the effect of different activities and environmental impact. Using sweat patches to collect sweat for testing provides a non-invasive alternative method of testing a liquid perspiration for opioids and other drugs of abuse.

Sweat is a vital body fluid that can be used to trap and analyze drugs of abuse. Previous studies have shown limitations, such as poor sensitivity and interferences from components in the sweat matrix. Yet, sweat contains drugs and drug metabolites that are present in the body. Therefore, the goal of this presentation is to introduce the development of an application for detecting drugs of abuse, such as opioids and fentanyl, through sweat using electrochemical sensing. Initial work was performed to detect a variety of opiate controls spiked in sweat. This was used to optimize sensor measurements and determine matrix effects. After the optimization of these mixtures, the sensors were further optimized and validated using real samples.

The paper-based devices were prepared utilizing sheets of chromatographic paper and thermal wax to create hydrophilic channels that are bounded by hydrophobic barriers. Electrode patterns were designed using silver chloride (AgCl) and pasted onto the electrode layer of the paper-based device. Upon analysis, the sweat patch allows for drug detection using aptamers in liquid perspiration. Aptamers that target six different opioids were selected and modified for better stability. By covalently linking these modified aptamers with the redox active molecule, changes occur in confirmation, resulting in enhanced signaling for the presences of opiates. The results show the current sensitivity detected, effect of interferences, and whether sweat collected during various activities results in different detection capability.

Overall, this paper-based electrochemical sensing method permits a low-cost, integrative, and cumulative response for the determination of opioids in sweat for the purpose of drug monitoring.

#### Drugs of Abuse, Sweat, Electrochemistry

### B65 Improving the Efficiency of Forensic Science Evaluations of Mass Disaster Damages

*Gustavo Costa, MS\*, Policia Federal, Belo Horizonte, Minas Gerais 30441170, BRAZIL*

**Learning Overview:** After attending this presentation, attendees will understand that it is possible to estimate and evaluate the financial impacts due to an event. This can result in preliminary responses for complex problems faced by forensic science. A company must recognize on the statement of financial position and the income statement the estimated amounts of liability, and forensic scientists can use this in considering the data bias.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing how difficult it is to estimate mass disaster damages.

This presentation seeks to present a relevant study developed after Brazil's Brumadinho dam failure. This disaster involved different areas of forensic science in Brazil.

Three years after the world's largest disaster in the history of mining, in Mariana, Minas Gerais State, Brazil, several government institutions had to work together to answer another dam failure case. On January 25, 2019, a rupture was experienced in the dam of the Córrego do Feijão mine, located in Brumadinho, Minas Gerais, Brazil (named the "Brumadinho dam"). The owner is a private sector, publicly traded company, headquartered in Brazil, and present in several countries around the world. Due to this mass disaster, 270 people lost their lives or are missing. Tons of iron ore waste were contained in the Brumadinho dam. The tailings contained in the dam have caused an impact of around 270km in extension, destroying some of the company's facilities, affecting local communities, and disturbing the environment. An important river and its ecosystems have also been impacted by the event. The company has been trying to mitigate and recover the social and environmental damages resulting from the dam failure. In this context, it is almost impossible to price all costs that may be incurred to restore ecosystems and repair all the damage caused. The detailed statistic results have been consolidated to demonstrate the importance of studying the historical cost recognized for the companies involved, even knowing the restrictions and underestimations employed. Other mass disaster data can be useful when presenting a strong correlation to support the forensic experts' reports.

It is well known that investing in infrastructure is one of the simplest ways of improving the results of forensic sciences. Another important issue is the need for ongoing training and encouraging studies for these professionals. All of these aspects are part of good criminalistics management practices and involve financial and human resources. Sharing experiences, understanding the limits of action of forensic science, and working together can improve the expert's work. It intensifies confidence and makes the institutions stronger. The involvement, articulation, and coordination among government institutions in this study present evidence of significant improvement for forensic results.

### B66 Front-End Fractionation of DNA and Proteins for the Simultaneous Genetic and Serological Analysis of Sexual Assault Case Samples

Morgan S. Peters\*, Ohio Northern University, Ada, OH 45810; Catherine O. Brown, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Heather E. McKiernan, PhD, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Dennis J. DeLuca, PhD, Ohio Northern University, Ada, OH 45810

**Learning Overview:** After attending this presentation, attendees will have gained insight into a workflow that permits the fractionation and simultaneous analysis of DNA and proteins in sexual assault samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing comparative data evaluating methodologies for the co-extraction of DNA and proteins. The results of this study demonstrate the compatibility of proteomic workflows and the importance of serological identification in sexual assault evidence testing.

In order to combat the sexual assault kit backlog in the United States, more efficient processes for serological and genetic sample preparation are needed. Currently validated serological methods (with the exception of microscopy) for semen/saliva identification suffer from limitations associated with specificity and sensitivity. By pairing simultaneous fractionation or co-extraction of cellular (DNA for genetic testing) and protein material for use with proteomic serological identification, these limitations associated with traditional antibody-based serological assays are overcome, providing practitioners and investigators with more actionable forensic results. Simultaneous preparation for proteomic and genetic analysis will also aid with expedited turnaround times.

Samples were prepared using single-source vaginal swabs from an individual abstaining from any form of sexual intercourse and single-source semen and saliva from a male donor. Vaginal swabs were solubilized and extract was pooled to normalize protein material. Vaginal extract was applied to clean cotton swabs and fortified with various dilutions of semen and/or saliva prepared in deionized water. Replicate sample preparations ( $n=10$  per method) were co-extracted using one of three evaluated sample fractionation workflows. The first method was a previously validated in-house sample preparation workflow for the proteomic analysis of biological samples in which soaking and centrifugation are used to pellet cellular material for genetic analysis while proteins remain in the supernatant. Protein material underwent a tryptic digestion prior to analysis. A phenol/chloroform organic extraction was utilized prior to genetic analysis. The second co-extraction method developed by Kranes et. al. employed a simultaneous DNA extraction and tryptic protein digestion followed by subsequent fractionation utilizing a Molecular Weight Cutoff (MWCO) filter.<sup>1</sup> The third fractionation method evaluated utilized a commercial product, the QIAGEN® AllPrep® DNA/RNA/Protein Mini Kit, which separates protein and genetic material fractions using selective binding filtration chemistries and protein precipitation. All protein fractions, regardless of front-end prep method employed, were assessed using Ultra Performance Liquid Chromatography-Tandem Mass Spectrometry (UPLC-MS/MS). All DNA extracts were quantified using the Applied Biosystems® Quantifiler® Trio quantification kit, amplified using the Globalfiler™ Polymerase Chain Reaction (PCR) amplification kit, and analyzed on an Applied Biosystems® 3500 Genetic Analyzer.

The three sample fractionation protocols were compared according to the following criteria: (1) peak area intensity observed via UPLC-MS/MS analysis for target protein biomarkers; (2) DNA quantification values; (3) overall quality of genetic profile obtained; (4) consistency among preparation replicates; and (5) speed/cost and ease of workflow. These data demonstrate that sufficient DNA and protein can be obtained from simulated sexual assault samples to allow for the simultaneous forensic analysis of each fraction, eliminating the need for forensic analysts to prioritize one type of testing over another.

#### Proteomics, Serology, Genetic Analysis

### B67 Vaping in the Fourth Generation: A Comparison of Nicotine Dose Capture in Different Forms of Concentrated Substances

*Erica Sales\**, Virginia Beach, VA 23453; *Justin L. Poklis, BS*, Virginia Commonwealth University, Richmond, VA 23219-0613; *Joseph B.M. Turner, PhD*, Virginia Commonwealth University, Richmond, VA 23284; *Michelle R. Peace, PhD*, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will be able to understand the use of fourth-generation electronic cigarettes (e-cigs) in illicit drug use and the danger this poses.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by further implicating the presence of e-cig use in the realm of controlled substances.

E-cigs were created as an alternative nicotine delivery system. Three generations of traditional e-cigs exist, designed to deliver nicotine through aerosol/vapor by heating an e-liquid solution made up of nicotine, various flavoring agents, propylene glycol, and vegetable glycerin. Two more generations have recently evolved: (1) the fourth generation device, focused on the ability to aerosolize plant material (marijuana), waxes, and dabs (THC based); and the fifth generation “pod mod,” focused on simplicity and ease of use. Novel devices also have more potential to be manipulated for use of other psychoactive substances.

The purpose of this experiment was to determine the efficiency of aerosolizing nicotine in different mediums using a fourth-generation e-cig (the Source Orb 4), which utilizes five different types of atomizers for a more customizable vaping experience.

Two different materials were introduced to each atomizer; a 12mg/mL 50:50 PG:VG nicotine e-liquid and a 12mg/mL nicotine/kava wax mixture. The atomizer was operated at 4.2V, and the generated aerosol was collected in a trap ( $n=5$ ). Nicotine concentrations were determined using a Shimadzu® LC30 Ultra High Pressure Liquid Chromatograph attached to a Shimadzu® LCMS-8050 Triple Quadrupole Liquid Chromatograph Mass Spectrometer (UHPLC-MS/MS). Chromatographic separation was performed on an Agilent® Zorbax® Eclipse XDB-C18, 4.6 x 75mm, 3.5-micron column with 10 $\mu$ L injections. Mobile phase A was 0.1% formic acid in water and mobile phase B was 0.1% formic acid in acetonitrile, introduced to the column at a 50% binary gradient and a flow rate of 0.5mL/min. The instrument was run in positive Multiple Reaction Monitoring (MRM) mode. The following transition ions ( $m/z$ ) with their corresponding collision energies (eV) in parenthesis for nicotine 163>130 (-23), 163>117 (-24), and nicotine-d<sub>4</sub> 167>134 (-25).

The average percent recovery delivered per puff for the five different atomizers ranged between 31%–80% for the nicotine e-liquid and 23%–189% for the nicotine/kava wax. The measured experimental dose ranged from 0.8–7.4 $\mu$ g for the nicotine e-liquid and 3.7–53.9 $\mu$ g for the nicotine/kava wax.

Depending on the atomizer and type of medium being vaporized, the amount of nicotine aerosolized will vary. The Source Orb 4 was able to weakly aerosolize nicotine in the traditional e-liquid, as compared to the wax. These results further imply the progression of the fourth-generation e-cig in distributing plant and wax material, in a device that has the appearance of a traditional e-cig. As a result, Drugs Other Than Nicotine (DOTNs) with pharmacological and psychoactive properties can be discreetly consumed in public, causing a concern in several aspects of public safety.

*This research was supported by awards from the National Institute of Justice and the National Institute of Health.*

#### Electronic Cigarettes, Nicotine, LC-MS/MS

### **B68 An Evaluation of the Investigator® 26plex QS STR Kit and a Comparison With Two Commercially Available Short Tandem Repeat (STR) Kits**

*Madeline G. Roman, BS\*, Sam Houston State University, Huntsville, TX 77340; Ryan Gutierrez, BS, Alvin, TX 77511-4161; Carrie Mayes, PhD, Sam Houston State University, Huntsville, TX 77340; Bobby Larue, Jr., PhD, Sam Houston State University, Huntsville, TX 77341; Rachel M. Houston, PhD, Sam Houston State University, Huntsville, TX 77340*

**Learning Overview:** This presentation will provide attendees with information regarding the performance of a new STR kit from QIAGEN® that has not yet been marketed in the United States. This project seeks to compare this new kit to two existing forensic STR kits in terms of their sensitivity, resistance to inhibitory compounds, usefulness for casework-type samples, and ability to interpret two-contributor DNA mixtures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information about the performance of a new human STR kit compared to two commonly used commercial kits.

STRs are the gold standard in forensic human identification. Several multiplex STR kits are currently on the market, and in recent years, kits have included an increasing number of loci, resulting in profiles with more discriminatory power. Before new kits are implemented in crime laboratories, they go through extensive validation studies. It is important that the chemistries be sensitive enough to produce profiles from low-quantity and low-quality samples. In addition, DNA profiling can be complicated by various Polymerase Chain Reaction (PCR) inhibitors common to forensic sample types, and some kits are better able to handle these inhibitors than others.

In this study, we evaluated the Investigator® 26plex QS kit and compared it to two kits commonly used in forensic laboratories: the Investigator® 24plex QS kit from QIAGEN® and the GlobalFiler™ PCR Amplification kit from Thermo Fisher Scientific™. The Investigator® 26plex QS kit is a new kit that simultaneously amplifies the Combined DNA Index System (CODIS) loci and the European standard loci, plus Penta D, Penta E, D6S1043, DYS391, and amelogenin, along with Quality Sensor (QS) markers to monitor for inhibition. A sensitivity study consisted of varying concentrations of control DNA between 16pg and 2ng. To test the kits' tolerance to common inhibitors, low, medium, and high concentrations of hematin, humic acid, calcium, and collagen were added to control DNA. In addition, a study was carried out to assess the effect of male/female DNA mixtures on profile interpretation. Finally, a variety of casework-type samples were run, including bone, hair, blood, decomposed muscle, Ultraviolet (UV) -damaged, buried bloodstains, and formalin-damaged tissue.

The data show that all three kits produce complete or nearly complete profiles with at least 32pg of DNA, and the Investigator® 24plex QS kit recovers more alleles than the other two kits at a 16pg DNA input. Additionally, the Investigator® 26plex QS kit has a wider dynamic range with relatively clean profiles at a 2ng input, while Investigator® 24plex QS and GlobalFiler™ experienced pullup between dye channels, making the resulting profiles more difficult to interpret. Investigator® 26plex QS and GlobalFiler™ were inhibited by high concentrations of calcium and collagen and experienced significant allele dropout in the presence of these inhibitors. Investigator® 24plex QS was resistant to all inhibitors and only experienced dropout at high collagen concentrations. The genotypes of the shared loci for the casework samples were concordant between the three kits, and the profile quality and completeness were similar. When two-contributor DNA mixtures were assessed, GlobalFiler™ had the most complete profiles for minor contributors. Investigator® 26plex QS and Investigator® 24plex QS preferentially amplified the major contributor alleles, resulting in more drop out of the minor contributor.

Overall, this research investigates and reports on the relative performance of three commercial STR chemistries, including a chemistry not currently available in the United States.

### B69 A Non-Destructive Genomic Analysis of Single Pollen Grains

*Luz J. Kelley, MS\*, National Center for Forensic Science, Orlando, FL 32816; Bryan McCullough, Orlando, FL 32826; Elizabeth J. Rose, BS, National Center for Forensic Science, Orlando, FL 32816; Matthieu Baudelet, PhD, National Center for Forensic Science, Orlando, FL 32816; Mauro Martinez Labrador, MPh, National Center for Forensic Science, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will have gained an appreciation of a non-destructive genomic methodology of single pollen grains that can be complementary to their microscopic analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a simplified, non-destructive procedure for the analysis of every single pollen grain in a sample, which can be utilized in forensic labs at the state or local levels.

With more than 300,000 plant species on the planet, palynology (i.e., the study of the structure and origin of pollen) plays an important role in forensic analysis. Each location has a unique flora at different periods in time, making pollen a perfect proxy to link person(s) or object(s) to a particular place or time. This is the basis of forensic palynology. It relies on the facts that: pollen is an ever-present feature of the environment; different geolocations have different pollen signatures, allowing for inference related to spatial tracking; and plants bloom at different times, allowing for temporal inference. Pollen is extremely durable and can be used for forensic studies decades after sample collection.

Forensic palynology has played a role in a large number of criminal investigations worldwide, including homicide, violent assault, rape, genocide, terrorism, suspected terrorism, and even intelligence on drug smuggling.

The considerable number of potential plant species that would need identification is handicapped by the few ones that are databased using traditional methods, reducing the potential for geolocation. These traditional methods rely on the examiner having a high level of expertise in microscopy and can be time-consuming. With the emergence of DNA barcoding, pollen genomics has an immense potential to classify and identify pollen taxonomically from its genetic signature. This approach characterizes pollen species using a short DNA sequence from a universal standard in the genome and can help transform the current standard vision of forensic palynology by making it readily accessible to a wide range of forensic laboratories and increase the taxonomic resolution of identification. In plants, three regions of the chloroplast genome (matK, rbcL, and trnH-psbA), as well as the nuclear ribosomal ITS2 region have been widely accepted for use as DNA markers, either in combination or separately. Two main advantages of using DNA barcoding in forensics are that: (1) it allows taxonomic identification of parts of the organism that do not display diagnostic morphological characters; and (2) the same method is used across multiple taxonomic groups, so it allows species to be classified without having to involve narrowly defined taxonomic experts.

To date, the most common cleaning process is acetolysis, which involves highly acidic conditions and chemicals that could damage or alter the exine morphology, in addition to destroying the pollen genetic material. Similarly, DNA analysis relies traditionally on the mechanical destruction of the pollen grain to liberate the genetic material. In this work, it is shown that single pollen grain can be examined using universally accepted genetic markers (rbcL, matK, and ITS2) for DNA barcoding using quantitative Polymerase Chain Reaction (qPCR) while keeping their morphological features for microscopy. This is possible by a simple low-temperature treatment of the pollen grain in ethanol, scalable from large quantities down to a single grain. For the first time, DNA and morphological information can be obtained for every single pollen grain in a sample, which can be stored for future examination.

#### DNA, Pollen, Palynology

### **B70 The Enhancement of Human Scent Profiles as Forensic Evidence**

*Alice B. Boone, BS\*, Florida International University, Miami, FL 33199; Kenneth G. Furton, PhD, Florida International University, Miami, FL 33199; Howard K. Holness, PhD, Miami, FL 33199*

**Learning Overview:** After attending this presentation, attendees will understand how human odor profiles can be collected and evaluated, why human scent can be utilized as an individual or class characteristic, and why there is a need for profile enhancement of odor profiles for all ethnicities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by portraying the reproducibility of findings in previous Caucasian and Hispanic human scent analyses, as well as the novel incorporation of African American odor profiles.

Human scent has been previously defined as a complex mixture of Volatile Organic Compounds (VOC's) detected in the headspace above a scent sample. Humans generate odor from several areas of the body, including the scalp, hair, mouth, hand, axillae, and foot. The analysis of the chemical composition of human scent has enabled scientists to demonstrate variations within these factors (age, gender, and ethnicity) to distinguish between individuals. Due to the novelty of human scent research, human scent evidence has been undervalued in the court of law. However, this type of evidence has significant value when physical evidence is not available at crime scenes. In order to increase the individualization and differentiation power of human scent evidence, this study aims to further investigate the identification of chemical signatures within the hands and axilla of specific ethnicities and genders.

During the study, the axilla of 68 participants were investigated. Upon collection, samples were extracted using Headspace/Solid Phase Micro extraction (HS/SPME) and Liquid-Liquid Extraction (LLE) and analyzed using Gas Chromatography/Mass Spectrometry (GC/MS). The utilization of SPME immediately followed by LLE complements the extraction of semi-volatile and non-volatile compounds, hence filling in the gaps of the compounds that could not be recovered using HS-/PME alone. This ensured that a full VOC profile is obtained, allowing for improved statistical analysis without requiring any additional sample collection. The samples were evaluated statistically via logistic regression to extrapolate data unique to specific individuals and groups.

Scientific advances have enabled the forensic science community to use scent as a feature for individual or class characteristic determination. The analyses of body odors using the VOCs emitted have proven that, when enhanced, human scent can be as useful as fingerprints and DNA in the attempt to identify individuals. In future work, the VOCs emitted from the axilla of human subjects can potentially correlate to specific Human Leukocyte Antigen (HLA) alleles. Additionally, once the unique odor profiles of each ethnicity can be identified and reproduced efficiently, live human scent training aids for canines can be improved.

### B71 Bondage Practices in an Asphyxiation Death: An Accidental Death

Alberto Alongi\*, University of Palermo Section of Legal Medicine, Palermo 90127, ITALY; Elvira Ventura Spagnolo, MD\*, University of Palermo, Palermo 90127, ITALY; Gennaro Baldino, MD\*, Palermo 90100, ITALY; Cristina Mondello, MD, University of Messina, Messina 98123, ITALY; Antonina Argo, PhD, University of Palermo, Palermo 90100, ITALY

**Learning Overview:** After attending this presentation, attendees will better understand the features of a suicidal hanging death that occurred during autoerotic practices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by emphasizing the role of medical-legal investigations in hanging death cases presenting with a mask and multiple ropes and knots, confirming the importance of a multidisciplinary approach for the resolution of cases of forensic interest.

Autoerotic death is an uncommon cause of death with higher prevalence in middle-aged Caucasian people, usually caused by accidental self-hanging. Limiting the flow of oxygen to the brain leads to the accumulation of carbon dioxide, which can induce feelings of euphoria, confusion, and vertigo, which contribute to intensifying orgasm. It is considered by the medical community to be an extremely risky and potentially deadly practice, even for experienced individuals.<sup>1-4</sup>

**The Case:** After numerous reports from some neighbors complaining about nauseating smells coming from an apartment, the corpse of a 34-year-old man was found hanging inside the locked apartment and the body was in an advanced state of putrefaction. A green mask with multiple conical studs was covering his face, his hands were tied with a rope in front of his neck, another rope was encircling his neck and fixed to the lower end of a door, the door handle was covered with a rag; and his feet were touching the floor. After conducting various and relevant examinations at the place of discovery, the body was taken for forensic investigations. Before performing the autopsy, a Computed Tomography (CT) dual scan detection was performed.

**Results:** The CT scan showed the anterior displacement of the hyoid bone, and no evidence of traumatic fractures were documented by the CT imaging. The autopsy findings were: tongue protrusion between clenched teeth; after removing the rope around the neck, a furrow with vital signs and an hemorrhagic infiltrate of the soft tissues and muscles under it were found. The histological findings confirmed the presence of vital signs in the furrow; but not much else because of the advanced state of putrefaction of the body. The study of the knots' disposition defined the death as a self-ligation procedure of the ropes.

In conclusion, the radiological imaging according to the autopsy, histological and toxicological findings, combined with police information, ascribed the death to mechanical asphyxiation occurring during autoerotic maneuvers. According to the witnesses, the man was used to performing self and heteroerotic practices using ropes and masks. The case was solved as an accidental death.

### **B72 The Characterization of Volatile Organic Compounds (VOCs) Present in the Headspace of Decomposing Livestock, Fish, and Human Remains**

*Jisook Min, PhD\**, National Forensic Science Institute, Gangwon-do 26460, SOUTH KOREA; *Youngwoong Han*, National Forensic Service, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Bohyun Kim*, National Forensic Service, Gangwon-do 26460, SOUTH KOREA; *Young-Shin Go*, Wonju-si, Gangwon-do 26460, SOUTH KOREA; *Seh Yeon Park*, Chilgok, Gyeongbuk, SOUTH KOREA; *Sangcheol Heo*, National Forensic Service, Wonju-si, Gangwon-do 220-170, SOUTH KOREA; *Kiwook Kim, MS*, National Forensic Service, Wonju-si, SOUTH KOREA; *Giwon Park*, National Forensic Institute, Wonju-si, Gangwon-do 26460, SOUTH KOREA

**Learning Overview:** The goal of this presentation is to present the VOCs between humans and animals.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community via the examination of this case study.

Locating human graves is important for crime-solving and archaeological purposes, and the development of tools and methods that can expedite locating clandestine graves has been of keen interest in the scientific community. The efforts focused on establishing the volatile chemical signature of compounds that could indicate the presence of buried human remains where surface clues are lacking and where the content of a potential grave is unknown.

This study analyzed the VOCs present in the headspace above partially decomposed animal tissue samples and directly compared them with results from decomposed human blood and tissues using established Solid-Phase Microextraction (SPME) and Gas Chromatography/Mass Spectrometry (GC/MS) methods. The source of variation between samples was evaluated using Analysis of Variance (ANOVA). ANOVA can assess whether altering the controlled factor, such as flow rate or material, produces a significant difference in the amount of compound collected compared with the differences found in replicate samples. Specifically, this study employed five class prediction methods: Partial Least Squares Discrimination (PLSD), Support Vector Machine (SVM), Decision Tree (DT), Naïve Bayes, and Neural Network. VOCs present in the headspace of different sample parts (muscle, fat, and skin) each from cows, pigs, and fish were identified and compared with human samples. Although there were compounds common to both non-human and human remains, the VOC signatures of each of the non-human remains differed from those of humans. Four VOC signatures (1 phenyl ethanone, pyridine 3 phenyl-, benzeneethanol, 2-(2 methylpropyl) 3,5 di(1 methylethyl)pyridine) were present in only human tissue samples. In addition to detecting six (pentanoic acid, benzaldehyde, 1 phenyl ethanone, pyridine 3 phenyl-, benzyl alcohol, 2-(2 methylpropyl) 3,5 di(1 methylethyl)pyridine) of ten human-specific compounds, one additional unique VOC (2 nonanone) was recorded from non-human samples that were present in non-human samples (beef, pork and fish).

The best decomposition odor class discrimination outcomes have been achieved by PLSD, SVM, and DT. Identifying VOCs that are unique to humans may be useful to investigate human-specific scent and may eventually lead to an instrument that can detect clandestine human burial sites. Further studies are required to routinely retrieve forensic information that is imprinted in VOCs of human decomposition, such as a variety of parts of the body, including large-scale sampling of decomposed animal and human remains, to support criminal investigation. According to the above methods, the analysis was performed to distinguish between human and non-human from the operating gown of the body used in an autopsy. Testing the gown provided good results.

#### **VOC, Human Remains, GC/MS**

### B73 An Assessment of Elemental Homogeneity in Glass Using Micro-X-Ray Fluorescence Spectroscopy ( $\mu$ -XRF) and Laser-Induced Breakdown Spectroscopy (LIBS)

*Oriana Ovide\**, Department of Forensic and Investigative Science, Morgantown, WV 26505; *Zachary B. Andrews\**, West Virginia University, Morgantown, WV 26505; *Ruthmara Corzo, PhD*, Gaithersburg, MD 20899-8371; *Tatiana Trejos, PhD*, West Virginia University, Morgantown, WV 26506

**Learning Overview:** After attending this presentation, attendees will have a better understanding of elemental homogeneity within a glass source and insight on the capabilities of XRF and LIBS for the forensic analysis of glass.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by comparing modern instrumentation (Silicon Drift Detectors [SDD] -XRF and LIBS) to traditional instrumentation currently utilized in forensic laboratories.

Glass is an important type of forensic trace evidence that can be encountered at various crime scenes, such as hit-and-runs, homicides, and burglaries. The elemental analysis of glass is useful for the discrimination of glass samples originating from different sources and for the association of glass samples originating from the same source.  $\mu$ -XRF is the most commonly used technique for the elemental analysis of glass in forensic casework. The elemental compositions of the known and questioned samples are compared using a match criterion (range overlap or  $\pm 3\sigma$ ) outlined in the standard method American Society for Testing and Materials (ASTM) E2926. However, the match criteria recommended in ASTM E2926 were selected based on error rates obtained for the analysis of glass samples using older instrumentation equipped with Si(Li) detectors. Modern XRF instruments equipped with SDDs are expected to provide better precision, which may increase the risk of false exclusions. Therefore, this study aims to assess the micro-homogeneity of glass using newer instrumentation to establish an appropriate pairwise comparison criterion that minimizes false exclusion rates.

An alternative to  $\mu$ -XRF is Laser-Induced Breakdown Spectroscopy (LIBS), a relatively new analytical technique. Its rapid analysis times and relative affordability make it an attractive option for the elemental analysis of glass. To date, no studies on micro-homogeneity of glass using LIBS have been published, and no standard method for the analysis of glass using LIBS is available. Thus, a secondary aim of this study is to assess sources of variability when using LIBS for glass analysis and establish an appropriate comparison criterion.

The reference glass material National Institute of Standards and Technology (NIST) 1831 was used to compare the analytical performance of  $\mu$ -XRF and LIBS in terms of limits of detection, limits of quantitation, inter-day variability, and intra-day variability. The performance of the  $\mu$ -XRF-SDD system used in this study was also compared to  $\mu$ -XRF-SiLi detectors' data reported in the ASTM method. A vehicle windshield was used to assess the variability of the elemental composition within a single pane. Each of the inner and outer glass panes was divided into 100 sections. Then, a random number generator was used to select 50 sections within each pane randomly. The glass pane was then broken, and 50 glass fragments were collected from both the inner and outer pane of a single windshield and analyzed using  $\mu$ -XRF and LIBS. Each fragment was measured in replicates from different locations (*LIBS*  $n=4$ ,  *$\mu$ -XRF*  $n=5$ ).

The  $\mu$ -XRF method detected nine elements above the quantitation limit for both windshields (Sodium [Na], Magnesium [Mg], Silicon [Si], Calcium [Ca], Titanium [Ti], Manganese [Mn], Iron [Fe], Strontium [Sr], and Zirconium [Zr]), which were further used for comparison between fragments. The false exclusion rates using the ASTM E2926 match criteria was  $>45\%$  for the inner pane and  $>50\%$  for the outer pane. Using a modified match criterion ( $\pm 3\sigma$ , with a minimum  $\sigma$  equal to 3% of the mean), the false exclusion rates were reduced to 11% and 7% for the inner and outer pane, respectively. The LIBS method detected eight elements in the windshields' glass fragments (Aluminum [Al], Barium [Ba], Ca, Potassium [K], Mg, Na, Si, and Sr) with precision ranging between 1%–15%, depending on the element, emission line, and concentration. The LIBS intra-day variability and inter-day variability was inferior to  $\mu$ -XRF but were reduced by estimating Signal to Noise Ratios ([SNR], signal to background near the peak) for each analyte of interest and then using ratios of SNRs to other elements or emission lines. The overall distribution of elemental composition within each glass pane was observed via heatmaps, box-plots, and Analysis of Variance (ANOVA). For pairwise comparisons, different criteria, including range overlap,  $\pm 3\sigma$ ,  $\pm 4\sigma$  was evaluated using three randomly selected fragments as the known sample and compared to one fragment as the questioned item. False exclusion rates were improved from 60% to 8% depending on the comparison criterion applied, the number of replicate measurements, the number of fragments used for comparison, and the data pre-processing methods.

#### Glass, Forensic Science, Elemental

### **B74 The Identification of the Polymer-Bonded Drugs on the Fabric Surface: A Challenge to the Forensic Drug Analysts**

*Shahnaz Akhtar, MPhil\*, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; Abdul Razaq, MPhil\*, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; Khalid S. Feras, MPhil\*, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; Muhammad Irfan Ashiq, PhD\*, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN; Mohammad A. Tahir, PhD, Punjab Forensic Science Agency, Lahore, Punjab 54000, PAKISTAN*

**Learning Overview:** After attending this presentation, attendees will have useful learning experience about a unique method of drug concealment adopted by drug smugglers and about the identification of polymer-bonded heroin.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating a new extraction.

Drug trafficking through concealment, by adopting various tactics, has always been a method of choice for drug traffickers worldwide. Due to an increase in global demands for illicit drugs, drug dealers and smugglers are designing and adopting new methods to camouflage these drugs to bypass tight security checks at regional and international borders. The detection and identification of drugs from the skillful tactics of smugglers has always been a challenge for law enforcement agencies, international border security forces, and crime laboratories. This case study reveals a new trend in the smuggling of illicit drugs through their concealment as a fabric coating with finishing polymers before exportation. This study also describes the challenges in detection and identification of polymer-bonded drugs.

Fabric bearing a suspected coating of a finishing chemical was seized from an international traveler by the Federal Investigation Agency of Pakistan. It was submitted for examination of the surface coating for the presence of any explosive or narcotic drugs. The surface morphology of the fabric was examined stereo microscopically and led toward the suspicion that it had some unusual coating on its surface. It was further examined by using Scanning Electron Microscope/Energy Dispersive X-ray Spectroscopy (SEM/EDX), which indicated the presence of an unusual coating different than normal finishing coating on the surface of fabric. The coating material was scraped off by using a spatula and extracted in acetone (30min sonication) for explosives analysis. The extract was screened for explosive material by using color tests. No traces of high- or low-explosive materials like Trinitrotoluene (TNT), Research Development Explosive (RDX), Pentaerythritol Tetranitrate (PETN), black powder, flash powder, or Improvised Explosive Mixture (IEM) were found. It was further analyzed by using Gas Chromatography/Mass Spectrometry (GC/MS) and Fourier Transform Infrared (FTIR), but no explosive material was detected. Instead, GC/MS results revealed the presence of heroin (diacetylmorphine). FTIR spectrum indicated the presence of a polymeric material and did not indicate the presence of heroin; possibly the heroin signals were suppressed due to the excessive amount of polymer.

Keeping in view all these results, the scraping of fabric coating was tested for narcotic drugs by using standard test methods that involve the use of methanol for extraction purposes. Methanol extract of the scraping was screened for the presence of illicit narcotic drugs, but no drug was detected. The standard method was modified by replacing the solvent methanol with acetone and including an additional step of sonication for 30min. Acetone extract presented a positive color test for heroin, and a strong signal of heroin appeared on the chromatogram by using GC/MS. This extraction method acted well to unbind the coated material from the fabric and disentangle the suspicious chemical in the coating material employed on the fabric through physical adhesion.

Awareness of the drug analysis community about this new way of concealing illicit drugs will be quite helpful in analysts' routine work.

### B75 The Influence of DNA Extraction Methods on the Quantity and Quality of Retained Genetic Material

Brian Kemp\*, University of Oklahoma, Norman, OK 73019; Kristine G. Beaty, PhD, University of Oklahoma, Norman, OK 73019; Brittany L. Bingham, BA, University of Oklahoma, Norman, OK 73019; Upuli A. DeSilva, University of Oklahoma, Norman, OK 73072; Mary Faith Flores, Norman, OK 73071; Cara Monroe, University of Oklahoma, Norman, OK 73019; Jodi Lynn Barta, PhD, Madonna University, Livonia, MI 48150

**Learning Overview:** After attending this presentation, attendees will better understand how to characterize the influence of various DNA extraction methods on the quantity (i.e., concentration) and quality (i.e., strand length) of resulting DNA eluates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how better documentation of the influence of DNA extraction and purification on the quantity and quality of DNA eluates will provide critical information for forensic and ancient DNA researchers to consider before choosing an extraction method. Moreover, the findings of this study should direct efforts toward improving extraction yields and decreasing damage during DNA extraction and purification.

DNA recovered from forensic and ancient DNA sources is generally expected to be in low copy numbers and degraded with regard to strand length. However, considering the following equation, it is important to realize that the exact amount of recoverable DNA from any source is unknown: net yield of DNA=original amount–loss in sampling–loss in extraction/purification–loss due to amplification bias (e.g., due to Polymerase Chain Reaction [PCR] inhibitors).

In most cases, these variables are unknown or poorly documented. This is also true regarding the degree of fragmentation caused by extraction and purification methods. Thus, it would be useful to have some estimation of these variables prior to initiating the study of compromised materials. In this study, the objectives included estimating: (1) the amount of DNA lost during DNA extraction and purification; and (2) with regard to strand length, the degree to which molecules are damaged as a result of the extraction method.

Four DNA standards were created from freshly extracted pig (*Sus scrofa*) liver DNA: (1) standard 1 was ~9,000–12,000bp at 90ng/μl (i.e., representing “intact” genomic DNA); (2) standard 2 was ~9,000–12,000bp at 1ng/μl (i.e., representing the conditions of touch DNA); (3) standard 3 was ~200–400bp at 100ng/μl (probably an unrealistic state, but interesting to test, nevertheless); and (4) standard 4 was ~200–400bp at 0.8ng/μl (i.e., representing forensic or ancient DNA). Ten aliquots of each of these standards were then subjected to 14 commercial extraction methods, many of which are marketed as suitable for forensic and ancient DNA applications (QIAGEN® DNA Investigator, QIAGEN® DNA Micro Kit, MinElute® PCR Purification, QIAGEN® DNeasy® Blood and Tissue Kit, Invitrogen™ Charge Switch, MP Biomedicals™ GeneClean Kit for Ancient DNA [Dehybernation A and B], Promega® DNA IQ, Thermo Fisher PrepFiler™, Bio-Rad™ InstaGene Matrix, TaKaRa NucleoSpin® gDNA Cleanup XP, NucleoSpin® DNA Trace, and TaKaRa NucleoSpin® Trace 8). These standards were also subjected to seven published ancient DNA extraction methods. “DNA in” of the standards was compared to “DNA out” using an Agilent® Fragment Analyzer that is capable of simultaneously measuring DNA quantity (i.e., concentration) and quality (i.e., DNA strand length).

Data regarding both DNA loss and fragmentation were obtained. Observations were made of both DNA loss and fragmentation. Some kits performed very well, whereas others were associated with tremendous loss and/or fragmentation. This indicates that DNA recovered from compromised sources may, in fact, be more concentrated and intact than is generally recognized. It also demonstrates that many extraction methods used to study degraded DNA are far from optimal, and that research should be focused on improving their efficacies.

#### Low Copy Number, Standards, Fragment Analyzer

### B76 Where, Oh Where, Has the DNA Gone?

*Kristine G. Beaty, PhD\**, University of Oklahoma, Norman, OK 73019; *Brittany L. Bingham, BA*, University of Oklahoma, Norman, OK 73019; *Upuli A. DeSilva*, University of Oklahoma, Norman, OK 73072; *Mary Faith Flores*, Norman, OK 73071; *Cara Monroe*, University of Oklahoma, Norman, OK 73019; *Jodi Lynn Barta, PhD*, Madonna University, Livonia, MI 48150; *Brian Kemp*, University of Oklahoma, Norman, OK 73019

**Learning Overview:** The goal of this presentation is to provide attendees with a better understanding of the potential for DNA loss from degraded and low concentration sources when utilizing commonly used silica-based extraction methods.

**Impact on the Forensic Science Community:** Findings of this study will impact the forensic science community in the development of more efficient DNA extraction protocols that specifically retain DNA from degraded and low copy number sources.

The behavior of aged, degraded, and/or low copy DNA during routine laboratory methods is still poorly understood. Previous research on this topic is sparse, but has demonstrated that ample amounts of DNA are inadvertently lost during extraction and purification. These observations suggest that there may actually be more DNA in compromised sources than is commonly recognized. Notably, some DNA extraction and purification methods cause DNA eluates to become lower in copy number than expected, or than would be useful for downstream applications. Considering the case of silica-based extractions, DNA can be lost via two mechanisms. First, it is possible that not all the source DNA binds to the silica column (i.e., DNA could be found in the flow through). Second, it is possible that DNA is not efficiently eluted off of the silica (i.e., DNA could be retained on the silica column).

In this study, DNA standards of known concentration were subjected to the QIAGEN® DNeasy® Blood and Tissue Kit (a silica-based extraction) to identify: (1) how much DNA has not bound to the silica, and (2) how much DNA has not been eluted off the silica column. In order to do so, DNA standards were created using genomic porcine DNA obtained from Zyagen. “Intact DNA” was represented by Standard 1Z, with a peak fragment length of 20k bp, at a concentration of ~100ng/μl. To represent “degraded DNA,” standard 3Z was sheared by sonication to a peak fragment length of roughly 300bp. Low copy variants of each of these standards were created through dilution of standards to <1ng/μl (Standard 2Z and 4Z).

High concentration standards 1Z and 3Z were extracted using the DNeasy® kit. After following the provided extraction protocol, each spin column was moved into a new collection tube and another 200μl of buffer AE was used to elute the DNA that potentially remained in the column. For Standards 1Z and 3Z, this was repeated until the column was eluted a total of ten times in ten separate collection tubes.

To determine if DNA fails to bind onto the columns, the flow through from the purification steps of the initial extraction was passed across a new spin column, washed, and eluted with AE buffer. DNA remaining on this column was eluted into new collection tubes a total of ten times. This was repeated eight more times, resulting in a total of total of 100 eluates from the original DNA. Low copy standards 2Z and 4Z were similarly tested, but silica columns were eluted five times, and four new silica columns were used to attempt to capture DNA from the four flow throughs (totaling 25 tubes). The DNA that was contained in these tubes was quantified using a Qubit® Fluorometer three times. The eluates were run on a Agilent® Fragment Analyzer to determine the size of the DNA fragments that were recovered in each step.

Molecules from all standards were recovered during this process, but detectable amounts varied by method used. For example, standard 1Z eluates had detectable amounts of DNA in 40 eluates (Qubit®) versus 56 eluates using the Fragment Analyzer. However, some general trends were detected. First, molecules were detected in the flow through of all standards, especially those at higher concentrations. Second, the larger fragments (over 4,000bp in length) were recovered at a higher frequency in initial elutions in a new spin column. Thirdly, smaller fragment standard (~300bp in length) eluates were not detectable using the Qubit®. In total, this suggests that modifications to the extraction protocol may be needed to recover adequate DNA from low concentration, damaged sources.

### B77 **Battling the Backlog: A Novel Bioanalytical System for the Separation and Collection of Intact Spermatozoa**

Sarah Wright\*, University of Notre Dame, Notre Dame, IN 46556; Norman Dovichi, PhD, University of Notre Dame, Notre Dame, IN 46556-5046

**Learning Overview:** The goal of this presentation is to demonstrate a novel technology that addresses the bottleneck separation of male from female DNA in rape kits for potential application to the forensic analysis of sexual assault evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a novel method utilizing a Capillary Zone Electrophoresis (CZE) system for the separation of intact cells collected from rape kits. The results presented will invite a meaningful dialog on the optimization and potential implementation of this technology that would significantly improve rape kit analysis speed and efficiency.

The national backlog in sexual assault cases is estimated to be between tens of thousands to half a million untested rape kits. The primary challenge crime labs face in analyzing these kits is the separation of purified male DNA from the mixture of primarily female DNA from gynecological swabs.<sup>1</sup> Standard protocols use Differential Extraction (DE), a manual separation technique that can take upwards of 12 hours to complete. The procedure incubates collected samples in detergents of increasing strength with varying time and temperature environments to differentially lyse fragile epithelial cells prior to stronger sperm cells. The final result contains, at best, a primarily male mixture of DNA that requires a trained analyst in Short Tandem Repeat (STR) mixture interpretation for perpetrator identification.<sup>2,3</sup>

This study addresses the bottleneck challenge of DNA separation in rape kit processing through the use of a novel CZE system.<sup>4</sup> CZE is a promising tool to perform the cell separation and has three major advantages over alternative technologies: a small amount of sample is consumed, which allows for replicate analyses of limited available evidence; rapid separation time compared to standard methods; and single cell detection and collection when interfaced with an automated fraction collector developed in-house. An electrokinetic injection of a simulated sexual assault sample is separated at a high voltage across a capillary with an inner diameter of 100 $\mu$ m. The CZE instrument is coupled with an automated fraction collector that deposits samples eluted from the distal end of the capillary into individual wells on a microtiter plate corresponding to a distinct migration time interval.

Quantitative Polymerase Chain Reaction (PCR) amplification of a Y-chromosome sequence is used to confirm the separation and collection of male DNA from sperm cells in a single well of the microtiter plate in fewer than 15 minutes, representing a significant improvement in separation time compared to current methods.<sup>5</sup> Furthermore, the system was designed to integrate seamlessly within the current work flow of a standard crime laboratory to increase its potential for adoption and implementation in battling the rape kit backlog.

### **B79 The Application of Optical Trapping to Obtain Single-Source Short Tandem Repeat (STR) Profiles From Forensically Relevant Body Fluid Mixtures With Modified DNA Analysis Workflow**

*Benjamin J. OBrien, BS\*, Virginia Commonwealth University, Richmond, VA 23220; Michael K. Valle, BS, Virginia Commonwealth University, Richmond, VA 23220; Nicole A. Auka, MSFS, Armed Forces DNA Identification Laboratory, Dover Air Force Base, DE 19902; Tracey Dawson Cruz, PhD, Virginia Commonwealth University, Richmond, VA 23284; Joseph E. Reiner, PhD, Virginia Commonwealth University, Richmond, VA 23284-2000; Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Richmond, VA 23284-3079*

**Learning Overview:** The goal of this presentation is to demonstrate the utility of optical trapping for separation of a diverse assortment of cells, such as spermatozoa and leukocytes, from forensically relevant mixed samples. Optical trapping is a method used to mechanically manipulate microscopic objects, such as cells. The major operating principle of optical trapping is to direct the momentum of light to impact an object of interest. A laser can be tightly focused through a 100x immersion objective into a point roughly 1 $\mu$ m in diameter. This laser will exert a gradient force on an object, drawing it closer toward the focal point until the gradient force is entirely offset by an on-axis scattering force that traps the object in place. This object can then be moved in three dimensions. Cells caught in the trap and moved on the order of 500 $\mu$ m/s will not be damaged.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating a method for deconvolution of DNA mixtures at the beginning of the DNA workflow through the use of optical trapping. This method can be applied to suspected mixed samples to separate a small population of target cells that can then be analyzed within the traditional forensic DNA workflow. Unlike currently in-practice techniques, such as differential extraction, this method can separate a variety of mixtures, such as blood/saliva. This method has the potential to save time at the end of the workflow by negating the need for lengthy mixture interpretation or probabilistic genotyping by generating a single-source STR profile.

The traditional DNA workflow used for analysis of samples that have been separated with optical trapping remains unchanged with only minor modifications. DNA is extracted, quantified, and amplified. Since optical trapping necessarily produces low-copy number samples, samples are concentrated down with vacuum centrifugation prior to amplification. This allows the entire extract to be amplified.

Previous research performed at Virginia Commonwealth University (VCU) has demonstrated that optical trapping can be used to capture and separate both spermatozoa and leukocytes from a larger mixed cell population. Spermatozoa were tweezed out from samples that contained a 1:1 mixture of semen to vaginal fluid in groups ranging from 8–55 cells. Quantification revealed total DNA quantity closely correlated with theoretical yield calculated based on the qualitative observation of the number of tweezed cells. Each sample produced a single-source STR profile with groups of 50 spermatozoa generating STR profiles with greater than 90% of expected alleles. This research demonstrated that small populations of cells could be successfully separated and analyzed from a larger sample; thus, further research was undertaken into other cell types.

A modified transfer protocol was developed that demonstrated improved results from the previous work. Twenty-one samples of leukocytes ranging from 5 to 22 cells were tweezed from liquid samples and analyzed as previously described. Full STR profiles were obtained from 8 of the samples, with 2 of these samples containing only 10 cells. Of the remaining 13 samples, 6 samples had greater than 90% of expected alleles.

### B80 The Development and Automation of a Swab In-DNA Out Platform Using Dynamic Solid Phase Extraction (SPE)

Leah M. Dignan, BS\*, University of Virginia, Charlottesville, VA 22903; Kimberly Jackson, Charlottesville, VA 22903; Michael Shane Woolf, MS, Charlottesville, VA 22903; Christopher J. Tomley, BS, University of Virginia, Charlottesville, VA 22903; James P. Landers, PhD, University of Virginia, Charlottesville, VA 22904

**Learning Overview:** After attending this presentation, attendees will have been introduced to a novel, automated microfluidic method for DNA extraction and purification from forensic samples based on dynamic SPE. Additionally, a novel microfluidic lysis protocol and a novel fluidic control strategy will be introduced and applied to forensic genetic sample preparation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a cost-effective, automated microfluidic technique to lessen sample preparation demands placed on forensic laboratories upstream of genetic analysis.

As the amount of DNA evidence collected in criminal investigations increases, demand for forensic genetic testing continues to grow. The influx of samples to forensic laboratories often outpaces their processing capabilities, leading to a backlog of untested samples. Silica-based SPE techniques are widely accepted forensically, but are time and labor intensive. Although SPE can be automated using liquid-handling robots to increase throughput and reduce contamination risk, these instruments are limited to use in a centralized laboratory. A portable, automated, and multiplexed swab in-DNA out microfluidic platform is proposed for the purification of DNA from buccal swabs using silica-based dynamic SPE (dSPE). The device contains four identical domains to allow for multiple extractions simultaneously. The DNA obtained from this device is amenable to direct amplification by Polymerase Chain Reaction (PCR) and subsequent Short Tandem Repeat (STR) profiling, which represents a significant step toward reducing sample preparation demands placed on forensic laboratories.

Previous work demonstrated semi-automated microfluidic dynamic solid phase extraction of PCR-ready DNA from whole blood, replacing pipetting steps with rotationally controlled fluid flow and magnetic mixing.<sup>1</sup> However, some fluidic control steps required user intervention, preventing complete assay automation. In the work presented, a novel laser-based valving strategy supplants the manual valves, introducing the possibility for complete assay automation. A single laser can be used to both open and close microvalves. This capability is essential for the sequential delivery of the wash and elution buffers required for DNA purification. The dSPE protocol initially utilized three washes to remove both contaminants and PCR inhibitors, including a chaotrope used to facilitate DNA-silica binding and Isopropanol (IPA), which is used to remove cellular components loosely adsorbed to the silica surface. To remove the residual IPA, a Tris/EDTA (TE) wash was implemented. However, as this was the same buffer used to elute the purified DNA from the beads, an appreciable amount of DNA was lost during this step. To prevent this, the TE wash was removed and a novel strategy for IPA removal was implemented. A gas-permeable membrane was incorporated onto the back of the elution chamber to allow for IPA evaporation without sample loss. DNA yields following this modified on-disc protocol ( $0.43 \pm 0.01 \text{ ng}/\mu\text{L}$ ) are comparable to a control reaction done in-tube ( $0.41 \pm 0.16 \text{ ng}/\mu\text{L}$ ), but with the added benefit of heightened reproducibility. The generation of full, 18-plex STR profiles following off-disc amplification and electrophoretic separation of amplicons demonstrates successful inhibitor removal and biocompatibility of assay reagents and device materials. Significant progress has been made toward complete automation of a microfluidic protocol for dSPE-based purification of DNA directly from buccal swabs. This includes integration of enzymatic lysis direct from buccal swab cuttings where the required volume of lysate for dSPE can be delivered directly to the purification architecture through device rotation and valving. Samples lysed and purified on the microfluidic device resulted in STR profiles with 100% correlation to control samples that were prepared in parallel via a conventional, in-tube protocol.

Adopting a microfluidic approach decreases the requirements for reagents and consumables relative to conventional SPE approaches and provides enhanced portability not possible with current forensic biorobotic protocols. Automation and multiplexing represent an important step toward a sample in-DNA out format, ultimately lessening the sample preparation demands exerted on forensic laboratories and increasing throughput.

## B81 Developing Investigative Leads and Potential Evidence in Wildlife Crime: Consideration of Human DNA Recovery From Handled Eggs and Birds of Prey Feathers

Katherine L. Wood, MS, UCL Centre for the Forensic Sciences, London WC1H 9EZ, UNITED KINGDOM; Georgina E. Meakin, PhD\*, University of Technology Sydney, Sydney, NSW 2007, AUSTRALIA

**Learning Overview:** After attending this presentation, attendees will know that human DNA can be recovered from handled eggs and birds of prey feathers, such that human DNA recovery can be considered in relevant wildlife crime investigations. Attendees will also understand that the sampling method choice will impact the DNA quantity recovered, and that additional studies are required to provide the empirical data to fully inform that choice and maximize the potential of DNA evidence obtained from wildlife-specific substrates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how human DNA can be recovered from handled eggs and birds of prey feathers. This presentation will present an initial dataset to inform the choice of DNA sampling method for these substrates, so that human DNA recovery can be implemented in relevant wildlife crime investigations.

In crimes against humans, it is routine to recover “touch DNA” for the identification of potential offenders.<sup>1</sup> To inform this practice, there are more than 200 published studies investigating the best methods for human DNA recovery from substrates relevant to such crimes, such as bullet casings, knife handles, clothing etc. While some of these could also be relevant to wildlife crime, there are particular substrate types that are wildlife-crime specific, such as animal carcasses, snares/traps, eggs, and feathers. However, there are only four published studies on human DNA recovery from carcasses and snares/traps and no published studies on human DNA recovery from eggs and feathers, although fingermark recovery from these substrates has been demonstrated.<sup>2-7</sup> There is a lack of published empirical data to inform the methods to employ for optimal human DNA recovery within wildlife crime contexts.

This proof-of-concept study examined whether human DNA could be recovered from handled eggs and feathers, and if so, which sampling method would maximize the DNA recovered. Chicken eggs were used as representative bird eggs, and common kestrel (*Falco tinnunculus*) contour and tail feathers (provided by Your Animal Kingdom) as representative birds of prey feathers. A single volunteer handled a cleaned egg or feather in one hand for 30 seconds and the substrate was immediately sampled with either a wet and dry cotton swab or a SceneSafe FAST™ mini-tape. Ten substrates were handled with alternating hands per day; ten eggs on days one and two, and five contour and five tail feathers on days three and four ( $n=40$  in total). Half of the substrates were swabbed and half were mini-taped, and the DNA was extracted, quantified, and profiled.

Human DNA was successfully recovered from both handled eggs and feathers, although in varying quantities. No significant differences were observed between DNA quantities recovered from substrates handled by right and left hands, irrespective of sampling method and substrate type (Mann-Whitney U test,  $p > 0.05$  for all comparisons tested). No significant differences were also observed between DNA quantities from eggs handled on different days ( $p > 0.05$ ) and between DNA quantities from the two types of feathers ( $p > 0.05$ ). As such, to compare the effects of sampling method and substrate type, egg data from both hands and days were combined, and feather data from both hands and feather type were combined. Median DNA quantities of 0.62ng (Interquartile Range [IQR]=0.31) and 0.96ng (IQR=1.03) were recovered from swabbed and mini-taped eggs, respectively, and of 0.22ng (IQR=0.25) and 0.35ng (IQR=0.21) from swabbed and mini-taped feathers, respectively. While the average DNA quantity recovered from eggs by mini-tapes was higher than that recovered by swabs, this was not statistically significant ( $U=46.0$ ,  $p=0.796$ ), presumably due to the wide spread of data obtained using mini-tapes. Use of mini-tapes recovered significantly more DNA from feathers than by swabbing ( $U=22.0$ ,  $p=0.035$ ), and swabbing recovered significantly more DNA from eggs than from feathers ( $U=10.0$ ,  $p=0.002$ ).

This study demonstrates that human DNA can be recovered from handled eggs and feathers and provides an initial dataset to help inform practitioners in their sampling method choice. This dataset needs to be expanded with further studies to investigate the impact of the many variables that affect DNA recovery from exhibits, such as time since DNA deposition, environmental factors, packaging methods, etc., to provide the required empirical data to ensure that practitioners are maximizing the evidence available from substrates encountered in wildlife crime.

### B82 Pyrosequencing-Based DNA Analysis for Species Identification

Mirna S. Ghemrawi, MS\*, Florida International University, Miami, FL 33199; Frank Fischinger, MS, Germantown, MD 20874; Mark Guilliano, PhD, Ashburn, VA; George T. Duncan, PhD, Nova Southeastern University, Dania Beach, FL 33004; Bruce R. McCord, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will be aware of the development of a quick and robust biological assay for species identification using a pyrosequencing technique.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a novel assay to identify species that were previously classified as non-human miscellaneous samples, as well as providing a novel real-time DNA quantitation assay that is vertebrate-specific.

In crime scenes, unknown biological samples are often human in origin, but some of them belong to other animals. Identifying the source of a biological sample in a crime scene, as well as in wildlife forensic cases, can be critical during investigation. Yet, forensic scientists often lack appropriate standardized protocols to categorize a non-human sample. While previous studies have shown the presence of potential genetic markers to differentiate species, there is still a lack of a quick, easy, and distinct method for species identification from tissue or body fluids.<sup>1,2</sup> Law enforcement agencies, police officers, prosecutors, and defense attorneys expect forensic personnel to have the capability to identify miscellaneous body fluids and tissue. However, no system proposed to date achieves this end using fast, easy, and inexpensive protocols.

With the emergence of novel techniques for DNA sequencing, older, less-specific procedures, such as the use of polyclonal/monoclonal anti-sera, can be updated and replaced.<sup>3</sup> In this study, next generation sequencing methods will be used to analyze a short mitochondrial amplicon that is known to be hypervariable between different species of mammals, birds, and fish. This study will utilize pyrosequencing as well as demonstrating the application on a novel massively parallel sequencer. The resultant sequences can be compared to a large database of known references for species identification.

For this purpose, silica-coated magnetic-particle technology was used to extract DNA from buccal swabs and livestock samples, followed by the SYBR<sup>®</sup> green-based quantitation method using in-house designed vertebrate-specific primers. Amplification and sequencing of 12s rRNA was then performed on the PyroMark<sup>®</sup> Q48 Autoprep instrument. Preliminary sequencing data of 30 different species that are commonly found in a household were aligned and compared. Some samples are from mammals, such as *Canis lupus familiaris*, *Felis catus*, and *Oryctolagus cuniculus*; birds, such as *Gallus gallus* and *Psittaciformes*; and fish, such as *Salmo salar* and *Thunnini*. Results show inter-species variability but intra-species concordance, confirmed with curated databases of known sequences. The goal of this study will be to provide law enforcement with a novel method that can be implemented in forensic DNA labs for a routine and user-friendly confirmatory test for species identification.

#### Species Identification, Pyrosequencing, Miscellaneous Samples

### B83 A Short Interspersed Nuclear Element (SINE) -Based Multiplex Quantitative Real-Time Polymerase Chain Reaction (qPCR) Assay for Human-Dog-Cat Species Identification and DNA Quantification

James W. Liang, BS\*, University of New Haven, West Haven, CT 06516; Heather G. Miller Coyle, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will understand the need for a robust animal species identification and quantification assay, principles of multiplex qPCR assay development, and the performance of SINE-based qPCR assays.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by drawing attention to the use of animal DNA evidence in forensics, SINEs as potential markers for forensic DNA applications, and an assay model that could be implemented in animal-related casework.

Although a majority of households in the United States own a pet, resulting in the likely transfer of animal DNA during crimes, this evidence oftentimes remains unutilized by traditional crime labs, which primarily focus on the extraction, quantification, and Short Tandem Repeat (STR) genotyping of human DNA.<sup>1</sup> Historically, there have been numerous cases in which animal DNA has been used to link suspects to victims and/or crime scenes, sometimes serving as the only evidence producing such linkages and resulting in convictions.<sup>2</sup> One way to incorporate animal DNA analysis in the typical workflow of traditional crime labs is to simultaneously quantify human and animal DNA in an evidence sample rather than in separate reactions, allowing for the determination of the presence and quantity of animal DNA without additional consumption of DNA evidence. This information can then be used to inform the analyst's decision of whether to proceed with STR genotyping and for which species.

The purpose of this research was to develop a multiplex qPCR assay using primers and dual-labeled probes that target species-specific SINEs for the simultaneous quantification of human, dog, and cat DNA in mixed forensic samples. Existing animal qPCR assays typically target species-specific mitochondrial sequences or low-copy nuclear genes, each of which has its own limitations.<sup>1</sup> Mitochondrial assays are more sensitive, but less accurate and predictive of STR genotyping success, whereas low-copy nuclear assays are more accurate and predictive but less sensitive. As repetitive nuclear elements, SINEs possess the advantages of both without their respective limitations. It was thus hypothesized that a SINE-based multiplex qPCR assay will be more sensitive, quantitatively accurate, and reliable than previously published assays for quantifying animal DNA.

First, previously published primers targeting human-, dog-, and cat-specific SINEs were validated via endpoint PCR and agarose gel electrophoresis for species specificity and multiplex compatibility with commercial DNA standards.<sup>3,4</sup> Preliminary results indicate that each primer set does not display cross-amplification in the other two species' DNA templates. Bands of comparable brightness were observed in duplex reactions, indicating that human-, dog-, and cat-specific SINE-targeting primers are multiplex compatible. These validation studies were conducted on the GeneAmp® PCR System 9600 in 10µL reactions containing 1x AmpliTaq Gold™ 360 Master Mix, 0.2µM human primers, 0.3µM canine primers, 0.4µM feline primers, and 10ng of each species' genomic DNA standard. The instrument cycling conditions were an initial hold of 95°C for 12 minutes, 40 cycles at 95°C for 15 seconds, 68°C for 30 seconds, and 72°C for 15 seconds, followed by a final extension at 72°C for 7 minutes.

Then, new primers and dual-labeled probes were designed for multiplexing using National Center for Biotechnology Information's (NCBI's) Primer Basic Local Alignment Search Tool (BLAST) and Primer Express 3.0. Human-, dog-, and cat-specific amplicons are 140, 101, and 98bp respectively. qPCR reactions were conducted using the Invitrogen® Platinum II Taq Hot-Start DNA Polymerase kit. The instrument's cycling conditions were an initial hold of 94°C for two minutes, followed by 40 cycles at 94°C for 15 seconds, and 60°C for one minute. Ten microliter singleplex reactions were conducted on the ABI® 7500 Real Time PCR system and contained 1X Platinum II PCR Buffer, 0.2mM dNTPs, 0.2µM forward and reverse primers, 0.1µM Taqman probe, and 0.8units of Taq. Early results indicate a PCR efficiency of 98.1%, an R<sup>2</sup> value of 0.98, and a detection limit of 10pg.

PCR conditions are being optimized in singleplex reactions for each primer/probe set to minimize the Ct value and maximize the amplification efficiency and linear dynamic range. A multiplex detection assay is in development and being optimized for balanced amplification of multiple targets with amplification curves comparable to their respective singleplex reactions. Forensic conditions are being simulated by performing each assay on DNA extracted from mixtures of human, dog, and cat blood at various concentrations.

### **B84 Using Environmental DNA (eDNA) and Vertebrate Metabarcoding to Characterize Biological Communities: A New Method for Conservation Genetics and Wildlife Forensics**

*Hillary L. Eaton, PhD\*, Embry-Riddle Aeronautical University, Prescott, AZ 86301; Catherine E. Benson, PhD, Embry-Riddle Aeronautical University, Prescott, AZ 86301; Matthew J. Valente, MS, Embry-Riddle Aeronautical University, Prescott, AZ 86301; Courtney S. Turner-Rathbone, BS, Embry-Riddle Aeronautical University, Prescott, AZ 86301*

**Learning Overview:** After attending this presentation, attendees will better understand the impact of vertebrate metabarcoding on wildlife forensics and wildlife management plans for threatened and endangered species, as well as those of conservation concern.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a novel technique for genetic species identification of unknown vertebrate biological samples for both conservation and law enforcement efforts in combating wildlife crimes.

Illegally poached wildlife products are estimated to bring \$20 billion in annual revenues from black market trading and has been established as a source of funding for terrorism. Poaching causes a dramatic drop in biodiversity, which leads to a further decline of the ecosystem, especially if keystone species, such as elephants, are targeted. Historically, surveys for fish and wildlife have required a significant number of person-hours in the field, using methods that can be stressful to the species being observed. However, the analysis of eDNA, left behind by organisms in water, soil, and air, is revolutionizing biologists' ability to rapidly assess biodiversity. Vertebrate metabarcoding represents an advance in high-throughput DNA sequencing that offers the wildlife community a dramatic improvement in the process of species identification, as it requires only one primer set for all samples, and not species-specific primers.

In this study, the application of the 16S rRNA mitochondrial gene for vertebrate eDNA metabarcoding was explored in Arizona's Verde River, home to more than 50 species of fish and wildlife that are endangered, threatened, or of conservation concern. Replicate water samples of 250mL volumes were collected consecutively from two sites along the river, both prior to and during the annual monsoon season to ensure a robust method in the face of increased organic matter during the monsoon season. Samples were vacuum filtered to collect eDNA onto cellulose nitrate filters. DNA was extracted, amplified by polymerase chain reaction, and libraries were prepared for sequencing on an Illumina® MiSeq® FGx Forensic Genomics System. Sequences were compared to the National Center for Biotechnology Information (NCBI) nucleotide database using the Basic Local Alignment Search Tool (BLAST).

Members of every vertebrate taxon were identified from sequences, including fish, reptiles, amphibians, birds, and mammals. All taxa that were detected corresponded to those known to occur in the Verde River riparian corridor, but there were also new discoveries at the species level.

This technique represents a novel method to characterize vertebrate communities from water samples that is more efficient than quantitative Polymerase Chain Reaction (qPCR), as it does not require species-specific primers, and less stressful to species than traditional survey methods, as no capturing of wildlife is required. Greater than 25 species from diverse taxa were identified with a single water sample collected in a few minutes. The use of eDNA can supplement or potentially someday replace more invasive techniques for surveying wildlife. This method can be used in conservation efforts by wildlife managers to track migration patterns, invasive species, and those of conservation concern, as a few examples. Examples of how this technique could also be applied to wildlife forensics will be discussed. This technique provides the wildlife community with a powerful analytical tool that has wide applicability across conservation and forensic disciplines and will increase the efficiency of investigations and surveys, while decreasing overall cost.

### B85 Human Identity From the Mosquito Midgut Using GlobalFiler™ Express

Mollie S. Comella\*, Pittsford, NY 14534; Joann Butkus, The Pennsylvania State University, University Park, PA 16802; Scott Lindner, PhD, University Park, PA 16802-2131; Reena Roy, PhD, The Pennsylvania State University, University Park, PA 16802

**Learning Overview:** After attending this presentation, attendees will better understand the evidentiary potential mosquitoes have in the forensic community. Complete and partial Short Tandem Repeat (STR) profiles generated from mosquitoes that fed on human blood will demonstrate to the DNA analysts that identification of a person can be obtained from the blood meal, even after several hours of ingestion.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees on possible methods and materials that can be used to utilize the minute quantities of blood present in the mosquito's midgut. The use of such a unique substrate could greatly impact the forensic science field.

There are currently three main forms of the *Anopheles stephensi* mosquito: typical, intermediate, and mysorensis. Despite the intermediate and mysorensis forms having poor vector status, the typical form is found in many urban areas and is known to spread various diseases such as malaria. While these insects are generally considered as pests and carriers of such disease, the female mosquitoes can be useful in forensic cases as they feed on human blood. Nucleated white blood cells found in the blood stored in the midgut of the mosquitoes can be useful in identifying the donor on which the female mosquito has fed. In the context of a forensic case, the ingested blood could help identify a suspect or link a victim to a crime scene.

Generation of Short Tandem Repeat (STR) DNA profiles by direct amplification is useful for identification of the donor of the blood that was ingested by the mosquito. Commercially available direct amplification kits allow for detection of the donor of a body fluid and bypasses the labor-intensive and time-consuming steps needed for extraction and quantification of DNA.

Previous research in this laboratory using another direct amplification kit indicated that DNA stored within the white blood cells of the mosquito gut starts to degrade after eight hours post-feed, and the DNA is completely degraded 72 hours post-feed. Partial profiles can still be obtained after eight hours of ingestion of blood. In this current study, mosquitoes were fed on warm blood meals and euthanized at zero hours, four hours, and eight hours post-feed. Several mosquitoes were euthanized at each time interval having fed on a single donor. A mixture of blood from two donors was also used in this study, and these mosquitoes were euthanized at the same time intervals.

This project utilized the GlobalFiler™ Express PCR Amplification Kit to perform direct amplification and generation of STR profiles. To assist in the direct amplification process, COPAN® microFLOQ® Direct Collection Devices were used for puncturing the midgut of each mosquito. These swabs contain a nylon-fiber tip with a lysis agent that helps to break open the nucleated white blood cells. Once a minute quantity of blood was collected on the tips, the tips were cut and placed into the Polymerase Chain Reaction (PCR) amplification tubes where they remained immersed in the direct amplification reagents during the thermal cycling process. A blood sample from each donor was used as reference to compare the results of profiles generated from the midguts of the mosquitoes.

This research indicated that DNA profiles obtained from the mosquitoes using GlobalFiler™ Express amplification kit were consistent between and within each donor. In addition, both donors could be identified in the mixture profiles. Full profiles for all sample types were obtained for zero hours, four hours, and eight hours post-feed. Additionally, it is hypothesized that variability between mosquitoes, both in their feeding and digestion patterns, affected the quality of the profiles obtained. In conclusion, DNA contained in a single or mixed human blood meal ingested by mosquitoes can be useful in determining the donors' identity using the GlobalFiler® Express PCR Amplification Kit. This is a robust method to establish the presence of one or more individuals at a location of interest, within a specific time window.

## B86 Signatures of Suicide in the Human Postmortem Microbiome

Katelyn A. Smiles\*, East Lansing, MI 48423; Jennifer L. Pechal, PhD, Michigan State University, East Lansing, MI 48824; Carl J. Schmidt, MD, Wayne County Medical Examiner's Office, University of Michigan, Detroit, MI 48207; Heather R. Jordan, PhD, Mississippi State University, Mississippi State, MS 39762; M. Eric Benbow, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will better understand the potential utility of the postmortem microbiome as a tool to aid in classifying forensic death investigation related to suicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into if and which postmortem microbial signatures exist for suicides.

While postmortem microbial communities have the potential to be used as biological biomarkers of forensic relevance (e.g., postmortem interval range indicator), limited data exists on the variability of postmortem microbial communities related to manner of death, especially suicides.<sup>1</sup> This presentation will describe the human postmortem microbiome associations of suicides from samples collected during routine death investigation.

According to the Center for Disease Control, in 2017, suicides are the tenth leading cause of death (second for individuals between the ages of 10 and 34 years) and were twice as common as homicides. As suicides are a significant contributor to deaths in the United States, it is important to identify if potential signatures from the human postmortem microbiome can identify suicides versus other manners of death (e.g., natural or accidental), which may eventually serve as another tool for forensic investigators in determining manner of death.

Postmortem microbial communities from the mouth and rectum were collected using sterile swabs from 44 cases (22 suicides and 22 natural or accidental deaths, matched for similar demographics). All samples were gathered by the Wayne County Examiner's Office in Detroit, MI, during routine death investigations in 2014–2015. Postmortem microbial DNA was isolated and quantified following a modified manufacturer protocol using commercially available kits, a fluorometer, and a microchannel-based automated electrophoresis system. Targeted amplicon (16S rRNA V4 gene region) high-throughput sequencing was conducted on individual sample libraries using a 2 x 250-base pair, paired end approach. Resulting postmortem microbial community data was analyzed using an open-source bioinformatic pipeline, and statistical analyses were implemented using open-source software. Machine learning algorithms were used to identify significant associations among the targeted gene amplicon sequences (postmortem microbiome) and manner of death (suicides versus non-suicides).

Cases in this dataset represented an equal number of samples between males and females aged 19 to 79 years, but cases were not balanced between race. Approximately 90.9% ( $N=20$ ) were White, while the remaining 9.1% ( $N=2$ ) were Black. In addition, the majority of the cases (90.9%) had an estimated postmortem interval range of less than 48 hours. Other variables investigated included antemortem health conditions, location of the event, season of death, and weight status. Overall, initial findings indicate that suicides may, in fact, have distinct microbial signatures present in their postmortem microbiome. In comparison to control data, suicides presented similar patterns of microbial diversity. However, machine learning identified several microbial taxa that may be useful as indicators for assisting determination of the manner of death.

The results from this dataset are important to future research as they provide data about postmortem microbial variability during routine death investigations. It is critical that datasets with larger sample sizes and increased geographic locations (state, national, and international levels) be developed to corroborate distinct microbial signatures for suicides. Further, recent findings surveying the postmortem microbiome have demonstrated postmortem microbiomes can be reflections of antemortem health status, such as with heart disease and tuberculosis.<sup>1,2</sup> This leads to the consideration of whether swabbing for microbial DNA should be required in all death investigations, due to the vast amount of information the postmortem microbial communities could provide about the decedent.<sup>3</sup> With further collaborative research, the suicide microbial signatures may assist in solidifying relationships between the postmortem microbiome and antemortem health conditions. This topic of study is still in its infancy but shows promise for future applications of using microbial communities in future clinical and forensic settings.

### Forensic Science, Postmortem Microbiome, Death Investigation

### **B87 The Impact of Environmental Exposure and Chemical Contaminants on Microbial Signature Associated With Forensically Relevant Human Biological Samples**

Denise Wohlfahrt, BS\*, Virginia Commonwealth University, Richmond, VA 23284; Francy S. Nogales, BS, Virginia Commonwealth University, Richmond, VA 23223; Raquel Green, BS, Virginia Commonwealth University, Richmond, VA 23220; Najai Bradley, Richmond, VA 23220; Kathleen D. Brim, BS, Richmond, VA 23221-3013; James P. Brooks, PhD, Virginia Commonwealth University, Richmond, VA 23284; Sarah J. Seashols Williams, PhD, Virginia Commonwealth University, Richmond, VA 23284-3079; Baneshwar Singh, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the microbial DNA associated with various human biological samples and how contamination and environmental changes can impact them.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by increasing understanding in how handling, transport, and storage conditions can alter these microbial signatures, specifically in forensic applications.

Studies such as the Human Microbiome Project have shown that human biological samples can be successfully identified based on their distinct microbial signatures. Identifying these microbial markers not only has the benefit of an additional identification method, but may also be used to supplement current methods to distinguish incomprehensive samples, samples with low human DNA content, as well as having the potential to be implemented into next generation sequencing panels for easy implementation into the forensic workflow.<sup>1</sup> Even though the microbial signatures of body fluids are found to be distinct and stable, the experimental samples often do not compare to those found at the crime scene. Here, environmental exposure or contamination through chemicals or mishandling can often cause severe degradation of forensic evidence.

Venous blood, saliva, semen, urine, feces, vaginal fluid, and menstrual blood were collected from female and male volunteers using Institutional Review Board (IRB) -approved collection methods. This study was designed to investigate how environmental or chemical changes influence the microbial signatures in body fluids. To assess these effects, body fluid samples were exposed to elevated temperatures at various exposure times, detergent, bleach, and Ultraviolet (UV) light. DNA was extracted from the treated samples using DNA Investigator kit with the standard Forensic Casework Sample protocol on the QIAcube for blood, semen, saliva, vaginal secretions, and menstrual secretions according to manufacturer's protocol. QIAamp® Power Fecal DNA kit was used to extract DNA from treated fecal samples, and DNA Micro kit was used to extract treated urine samples, according to the manufacturer's protocols. These treated samples were compared to positive controls (untreated samples) to evaluate changes in bacterial DNA concentration, sequencing read variations, as well as identifying how the microbial taxa would vary between treatments.

Immediately after extraction, the V4 region of 16S rDNA was sequenced on MiSeq® FGx sequencing platform following the dual-indexing protocol as described by Kozich et al.<sup>2</sup> Sequences were then analyzed using mothur version 1.39.5, and statistical analysis was performed using R version 3.5.0.<sup>3,4</sup>

At the phylum level, similar patterns of relative abundance of bacterial phyla were seen between treatments. Major variations of these phyla were seen in the bleach-treated samples in all body fluids. At the genus level, major variations in the relative abundance were seen in the UV-treated blood samples and fecal samples treated with extended periods of elevated temperatures. Menstrual blood and vaginal fluid were least impacted by the treatments, while semen and urine showed the most variation when compared to the positive controls.

In conclusion, the microbial signature-based body fluid identification method is robust and reliable with common environmental extremities and contaminants. Findings from this study will help in minimizing errors associated with the accuracy of the microbial signature-based method for body fluid identification.

### **B88 A Multidisciplinary Effort to Identify the Cat Killer of Silicon Valley**

*Jeremiah Garrido, BS\*, Santa Clara County Crime Lab, San Jose, CA 95110-1717; Christina D. Lindquist, MS\*, University of California Davis, Davis, CA 95616; Michelle L. Bell, BA\*, San Jose, CA 95110*

**Learning Overview:** The goals and key educational objectives that will be highlighted in this presentation include: (1) criminalists working side by side with a veterinarian to identify, document, and collect various physical evidence; (2) the detection and forensic Short Tandem Repeat (STR) analysis of human DNA detected on the feline victims by the Santa Clara County Crime Laboratory Forensic Biology Unit; (3) efforts of the Veterinary Genetics Laboratory Forensic Unit at University of California, Davis to help determine how many different cats the suspect may be associated with harming; (4) screening/characterizing numerous reddish-brown stains that appeared to be non-human blood on various items collected from Robert Farmer's vehicle through presumptive blood testing and quantitative Polymerase Chain Reaction (PCR); and (5) legal aspects and challenges of animal cruelty cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how a multidisciplinary team of criminalists (from various disciplines and forensic laboratories), veterinarians, prosecutors, and law enforcement officers can work together to navigate through the analysis of human and non-human physical evidence in animal cruelty cases.

People often regard their pets as "members of the family," so when numerous domestic cats were reported missing, and subsequently found mutilated and deceased during the months of September and October of 2015, residents of Silicon Valley's Cambrian Area were extremely concerned. A cat killer was on the loose and the number of feline victims was increasing. Given that many individuals who commit crimes against animals are likely to go on to commit crimes against humans, residents of this tight-knit community were rightfully concerned that this could be a serious public safety issue. The case erupted and gained significant media attention following the discovery by San Jose Police Department of a deceased cat in the center console of a vehicle owned by a man in the nearby area named Robert Farmer.

A multidisciplinary team consisting of criminalists (from various disciplines and forensic laboratories), veterinarians, prosecutors, and law enforcement each played invaluable roles in the evaluation of the numerous feline victims, as well as the human and non-human physical evidence that was seized and analyzed. The prosecuting attorney assigned to this case navigated through the complex legal intricacies of animal cruelty law (California Penal Code Section 597[a]) and worked closely with members of the community that were impacted.

In this case study presentation, members of the multidisciplinary team will highlight their efforts to evaluate and analyze the feline victims and the physical evidence that was crucial to linking suspect Robert Farmer to many more victims than was originally anticipated. Some of the key factors that will be highlighted include: (1) criminalists working side by side with a veterinarian to identify, document, and collect various physical evidence; (2) detection and forensic STR analysis of human DNA detected on the feline victims by the Santa Clara County Crime Laboratory Forensic Biology Unit; (3) efforts of the Veterinary Genetics Laboratory Forensic Unit at University of California, Davis to help determine how many different cats the suspect may be associated with injuring or killing; (4) screening/characterizing numerous reddish-brown stains that appeared to be non-human blood on various items collected from Robert Farmer's vehicle through presumptive blood testing and quantitative PCR; and (5) legal aspects and challenges of animal cruelty cases.

The team approach taken proved to be a huge success in providing answers to key case questions and resulted in an increase in the number of counts against Farmer and will be relied upon for future cases of animal cruelty in Santa Clara County.

#### **Animal Cruelty, Cat Killer, Serial Cat Killer**

### **B89 “A Gun Too Far”—Reconstruction of a Homicide**

*Alexander Jason, BA\*, ANITE Group, Pinole, CA 94564*

---

**Learning Overview:** The goal of this presentation is for attendees to become familiar with techniques of shooting incident reconstruction in a homicide.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how evidence evaluation, observational experiments, and graphic exhibits can be utilized in a trial. Attendees attending this presentation will understand the procedures used to investigate a shooting incident, the value of witness statements, and how to make determinations on the dynamics and the limitations of gunshot residue evidence. All of these teaching details are used to integrate discrete evidence elements into a significant shooting reconstruction.

A woman was found fatally shot. It was either a homicide or a suicide: did she shoot herself or was she shot by someone? This issue required experimental testing and modeling. The primary physical evidence at the scene was both the presence and the absence of gunshot residue, a shooting distance determination, and blood spatter. This was a case that required an analytical shooting reconstruction to determine what was and was not possible.

The only witness to the fatal shooting was the boyfriend of the victim. Both the victim and the suspect were in a bedroom when the shot was fired. While there were several other people inside the house (all of whom heard the shot), none of them witnessed the incident. A forensic expert retained by the defense concluded that the incident was a suicide and that the evidence in the form of bloodstains on the victim’s outstretched arm supported his case for suicide.

This case went to trial and the full shooting incident reconstruction was presented to inform the jury about the impossibility of the woman using the particular handgun to shoot herself. Anthropometric data produced by a kinesiologist was used to validate the length of the victim’s arms and the limits of the victim’s reach.

One issue was the early crime scene photos that showed the location and the orientation of the revolver used in the incident. The handling of the firearm by the first arriving police officer was somewhat uncommon, but his actions were very helpful in subsequent analysis of the incident and in the understanding of what could and could not have occurred.

One of the principle evidence items used by both prosecution and defense in the criminal trial was the absence of gunshot residue on the suspect and on the blanket that covered the victim. An identical blanket was obtained and used for gunshot residue testing which, when compared with forensic laboratory testing, provided a valid distance determination. An important part of the reconstruction was to understand and communicate the significance of the gunshot residue evidence to the jury. The limitations of the significance of gunshot residue on a suspect’s hands was researched in the forensic literature and in the guidelines and practices of several forensic and law enforcement agencies. Additional evidence was evaluated by use of a human model to simulate the victim’s ability to hold the firearm.

---

### **Shooting Reconstruction, Bloodstain, Gunshot Residue**

### **B90 Crowbar Paints in Forensic Investigations With In-Depth Techniques: A Casework Investigation and the Start of a Multi-Technique Database**

*Peter de Joode, Rotterdam, Zuid Holland 3085NP, NETHERLANDS; Xiaoma Xu, PhD, Netherlands Forensic Institute, The Hague, ZH 2497 GB, NETHERLANDS; Jill R. Klaasse, The Hague, NETHERLANDS; Maurice Olderiks, Netherlands Forensic Institute, The Hague, South Holland 2497 GB; Zita Y. van Zanten, Netherlands Forensic Institute, The Hague 2497GB, NETHERLANDS; Gerard J.Q. van der Peijl, PhD\*, The Hague 2490 AA, NETHERLANDS*

**Learning Overview:** This presentation addresses the application of highly discriminating multi-technique investigations in crowbar paint investigations, demonstrates how information on the background variation can be obtained, and how these results can be used in reports to assist the court.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how detailed information can be extracted from the paints and used in highly discriminating in-depth comparison investigations, how to obtain information on the meaning of any matches found, and interpret and report this information to the courts.

Crowbar paints are often very discernible (e.g., an orange crowbar paint on a white door frame in a burglary). The preconception was that the paint in many situations consists of a single layer. As in most other forensic institutes, the backbone of the Netherlands Forensic Institute (NFI) paint investigation is the visual investigation and comparison of paints using microscopy and Fourier Transform Infrared (FTIR) investigations. A database of FTIR data with 49 orange/red burglary tool paints is presently used for reference purposes and to assist in interpretation. For interpretation, a likelihood approach is used in which the probability of results in the prosecutors' scenario is estimated relative to the results in the defense scenario. A Likelihood Ratio (LR) range approach is used and expressed in verbal terms.

At the NFI in recent years Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) is also used in paint investigations. Results will be presented for a single series of five attempted burglaries where orange-red paint found at the site of the burglaries is compared to original paint from a crowbar as found with a suspect, and paints found on the crowbar are compared to original paints from the sites of the burglaries to determine potential paint cross-transfer. Results from microscopic, FTIR, and LA-ICP/MS investigations from this casework investigation complex will be presented and discussed.

Conclusions for these five burglaries ranged from appreciably more probable (LR 100–10,000), through more probable (LR 10–100), and slightly more probable (LR 2–10), to approximately equally probable (LR 1–2) that the investigated object had been in contact with the orange-red crowbar under investigation relative to the situation that the investigated object had been in contact with another at-random orange-red crowbar.

For one attempted burglary, the transferred orange-red paint was clearly different from the crowbar under investigation but might have been transferred from another orange-red crowbar. Therefore, for this specific attempted burglary, no indication was found that the investigated object had been in contact with the orange-red crowbar under investigation.

As part of further improvement of the NFI crowbar paint investigation process, paints from a set of 21 orange/red crowbars and 13 paint samples from orange/red crowbars were investigated using the above techniques. In addition, Liquid Chromatography/Mass Spectrometry (LC/MS) was used to obtain information on colorants.

Overall, more than 50 (organic and inorganic) colorants and some colorant/binding-related organic compounds were identified using LC/MS.

Visual, FTIR, LC/MS, and LA-ICP/MS results will be presented for these paints and discussed. Variation within the paint on a single crowbar using these techniques will be addressed. In this way, information on the background variation (variation in these characteristics for visually similar orange and orange-red paints of crowbars, unrelated to the crime being investigated) can be extracted for these characteristics.

Discussion will include how to use the results from this limited set of paints to assist in the interpretation of matches in crowbar paint comparisons to visually similar paint observed (e.g., at a burglary site).

#### **Crowbar Paint, LC/MS, LA-ICP/MS**

### B91 The Refinement and Application of a Kinetic Model to Predict the Evaporation of Gasoline for Fire Debris Analysis

Amanda L. Setser, MS\*, Michigan State University, East Lansing, MI 48824; Victoria L. McGuffin, PhD, Michigan State University, East Lansing, MI 48824-1322; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** The goal of this presentation is to demonstrate refinement of a kinetic model to predict the evaporation of gasoline for use in forensic fire debris analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing the theoretical basis, refinement, and application of the model, which is subsequently used to predict chromatograms corresponding to gasoline evaporated to different levels.

One of the major challenges encountered in identifying gasoline in fire debris is the evaporation that occurs due to the high volatility of the liquid. In the heat of fire, the more volatile compounds undergo evaporation, changing the chemical composition of the liquid. The evaporation process can make comparisons of chromatograms of fire debris samples to ignitable liquids in a reference library more challenging. To address this challenge, reference libraries often contain chromatograms of experimentally evaporated ignitable liquids. However, as experimental evaporations can be time consuming, not every liquid in the library will be evaporated, and many liquids may only be evaporated to a few different levels.

The work presented here describes the refinement of a previously developed kinetic model to predict evaporation rate constants of compounds in ignitable liquids as a function of retention index ( $I^T$ ). In this case, retention indices are used as a surrogate for boiling point or vapor pressure, such that the chemical identity of the compounds in the liquid need not be known. The predicted rate constants are used to determine the total fraction remaining ( $F_{Total}$ ) of the liquid, which is related to the evaporation level. The fraction remaining is then plotted as a function of  $I^T$  to predict chromatograms corresponding to a range of evaporation levels. The model was originally developed and validated with petroleum distillates and, for these liquids, strong correlation was observed between experimental and predicted chromatograms corresponding to evaporation levels of 30%–90% evaporated. However, for gasoline, only moderate correlation was observed between experimental and predicted chromatograms, particularly at higher evaporation levels.

In this work, the model was refined to enhance the predictive accuracy, specifically for gasoline. The original model was developed across the  $I^T$  range 800–2,200; however, gasoline contains very volatile compounds that elute at  $I^T < 800$ . The first step in refining the model was to identify these volatile compounds and to experimentally determine corresponding evaporation rate constants. Unevaporated gasoline samples were analyzed by Gas Chromatography/Mass Spectrometry (GC/MS), and volatile compounds eluting before toluene ( $I^T=750$ ) were identified. A total of 14 compounds with  $I^T < 750$  were identified, including methyl butane ( $I^T=478$ ), hexane ( $I^T=600$ ), benzene ( $I^T=640$ ), heptane ( $I^T=700$ ), and methylcyclohexane ( $I^T=710$ ).

For safety reasons, two-component mixtures of the 14 volatile compounds were then prepared and experimentally evaporated to determine evaporation rate constants. Each mixture was evaporated in replicate in a temperature- and humidity-controlled chamber for up to 16 hours. Samples were removed at various time points during the evaporation process and analyzed by GC/MS using standard procedures. The chromatographic abundance of each compound was normalized and plotted versus time to generate first-order decay curves, from which the experimental rate constant was determined. For example, the experimentally determined evaporation rate constants for heptane, toluene, and octane were  $0.298\text{hr}^{-1}$ ,  $0.168\text{hr}^{-1}$ , and  $0.118\text{hr}^{-1}$ , respectively, which compare well with the rate constants predicted using the original model ( $0.307\text{hr}^{-1}$ ,  $0.189\text{hr}^{-1}$ , and  $0.105\text{hr}^{-1}$ , respectively). The experimentally determined rate constants were then plotted as a function of  $I^T$ , and linear regression was performed to refine the model across the  $I^T$  range 500–800.

### B92 Photogrammetry Using Visible, Infrared, Hyperspectral, and Thermal Imaging of Crime Scenes

Gerda Edelman, *Netherlands Forensic Institute, The Hague, 2497 GB, NETHERLANDS*; Maurice Aalders\*, *AMC, Amsterdam, North Holland 1105AZ, NETHERLANDS*

**Learning Overview:** The goal of this presentation is to show the possibilities and challenges of the use of photogrammetry for 3D recording of crime scenes with various layers of information, such as thermal and chemical.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by offering a method for revisiting the crime scene in 3D, including the possibility of extracting chemical and thermal information of the objects in the scene.

Photogrammetry is used to obtain virtual 3D models of objects and scenes. The photogrammetry variant Structure-from-Motion (SfM) uses computer vision methods that detect and match features between multiple images to estimate camera locations and orientations and the 3D structure automatically, without the need for previously placed targets. The technique has proven its value in many application areas, especially in geoscience, remote sensing, and archaeology. In forensic casework, the technique is increasingly used to record the crime scene in its original, undisturbed state. Some application areas where this geometrical mapping is especially useful are the investigation of traffic incidents; for example, high resolution documentation of surfaces of human bodies that have been injured and reconstruction of a suspect's height have been accomplished. The technique also provides a complete and metric 3D registration of objects at the crime scene, thereby allowing digital revisitation of the crime scene after its release, in turn enabling additional measurements and inspection of the crime scene from different angular perspectives. Its rapid, remote, and non-destructive manner of operation renders photogrammetry a powerful analytical tool ideally suited to the needs of both forensic science and forensic casework. Furthermore, its low cost, speed, accuracy, and ease-of-use facilitate its application at the crime scene by non-specialists and, consequently, its introduction into standard crime scene investigation protocols.

Recent developments of advanced imaging techniques have led to the exploration of the potential added value of cameras operating beyond the visible light range for forensic applications, in addition to the standard red/Green/Blue (RGB) imaging. For example, Infrared (IR) imaging can be used to detect gunshot residues or latent blood stains on dark surfaces. Furthermore, Edelman et al. showed that by using hyperspectral imaging (a combination of diffuse reflectance spectroscopy and digital imaging), it is possible to detect, identify, and even estimate the time of deposition of blood traces at the crime scene in an entirely non-contact fashion.<sup>1</sup> Similarly, thermal imaging has proven to be of forensic value in trace detection and is currently also being explored as a tool to measure postmortem human body temperatures. Together, these extra layers of information would be greatly beneficial in the reconstruction of crime scenes, revealing traces, invisible to the naked eye, along with their chemical composition and thermal properties.

In this presentation, several scaled 3D models made from stacks of visible, IR, hyperspectral, and thermal images will be shown using the photogrammetric technique SfM and will demonstrate the benefits for crime scene investigations. While some practical challenges remain to be addressed prior to standard application of the technique at real crime scenes, these results establish SfM as a powerful forensic tool and substantiate the added value of such consolidated data sets in forensic investigations.

### B93 Forensic Gait Analysis: The State of the Science and a Case Study

Michael S. Nirenberg, DPM\*, *Friendly Foot Care, PC, Crown Point, IN 46307*

**Learning Overview:** After attending this presentation, attendees will understand the current scientific foundations and limitations of utilizing forensic gait analysis to link a suspect to a criminal based on how they walk (their gait).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight and knowledge into the relatively new, emerging field of forensic gait analysis, which has been used in more than 100 criminal cases in the United Kingdom and is now being increasingly used in the United States.

Forensic gait analysis allows investigators to link (or unlink) suspects to criminals by how they walk (their gait)—evidence that in the past has often been overlooked. With increasing frequency, perpetrators are captured on surveillance video and, at times, even with their faces obscured or hidden; their gait may link the image to a suspect.

In the United Kingdom, forensic scientists in conjunction with government officials are finalizing a Forensic Gait Analysis Code of Practice setting forth guidelines on how forensic gait analysis should (and should not) be utilized. The Code defines forensic gait analysis as "... the analysis, comparison, and evaluation of features of gait to assist the investigation of crime."<sup>1</sup>

Discussion will include how gait analysis was used to show that a person charged with murder walked differently than the perpetrator and will include a co-authored paper on the use of gait as evidence with an analysis of criticisms of the science.<sup>2</sup>

Recent research has established the repeatability and reproducibility of forensic gait analysis using a specific methodology in addition to other factors that may affect the accuracy of forensic gait analysis.<sup>3,4</sup> As a result, this presentation will emphasize the limitations of forensic gait analysis and also its strengths by showing examples from a case study in which an armed robber was linked to a suspect.

Precautions and appropriate qualifications of persons who endeavor to become specialists in forensic gait analysis will be reviewed, in addition to discussing steps experts can employ to reduce bias and increase accuracy during the analysis process.

With video surveillance increasing and devices that enable recording of crimes becoming more widespread, the need for forensic gait analysis will likely grow, and, with biometric advances, the possible future of forensic gait analysis—a mix of technology and expert analysis—will be suggested.

### B94 Interdisciplinary Forensic Investigations—Combining Evidence in Complex Cases

*Irene Kuiper, Netherlands Forensic Institute, The Hague, Zuid Holland 2497 GB, NETHERLANDS; Jan A. De Koeijer, MD, Netherlands Forensic Institute, The Hague, Zuid Holland 2497 GB, NETHERLANDS; Gerard J.Q. van der Peijl, PhD\*, The Hague 2490 AA, NETHERLANDS*

**Learning Overview:** This presentation addresses the combination of evidence in interdisciplinary casework investigations to improve assistance to the courts in using the combined value of this forensic evidence. Attendees will learn how this can be accomplished and how this functions in practice.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the strength of forensic science in the use and reporting of combined evidence to the courts.

Single forensic expertise results are already relevant in police investigations and court cases. However, combining results from various expertise areas often contribute even more than the single expertise results. The question is, of course, how to combine these results.

This presentation will address the combination of results from complex interdisciplinary casework investigations at the Netherlands Forensic Institute (NFI) by certified experienced experts (three certified experts out of a population of 136 NFI experts). These three experts have had additional training to be an expert in combining results from specific expertises (pathology, toxicology, DNA, fibers, glass, Gunshot Residue (GSR), guns, digital evidence, etc.). Two other experts are presently trained for this role.

A combined expertise report is produced in these interdisciplinary casework investigations in which the combination of results from the separate disciplines is evaluated using at least two mutually exclusive scenarios, as agreed on by both the prosecutor and the defense. Often, results from the separate expertises need to be re-evaluated under these scenarios, common to all disciplines. Sometimes additional investigations are instigated. Previously, results from each single expertise have generally already been reported separately at source level using scenarios that are tailored to the strength of the specific discipline.

The interdisciplinary scenarios are mostly at the so-called activity level. Currently, the evaluation and reporting of forensic evidence at the activity level is one of the major challenges for the forensic community. Much has been written already on activity level evaluation for trace evidence, such as DNA, fibers, glass, etc. Bridging the gap between source level and activity level interpretation is still a major challenge, however. It promises to bring a wealth of possibilities for a more formal interdisciplinary approach to the evaluation of forensic evidence. In this presentation, a methodology is proposed for the evaluation of interdisciplinary evidence within the likelihood ratio framework.

Prosecution and defense scenarios are analyzed for forensically verifiable “core elements” (often offense-related activities in the case) for which activity level core propositions are formulated. Evidence schemes are introduced in which two main types of evidence relations are identified: serial and parallel evidence.

The evidential value of a serial evidence chain is analyzed in detail and shown to be at least as strong as the weakest link in the chain. Parallel evidence chains from one or more forensic disciplines evaluated in light of the core propositions may be combined, taking into account possible conditional dependencies.

The likelihood framework in combination with the evidence schemes allows the expert to combine interdisciplinary evidence in a probabilistic but still intuitive manner. Assumptions and choices are made in a transparent way. If conditional dependencies are present, a Bayesian network may be set up to take into account these dependencies.

At the NFI, these interdisciplinary reports are reviewed by a team of experts: both the experts for the original expertise areas from which results are used in the report, another interdisciplinary expert, and one of the NFI principal forensic scientists.

Specific examples will be presented on how this approach is applied in casework investigations. The present approach is the result of NFI’s experience over the past 20 years in combining results in interdisciplinary casework investigations in one form or another.

### **B95 See the Forest for the Trees: A Non-Targeted Approach to Discerning Exposure to Explosives Using Matrix-Assisted Laser Desorption/Ionization-Mass Spectrometry (MALDI-MS) and the Multivariate Statistical Model Random Forest**

Cameron M. Longo, BS\*, State University of New York at Albany, Albany, NY 12222; Samira Beyramysoltan, PhD, State University of New York at Albany, Albany, NY 12222; Rabi A. Musah, PhD, State University of New York at Albany, Albany, NY 12222

**Learning Overview:** After attending this presentation, attendees will have learned about the field of touch chemistry biometrics, how this can be applied to establishing an individual's exposure to explosive materials, some of the challenges associated with this type of analysis, and how these challenges can be overcome using a multivariate statistical analysis-facilitated approach to determine compounds that are diagnostic of exposure to explosives.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the benefits of performing MS analysis on latent fingerprint evidence and demonstrate an approach to do so. This presentation will also acquaint attendees with using statistical analysis methods to extract pertinent information from acquired data and use it to establish exposure to a substance when diagnostic ions are not immediately apparent in the mass spectra.

**Hypothesis:** MALDI-MS can be used with multivariate statistical analysis to extract information about which masses detected in latent fingerprints are diagnostic of exposure to explosives.

**Synopsis:** Experiments aimed at detecting and imaging of explosive compounds in fingerprints for the purposes of establishing exposure is the subject of this work. This is accomplished through MALDI-MS imaging and the identification of ions that are diagnostic of a particular explosive. For example, for TNT, a prominent ion at nominal  $m/z$  226 is detected, corresponding to the (M-H)<sup>+</sup> ion. However, for some explosives, intuitively obvious diagnostic ions are not as readily apparent. For example, while RDX produces diagnostic ions by Direct Analysis in Real-Time Mass Spectrometry (DART<sup>®</sup>-MS), these ions are not observed by MALDI-MS.<sup>1</sup> This could be due to interference from the matrix required to ionize the sample or the differences in ionization mechanisms between the two techniques. Nevertheless, exposure to RDX can still be revealed using statistical analysis of the mass spectral data. By using the entire body of information collected from an MS experiment, instead of simply selecting one or two diagnostic ions, a discrimination model that enables identification of indicative fragment ions can be created. The work presented here will demonstrate that MALDI-MS analysis of latent fingerprints, combined with multivariate statistics, can be used to confirm an individual's exposure to explosives such as RDX.

**Methods and Results:** Briefly, five volunteers donated fingerprints for MALDI-MS analysis. Control fingerprints were taken prior to exposure, and RDX-laden fingerprints were taken after donors rubbed their forefingers through ~50 $\mu$ L of dilute RDX that had been dried to a residue on a watch glass. The matrix 9-aminoacridine was then applied to the fingerprints, after which they were analyzed by MALDI-MS. A total of 500 spectra were collected from RDX-laden fingerprints. These spectra were used as the basis for training a Random Forest (RF) model using MATLAB<sup>®</sup>. The RF was performed with two classes: (1) RDX-laden fingerprints; and (2) control prints and background. One-third of the data collected were used for validation of the model. Permutation-based importance of predictive variables was used to extract information about which  $m/z$  values were important in enabling accurate classification of samples. This model was used to successfully discriminate RDX-laden prints from others, with an accuracy rate of 100%. Additionally, the masses predicted as important for discrimination include nominal  $m/z$  102 and 129, which are known RDX fragments whose formation has been studied by both tandem mass spectrometry and density functional theory.<sup>2</sup>

**Conclusion:** The chemical information stored within a fingerprint could be of great value to investigators, though it generally remains underutilized. This information can be probed with MS imaging techniques and used to provide insight about donor exposure to chemicals of forensic relevance, such as explosives. In cases where diagnostic ions are not known or apparent, multivariate statistics can be used with the MS data acquired to reveal which ions are indicative of exposure.

### B96 Smokeless Powder Additive Profiles and Compound-Specific Stable Isotope Signatures for Potential Brand Identification and Sample Discrimination

Claire J. Page\*, Pennsylvania State University, State College, PA 16801; Ryan Schonert, MPS, VUV Analytics, Cedar Park, TX 78613; Todd Sowers, Pennsylvania State University, State College, PA 16801; Wayne Moorehead, MS, forensicTRACE, Rancho Santa Margarita, CA 92688; Jack Hietpas, PhD, Pennsylvania State University, University Park, PA 16802

**Learning Overview:** After attending this presentation, attendees will better understand the strengths and limitations of Gas Chromatography/Mass Spectrometry (GC/MS) profiling and isotopic analysis for differentiation, comparison, and potential brand identification of commercially available smokeless powders.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the value of utilizing multiple techniques for the characterization and comparison of smokeless powders that can potentially be recovered from inefficient and/or undetonated Improvised Explosive Devices (IEDs).

Small Arms Propellants (SAP) are readily accessible and cost-effective materials that firearms enthusiasts can acquire for the legitimate assembly of ammunition. Unfortunately, the ease of access to and low cost of these materials is advantageous for their utilization in the construction of IEDs. Typically, the SAP charge is loaded into a metal pipe and sealed with screw-fit end caps. Two recent high-profile domestic terrorist attacks using IEDs (Boston Marathon Bombing and New York/New Jersey attempted bombings) demonstrate their continued usage. Thus, there is a need to develop robust metrics for the characterization of propellants that are used as explosives, as well as for comparisons between exemplar and recovered explosive residues.

The goals of the presented research are to investigate GC/MS additive profiles of SAP and compound-specific stable isotope signatures of SAP for potential brand identification and sample discrimination. One hundred sixty one-pound canisters of SAP were purchased from local firearms stores. The samples represent a wide selection of different distributors ( $n=8$ ) and product brands ( $n=160$ ). For GC/MS additive profiling, aliquots of 250mg for each sample were extracted with 5mL of 3:1 methanol:n-butanol, following the method described by Reardon and MacCrehan.<sup>1</sup> This method was chosen because it preferentially extracts the additives, leaving behind the bulk nitrocellulose. Samples were run using an HP6890 series gas chromatograph equipped with an Agilent® 5973 MSD and an RTX-1 column (30m x 0.25mm ID x 0.25 $\mu$ m). The identified additives were primarily nitroglycerin, ethyl centralite, diphenylamine, and dibutyl phthalate. Of the 110 samples analyzed by GC/MS, 83% were double-base and 17% were single-base powders with 80% of the analyzed powders containing diphenylamine, 45% of the powders containing dibutyl phthalate, and 65% of the powders containing ethyl centralite; 73% of the additive profiles analyzed by GC/MS were the same as at least one other profile. It was noted that many samples that gave the same GC/MS additive profiles could be differentiated by powder granule morphology.

Nitrogen and carbon isotope signatures were measured using isotope ratio mass spectrometry. This was accomplished by loading samples into a Costech 4010 element analyzer. The capsule containing the samples was placed into a heated zone containing chromium and cobalt catalysts along with pure oxygen to convert all of the nitrogen ( $N_2$ ) and carbon to nitric acid (NO) and carbon dioxide ( $CO_2$ ). The helium carrier stream carries the  $N_2$ , NO, and  $CO_2$  to a reduced copper furnace where the NO species are reduced to  $N_2$ . The sample stream then proceeds to a GC column where the  $N_2$  and the  $CO_2$  are chromatographically separated. The separate  $N_2$  and  $CO_2$  peaks are then routed to a ConFlo III interface. The open split in the ConFlo III feeds the MAT 252 MS along with reference peaks of pure  $N_2$  and  $CO_2$ . All peaks were integrated and the  $\delta^{15}N$  and the  $\delta^{13}C$  of the samples calculated relative to the reference peaks in the chromatogram.

The SAP sample isotopic compositions were examined to determine if there were recognizable geographic signatures. SAP manufactured in Canada and Belgium cluster in the most negative  $\delta^{15}N$  and the  $\delta^{13}C$  space. The samples from Finland tightly cluster with negative  $\delta^{13}C$  and positive  $\delta^{15}N$ , thus allowing for discrimination of these powders. Samples from Sweden cluster in the center of the data set. Samples from the United States and Australia tend to show the least negative  $\delta^{13}C$  compositions and the positive  $\delta^{15}N$  signatures. This clustering is encouraging but will require a more complete dataset to draw robust conclusions.

The results from this study show there is a need for the fusion of data from different analytical methods for more robust sample differentiation and comparison.

### **B97 A Study of the Thermal Decomposition of Nitrate Ester Explosives by Gas Chromatography/Vacuum Ultraviolet Spectroscopy (GC/VUV) and Its Application to Post-Blast Debris**

*Courtney Cruse, BS\*, Indianapolis, IN 46217; John V. Goodpaster, PhD, Forensic and Investigative Sciences Program, Indianapolis, IN 46202*

**Learning Overview:** After attending this presentation, attendees will be better informed about the thermal decomposition of nitrate ester explosives and its impact on analyzing realistic post-blast debris.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by discussing a recently developed detector for GC/VUV and its applicability to the analysis of nitrate ester explosives and post-blast debris.

The method employed in this research consisted of an Agilent® 7890B GC (50°C hold 0.5min, ramp 20°C/min to 280°C) with a multimode inlet (50°C to 280°C at 900°C/min), a hydrogen carrier gas (3.2ml/min flow rate), and a Restek® Rtx-5MS column (15m x 0.32mmID x 0.25µm) was utilized in line with a VGA-101 VUV spectrometer. The VUV spectrometer was operated with nitrogen as the make-up gas (0.35psi) and a transfer line/flow cell temperature range of 190°C to 300°C between 125nm and 430nm. This method was utilized to analyze the thermal decomposition of four nitrate ester explosives: NG, EGDN, ETN, and PETN, as well as post-blast debris of double-base smokeless powders.

Nitrate ester explosives thermally decompose in the transfer line of the VUV detector into nitric oxide, carbon monoxide, formaldehyde, oxygen, and water. The explosives decompose into differing stoichiometric ratios of the decomposition products and contribute to variation in each nitrate ester explosive VUV spectrum. Due to adherence to Beer Lambert Law, the percentage of each decomposition product was determined by spectral subtraction. The percent contribution of the decomposition products at 300°C was optimized using the Excel® Solver tool. The explosives decreased in concentration with increasing temperature in a logistical fashion. Using JMP software, a 2 parameter logistic fit was utilized to identify the inflection point (the point at which 50% of explosives were degraded) of the sigmoidal curve. These temperatures ranged from 243.74°C to 248.23°C.

The sensitivity of the GC/VUV for nitrate ester explosives was evaluated by looking at the peak area over the range of transfer line/flow cell temperatures. Results indicated that at lower temperatures, NG and ETN had greater sensitivity, while PETN had variable responses and EGDN did not have significant changes in peak area with changing temperatures. Limits of detection for these compounds analyzed with a transfer line/flow cell temperature of 240°C were calculated at low ppm.

To investigate the applicability to forensic post-blast debris analysis, the Indiana State Police Bomb Squad assisted in obtaining realistic samples of post-blast residues of double-base smokeless powder (Alliant Red Dot) on galvanized steel and Polyvinyl Chloride (PVC) pipe fragments. The pipes were placed in a perforated steel box prior to initiation to allow for collection of the post-blast debris for analysis. These samples were analyzed using the same method described above at a transfer line/flow cell temperature of 240°C. The analysis of the post-blast debris of these two types of devices showed that, for the first time, GC/VUV can be used to identify NG as the energetic material with diphenylamine and ethyl centralite as additives in post-blast debris.

### **B98 An Update on the Academy Standards Board (ASB) Firearms and Tool Marks (FATM ) Consensus Body**

*Gregory E. Laskowski, MPA\*, Criminalistics Services International, LLC, Bakersfield, CA 93308*

---

**Learning Overview:** The goals of this presentation are to describe to attendees the purpose of the ASB FATM Consensus Body and to present updates as to the Body's work on developing and approving standards in the disciplines of firearms and tool marks analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees information on what the mission of the FATM Consensus Body is and the progress it has made and is making in creating standards in the area of firearms and tool mark examinations.

The American Academy of Forensics Sciences created the Standards Board (ASB) as a response to the need for standardization from the forensic community. This was in line with recommendations in the 2009 NAS Report.<sup>1</sup> It is now working in cooperation with the Forensics Science Board of the Organization of Scientific Area Committees (OSAC). The purpose of the FATM Consensus Body is that it focuses on standards and guidelines related to the examination of firearm and tool mark evidence. This includes the comparison of microscopic tool marks on bullets, cartridge cases, and other ammunition components and may also include firearm function testing, serial number restoration, muzzle-to-object distance determination, and analysis of tools and tool marks.

This presentation will discuss the inception of the ASB, its legal status as an entity, its membership, its mission, a discussion on its consensus bodies with particular emphasis on the discipline of firearms and tool marks. Created in 2016, and under ASB Secretariat Brad Wing, the FATM Consensus Body is made up of 33 members representing a number of disciplines that include subject matter experts, general interest, consumer groups, user/government (federal, state, and local), academia, producers, and user/industry. Besides members, there are observers, as well as managers from the ASB. Observers and other non-members are encouraged to participate by reviewing documents and offering comments. Standards can be developed by the Consensus Body or offered by other bodies, such as the OSACs. Once documents containing recommended standards and guidelines are submitted to the Consensus Body, they will be reviewed by members of that body, and changes to those documents may be made to meet American National Standards Institute (ANSI) publishing guidelines. Once the documents have been reviewed, they will be offered up for public comment. Any and all public comments must be reviewed and addressed by the Consensus Body. After final review, the documents will be published as guidelines or standards.

It is imperative that all members participate, and that those individuals and bodies affected by proposed standards and guidelines participate by subscribing to FATM Consensus Body communications, listen in to meetings, which are broadcast on Join Me, read the documents, and offer constructive comments.

### B99 Forensic Implications of a New Polymer Bullet

*Peter J. Diaczuk, PhD\*, Pennsylvania State University, State College, PA 16802; Xiao Shan Law, MPS, Albany, NY 12206*

**Learning Overview:** After attending this presentation, attendees will have an understanding of the manufacturing process for this non-traditional polymer bullet, its behavior at impact with some common substrates, and its composition and microscopy.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the challenges to correlating a polymer bullet to the firearm using comparison microscopy.

A few years ago, a new entry into environmentally friendly ammunition appeared on the commercial market. PolyCase® Inceptor® ammunition, out of Savannah, GA, has created a new bullet design and construction. PolyCase® Inceptor® ammunition has some novel design features in all of their marketed products, specifically the construction and unique shape of their ARX® Defense bullet. Prior studies have shown that traditional jacketed and hollow point bullets have predictable interactions with many yielding and non-yielding intermediate substrates. The newly marketed ARX® Defense bullet behaves quite differently than previous bullet designs. Not only is the bullet lead free, it is comprised of a metal-polymer matrix, manufactured using an injection molding process. This manufacturing process does not lend itself to a traditional hollow point design; however, the bulletsmiths at PolyCase® Inceptor® ammunition have devised a unique alternative to a cavity in the form of three large “flutes” in the ogive of the bullet. The resulting non-expanding design of the ARX® Defense bullet is lightweight and, thus, travels faster than its lead or jacketed counterpart.

To determine the ingredients of this new line of polymer bullets, samples were deconstructed by dissolving the polymer in a suitable solvent, which allowed the metal spheres to settle to the bottom of the vessel. The metal spheres were assessed with scanning electron microscopy/energy dispersive spectroscopy, which as the manufacturer acknowledges, were found to be copper. Infrared spectroscopy revealed that the polymer is nylon. Nylon is by no means a newcomer to ammunition, as it has been used as a coating in some calibers, notably .38 Special, for decades. However, in the old S&W® and Federal® offerings, whether in .38 Special or their other calibers, the nylon merely encased a lead core. This is where the PolyCase® Inceptor® ammunition differs substantially, as the lead core has been eliminated.

Several calibers and styles of PolyCase® Inceptor® ammunition were test-fired at various barriers, including concrete block, gypsum drywall, paneling, plywood, architectural glass, windshield glass, and sheet metal of different thicknesses or gauges. Automobile sheet metal provided the most characteristic bullet holes when perforated by the fluted ARX® Defense bullets as compared to traditional hollow point or full metal jacket bullets. The fluted ARX® Defense bullets consistently created holes in the sheet metal that were triangular in shape. The larger the caliber, the larger the size of the triangular bullet hole. The results were replicated using firearm barrels with both left-hand and right-hand twist directions, and different barrel lengths, which offered slightly different velocities as measured with a chronograph near the muzzle of the firearm. These variables did not have a visible effect on the shape of the holes created.

In addition to assessing the bullet hole itself, high-speed photography revealed that a piece of metal was being dislodged from the substrate by the bullet’s impact. To capture this “punchout” or “plug,” ballistic gelatin was placed near the anticipated exit hole of the bullet, which allowed recovery of many of the small metal pieces that were dislodged. Interestingly, these metal pieces were also triangular in shape, whereas punchouts or plugs from traditional hollow point or full metal jacket bullets are rosette or circular, respectively.

Last, comparison microscopy was attempted in an effort to associate a fired bullet to the firearm from which it was fired.

### **B100 The Power of Statistics and Machine Learning Applied to Orthogonal Rapid Methods for the Identification of Inorganic Gunshot Residue (IGSR) and Organic Gunshot Residue (OGSR) Markers**

*Korina Menking-Hoggatt, MS\*, Morgantown, WV 26501; Colby E. Ott, MS, Shippensburg, PA 17257; Courtney H. Vander Pyl, MS, Department of Forensic and Investigative Science, Morgantown, WV 26506; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506; James M. Curran, PhD\*, University of Auckland, Auckland 1142, NEW ZEALAND*

**Learning Overview:** After attending this presentation, attendees will be aware of a novel fast approach to detect IGSR and OGSR and machine learning tools to interpret the data.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a method to rapidly detect GSR that could provide investigative leads and improve intelligence operations for firearm-related crimes, which could create a greater sense of well-being in society, considering the risk to public safety posed by firearms.

Machine learning is a powerful tool for providing rapid information in our data-driven world. Reliance on these algorithms extends to everyday life in order to search the internet, to provide directions when traveling, to protect devices using facial recognition, and to enhance the reliability of a medical diagnosis, to name a few applications. Machine learning can be applied to the identification and interpretation of forensic evidence, providing fast results when time is of the essence. Firearm-related investigations is a field in forensics that requires fast decision-making. In one example, acoustic systems have been adopted in more than 90 United States cities to detect the location of possible gunshots and allow for police response to the scene in a matter of minutes. In another example, the current method of detection of GSR from the hands of individuals of interest is time-consuming and cannot deliver results fast enough to provide efficient investigative leads. This research presents the development of a rapid method for the detection of both IGSR and OGSR using two orthogonal technologies: Laser-Induced Breakdown Spectroscopy (LIBS) and Electrochemistry (EC), with machine learning for data interpretation.

A study was conducted on 100 background samples and 80 known shooter samples collected using conventional GSR stubs (carbon adhesive on aluminum Scanning Electron Microscopy [SEM] pin mounts) and processed using two sequential rapid methods on the same sample. First, LIBS was conducted using micro-chemical mapping to provide IGSR detection within less than two minutes per sample. Following LIBS, EC was performed on the same stub. The ablation area was spiked with 50 $\mu$ L of acetate buffer pH 4.5 followed by 50 $\mu$ L of acetonitrile, which was evaporated and reconstituted with the aqueous fraction before being applied to a disposable Screen-Printed Carbon Electrode (SPCE). Square-wave voltammetry was applied for an analysis time within five to ten minutes. Lastly, data preprocessing was performed for the application of three different prediction algorithms: Naïve Bayes, logistic regression, and a neural network.

LIBS allowed the detection of IGSR markers (lead [Pb], barium [Ba], antimony [Sb], copper [Cu], aluminum [Al], zinc [Zn]) while electrochemistry complemented the detection of IGSR (e.g., Sb, Cu, Zn, and superior detection of Pb) and also identified the presence of OGSR compounds, such as 2,4-Dinitrotoluene (DNT), Diphenylamine (DPA), Nitroglycerin (NG), Methyl Centralite (MC), and Ethyl Centralite (EC). The performance of these methods was evaluated individually, then combined. Alone, the accuracy of the LIBS method was better than 86%, and the EC method was better than 75%, depending on the classification method. When the two techniques were combined, the accuracy improved to better than 92%.

In the future, this study will be expanded to include modern ammunition that could lack the typical GSR markers of Pb, Ba, and Sb to test the ability of machine learning to differentiate between different classes of ammunition. In addition, samples from individuals with professions or hobbies where false positives are common will be included and deemed a “high-risk” sample population. The high accuracy of the combined methods fills a critical need in the forensic science community for a rapid technique for the detection of GSR.

#### **Gunshot Residue, Machine Learning, Rapid Technology**

### **B101 The Characterization and Detection of Organic and Inorganic Firearm Discharge Residue (FDR) Using High-Performance Liquid Chromatography-Triple Quadrupole (HPLC-QQQ) and Host-Guest Chemistry**

*William Feeney, BS\*, New Martinsville, WV 26155; Suzanne Bell, PhD, West Virginia University, Morgantown, WV 26506; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506*

**Learning Overview:** After attending this presentation, attendees will better understand a novel method developed for the detection of Inorganic Gunshot Residues (IGSR) and Organic Gunshot Residues (OGSR) by LC-QQQ and how its use in forensic laboratories could enhance interpretation of GSR evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by contributing toward the enhancement of the evidentiary value of FDR by providing dual detection of IGSR and OGSR, as well as assisting in the understanding of metal-ligand interactions for other types of applications (e.g., environmental extractions, drug delivery, and organometallics).

FDR or GSR contains both organic compounds (OGSR) and inorganic particulates (IGSR) originating from the powder and primer, respectively. When fired, the heat of the ignition burns the powder and propels a bullet or pellets forward. After the projectile leaves the barrel, a plume of burned and unburnt particulates and powder are spread into the surrounding environment and attach to nearby persons and objects. The current standard practice for GSR analysis relies on the identification of particle morphology and elemental composition of IGSR (American Society for Testing and Materials [ASTM] E1588-17). Nonetheless, there is still a need to complement the examination of IGSR by detecting organic residues' markers. Advances in multiple analytical techniques allow for the detection of OGSR in the ppm and ppb range and IGSR in the ppb to ppt range using Liquid Chromatography/Mass Spectrometry (LC/MS), Gas Chromatography/Mass Spectrometry (GC/MS), and Inductively Coupled Plasma/Mass Spectrometry (ICP/MS). The goal of this project was to perform a simplified confirmatory analysis of both IGSR and OGSR components using the same sample, the same column setup, on one instrument, via an HPLC-QQQ.

In this work, 11 analytes were under investigation: barium (Ba), lead (Pb), antimony (Sb), zinc (Zn), copper (Cu), N-nitrosodiphenylamine (N-NDPA), 4-nitrodiphenylamine (4-NDPA), 2-Nitrodiphenylamine (2-NDPA), Diphenylamine (DPA), Ethyl Centralite (EC), and Methyl Centralite (MC). To be analyzed by QQQ, the inorganic constituents must interact with larger, transporter molecules to traverse the columns toward the detector, whereas the organic molecules require no modification for characterization. The proposed idea includes two different types of binding agents, a cavitand (crown ether species) and a chelating agent (tartaric acid). A pre-column/column setup was used, consisting of a Polymeric Reversed-Phase (PRP) guard column with a trimethylammonium functional group for the tartaric acid and a Pentafluorophenyl (PFP) column for the separation and retention of crown ether complexes and organic constituents. Multiple Reaction Monitoring (MRM) methodology of HPLC-QQQ analytes was used for confirmation of isotope ratios and patterns for these analytes.

Furthermore, to corroborate the accuracy of the technique in characterizing and identifying Metal-Ligand (M-L) complexes, molecular modeling and High-Resolution Mass Spectrometry (HRMS) techniques such as Orbitrap™ were implemented. This work will demonstrate the extraction of multiple species from a single hand swab and address the efficiency of crown ether and tartaric acid complexation with the metals and species formed after the firing event. The validation of the proposed method includes analysis of standard solutions and a set of 50 blind samples collected from the hands of individuals who fired a gun and from those who had not handled a gun. Selectivity, sensitivity, and error rates are reported for the blind set. Limits of detection in the order of 1ppb to 10ppb and limits of quantitation between 3ppb to 30ppb were observed for all analytes of interest, with intra-day and inter-day precision better than 5% Relative Standard Deviation (RSD).

#### **Gunshot Residue (GSR), Simultaneous Detection Technique, HPLC-QQQ**

### **B102 A Study on the Transfer of Gunshot Primer Residue (GSR) From Fabric to Other Surfaces**

*Christopher P. Chany, MS\*, Texas Department of Public Safety, Austin, TX 78752; Thomas R. White, BS\*, Texas Department of Public Safety, Austin, TX 78752; Rebekah D. Lloyd, BS, Texas Department of Public Safety, Austin, TX 78752; Ashley Pittman, BS, Austin Crime Lab, Austin, TX 78752; Juan A. Rojas, BS, Texas Department of Public Safety, Austin, TX 78752*

**Learning Overview:** After attending this presentation, attendees will have a better understanding of the potential for GSR particles to transfer from fabric surfaces onto other surfaces.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing practitioners insight into the dynamics of GSR particle transfers from clothing to other surfaces. This presentation also describes the methods used to test this theory of transfer of GSR.

GSR is produced by a firearm when it is discharged. The primer for centerfire cartridges is mainly composed of lead styphnate, barium nitrate, and antimony sulfide. The residue from the primer explosion escapes from openings in the gun and is deposited on nearby surfaces, including a person's hands and clothing. These particles can be collected and analyzed using automated Scanning Electron Microscopy/Energy Dispersive X-ray Spectrometry (SEM/EDS). Characteristic GSR primer particles have a molten appearance and are composed of barium, antimony, and lead.

There have been numerous studies addressing the potential for the transfer of gunshot primer residue from hands to other surfaces (hands to hands, hands to clothing, etc.) However, there is a lack of research addressing the potential of GSR transfer from fabric to another surface. In this study, three types of transfers are addressed: transfer from one piece of cloth to a second clean piece of cloth, transfer from a piece of cloth to clean hands, and tertiary (and more) transfers between fabric surfaces.

Oftentimes, investigators will submit multiple items of clothing in the same paper bag and ask for GSR analysis on all the items. Occasionally, questions arise of not only whether GSR was present, but specifically where on the garments the GSR particles were recovered from. In order to answer this question, the GSR analyst needs to be able to assess the potential for GSR transfer between two pieces of fabric. This portion of the study consisted of shooting a cloth target, then placing a clean target into contact with the shot target.

In some shooting cases, a person of interest will state that they did in fact touch the victim either to perform Cardiopulmonary Resuscitation (CPR) or check to see if the person was alive. Since more gunshot primer residue escapes from the barrel than from near the handle, the majority of both homicide and suicide victims have gunshot primer residue on their person. To answer the question of whether or not this is a reasonable explanation for the presence of GSR on the hands, a study was conducted in which a target was shot at and an individual with clean hands touched the target near the bullet hole to determine if GSR can transfer from a comparatively porous surface (the cloth target) onto a comparatively smooth surface (the hands).

There have been several studies that examine the transfer of gunshot primer residue to the interior of police cars from a person who has gunshot residue on their person. There have not been studies conducted that try to determine the number of times gunshot primer residue particles could transfer from one surface to another. An analyst who does not handle firearms either in the lab or at home spent a day of training in the firearms section. At the end of the training, the analyst was asked to stub her clothing, her cubicle chair, the driver seat of her car, and any chairs that she may have sat in at her home in the same clothing she had worn to the training. These stubs were analyzed using SEM/EDS instrumentation using standard laboratory procedures for the analysis of gunshot primer residue.

This presentation will detail the results of a series of studies on the transfer of gunshot primer residue from clothing to clean areas that come in contact with the GSR-contaminated clothing. This research takes a novel approach by investigating the likelihood of transfers from clothing to other surfaces, including hands.

#### **GSR, SEM/EDS, Locard's Theory**

### B103 The Relationship Between Terminal Velocity and Glass Fracture via .177 Caliber Steel BBs

Jocelyn J. Beach, BA\*, John Jay College, New York, NY 10019; Linda C. Rourke, MS, John Jay College, New York, NY 10019; Peter J. Diaczuk, PhD, Pennsylvania State University, State College, PA 16802

**Learning Overview:** After attending this presentation, attendees will have gained knowledge in the study of low-velocity projectile impacts and the resulting fracture patterns on double-strength architectural glass. Attention will be focused on the Doppler radar system and its measurement of projectile velocity.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the effects of low-energy projectiles on architectural glass, which can be helpful in reconstructing glass fracture patterns at crime scenes.

Glass is an abundant material in the environment and can also be an abundant material found at crime scenes. It may often be the only thing between a bullet and its intended target, which is where fractography becomes necessary. “Fractography is the means and methods for characterization of fractured specimens or components.”<sup>1</sup> The majority of bullets will perforate or shatter most categories of glass; however, in some cases, the bullet may not have sufficient energy to shatter the glass at all. Correlating terminal velocity to the degree of glass fracture can provide useful information regarding the muzzle-to-target distance for a particular firearm/ammunition combination.

Mechanical glass fracture from a projectile impact can result in different types of fracture patterns, including radial and concentric fractures. The degree of fracture depends on several factors, including: type of glass, the thickness of the glass, curvature (if any), distance from the muzzle, and type of projectile. This research focuses on the terminal projectile velocity of .177 steel BBs shot from a pneumatic air rifle. Double-strength glass panes, of 1/8" thickness, were chosen due to its common use in commercial and residential properties. A Doppler radar system was used to measure the projectile velocity from muzzle to target and potentially beyond the target for perforated targets.

Other research has been presented on the subject of dynamic impact glass fracture using timekeeping instruments such as traditional chronographs.<sup>2-5</sup> The use of a Doppler radar system has the advantage of coupling Doppler processing with pulse radars to provide accurate velocity information with superior precision.

Pilot studies have been conducted to ascertain suitable muzzle-to-target distance ranges (12 to 20 feet), the number of pumps required to pressurize the air rifle propulsion system (one to three), and the means of measuring the ricochet distance for projectiles that do not perforate the glass substrate. The experimental methodology was developed from the pilot study results.

The goal of this research is to characterize the relationship between impact velocity and glass fracture pattern. The results of this study can be used to develop future experiments using other types of firearms and ammunition to study glass fracture patterns. It is intended that this research will aid in the advancement of glass fracture analysis, which can be useful in crime scene reconstruction.

### **B104 On the Migration Route: Challenges in the Forensic Application of Massively Parallel Sequencing (MPS) in Human Body Identification**

*Lucija Barbaric\**, Forensic Science Centre “Ivan Vucetic,” Zagreb 10000, CROATIA; *Ivana Horjan, PhD*, Forensic Science Center “Ivan Vucetic,” Zagreb 10000, CROATIA; *Adela Makar*, Forensic Science Center “Ivan Vucetic,” Zagreb 10 000, CROATIA; *Andrea Ledic, MS*, Croatian Forensic Science Centre Ivan Vucetic,” Zagreb 10000, CROATIA

**Learning Overview:** After attending this presentation, attendees will have an overview of the data obtained using MPS in the personal identification of migrants who perished on their way to Europe.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insights into the challenges of forensic identification as consequences of the migrant crisis in Europe.

The recovery of DNA profiles from unidentified individuals is an essential part of the identification process. The limits of traditional DNA typing, which is based on matching the DNA profile of the deceased to the family references or antemortem samples, is evident in cases without any available sample for comparison. Emerging technologies such as MPS generate more data from the DNA sample, without the need for a reference sample for comparative analysis. Moreover, the assessment of externally visible characteristics and biogeographical ancestry may be of assistance in the police investigation. The latter is additionally relevant in cases of missing persons and unidentified migrants who die when crossing borders. The Western Balkan Route has been one of the predominate migration pathways from Africa and the Middle East into Europe. Croatia is the most southeastern European Union member state on the abovementioned migration route. Recently, the Forensic Biology Laboratory (FBL) of Forensic Science Center “Ivan Vučetić” has received an increased number of human identification cases in which remains were recovered from the river borders between Croatia and neighboring countries. The aim of this study is to assess the applicability of the MPS method in the forensic identification of human remains without any family references and antemortem data.

Blood samples were obtained from well-preserved bodies and teeth and tissue samples from decomposed bodies, respectively. DNA typing was performed using the Applied Biosystems® GlobalFiler® and Y Filer® Plus PCR Amplification kits on AB3500 Capillary Electrophoresis (CE) instrument. Laboratory procedures and data interpretation using Gene Mapper® ID-X v.1.4 were completed according to the accredited workflow at the FBL.

In addition, a library was prepared using the Verogen ForenSeq™ DNA Signature Prep Kit B. A positive 2800M control, negative amplification control, and reagent blank were included. The library pool was sequenced on the Illumina® MiSeq® FGx Instrument. All steps were performed following the manufacturers’ instructions. Subsequent data analysis was performed using ForenSeq™ Universal Analysis Software (UAS) v.1.3 with default threshold settings. In order to estimate biogeographic ancestry and phenotype, the ForenSeq™ UAS and Snipper app v.2.5 were compared. In addition, paternal inheritance was evaluated using Whit Athey’s algorithm using a Bayesian approach.

The run quality metrics (cluster density, clusters passing filters, phasing, and prephasing) were within the recommended range. In total, 231 Short Tandem Repeat (STR) and Single Nucleotide Polymorphism (SNP) loci were typed for each sample, without contamination observed during the DNA typing process. Autosomal and Y-chromosomal Short Tandem Repeat (Y-STR) data obtained using MPS showed concordance with CE data. ForenSeq™ UAS classified four out of five samples in admixed American populations and one sample had European ancestry. However, Snipper assigned one sample in the European cluster, two samples between Europe and South Asia, one sample in the South Asia, and one sample slightly displaced toward the African cluster. This was consistent with the prevalence of determined Y-chromosome lineages. The UAS and Snipper prediction models agreed on the prediction of hair and eyes color. Moreover, the hair color of each individual was concordant with the data obtained from the medicolegal reports while eye colors could not be verified due to body decomposition.

The application of MPS can provide valuable data for personal identification in challenging forensic samples, such as human remains of migrants who die when crossing borders. The prediction of hair color, autosomal STR, and Y-STR data was consistent. However, the discordance was evident in ancestry prediction due to the lack of certain Eurasian population databases such as the Middle East. In the meanwhile, an individual of European ancestry has been identified and, for four remaining individuals, the analysis conducted here may contribute to the ongoing investigation.

#### **Massively Parallel Sequencing, Human Identification, Migration**

## B105 Advances in Microhaplotypes (Microhaps) as a Comprehensive Forensic Marker

Fabio Oldoni, PhD, The George Washington University, Washington, DC 20007; Leena Yoon, BS, Arlington, VA 22209; Aishwaryaa Subramanian, The George Washington University, Washington, DC 20052; Sathya Prakash Harihar, The George Washington University, Washington, DC 20007; Drew A. Bader, Washington, DC 20007; Sharon C. Wootton, PhD, South San Francisco, CA 94080; Robert Lagace, BS, Foster City, CA 94404; Ryo Hasegawa, BS, Foster City, CA 94404; Joseph P. Chang, BS, Thermo Fisher Scientific, South San Francisco, CA 94080; Kenneth Kidd, PhD, Yale University School of Medicine, New Haven, CT 06520; Daniele S. Podini, PhD\*, Department of Forensic Science, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will understand the current status of the research conducted on microhaps for forensics applications.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how microhaps are a comprehensive forensic DNA tool and how their implementation can complement conventional Short Tandem Repeat (STR) -based analysis.

Microhaps are biomarkers less than 300 nucleotides long that display multiple allelic combinations.<sup>1</sup> The main advantages of microhaps over conventional STRs include the absence of stutter, same-size alleles within each locus, lower mutation rate, and ancestry informative alleles. These forensically relevant loci can yield a power of discrimination similar to STRs while enhancing Human Identification (HID), mixture deconvolution, and biogeographic ancestry prediction. Sanger sequencing does not allow determining the cis/trans relationship among closely related SNPs while Massively Parallel Sequencing (MPS) allows determining the parental haplotypes at each locus by clonally sequencing of each DNA molecule if they are included in the same amplicon. Currently, STR panels are used for mixture deconvolution and SNP assays are used for ancestry inference. Microhaps can be used for both functions allowing, for example, to infer the ancestry of a minor contributor to a mixture (DNA intelligence). In this study, the current status of the research conducted in the George Washington-Forensic Molecular Lab (GW-FMB) lab and elsewhere on this new multi-function DNA marker and its potential impact to the field of forensic genetics will be discussed.<sup>2</sup>

A newly developed MPS assay of 74 microhap loci was evaluated on the Thermo Fisher Scientific™ Ion Torrent S5™ system to address different forensic research questions including human identification, mixture deconvolution, and ancestry inference.<sup>3-5</sup> For mixture deconvolution, two- to five-person mixtures at different DNA input were simulated, with each donor with a distinct ancestry and contribution ratio to simulate casework-like DNA samples. Mixture results were compared to conventional capillary electrophoresis-based STR and sequence-based STR analysis. To assist in the interpretation of microhap mixed profiles, two Probabilistic Genotyping (PG) software, LRMixStudio v2.1.4 (semicontinuous) and DNANView MixtureSolutions v18-6-20 (continuous), were adapted to microhap mixture data intake to evaluate the output compared to STRs.

The MPS assay improved the deconvolution of all tested mixtures and complemented results of size-based and sequence-based STR analysis. Overall, PG software facilitated and reduced the analysis time of microhap mixed profiles, proving the amenability of microhap data to casework implementation. These results also point toward the rapid development of new mixture deconvolution tools for the implementation of microhap profiling in casework in the near future as new and extremely polymorphic markers are being discovered. Rare variants have been identified that increase the power of discrimination of the assay and the ability to correctly infer the number of contributors to a mixture. Furthermore, biogeographic ancestry of the minor DNA contributor detected in a 10:1 and 20:1 two-person mixtures was accurately inferred by considering the unique minor alleles reported.

These results indicate that the emerging microhaps are an effective and comprehensive biomarker tool, which can be used to enhance and broaden forensic DNA investigations.

### Massively Parallel Sequencing, Microhaplotypes, Forensic Applications

### **B106 Assessing the Reliability of Single Nucleotide Polymorphism (SNP) Micro-Array Data for Forensic Genealogy**

*Robert A. Bever, PhD\**, Bode Cellmark Forensics, Lorton, VA 22079; *Jon Davoren, MS*, Bode Technology, Lorton, VA 22079-2625; *Erin Sweeney, MS*, Bode Technology, Lorton, VA 22079; *Teresa Vreeland, BS*, Bode Technology Group, lorton, VA 22079; *Mike Cariola, MFS*, Bode Technology, Lorton, VA 22079

**Learning Overview:** After attending this presentation, attendees will understand how the source of tissue, quantity of template DNA, and degree of degradation affects high-density SNP micro-array results. Additionally, attendees will learn how these variables affect the ability to identify related individuals through the searching of genealogical databases consisting of high-density SNP genotypes.

**Impact on the Forensic Science Community:** The data presented will provide the forensic science community with basic information regarding the effect of DNA quality and quantity on the accuracy and call rate of high-density SNP genotype profiles. The data presented can be used to determine whether DNA extracted from forensic samples will be suitable for SNP micro-array processing used in forensic genealogical applications.

Forensic Genealogy (FG) is a powerful investigative technique to aid in the identification of victims and suspects of unsolved crimes. By establishing the capabilities and limitations of FG, the community will be able to address the inevitable court challenges and more effectively use this technique to provide investigative leads associated with unsolved murders, sexual assaults, and missing person cases.

FG is a three-step process. Step 1 is the extraction and quantitation of DNA from forensic evidence or human remains. Step 2 is the generation of SNP genotypes using either high-density SNP micro-arrays or whole genome sequencing. These steps serve as the genetic foundation of subsequent downstream genealogical investigation. The final step is comparing the SNP data to genealogical databases by a professional genealogist.

In this study, the quality of high-density SNP micro-array data using varying amounts of DNA from blood and post-coital samples was evaluated by sending the same samples to three laboratories for either SNP chip or whole genome analysis. DNA extracts (2 to 200ng) purified from blood or post-coital samples were analyzed using the Illumina® Infinium™ National Institute of Standards and Technology Global Screening Array (GSA), the Infinium™ CytoSNP-850K Bead chip, and Whole Genome Sequencing based on the Illumina® NovaSeq™ technology. The SNP micro-array genotypes and sequence results were evaluated on call rates, accuracy (as compared to the whole genome sequence), and reproducibility within and between chips.

DNA extracted from blood and analyzed on the CytoSNP or the GSA chip had SNP call rates that ranged from 88.9% (2ng) to 99.78% (200ng). SNP call rates associated with post-coital DNA and analyzed with the GSA chip ranged from 50% (2ng) to 76% (50ng), whereas the same DNA processed on the CytoSNP array had call rates from 64% (2ng) to 91% (50ng). Intra-chip reproducibility was greater than 99% for samples with >10ng and as low as 97.8% for 2ng samples. Only 104,385 SNPs were common to both chips; concordant SNP genotypes between the two chips at these SNPs ranged from 82% to 89% with blood or post-coital DNA samples that had at least a 70% call rate.

When SNP genotype calls were compared to Whole Genome Sequencing data, the degree of concordance varied based on the amount of DNA, the degree of degradation, and the stringency level of the GENCALL Score using the Illumina® Genome Studio software. All the non-degraded DNA from blood and the post-coital samples with at least 10ng of DNA could be used to reliably match samples entered into genealogical databases, whereas highly degraded DNA with low-template amount could not match samples in the genealogical databases.

### **B107 Multi-Marker Match Statistics: Combining Results Across Sequence-Based Short Tandem Repeat (STR) and Identity Single Nucleotide Polymorphism (SNP) Markers**

*Katherine B. Gettings, PhD\*, National Institute of Standards and Technology, Gaithersburg, MD 20899; Andreas Tillmar, PhD, National Board of Forensic Medicine, Linköping SE-58758, SWEDEN; Peter M. Vallone, PhD, National Institute of Standards and Technology, Gaithersburg, MD 20899-8314*

**Learning Overview:** After attending this presentation, attendees will understand the considerations for calculating multi-marker statistics in kinship and routine forensic cases.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by ensuring attendees have an improved understanding of the statistical considerations for combining results across loci/markers, and ForenSeq™ users in attendance will receive actionable guidance.

Analyzing signs of linkage disequilibrium among population samples and father-son pairs will inform decisions regarding statistically combining markers.

Significant progress has been made in the past five years in developing the assays, bioinformatic methods, and population frequency data needed for the implementation of routinely sequencing STR markers. In addition, the forensic community is determining the utility of sequencing identity SNP markers, the smaller targets of which can outperform STRs in degraded samples. When both autosomal STR (auSTR) and autosomal identity SNP genotype data are present for a casework sample and these genotypes are consistent with a person of interest, laboratories are faced with the new challenge of reporting match statistics for a combination of marker types.

At this time, the most likely combination of markers to be genotyped concurrently, due to commercial availability, are the 27 auSTR and 94 Identity Informative SNP loci included in the Verogen ForenSeq™ DNA Signature Prep Kit. In the associated software user guide, the manufacturer indicates that the 121 autosomal genetic identity markers generally meet expectations of independence at the population level but may not be independent for the purposes of kinship analysis.<sup>1</sup> In such cases, they recommend either the use of haplotype frequencies for the pair of loci or performing the calculation using the more informative of the two loci within a particular case.

Tillmar and Phillips discussed the issue of linkage and provided a method for evaluating the effect of linkage in identity and relationship testing.<sup>2</sup> Regarding Linkage Disequilibrium (LD) assessment, this study provides tables of locus pairs within 0.5cM and evaluated these pairs for signs of LD with HapMap data and proxy SNPs as needed (e.g., for all STR loci). For the 121 ForenSeq™ STR and Identity Informative SNP loci, this study reported five pairs located within 0.5cM of one another and none showed signs of LD.

In this study, LD evaluation will be performed between these 121 SNP and STR loci using National Institute of Standards and Technology (NIST) population sequence data for approximately 1,400 samples, including 400 father-son pairs (auSTR data reported).<sup>3</sup> This analysis is representative of the use-case, as it will not require proxy SNPs, and it will be based upon the STR sequences, which are expected to be used for forensic casework calculations. In addition to outlining a method that can be reproduced for other current or future assay/marker combinations, this work will provide refined guidance to ForenSeq™ users on statistically combining results in identity and kinship cases.

### **B108 An Evaluation of the Illumina® Infinium™ Omni Express Exome Bead Chip for Forensic Testing**

*Jon Davoren, MS\*, Bode Technology, Lorton, VA 22079-2625; Giovanna M. Vidoli, PhD, University of Tennessee, Knoxville, TN 37996; Amy Z. Mundorff, PhD, University of Tennessee, Anthropology, Knoxville, TN 37996-1525*

**Learning Overview:** After attending this presentation, attendees will understand the performance of the Infinium™ Omni Express Exome 8 Bead Chip on DNA from blood and bone samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the current benefits and limitations for Single Nucleotide Polymorphism (SNP) chip genotyping of forensic samples.

SNP chips provide hundreds of thousands to millions of loci in a single test. The large number of loci can provide prediction of ancestry, phenotypic information, and relatedness well beyond the limits of Short Tandem Repeat (STR) technology. The main limitation to using Infinium™ SNP chips is that they are designed for use on much higher levels of relatively intact DNA than is found in most forensic samples. Research into the effects of running lower template levels and degraded template on SNP chips is currently lacking. This study aims to evaluate the performance of the ~960,000 SNPs on the Infinium™ Omni Express Exome-8 BeadChip across a range of template amounts from human blood and bone samples.

Blood samples were collected approximately one week postmortem and bones were sampled at four to eight years postmortem. All samples were extracted using QIAGEN® chemistry, showed minimal inhibition and degradation when tested with Quantifiler® Trio, and gave full or nearly full STR profiles when tested with the Globalfiler® system. A DNA dilution series from 250pg to 10ng, for blood and bone samples, was tested using the Omni Express Exome system. The chips were read on an Illumina® iScan® instrument, analyzed in the GenomeStudio® software using the manufacturer recommended settings, and then compared for accuracy, reproducibility, and sensitivity.

The SNP call rates varied by individual tested, were lower for the DNA from bones, and were reduced as the template levels were lowered. The blood and bone DNA at 10ng of template had ~72% and ~30% call rates, respectively. At the lowest call rate, approximately 300,000 SNPs were called. The accuracy of the SNP calls fell dramatically when the call rates were below 70% with up to 50% error rates. Re-analysis in the genome studio software with higher stringency settings lowered error rates but also lowered call rates.

Phenotype and ancestry predictions, using the Paragon® Snapshot® system, for samples with at least a 70% SNP call rate, were consistent with the known hair color, eye color, skin color, and ancestry of the individual. For the samples with less than a 70% SNP call rate, the confidence levels of the predictions were too low to be significant.

The results of this evaluation suggest that the Infinium™ Omni Express Exome SNP chip has potential to be useful for forensic-type sample testing; however, additional development work is needed to increase call rates and accuracy for samples with lower levels of DNA and/or degraded DNA.

*This project was funded through an award from the National Institute of Justice.*

## B109 DNA Storage Under Multiple Conditions

Nicole S. Cusack, BS\*, The George Washington University, Washington, DC 20011; Laksh Malik\*, The George Washington University, Arlington, VA 22209; Daniele S. Podini, PhD, Department of Forensic Sciences, Washington, DC 20007; Moses S. Schanfield, PhD, Department of Forensic Sciences, The George Washington University, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will understand the long-term storage of DNA under multiple conditions that reflect those in a laboratory setting and those in field work.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing guidelines in regard to DNA storage under multiple conditions that will still maintain functional integrity for downstream forensic analysis.

Extracted DNA stored in a Tris-EDTA (TE) buffer at ambient temperatures of 18–20°C will not show significant degradation in quality or concentration that would impede downstream forensic analysis. Tris-EDTA is a widely used buffer in DNA storage, and it is accepted that DNA can be stored short-term at 4°C and long-term at -20°C.<sup>1</sup> This method of storage is reliant on consistent access to a power source to maintain temperature in the refrigerators and freezers. This is manageable in many first-world countries, but may not be possible in developing countries where fieldwork may be performed due to an increase in sexual violence.<sup>2</sup> It is imperative that DNA be properly maintained in order to be considered legally admissible.<sup>3</sup>

Samples were extracted from a single-source blood donor and spun down in order to pellet the red blood cells. The buffy coat was removed and washed with Deionized (DI) water through repeated centrifugation and removal of the supernatant to concentrate the white blood cells, from which the DNA was extracted using QIAGEN® QiAmp® DNA Investigator.<sup>4</sup> Samples were then eluted into the QIAGEN® ATE storage buffer, DI water, and Invitrogen™ Tris-EDTA. The samples were then pooled by storage media and diluted 1:200, and samples stored at 4°C and -20°C were aliquoted to avoid repeated freeze-thaw cycles. Samples were stored at 4°C, -20°C, 18–20°C, and 35°C in Eppendorf® DNA LoBind tubes and quantified using Quantifiler® Trio every two weeks in order to track degradation trends through the degradation index and concentration.<sup>5</sup> The data obtained from these quantifications will be analyzed using IBM SPSS statistics v23. Once degradation became apparent, samples were amplified using Identifiler® Plus and run through Capillary Electrophoresis (CE) on an ABI® 3500 Genetic Analyzer in order to obtain a genetic profile.<sup>6</sup> As of August 1, 2019, 200 samples have been quantified and amplified, and 80 samples have been run through CE to obtain a genetic profile. Initial attempts to run CE had encountered a technical problem and the samples are being rerun.

The study, as of writing this, has completed 18 weeks of experimentation. DNA stored in DI water at 35°C has shown complete degradation and evaporation at ten weeks with no detected DNA and no detected degradation index. This sample has been discontinued from future quantifications and amplifications.

**Table 1. Degradation index (DI) and concentration (ng/μL) for DNA stored under various conditions at 18 weeks**

	-20°C		4°C		18°C		35°C	
	DI	Conc.	DI	Conc.	DI	Conc.	DI	Conc.
QIAGEN® ATE	0.85	4.7	1.15	4.65	1	3.65	1	4.45
Invitrogen™ TE	0.95	4.2	0.9	0.9	0.8	0.1	0.95	1.05
DI Water	1.1	3.4	0.9	2.5	1.8	0.8	N/A	0

The degradation index is measured between <1 (no degradation/inhibition unlikely), 1–10 (slight to moderate degradation/inhibition possible), and >10 or blank (significant degradation/inhibition possible).<sup>5</sup> The degradation index for all samples at these temperatures have not shown to significantly differ, and the slight levels were not enough to impede downstream analysis. Samples stored under these conditions did not show a significant decrease in concentration that would impede downstream amplification or analysis, or an increase in level of degradation, over the study thus far.

## DNA Storage, DNA Degradation, Time Study

### B110 Optimizing an Integrated Workflow for Processing Paper Evidence in a Multidiscipline Crime Laboratory

Ashley Morgan, MS\*, Harrisburg, NC 28075; Patrick McLaughlin, BS, John Jay College of Criminal Justice, New York, NY; Mechthild K. Prinz, PhD, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** After attending this presentation, attendees will better understand an optimized multidisciplinary workflow for processing paper evidence for DNA, questioned documents, and latent print analyses. This workflow can be applied to crime laboratories that encounter paper evidence and must share evidence among disciplines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an evaluation of workflow options in processing paper evidence for DNA analysis while maintaining the integrity of the evidence for other disciplines to process. This presentation will offer suggestions for non-destructive sampling of paper evidence for DNA analysis prior to transfer of evidence to another discipline for further analysis.

Paper evidence is encountered in crimes such as robberies, kidnapping, forged checks, forged prescriptions, and harassment. Traditional methods for processing paper for touch DNA, including cutting pieces of paper and wet/dry swabbing of paper, are destructive to the evidence. Such sampling for DNA analysis may decrease the evidentiary value of the paper for other disciplines (for example, questioned documents and latent prints). Due to the difficulties of processing paper for touch DNA, the flow of the evidence upon submission to the laboratory may start with the questioned documents discipline, then transfer to the latent prints discipline, skipping the DNA discipline altogether. An alternative workflow may involve collecting DNA samples from the paper evidence after it has been processed by the other disciplines. Submitting paper evidence for latent print processing and questioned document analysis prior to DNA analysis may compromise the ability to perform DNA analysis. Both latent print chemical development and questioned document examination may introduce extraneous DNA on the evidence, if clean technique is not used during the processing. As such, the evidence would be rendered unsuitable for DNA analysis after other laboratory sections have completed their testing. An optimized workflow for processing of paper evidence is needed to address the difficulties that may arise in sharing paper evidence among the DNA, questioned documents, and latent print disciplines.

A series of small-scale studies were completed to determine optimal paper sampling for touch DNA, extraction method, latent print chemical development method, and workflow for paper evidence to be shared among the DNA, questioned documents, and latent print disciplines within the laboratory. Evaluation of the data from the small-scale studies and the literature guided the decisions for how the evidence would flow among the three disciplines. A proposed workflow was developed that started with DNA sampling and analysis followed by questioned document examination. Latent print examination was last.

A study of mock evidence using the proposed workflow was conducted by collecting handwritten samples from 12 volunteers. Two paper types, 20lb copy paper and 16lb notebook paper, were tested. DNA samples were collected by dry vacuum swabbing the paper.<sup>1</sup> After swabbing, papers were photographed to document visible markings on the paper, then processed for indented handwriting using the Electrostatic Detection Apparatus (ESDA). After ESDA, papers were returned to their original containers and transferred to the latent print unit for chemical development and evaluation by a latent print examiner. DNA was detected for all samples at quantitation and samples were amplified with the Applied Biosystems® GlobalFiler® PCR Amplification Kit. Profiles were obtained for all samples collected and varied in quality. Profile quality corresponded with quantitation value obtained—the lower the quantitation value, the lower quality of the profile in terms of number of loci with allelic drop-out or peaks below the stochastic threshold. The vacuum swabbing method did not impact the ESDA development of the indented writing for each paper sample. Latent prints of value for comparison were developed for 22 of 24 samples. The results of the testing of the proposed workflow on the mock evidence demonstrate that paper evidence can be shared among DNA, questioned document, and latent print disciplines without loss of evidentiary information. The study gives multidiscipline crime laboratories a framework of how paper evidence should flow through the laboratory once it has been submitted for analysis.

### **B111 Data Interpretation Guidelines for Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS) - Based Forensic Proteomics**

*Kristin Jarman, PhD\*, Pacific Northwest National Laboratory, Richland, WA 99352; Eric D. Merkley, PhD, Pacific Northwest National Laboratory, Richland, WA 99354; Karen L. Wahl, PhD, Pacific Northwest National Laboratory, Richland, WA 99354*

**Learning Overview:** After attending this presentation, attendees will: (1) gain an appreciation of the unique data interpretation challenges of forensic proteomics; and (2) take home specific guidelines for constructing objective and defensible proteomics assays.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by establishing common practices among the relevant communities and continue to increase visibility and acceptance of this emerging discipline.

Proteomics has become a standard approach to the study of cellular function. Based on LC/MS/MS measurements of fragmented proteins (called peptides) coupled with bioinformatics tools to identify those peptides, proteomics can be used to detect and quantify proteins in a sample. LC/MS/MS instrumentation provides high molecular specificity across a broad range of peptides, allowing for the identification of a virtually unlimited variety of proteins in a single sample. This makes proteomics a desirable alternative to the more traditional single-agent protein assays, such as Enzyme-Linked Immuno-Sorbent Assay (ELISA) and immunoelectrophoresis. As a result, the field of forensic proteomics is a steadily growing area of research. To date, a number of forensic proteomics applications have been explored, including microbial identification, characterization of microbiological growth media, human hair analysis, bodily fluid identification, species identification from bones and other tissues, identification of protein toxins, such as ricin and the botulinum neurotoxin, and the characterization of various historical and archaeological artifacts.

There are two common types of proteomics methods that employ LC/MS/MS: targeted and untargeted. With targeted methods, the instrumentation is tuned to detect a small number of pre-specified peptides. The data produced by targeted LC/MS/MS assays amounts to a list of peak intensities corresponding to the peptides searched for by the instrument. Research and development of targeted assays involves selecting the most protein-specific peptide markers to measure, constructing standard operating protocols, characterizing the limit of detection, and measuring the sensitivity and specificity of the overall method. In this way, targeted proteomics assays are similar to traditional MS-based chemical assays. Untargeted LC/MS/MS methods, while less sensitive than their targeted counterparts, offer the ability to detect a virtually unlimited variety of peptides in a single measurement. They achieve this by operating in data-dependent mode, where the instrumentation is set to detect as many peptides as possible, producing thousands of mass spectra in a single experiment. Because of the vast number and diversity of fragmentation spectra involved, untargeted proteomics methods rely heavily on search databases and bioinformatics tools to identify peptides in an unknown sample and associate those peptides with proteins and/or protein sources. This creates unique data analysis and interpretation challenges that must be addressed when establishing the statistical defensibility of untargeted forensic proteomics methods.

In this presentation, statistical issues associated with the emerging field of targeted and untargeted forensic proteomics will be discussed. Key considerations for meeting the *Daubert* criteria will be presented, including establishing reliability of a method and developing a framework for interpreting the strength of proteomics evidence. The importance of standardized data analysis protocols, objective data interpretation criteria, and appropriate search databases will be demonstrated. An untargeted proteomics method for the detection of protein toxins, such as ricin and abrin, will be presented and used to illustrate the potential of this emerging discipline.

*This work was supported by the Department of Homeland Security Science and Technology Directorate.*

### B112 The Identification of Cadaver Liver Tissues Using Postmortem Transcriptome Biomarkers

*Gulnaz T. Javan, PhD, Alabama State University, Montgomery, AL 36104; Sheree J. Finley, PhD\*, Alabama State University, Montgomery, AL 36104; Erin K. Hanson, PhD, University of Central Florida, Orlando, FL 32816; Silvia D. Visona, MD, University of Pavia, Pavia 21100, ITALY; Antonio M.M. Osculati, MD, University of Pavia, Pavia 27100, ITALY; John Ballantyne, PhD, University of Central Florida, Orlando, FL 32816-2366*

**Learning Overview:** After attending this presentation, attendees will have learned how to use postmortem messenger RNA (mRNA) transcripts in decomposing tissues to gain insight into the identification of tissue segments arising from organs collected from actual cadavers from ongoing criminal cases. Precisely, attendees will understand that RNA is stable in cadavers' liver tissues and is adequate for profiling gene expression and that gene expression signatures of mRNA exposed for up to 37 days of autolysis can be used to identify putative tissue fragments.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the determination of internal organ sources from criminal casework that may assist in death investigations.

The human transcriptome is the complete expression of mRNA transcripts produced in all tissues. Approximately 10% of mRNA transcripts are encoded by tissue-enriched genes and a variety of genes are enhanced to a greater extent in one tissue type, some up to five times the maximum levels of all other tissues. RNA quality is contingent on tissue source; for example, liver and spleen are more abundant in ubiquitous RNases that degrade RNA molecules more rapidly and with a higher activity than less RNase-rich tissues (e.g., heart and muscle).

This study hypothesized that as a human body decays, mRNA profiles will permit organ identification using biomarkers on bona fide autopsy-derived sources. This study is the first of its kind to use actual cadaver tissue from ongoing criminal cases in a postmortem transcriptome identification assay. To test this hypothesis, total RNA was extracted and the approach was prioritized by performing targeted transcriptome analysis using RNA sequencing (RNA-Seq) in liver tissues obtained at autopsy from 30 criminal casework cadavers in Italy and the United States. Fifty nanograms of total RNA were converted to complementary DNA (cDNA) using reverse transcriptase and random primers. Targeted Oligonucleotide Pool (TOP) was hybridized to the cDNA on a streptavidin bead matrix. The resulting libraries were sequenced on the MiSeq<sup>®</sup> instrument. Percent contributions of liver biomarkers versus Postmortem Interval (PMI) for the overall set were determined and graphed. The results demonstrated that in each of the cadavers, the tissue was correctly identified as a liver sample. Furthermore, 98%–100% of the reads were attributable to liver biomarkers (e.g., AMBP, AHSG).

In conclusion, the results demonstrate as a proof of principle that a specific 8-biomarker liver assay is capable of identifying the original source of liver specimens from using cadaver tissue. The results also confirm that RNA molecules are stable in postmortem liver samples up to seven days, which makes RNA a sufficient molecule for gene expression studies. The design of this study validates a technique that will meet the demand for rapid and reproducible postmortem transcriptome methods to identify tissue fragments present in a variety of medicolegal investigations.

### **B113 An Analysis of Unusual Mutation Patterns in Father-Son Pairs Using a ForenSeq™ DNA Signature Prep Kit and a YFiler™ Plus Polymerase Chain Reaction (PCR) Amplification Kit**

*Tyler L. McDermott, MS\*, Manchester, CT 06042; Robin W. Cotton, PhD, Boston University School of Medicine, Boston, MA 02118*

**Learning Overview:** The goal of this presentation is to present some unusual Y-chromosomal Short Tandem Repeat (Y-STR) mutations that led to discordance between a father and his sons.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by displaying examples of father-son discordance that, if not understood, could lead to wrongful convictions based on Y-chromosome analysis.

The application of Y-chromosome analysis is expanding in fields such as forensic science and genealogy. By researching the potential polymorphisms this chromosome can present, we can further our ability to assess DNA profiles for these disciplines to avoid erroneous exclusions of paternal linkage, wrongful convictions based on forensic evidence, and other misinformed genetic conclusions. The conservation of Y-haplotypes during transmission occurs due to lack of genetic recombination events in the inheritance of the Y-chromosome (with the exception of the pseudoautosomal region). However, mutation events can occur on the Y-chromosome, resulting in haplotype changes. These changes can include duplications and deletions that may occur at Short Tandem Repeat (STR) or Single Nucleotide Polymorphism (SNP) loci used in forensic DNA analysis. These mutation events can become important in cases of sexual assault where male-female mixture samples have low amounts of male DNA such that the male signal is not amplified in currently used STR multiplexes and analysis using Y-STR loci is used.

This study analyzed DNA from a father and his 11 sons using two different methods for forensic genetic analysis; next generation sequencing and capillary electrophoresis. The DNA from Council on Education for Public Health (CEPH) /Utah Pedigree 1413 was obtained from the Coriell Institute for Medical Research, Hamden, NJ, in the form of frozen DNA extracts isolated from a blood lymphocyte cultured cell line. Sample DNA was tested with the ForenSeq™ DNA Signature Prep Kit using primer set A and the YFiler™ Plus PCR Amplification Kit. Using these two platforms, three Y-STR loci were discordant between the father and each of his 11 sons. At all three loci, the father possessed the same allele as the sons, as well as one additional allele. At two of these loci (DYS449 and DYS635), the additional allele was one repeat (4 bp) longer than that of the shared allele. At the third locus (DYS458), the additional allele was three repeats (12bp) longer than that of the shared allele. Following read count and peak height analysis, it was concluded that these double allele loci did not result from the presence of a single true allele and a corresponding n-1 stutter allele. With the knowledge that the DNA was extracted from a blood lymphocyte cell line, it was postulated that a somatic mutation may be present in the cell line. However, this study was not able to determine whether the mutations exist in the blood of the father (therefore, true somatic mutations) or occurred as a result of the cell culture process.

Details concerning the position of these loci on the Y-chromosome, the repeat motifs of the alleles, and the potential for duplication versus stutter as the originating event will be discussed. Potential locus duplications were compared to those reported on the STRBase list of allele variations and to information found in literature. The observed DYS635 locus had an allele designation of 21, 22, which is reported on STRBase. The DYS449 and DYS458 loci showed potential allele-specific locus duplications that were not found on STRBase. The implications of non-inheritable allele patterns in the Y-chromosome, such as this, can be significant when considering comparisons between DNA obtained from germline cells (sperm) versus a known sample obtained from blood or saliva.

### **B114 Mitochondrial Analysis of Challenging Samples Utilizing the ForenSeq™ mtDNA Control Region Solution on the MiSeq® FGx**

*Ryan Gutierrez, BS, Alvin, TX 77511-4161; LeAnn M. Harrel, BS, Sam Houston State University, Huntsville, TX 77340; Sheree R. Hughes, PhD, University of Queensland, Brisbane, Queensland, AUSTRALIA; Rachel M. Houston, PhD, Sam Houston State University, Huntsville, TX 77340; Bobby Larue, Jr., PhD\*, Sam Houston State University, Huntsville, TX 77341*

---

**Learning Overview:** After attending this presentation, attendees will comprehend the application of massively parallel sequencing technologies to mitochondrial control region analysis. Additionally, attendees will be given an overview of the advantages and limitations of massively parallel sequencing as it applies to data analysis and sample throughput for mitochondrial DNA (mtDNA) processing using the ForenSeq™ mtDNA Control Region Solution on a MiSeq® FGx.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the advantages of applying massively parallel sequencing to mitochondrial control region analysis. With scalable sample preparation and low limits of detection, this technology could make mtDNA analysis easier to accomplish for current analysts and more accessible to forensic laboratories that wish to expand services.

While Short Tandem Repeat (STR) genotyping is the best practice for human identification, mtDNA sequencing is a supplementary analysis with a great impact on forensic genetics. In some cases, including highly degraded bones, mass disaster remains, or rootless hairs, STR analysis cannot be used to positively identify a sample. This leaves important forensic questions that can be answered with mitochondrial genotyping. While not as discriminatory as STR typing, mtDNA analysis remains a powerful tool for forensic analysts in source attribution and identification. Despite the utility of mtDNA testing, it has been limited to few laboratories because it is labor intensive with high error rates and requires substantial time on valuable capillary electrophoresis instrumentation. Many of the limitations of Sanger sequencing can be overcome through the use of massively parallel sequencing technologies. As this newer instrumentation is implemented in forensic laboratories, it will allow for the expansion of forensic services to include mtDNA analysis of highly challenging samples.

This study utilized the newly released ForenSeq™ mtDNA Control Region Kit for the Illumina® MiSeq® FGx to genotype the mitochondrial control region of typical mock forensic samples, including buccal swabs, challenging bone samples, and rootless hairs. This study also tested the limits of detection for the assay as well as both manufacturer-supported library normalization protocols. This data was analyzed using the integrated ForenSeq™ Universal Analysis Software. Variant calls generated with this assay and software package were confirmed using traditional Sanger sequencing.

This assay is designed around multiple overlapping small amplicons that cover the control region of the mitochondrial genome. This chemistry is scalable for variable sample multiplexing allowing for high or low throughput based on analyst needs. Discriminatory mitochondrial profiles can be generated using as little as 1pg of input DNA, and the system allows for potential advances in the reporting of heteroplasmy in samples. All results obtained with massively parallel sequencing were concordant with those found with Sanger sequencing.

---

## B115 Investigator-Mediated DNA Transfer

Michelle Le, BS\*, Surrey, BC V4N 4S3, CANADA; Jason Moore, MA\*, Burnaby, BC, CANADA; Steen Hartsen, BS, Burnaby, BC V5G 3H2, CANADA; Georgina Jayne Lush, Burnaby, BC, CANADA

**Learning Overview:** After attending this presentation, attendees will better understand the challenges in assessing alleged contact DNA transfer events and complex DNA mixtures.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating how the high sensitivity of current forensic DNA technology enables the detection of an individual's DNA on an object they never directly contacted, which has the potential to produce falsely incriminating evidence.

Ongoing improvements in forensic DNA analysis technology allow increasingly small amounts of DNA to be detected. This had led to increased success in obtaining results from low template samples; however, research to evaluate the risks of passive DNA transfer has not progressed with the advances in technology. Because bias creates a tendency to associate a crime scene profile with direct evidence of criminal activity, there are significant risks in the lack of understanding of DNA transfer.

The purpose of this study was to explore the possibility of investigator-mediated transfer of contact DNA, based on a homicide case in which the defense raised this theory to question the presence of the suspect's DNA on the murder weapon. The officers at the crime scene reported that the coroner had handled a Lululemon bag, possibly containing the suspect's DNA, followed by the handgun he discovered on top of the bag, without changing gloves. The experimental design of this study modeled this alleged tertiary DNA transfer chain, from the Lululemon bag, to nitrile gloves, to a gun, following the procedure used by Fonnelop, Egeland, and Gill.<sup>1</sup> This was done having zero, one, two, and three individuals handling the gun prior to the transfer procedure, in order to examine the effect of background DNA.

DNA was extracted by the organic extraction and microfiltration method. The samples were quantified using the Quantifiler® Trio kit before amplification using the GlobalFiler® kit, with capillary electrophoresis performed using a 3500 Genetic Analyzer. DNA profiles that indicated the presence of a mixture were analyzed in STRmix™.

A shedder test was first conducted as per Goray et al. in order to estimate the shedder abilities of the four participants in the study.<sup>2</sup> One participant was selected based on their good shedder classification to act as the primary donor, or "suspect." The other three participants were classified as poor shedders, who deposited partial DNA profiles. One appeared to be a very poor shedder, who deposited more of another individual's DNA than their own.

In the first DNA transfer experiment, a full primary donor DNA profile was found on the gun in two out of three replicates, despite the fact that the primary donor never held the gun. A full DNA profile was found on the bag and glove in all three replicates. A repeated measures Analysis of Variance (ANOVA) with sphericity assumed determined that the mean DNA concentration was significantly different between the three substrates ( $F[2, 4]=10.022, p=0.028$ ). Mauchly's test,  $\chi^2(2)=5.341, p=0.069$ , did not indicate any violation of sphericity.

When one individual had handled the gun prior to the transfer of the primary donor's DNA, near full primary donor DNA profiles were found on the gun. There was very strong support for the inclusion of the primary donor's DNA in the mixture. In one sample, the DNA profiling results are 41 trillion times more likely if they had originated from the primary donor and three unknown individuals than if they had originated from four unknown individuals. Where two and three individuals, respectively, handled the gun prior to transfer, the primary donor's DNA was not readily resolvable from the mixture. The primary donor was excluded as a contributor in most three-person mixtures, but likelihood ratios provided limited support for their inclusion in four-person mixtures. Notably, there was support for the exclusion of the very poor shedder from the mixture, despite them directly handling the gun.

These results suggest that there is currently a paradoxical relationship between the expanded forensic DNA technological capabilities and the level of confidence that can be placed on the nature or origin of contact DNA samples and the inclusion of minor contributors in a complex mixture. This study provides evidence that low template contact DNA evidence should be interpreted with caution.

### DNA Transfer, Contact DNA, Complex Mixtures

### B116 An Assessment of Cell Suitability of Touch DNA Samples for Forensic DNA Profiling

Jessica Surratt\*, University of New Haven, West Haven, CT 06516; Claire L. Glynn, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** The goal of this presentation is to inform attendees of the potential for nucleic acid binding dyes to be used as a screening method for touch DNA samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight into visualizing touch DNA using nucleic acid binding dyes as a means of screening samples to assess suitability for further processing (i.e., DNA profiling). This will ultimately allow investigators to sample more areas suspected to contain touch DNA, thereby increasing the recovery of probative information.

Touch DNA, also known as trace or transfer DNA, is typically deposited on surfaces by a person touching an item and leaving behind cellular material. The origin of touch DNA is suggested to come from several sources. It is hypothesized that the DNA comes from nucleated cells from the hands or other parts of the body that have been touched, cell-free DNA from residual body fluids, and cell-free DNA from cells that have undergone apoptosis.<sup>1</sup> In forensic investigations, touch DNA is commonly collected from surfaces using the double-swab method or by collection using adhesive tape (e.g., mini-taping). As these cells are microscopic, the investigator is blindly sampling areas where it is suspected to have been touched. These sampled areas may contain little to no DNA, which is not realized until DNA extraction and quantitation has been performed. Therefore, a screening method to visualize the cellular material present would serve to assess if the samples contain sufficient cellular material for further processing. Nucleic acid binding dyes have recently come to light as a novel tool for this purpose. Nucleic acid binding dyes will bind to double-stranded DNA and can be visualized using fluorescence microscopy. There are several commercially available dyes that either intercalate between the nucleotides or bind to a groove in the DNA structure. This research investigates five different nucleic acid binding dyes on touch DNA samples collected using both the double-swab and mini-taping methods.

Following ethical approval from the Institutional Review Board (IRB), with informed written consent, touch DNA samples were deposited on different surfaces. A range of surfaces that are commonly encountered in forensic casework were tested, including white cotton, black cotton, blue denim, polyester, glass, ceramic tile, and wood. The methods used to collect the samples from the surfaces were mini-taping and the double-swab method. Eight different types/brands of swabs were investigated including cotton, polyester, and foam swabs. The dyes used were GelGreen® Nucleic Acid Gel Stain, EvaGreen® dye, Diamond™ Nucleic Acid Dye, RedSafe™, and SYBR® Green Nucleic Acid Gel Stain. Following collection, the swabs/tapes were dyed using each dye, and visualized using the Dino-Lite® fluorescent microscope with an excitation wavelength of 480nm and an emission wavelength of 510nm. Images were captured using the DinoXcope software (version 1.24). Samples treated with each dye were Short Tandem Repeat (STR) profiled to assess interference with profile generation.

The results of this research showed that all touch DNA samples collected from each surface using both collection methods were visualized using each dye. The mini-taping collection method provided more clarity in the images collected compared to the swabbing method, thereby allowing more optimal assessment of the cellular material present. The foam-tipped swabs were the preferred material of all the swab types as they produced the least background fluorescence. The Diamond™ Nucleic Acid Dye was shown to provide the strongest fluorescence compared to the other dyes; it is a cost-effective method, easy to use, and is non-mutagenic. All samples STR profiled produced full profiles.

This research highlights the potential of this novel screening tool to assess the suitability of touch DNA samples collected from evidence items and crime scenes prior to submission to the DNA profiling laboratory. This screening method will allow investigators to sample more areas for screening, with the purpose of submitting only the samples known to contain sufficient cellular material, thereby recovering more probative information.

### B117 How Sharing ChapStick® Influences DNA Profiles Obtained From the Rim of Ceramic Mugs

*Sidney Thompson, BA\*, Indianapolis, IN 46227; Mary Rebekah Judkins, BS, Indianapolis, IN 46227; Laura K. Scheid, BA\*, Indianapolis, IN 46237; Emily Taner, BA, University of Indianapolis, Indianapolis, IN 46227; Krista E. Latham, PhD, University of Indianapolis, Indianapolis, IN 46227; Lindsey Williams, BS, Strand Diagnostics, LCC, Indianapolis, IN 46241; Gay L. Bush, PhD, Strand Diagnostics, Indianapolis, IN 46241*

**Learning Overview:** The objective of this presentation is to demonstrate the potential for simultaneous direct and indirect transfer from the lips to the rim of ceramic drinking vessels after the application of shared ChapStick®.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding to a growing body of research that influences the understanding and interpretation of transfer DNA evidence in medicolegal investigations.

DNA introduced to a crime scene through indirect transfer has become an area of concern in the forensic science community as increasingly sensitive technology continues to improve the detection of DNA unrelated to the criminal event, thus resulting in mixed profiles. A wealth of research on transfer DNA over the past decade has sought to better understand how the DNA within a trace sample was deposited on the surface where it was collected. It is accepted by the scientific community that DNA can be deposited by direct and indirect means on surfaces. The complexity of these transfer events can result in simultaneous direct and indirect transfer. The person contacting the object may transfer their DNA through direct contact as well as act as a vector for the indirect transfer of DNA not their own.

The rims of beverage cans, bottles, and glasses are commonly swabbed for DNA profiles related to missing persons cases or criminal investigations. While it is discouraged to share cosmetics for sanitary and health-related purposes, it is still common practice for lip balms to be used by multiple individuals. This study investigates the DNA profiles obtained from ceramic coffee mugs when lips covered in shared ChapStick® contact the rim of the drinking vessel. During the study, one participant (called the primary user) opened a new tube of ChapStick® in the morning, used it three times throughout the day, then shared the tube with a second participant (called the secondary user). The primary user then reapplied the ChapStick®. Five minutes later, both participants “drank” five times from an empty ceramic coffee mug, the rim of which was subsequently swabbed for DNA profiling to test the following null hypotheses: (1) a mixed DNA profile will not be detected in samples obtained from the mug rim of the primary ChapStick® user, and (2) a mixed DNA profile will not be detected in samples obtained from the mug rim of the secondary ChapStick® user. The DNA was purified from the swabs using the QIAGEN® QIAamp® DNA Mini Kit, quantified using Life Technologies™ Quantifiler® Trio, and amplified using Life Technologies™ GlobalFiler® Amplification Kit.

DNA profiles were generated from all of the samples. One sample produced a partial DNA profile consistent with the drinker. For 18.75% of the samples, mixed profiles were detected that were consistent with both participants. Two of these samples originated from swabs of the secondary user’s mug and one from the primary user’s mug. Therefore, both null hypotheses can be rejected. In all cases, the major profile was consistent with the drinker. There were no patterns detected regarding length of use of the ChapStick® (primary user versus secondary user) and indirect DNA transfer.

However, the results of this scientific study do demonstrate that the simultaneous direct and indirect transfer of DNA is possible from the lips of an individual who is wearing shared lip balm. Given that lip balm is a personal item that may be shared between individuals, it is important to show that a mixed DNA profile could be obtained after shared use.

---

### **B118 The Evaluation of New Field and Laboratory Techniques for the Recovery of Touch DNA From Handled Improvised Explosive Devices (IEDs) Rendered Safe and Post-Blast**

Wyatt Barie\*, Arcadia University, Glenside, PA 19038; Heather E. McKiernan, PhD, Center for Forensic Science Research & Education, Willow Grove, PA 19090; Alan Stuart, MS, Montgomery County Sheriff's Department, Norristown, PA 19401; Heather L. Harris, JD, Glenside, PA 19038; Thomas V. Walsh, MSFS, NMS Labs, Willow Grove, PA 19090; Megan M. Foley, MSFS, Center for Forensic Science Research & Education, Willow Grove, PA 19090

**Learning Overview:** After attending this presentation, attendees will better understand the effects of new field techniques for pipe bomb disposal on the ability to recover a Short Tandem Repeat (STR) profile from touch DNA as well as the effects of detonation of a pipe bomb on touch DNA recovery.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about how updated and improved field and laboratory techniques can impact the ability to recover DNA to identify individuals who assembled and/or handled IEDs.

Bombing incidents, most utilizing IEDs, account for an appreciable percentage of terrorist events across the globe. In order to counteract and prevent explosions, various methods are utilized by law enforcement in order to properly diffuse or dispose of these IEDs. In the case of pipe bombs, the explosion is caused by a buildup of pressure in the sealed pipe caused by the interior components undergoing chemical reactions with one another. To prevent this, methods are used to release the pressure build-up, therefore, stopping the explosion from occurring. However, past studies have shown that the methods utilized to render an IED safe can be detrimental to the ability to develop a DNA profile. Ideally, samples collected from the rendered safe explosives would yield touch DNA profiles left on the IEDs during assembly. As a separate issue, heat generated during deflagration can degrade this DNA again, making it difficult to determine the identity of those involved in assembly.

A new field technique utilizing a Nitro Turkey® shotgun round has been adopted by bomb squad units for the disposal of devices. In the past, both water and clay shot were used in order to try and ventilate the device. However, these methods caused the DNA evidence on the pipe to be lost or washed away to varying degrees, depending on the shot used. This study evaluated the effects of the new rendering safe technique using a Nitro Turkey® shot on the ability to recover DNA.

Pipe bombs ( $n=30$ ) of various materials (PVC and steel) were rendered safe utilizing the Nitro® shots, while an additional 15 pipe bombs of each material were assembled but not diffused. A dual swab technique using two swabs with 2% Sodium Dodecyl Sulfate (SDS) as the moistening agent was performed. Three samples were collected from each device, including separate samples from each end cap as well as the shaft. DNA was then extracted using a PrepFiler® Express BTA™ Forensic DNA Extraction Kit using an AutoMate Express™ DNA Extraction System. The DNA was quantified using a Quantifiler® Trio DNA Quantification Kit on 7500 Real-Time Polymerase Chain Reaction (PCR) System, amplified using a Fusion 6C Amplification Kit on a GeneAmp® PCR System 9700, and then genotyped using an Applied Biosystems® 3500 Genetic Analyzer. The quantity and quality of the resulting profiles obtained from the touch DNA were compared between undiffused pipe bombs and ones diffused using Nitro Turkey® shots for both pipe materials. These results will be compared to results generated in a previous study using the old rendering-safe techniques and less sensitive laboratory procedures. In addition, several steel pipes will be detonated in order to determine whether sufficient touch DNA remained on the pipe to generate an informative genetic profile utilizing either a traditional Capillary Electrophoresis (CE) -based approach or next generation sequencing using a MiSeq® FGx™ Forensic Genomics System. Preliminary data suggests that the rendering safe technique using the Nitro Turkey® shot does not have a significant impact on the amount of DNA collected from either steel or PVC pipe. This study demonstrates that newer applied laboratory methodologies and field techniques used for rendering IEDs safe may improve an analyst's ability to generate informative DNA profiles from rendered safe and conflagrated IED samples and highlights the need to continually reevaluate protocols used for genetic analysis of challenging sample types.

### **B119 Forensic Identification: An Investigation to Corroborate Volatile and Biological Profiles for Subject Identification**

*Chantrell Frazier, BS\*, Florida International University, Miami, FL 33199; Kenneth G. Furton, PhD, Florida International University, Miami, FL 33199; DeEtta Mills, PhD, Florida International University, Miami, FL 33199*

**Learning Overview:** After attending this presentation, attendees will understand that the unique microbial composition on an individual's hand determines the person's Volatile Organic Compound (VOC) profile.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the potential for an idiosyncratic profile that combines chemistry (VOCs) and biology (DNA) as a viable resource for forensic identification. This resource/tool increases the potential for trace samples to discriminate between individuals at a crime scene.

Hands are an integral part in transferring cellular material, both human and microbial, to and from our surroundings. As a result, hands are significant in provenance investigations as specific microbiota can be deposited on everyday objects through touch interactions. Skin microbiome, including bacteria, fungi, and viruses, are unique to each person, and this "uniqueness" can be exploited and applied to forensic identification. Skin microbiota and VOCs are intrinsically linked due to microbial metabolic transformation of non-volatile organic compounds to VOCs that are characteristically represented in human scent. The ribosomal operons within bacteria are ubiquitously present and easy to amplify through Polymerase Chain Reaction (PCR) because of its highly conserved primer sites and plethora of phylogenetic information. Traditionally, the small sub-unit of the prokaryotic ribosome encoding the 16S rDNA gene is used to identify bacterial species. However, analyses of microbiota from touch interactions have proven to be difficult due to the low quantity of genomic DNA (gDNA) that can be collected and extracted.

Headspace/Solid Phase Microextraction-Gas Chromatography/Mass Spectrometry (HS/SPME-GC/MS) is commonly used to conduct VOC analyses of air and water samples. Previous studies have utilized HS/SPME-GC/MS as a forensic approach to examine VOCs collected from various regions of the body as a form of identification. The objective of this research is to analyze samples collected from the subject's palms to determine the relationship between the individual's bacterial genetic profile and the VOC profile. Palmar sweat samples and epithelial swabs were simultaneously collected for VOC and DNA analysis, respectively. DNA was initially screened using Length Heterogeneity Polymerase Chain Reaction (LH-PCR) to obtain an initial assessment of the bacterial community's diversity. Next generation DNA sequencing of the V3-V4 region of the 16S rDNA gene was performed to identify each individual species present. Preliminary data have also demonstrated the ability to provide human Short Tandem Repeat (STR) markers from the same samples that will enhance the information collected from corroborated profiles.

Whereas previous standalone touch DNA analysis and standalone VOC analysis has proven to be challenging and limited in the information it provides, concatenation of these combined data will allow for the advancement of human scent studies for forensic identification.

### B120 The Reproducibility of Individual DNA Deposits Detected With Diamond Dye

Natalee Small-Davidson, BS\*, John Jay College of Criminal Justice, New York, NY 10019; Xiao Chen, BS, John Jay College of Criminal Justice, New York, NY 10019; Tebah Browne, BS, John Jay College of Criminal Justice, New York, NY 10019; Mechthild K. Prinz, PhD, John Jay College of Criminal Justice, New York, NY 10019

**Learning Overview:** After attending this presentation, attendees will have learned how differences in DNA shedding propensity can be tested using a nucleic acid stain and how stable individual shedding propensity is over multiple depositions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by adding information on different approaches to test for shedding propensity. Data on individual variation of how much DNA is deposited via direct transfer informs expert opinions on transfer probabilities.

Contact traces are an important part of DNA casework in all crime laboratories and, with optimized recovery, detection, and interpretation methods, many samples now lead to positive associations to a person of interest. The probative value of these associations and the possibility of passive transfer need to be considered carefully. It has long been established that there is individual variation on how much DNA is left behind when touching an item and at least on scientific study on transfer via handshakes concluded that it was “the relative shedding ability” of the two volunteers that had the largest effect on whose DNA was detected.<sup>1</sup> In 2018, Kanokwongnuwut et al. published an elegant method for testing shedding variability.<sup>2</sup> This study aimed at reproducing their DNA staining/cell counting approach.

Volunteers were asked to deposit a left ring finger print on a clean glass slide, then wash their hands and, after waiting for 30 minutes while not touching anything, deposit a right finger print. Prints were stained with 20x Promega® Diamond™ Dye and read at the Fluorescein Isothiocyanate (FITC) filter setting (495nm excitation and 550nm emission) on a Nikon® Eclipse® E600 fluorescent microscope. Signal counts were scored at 100x magnification for three different 0.5 x 0.5mm squares. The method worked well and gave clear signals. Signal density for prints collected prior to handwashing (left ring finger) was often very high, which made counting difficult. This was not a problem for washed hands (right ring finger), where cell nuclei counts were much lower (average 24 +/- 14, n=10). Not unexpectedly, there was a lot of variation in cell counts between two independent collection events for the unwashed print; for ten volunteers, only four had counts within 20% of each other. Differences ranged from 8% to 81%. This was similar for washed finger prints, where only three data sets had a difference smaller than 20% and the range was 11%–105%. The latter was unexpected; after handwashing and not touching anything, cell counts should have been closer to each other. Ranking volunteers as heavy and low shedders produced similar results for both types of prints; the same three were the highest shedders and the same two the lowest, which means unwashed prints also represent shedder status. In conclusion: in our hands, the method was not as reproducible as described by Kanokwongnuwut et al., but showed a similar distribution of heavy, intermediate, and light shedders.

### B121 The Detection of Cryptic Single Nucleotide Polymorphism (SNP) Variants for Enhancing Human Identification Capabilities

Leena Yoon, BS\*, Arlington, VA 22209; Fabio Oldoni, PhD, The George Washington University, Washington, DC 20007; Chiara Fantinato, Vicenza, ITALY; Chantal Roth, PhD, South San Francisco, CA 94080; Daniele S. Podini, PhD, Department of Forensic Science, Washington, DC 20007

**Learning Overview:** After attending this presentation, attendees will be able to appreciate the advantages of using Massively Parallel Sequencing (MPS) technology to improve human identification capabilities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that the detection of additional rare SNP variants within a microhaplotype region can increase the power of discrimination of DNA evidence.

Microhaplotypes (microhaps) are loci with two or more SNPs within an expanse of 300 nucleotides associated in multiple allelic combinations.<sup>1</sup> These biomarkers have small amplicon size, ancestry informative alleles, no stutter, and lower mutation rates than Short Tandem Repeats (STRs), which make them useful for human identification, relationship testing, mixture deconvolution, and ancestry inference.<sup>2</sup> Sanger sequencing does not provide the *cis/trans* relationship between individual SNP alleles while MPS allows distinguishing the parental haplotypes by clonal sequencing of each individual DNA strand. The detection of rare (cryptic) SNP variants can potentially increase the power of discrimination of these markers and the ability to correctly infer the number of contributors to a mixture. This study explored the potential of a newly developed pipeline to identify rare SNP variants within microhaplotype alleles and their impact on human identification.

A MPS panel of 74 microhap loci was implemented and evaluated on the Thermo Fisher Scientific™ Ion Torrent™ S5™ system.<sup>3</sup> To expand the potential of microhaps to human identification, a custom bioinformatic pipeline was developed (Microhaplotyper\_CR\_v1.0), which uses an alignment-specific tool to enable the detection of the SNP defining the microhap loci while identifying additional SNP variants potentially present in between the SNPs that define the locus. These extra variants can be highly informative if detected as they are generally rare and consequentially increase the power of discrimination of the overall profile when present. To evaluate the performance of the pipeline, 18 single-source samples of African origin were selected and run on the Ion S5™ platform. All DNA samples were genotyped using the Microhaplotyper\_CR\_v1.0 pipeline, which was installed as a plug-in on the S5™ server. The output file identifies the alleles based on the SNPs that define the locus and also detects all other variants present within the amplicon. The frequency of the additional SNPs of interest was queried on the public database SNP (dbSNP), which includes allele frequencies of global populations from multiple data sets.

On average, this study identified eight additional SNP variants per each individual tested. Preliminary analysis showed that six rare SNP variants were observed only once within the sample set tested at a frequency of 0.1%–4.6% in African populations reported on dbSNPs. Eighteen different additional SNP variants were detected at high allele frequencies in African populations (10%–40%) and frequencies ranging from 1%–9% in other global populations, including Europeans, East and South Asians, and Americans. For instance, one of the identified SNP variants (rs79763993) was found at 19.4% in the African population, 0.01% in the European, 1% in the American, and undetected in East and South Asian populations. Comprehensive analyses on a set of more than 800 individuals from 14 global populations are ongoing to identify additional rare SNP variants.

Preliminary findings suggest that rare SNP variants are present within the targeted microhap regions and can be identified with the newly developed pipeline. Detecting these variants will increase the discrimination power of a profile and will increase the mixture deconvolution capabilities of this microhap assay.

### B122 Lectin Blot-Based Profiling of Salivary Fluid Glycoproteins Distinguishes Different Patterns Among Individuals

Oluseyi A. Vanderpuye, PhD\*, Albany State University, Albany, GA 31705

**Learning Overview:** The goal of this presentation is to show that salivary fluid glycoprotein patterns differ among individuals and how they can be detected by Sodium Dodecyl Sulfate (SDS) gel electrophoresis and Western blotting with lectin staining.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing new knowledge of the differences (polymorphisms) in salivary glycoproteins. This study may facilitate the identification of the origin of saliva samples.

It is hypothesized that individuals have unique profiles or patterns of carbohydrates on their salivary glycoproteins. It is further hypothesized that differences in salivary glycoprotein profiles may be used in forensics to identify the source of saliva. There are precedents in the available literature of inter-individual differences in protein carbohydrates. For example, ABO blood group antigens are carbohydrate structures present on salivary mucins. Furthermore, whether individuals can express ABO blood group structures in saliva is dependent on a second genetic system—the Secretor gene. It is proposed that there are other inter-individual differences in salivary protein carbohydrate structures to be discovered per previous work.<sup>1,2</sup>

The specific goal of this research was to define the patterns of carbohydrate structures on salivary glycoproteins from different individuals that were detected by selected lectins (carbohydrate binding proteins) and determine if individuals have distinct profiles that differ from others and that can serve as a means of identification.

In regard to methods, glycoproteins in salivary fluid samples were separated by Polyacrylamide Gel Electrophoresis in the presence of Sodium Dodecyl Sulfate (SDS PAGE) on the basis of size. Staining of the pattern of proteins after transfer to nitrocellulose with carbohydrate binding proteins (lectin blots) was used to characterize the pattern of the glycoproteins in the different proteins. This technique has been previously validated by researchers in other institutions and works well on salivary glycoproteins.<sup>1-5</sup>

Biotinylated lectins derived from plants were used on salivary fluid from eight individuals and were: UEA-I (*Ulex europaeus* I), PNA (peanut agglutinin, *Arachis hypogaea*), ECA (*Erythina cristagalli*), TL (tomato lectin, *Lycopersicon esculentum*), and STA (potato lectin, *Solanum tuberosum*).

The results obtained showed that generally each lectin reacted with a different pattern of protein bands so that the patterns were mostly distinct for each lectin for the different samples. When the staining patterns for the five lectins were compared side by side for all samples, the patterns were different. It was found specifically that UEA-I did not stain proteins in two samples, weakly stained one sample, and stained proteins in five samples. PNA stained one major band in four samples and multiple bands in four other samples. ECA only faintly stained six samples and reacted more strongly with six others. TL stained all samples, but one had a high molecular mass component absent from the others. STA stained high molecular mass bands of different size in three samples but not in three other samples.

The conclusion was that a panel of five lectins UEA-I, PNA, ECA, TL, and STA had different patterns of reactivity that distinguished saliva samples from different sources. This finding may be further investigated for forensic applications.

### B123 Electrochemical Screening of Synthetic Cannabinoids

*Miriam Barquero Quirós, PhD, University of Costa Rica, San Pedro, San Jose 11504, COSTA RICA; Mario Molina Porras, University of Costa Rica, San Jose 11501, COSTA RICA; Luis E. Arroyo, PhD\*, West Virginia University, Morgantown, WV 26506-6121; Jerson González, MS, University of Costa Rica, San Jose 11501, COSTA RICA*

**Learning Overview:** After attending this presentation, attendees will be able to understand the use of electrochemical techniques as screening tools in forensic science.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by advancing toward a micro electrochemical novel sensing method that will provide qualitative and quantitative information to enhance workflow in laboratories to speed up screening tests and analysis samples, reducing costs.

The proposed approach will allow on-site testing of synthetic cannabinoids supporting for non-invasive sample analysis with minimal volume at a low concentration as a rapid detection system. New screening tools in forensic science are of growing importance and will have implications in screening of new abuse drugs that pose a significant threat to the United States people and other countries. The collective term Synthetic Cannabinoids (SCs) addresses a drug group that doesn't have any resemblance to classical cannabinoids. The name has its origin in the effect that these substances exert on the central and peripheral nervous system. A large number of intoxications and some deaths have been linked with its use. Most new versions of SCs are chemically modified quickly and thus are not banned as illegal substances.

Newest generation SCs include N alkyl indole indazole derivatives. Usually, chemical analysis of cannabinoids can be accomplished by means of gas and liquid chromatography with mass detection. While these are definitive techniques, the high cost of chromatographic equipment should be considered by laboratory facilities. By contrast, electrochemical techniques could be used as preliminary screening tests because they use low cost equipment and miniaturized electrodes, require minimal sample amounts, and can be easily adapted to forensic science research. Moreover, the development of portable equipment is an attractive advantage. Although electrochemical techniques should be considered, there are some difficulties with electrochemical determination, such as high oxidation potentials. Another problem is contamination of electrodes with insoluble oxidation products. Both were overcome using Diamond Boro Doped (DBD) electrodes and optimizing an electrochemical procedure of cleansing. Thus, this electrochemically eco-friendly method was developed for the screening of synthetic cannabinoids. This was performed in a 100 $\mu$ L cell of home-built design. Analysis of cannabinoids was performed at concentrations between 0.1mg/L–1.0mg/L at pH 5.02 in an artificial saliva media by Pulse Differential Voltammetry (DPV) in cathodic and anodic mode. Peak potentials were determined for 11 synthetic cannabinoids. The same cell was used to obtain calibration curves in Acetonitrile/Tetraethyl Ammonium Perchlorate (CH<sub>3</sub>CN/TEAP 0.01 M) in low concentrations using DPV. Cyclic Voltammetry (CV) was also performed in CH<sub>3</sub>CN/TEAP 0.01M. At concentrations between 8–20mg/L of cannabinoids using Pipette Tip Solid-Phase Extraction (PTSPE) with another cell adapted for organic solvents, peak potentials were determined on drops of solution. Three micro methods were developed and applied to 25B-NBOMe.HCl, N benzyl piperazine; 1,3 chlorophenyl piperazine; NN dimethyl tryptamine, Cis 4,4 dimethyl aminorex, JW018, JW073; XLR 11, MAM220, and AB Pinaca and Fubinaca. All are known drugs of abuse in seized street samples. Absorption spectra were obtained for every compound tested. The use of these micro methods is possible as a presumptive screening method prior to identification.

### **B124 Optimal Extraction of Fentanyl Volatile Organic Compounds (VOCs) for the Development of Canine Training Aid Mimics**

*Leann Forte, BS\*, Vero Beach, FL 32960; Kenneth G. Furton, PhD, Florida International University, Miami, FL 33199*

**Learning Overview:** The main objectives of this presentation are to teach attendees how VOCs are used for mimicking sent profiles as well as how proper canine training aid mimics are developed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees how training aids are used in police work to safely train canines on the scent profiles of illegal drugs. This training aid was developed to help train canines on the scent profile of fentanyl. Since fentanyl is such a potent and dangerous drug, many police agencies are fearful of training their canines due to the life-threatening risks. This training aid will not only take away those risks, but it will also safely prepare canines to alert to fentanyl while working. This will not only help limit the amount of fentanyl coming into our country or onto our streets, but it will also help to decrease the number of fentanyl-related overdoses.

Using canines as a way to detect controlled substances, such as illegal drugs, can be dangerous since trainers and handlers are working with a living biological detector. The danger mentioned can stem from the potency of the drug being detected as well as the health effects the drug can pose on the canine if the drug is inhaled. This led to the development of safe training aids that mimic the scent profile of illegal drugs. Training mimics have been developed for drugs such as cocaine, methamphetamine, and MDMA. This project investigates the development of a training aid mimic for fentanyl.

Prior studies have concluded that fentanyl is 100 times more potent than morphine. This potency can not only be dangerous for humans but for police canines as well. Since police canines work exclusively with their sense of smell, the inhalation of fentanyl can be fatal. It is for this reason that many police agencies choose not to train their canines to detect fentanyl. However, there are a few police agencies that are taking the risk to better prepare themselves against the fight with fentanyl. Current methods for training police canines to detect fentanyl pose a threat to the canine's lives by exposing them to pure fentanyl or assuming that the scent profile is similar enough to heroin and the canine will alert.

This study investigates the scent profile of fentanyl by using a Solid Phase Microextraction (SPME) Gas Chromatograph/Mass Spectrometry (GC/MS) method to detect the VOCs in the headspace of fentanyl. When using this method, specific VOCs are isolated and introduced to canines that have been trained on fentanyl. This was done with the expectation that canines will alert to the odor of these VOCs in the same way they would alert to fentanyl. Once the proper scent profile was detected, it was used to create a training mimic that can be used to safely train canines to detect fentanyl.

The goal of this study was to create a training aid mimic to safely train police canines to detect fentanyl. This study was completed to not only properly prepare police canines to detect fentanyl, but to then utilize those canines to decrease both the amount of fentanyl entering the country and the number of fentanyl-related overdoses.

### B125 The Forensic Analysis of Temporary Tattoos

*Erika Bravo, MS, John Jay College of Criminal Justice, New York, NY 10019; Paige Cooper, MS, John Jay College of Criminal Justice, New York, NY 10019; Thomas Kubic, JD, PhD, Northport, NY 11768; John Lombardi, PhD, New York, NY 10031; Michelle D. Miranda, PhD\*, Farmingdale State College, State University of New York, Farmingdale, NY 11746*

**Learning Overview:** After attending this presentation, attendees will better understand the physical and chemical characteristics of temporary tattoos, including transferable picture tattoos and freehand inks marketed toward both children and adults.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing examiners with information that will help them distinguish a temporary tattoo from a permanent tattoo, which may prove useful in investigations and identifications.

For thousands of years, cultures worldwide have used permanent tattoos for social identification and artistic expression. More recently, temporary tattoos have become more common and can potentially be used to identify individuals when biometric traits are unavailable. Transferrable picture tattoos are available for both children and adults, and inks to produce freehand, temporary tattoos are being marketed toward adults. The different types of temporary tattoos can be analyzed and distinguished from permanent tattoos and further distinguished from one another utilizing a variety of analytical methods.

Visual, microscopic, chemical, and spectroscopic methods were used to analyze the temporary tattoos. Visual examination consisted of evaluating the package ingredients listed and comparing them to alternate data sources made available by the manufacturer, such as MSDS, and observation of the tattoos/inks with an alternate light source at various wavelengths of radiation to assess fluorescence properties. Microscopic examination was conducted utilizing stereomicroscopy and brightfield microscopy in an effort to evaluate the dye distribution and printing patterns. Chemical extractions were performed in an attempt to isolate the dyes in the temporary tattoos and remove the colorless adhesive present. Spectroscopy, specifically Ultraviolet/Visible (UV/Vis) light spectroscopy and Fourier Transform Infrared (FTIR) spectroscopy, was employed in an attempt to identify the chemical composition of both the freehand inks and layers of the transferable picture tattoos. IR spectroscopy was used to analyze and compare different sections of temporary tattoo samples through the use of Attenuated Total Reflection (ATR) and Reflection-Absorption (RA) spectroscopy.

Some temporary tattoo companies do not openly disclose the ingredients present in their products, making it difficult to assess the composition of the temporary tattoos from packaging alone. Of the many temporary tattoo samples viewed with an alternate light source, only a handful of samples exhibited fluorescence, albeit weakly. The optimal conditions for fluorescence were found to be with a red filter and light with a wavelength of 555nm. Brightfield microscopy revealed that different printing patterns can be observed within one temporary tattoo sample and between samples from different brands. UV/Vis spectroscopy revealed that for the transferrable picture tattoos, the wavelengths of maximum absorption did mostly correspond with what would be expected for each color, with the exception of the secondary colors orange and purple. Seven out of ten henna samples shared an absorption band at 670nm, but there were otherwise few notable similarities in their spectra. ATR provided valuable information about the similarities and differences between the temporary tattoo samples. In general, temporary tattoos of the same type (such as henna or jagua) or same brand of transferrable picture tattoo had similar spectra, while transferrable picture tattoos from different brands had noticeably different spectra. IR spectral data was overwhelmingly characteristic of the adhesive layer, with individual dyes being undetected. RA results were consistent with the ATR data, with differences observed in spectral resolution.

The most effective ways to distinguish temporary tattoos from permanent tattoos and to differentiate between temporary tattoos are microscopy and IR spectroscopy. Specifically, the discriminating characteristics found in this study were the printing pattern of the transferable picture tattoos and the chemical composition of the adhesive layer of transferable picture tattoos. If a printing pattern is observed, the tattoo is likely temporary. IR spectroscopy can distinguish between henna or jagua, two common types of freehand temporary tattoos. IR spectroscopy can also yield results consistent with an adhesive, another indicator of a temporary tattoo. As a preliminary study, this research sets the stage for future studies in evaluating children's and adult temporary tattoos for forensic purposes.

#### Tattoo, Microscopy, Spectroscopy

### **B126 The Calculation of Calibrated Likelihood Ratios (LRs) for Glass Using a Multivariate Kernel Density Model: Introducing a User-Friendly Graphical User Interface (GUI)**

Anuradha G. Akmeemana, PhD\*, Florida International University, Miami, FL 33199; Ruthmara Corzo, PhD, Gaithersburg, MD 20899-8371; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** The goals of this presentation are to demonstrate the calculation of LRs for glass using a GUI and the interpretation of evidence using numerical values.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how this software will help forensic scientists calculate LRs easily for casework glass using this GUI.

Laser Ablation-Inductively Coupled Plasma/Mass Spectrometry (LA-ICP/MS) for the quantitative elemental analysis of small fragments of glass evidence is considered the “gold standard” in the forensic analysis and comparison of glass.<sup>1</sup> The Organization of Scientific Area Committees (OSAC)-approved American Society for Testing and Materials (ASTM) E30 standard test method of analysis measures the concentrations of 17 elements and describes the comparison of glass samples collected from a victim or suspect to a known source. If the ASTM method results in no significant difference between the elemental concentrations of the recovered and the known source, a likelihood ratio can be calculated to better report the weight of the “match” between the glass samples. It has been previously reported that the use of a Multivariate Kernel (MVK) density 2-level model can be calibrated using Pool Adjacent Violators (PAV) that result in very low Rates Of Misleading Evidence (ROME), less than ~1% false exclusions and less than ~1% false inclusion rates.<sup>2,3</sup> Three glass databases were used to evaluate the performance of the LR; the first database includes 420 automotive windshield samples of known (authenticated) sources, the second database includes 385 glass samples from casework (the Federal Criminal Police Office of Germany [in German: Bundeskriminalamt, BKA]), and the third is a combination of the two. In addition to low ROME rates, the calibrated LRs limited the magnitude of the misleading evidence, providing only weak support for the incorrect hypothesis. Finally, most of the pairs found to be “falsely included” were explained by similarity of manufacturer of the glass source.

This presentation will focus on the simplification of the application of the previously developed R code for routine calculation of the LR in casework. One of the disadvantages in utilizing R programming is that it requires considerable knowledge in using the R software. The aim of the current effort is to develop a GUI to access the in-house written R code to calculate LRs to interpret the forensic glass evidence. The current R code has five main sections including: (1) installing and loading the required R-packages; (2) loading the background database (any glass database with the log<sub>10</sub> of elemental concentrations of glass); (3) calculation of LRs for the samples in the background database (same source and different source) using the combination MVK+PAV calibration model; (4) load the casework data to be considered; and (5) calculate and calibrate the LRs obtained for casework data. All of the above steps within the process will be presented as graphical widgets within the GUI interface. The calculated LRs will be displayed in the “output” interface and the data will be saved as a “.csv” file. This presentation will include instructions on how to access the original R code, the simplified GUI interface with detailed instructions, and also make the background databases available.

The goal of this effort is to reduce the computational barriers to calculate LRs using the previously published MVK+PAV calibration model so that forensic practitioners can routinely use a quantitative and objective method for reporting glass evidence comparisons using an LR and couple verbal statements with a numerical interpretation of the casework evidence.

### **B127 An Evaluation of Materials for Documenting Injuries From Blunt and Sharp Implements**

*Sienna S. Brown, Woodinville, WA 98072; Judy Melinek, MD\*, PathologyExpert, Inc, San Francisco, CA 94121*

**Learning Overview:** The goal of this presentation is to provide forensic science practitioners with a direct comparison of materials used in making impressions for documenting injuries from blunt force and sharp instruments. This presentation equips forensic scientists with cost-benefit insight that may help them in deciding which materials may be most suitable to use in different circumstances, given access and availability.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with insight into different materials that can serve investigations in areas where expensive materials may not be accessible. This presentation will enhance their ability to evaluate alternatives when silicon-based impression materials are not an option, unavailable, or do not fit the needs of the forensic scientist.

Collecting and preserving tool mark impression evidence is critical for forensic autopsy. This evidence is often used to identify weapons used in homicide as well as to demonstrate the cause of death in legal settings. Medical examiners must use impressions to determine the mechanism of an injury and to identify the weapons used to cause those injuries. While the collection and preservation of evidence is an important part of field forensics, there is tremendous variation in the cost and variability of materials to make these impressions.

This investigation provides forensic science practitioners with a direct comparison of materials used in making impressions for documenting blunt force and sharp instrument injuries. This study tested the hypothesis that there are less expensive and easier-to-obtain materials that are just as good as expensive materials in documenting pattern injuries from blunt and sharp implements. The methodology used four implements to test across three different materials. The three different materials were: AccuTrans™ Casting Silicone (\$135 for 10oz), Polyform Model Air by Polyform Products, Inc. (\$12.49 for 16oz), and Mold Putty by Alumilite Corporation (\$26 for 10.58oz). Each implement was tested in different dimensions and orientations. The substances were impacted and then photographed with measurements taken and changes documented over time. The differences in measurement and aesthetic appearance were calculated and compared via photography. Measurements were taken daily for the first week, then again on day 14 and day 21. The results showed that all tools and material compounds showed variability in the first seven days. The data revealed that stable measurements could be obtained for all materials after two weeks when little variability was seen in any of the materials.

Based upon the data, the AccuTrans™ Casting Silicone provided the most stable and consistent measurements with low variability for some blunt force and sharp instruments. Inspection of the molds also showed extra detail on the AccuTrans™ Casting Silicone and the AccuTrans™ Casting Silicone appeared to be the most consistently accurate impression material overall. Surprisingly, the much less expensive Polyform Model Air was almost as accurate and showed the same low variability after two weeks. The results indicate that the AccuTrans™ Silicone Casting is best suited for small surface areas as it can be difficult to use to record large or multiple injuries.

This study reveals that while expensive materials for making impressions documenting blunt force and sharp instrument provide the most stable and consistent measurements, much less expensive materials perform almost as well, depending on the injury impression required. The less expensive material could be particularly useful for blunt force or sharp instrument injuries covering a large area or where the impressions across a large area need to be made in proximity. Finally, this investigation provides attendees with insight into different materials that can serve investigations in areas where expensive materials may not be accessible. This study enhances the ability to evaluate alternatives when expensive impression materials are not an option, unavailable, or do not fit the requirements for measuring the injuries presented because of mitigating circumstances or cost concerns.

#### **Impression Materials, Blunt Instrument Injury, Forensic Molds**

### B128 An Analysis of Amino Acids in Latent Fingerprints Using Gas Chromatography/Mass Spectrometry (GC/MS)

*Shokouh Haddadi, PhD\**, State University of New York at Oswego, Oswego, NY 13126; *Shelby N. Barnes*, State University of New York at Oswego, Oswego, NY 13126-3599; *Jenna M. Covey*, State University of New York at Oswego, Oswego, NY 13126-3599

**Learning Overview:** The goal of this presentation is to inform attendees of the method developed for removing latent fingerprints from a glass surface and the subsequent derivatization and analysis of amino acid content of latent fingerprints using GC/MS. Attendees will learn how each step of the sample preparation and instrumental analysis is optimized and developed for a successful analysis. Attendees will be presented with the data obtained from the analysis of standard mixtures of amino acids as well as the data obtained from real latent fingerprint samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a method that can potentially be used at crime scenes for the analysis of amino acid content of latent fingerprints. The amino acid content has the potential to provide information about the suspects, such as gender, possible diseases, or even ethnicity, which can help narrow the list of suspects when a match is not found in the national database.

Latent fingerprints are formed by the deposition of perspiration and oils, contained in the ridges of the skin, on a surface. In the case of a crime, latent fingerprints located at a crime scene are developed, and the ridge patterns are compared to those of possible suspects or criminal databases for identification purposes. However, if no suspect exists or there is no database match, the developed fingerprint is merely saved within the database for future reference. Recently, scientists have demonstrated that fingerprints can provide more information about potential suspects than the physical pattern of their skin ridges. One study has demonstrated a qualitative relationship between the overall levels of amino acids and the sex of the individuals. Since amino acid levels in biological samples of individuals are influenced by many factors, such as ethnicity, sex, diseases, and dietary habits, accurate amino acid profiling could help to provide more physiological insight into the individual who has left the fingerprint behind at a crime scene. However, the procedures employed to date have not been successful in individual analysis of amino acids in fingerprints and are not readily applicable in everyday crime scene situations, and more practical procedures need to be developed and validated.

The purpose of this project was to develop a quantitative and feasible method for reliably removing and analyzing amino acids from latent fingerprints. In this study, the amounts of individual amino acids were measured in latent fingerprints after being deposited on glass slides. The deposited latent fingerprint was first swabbed from the surface using a Q-tip<sup>®</sup> soaked in a mixture of solvents (n-butanol:acetic acid:acetone:toluene:water), which was then transferred to a vial and washed two times with the same mixture. The wash mixture was then evaporated, and the proteins and peptides in the fingerprint were hydrolyzed with a 6 M HCl solution at 110°C overnight. The HCl solution was then evaporated, and the derivatizing reagent and solvent, N,O-Bis(trimethylsilyl)trifluoroacetamide (BSTFA) and acetonitrile, were added respectively after purging the vial with nitrogen gas. The derivatization was performed at 60°C for four hours. The derivatized amino acids were then separated and identified using GC/MS. Identification was performed by comparing the mass spectra and retention times of the derivatized amino acids in the fingerprints to those of the derivatized standard amino acids. The developed method was tested for the analysis of amino acids in male and female latent fingerprints. To perform quantitative analysis, the same procedure was applied to the glass slides spiked with a mixture of standard amino acids at different concentrations. The hydrolysis step was omitted for the standard mixtures. The data obtained from the standard amino acids were used to plot calibration graphs, which were used to calculate the amount of identified amino acids in the fingerprint samples.

#### Latent Fingerprint, Amino Acids, Gas Chromatography

### B129 High-Throughput Screening of Drugs of Abuse Using a Robust Thermal Extraction Ionization Source (TEIS)

*Pierre Negri, PhD\*, SCIEX, Redwood City, CA 94065; Oscar G. Cabrices, PhD, SCIEX, Redwood City, CA 94065; Neil Davenport, SCIEX, Centre Park, Warrington UK WA1 1RX, UNITED KINGDOM; Ashley Sage, SCIEX, Centre Park, Warrington UK WA1 1RX, UNITED KINGDOM; Peter Luke, Mass Spec Analytical, Bristol UK BS34 7RP, UNITED KINGDOM; Carl Fletcher, Mass Spec Analytical, Bristol UK BS34 7RP, UNITED KINGDOM*

**Learning Overview:** The objective of this study is to demonstrate the high level of sensitivity and robustness of this combined system for rapid and confident compound identification of drugs of abuse.

**Impact on the Forensic Science Community:** The abuse of opioids and other related drugs continue to pose serious public health and safety issues worldwide. As these substances continue to cause widespread intoxications resulting in fatalities worldwide, robust and comprehensive detection is critical to enable forensic laboratories to rapidly and accurately identify these substances. This presentation will impact the forensic science community by describing a method combining a TEIS coupled with a Mass Spectrometry (MS) system used for ultra-fast screening of drugs of abuse without the need for chromatography or extensive sample preparation. The combined system can quickly identify unknown drugs of abuse with a high level of confidence suitable for rapid forensic screening.

**Methods:** The TEIS was combined to an MS system for the identification of drugs of abuse. Upon integration of the source to the mass spectrometer, the source was heated to 285°C to volatilize the solvent injection, and a sample pump was used to draw the gaseous molecules toward the ionization region. Samples were injected via a microliter syringe into an injection port at the front of the top block for liquid standards or a slot between the two heated blocks for paper swabs. MS detection was performed in positive mode using a multiple reaction monitoring scheme to detect precursor and product ions of each of the targeted analytes.

**Results:** The use of the TEIS on a mass spectrometer enabled the rapid acquisition of MS data for high-throughput screening. First, drug-of-abuse standards were injected into the source and MS parameters were tuned. This process was used for each of the drug-of-abuse standards to determine the fragmentation pattern of each analyte and to appropriately select two product ions. Drug-of-abuse residues were tested by swiping a piece of paper on a dry surface onto which an unknown drug-of-abuse mixture was left to dry. The piece of paper was then inserted into two heated blocks of the TEIS and positive identification of the unknown drugs of abuse was accomplished by monitoring the thermal desorption profile in the form of an Extracted Ion Chromatogram (XIC) for two transitions monitored for each drug analyte. This process enabled the confident detection and quantitation of cocaine, amphetamine, and MDMA as the unknown compounds in the swab residue. Quantification of the drug residues present on a cell phone screen was also performed. The amount of the drug residues transferred to the paper swab was calculated using the area value for each of the XIC peaks resulting from the thermal desorption profile for each of the two transitions and solving for  $x$  using the linear regression equation. Using this method, the averaged values for cocaine, amphetamine, and MDMA were found to be 8.16 ng, 7.84 ng, and 5.53ng, respectively.

**Conclusion/Discussion:** Accurate identification and confident identification of low levels of drug residues is feasible using the extracted XICs based on the MRM transitions for the drug analytes. This demonstrates that the combination of Atmospheric Pressure Chemical Ionization (APCI) with thermal desorption is suitable as a fast sampling and screening method for trace analysis of drug residues. This approach shows potential application for trace analysis of drug residues from containers and parcels for high throughput security screening.

#### Drugs of Abuse, Mass Spectrometry, High-Throughput Detection

### **B130 Pepper Plants and Magic Mint—The Application of Ambient Mass Spectral Analysis for the Rapid Detection and Quantification of Psychoactive Compounds in the Complex Matrices of Plant-Based Legal-High Substances**

Megan I. Chambers, BS\*, Guilderland, NY 12084; Amy M. Osborne, BS, State University of New York at Albany, Albany, NY 12222; Justine E. Giffen, BS, State University of New York at Albany, Albany, NY 12222; Rabi A. Musah, PhD, State University of New York at Albany, Albany, NY 12222

**Learning Overview:** After attending this presentation, attendees will better understand how mass spectrometric techniques can be applied to the identification of plant-based legal-high substances and the quantification of the psychoactive compounds in complex plant matrices.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a protocol that will enable law enforcement and forensic crime laboratories to rapidly detect and quantify plant-based legal-high substances that are otherwise indistinguishable from plants that are non-psychoactive.

*Piper methysticum* and *Salvia divinorum*, commonly known as kava and salvia, respectively, are psychoactive plants identified by the United Nations Office on Drugs and Crime (UNODC) as two of the “20 plants of concern” containing psychoactive compounds. The non-characteristic appearance of these plants of abuse and their derived products make it difficult for law enforcement and forensic crime laboratories to distinguish them from plants that are not psychoactive or mind-altering. Current methods of analysis often include time-consuming sample preparation, lengthy run-times, overlapping retention times, and are heavy on the use of solvents. Although neither of these plants are federally classified as controlled substances, in states where they are scheduled or restricted, cases are rarely prosecuted because of the difficulties and challenges associated with proving the plant material to be what it is. The investigation presented here focused on resolving these problems with a method that circumvents the challenges associated with other methods, rapidly screens for unique chemical biomarkers of these plants, and quantifies their psychoactive constituents. Because of its unique attributes and features, the use of Direct Analysis in Real-Time High Resolution Mass Spectrometry (DART®-HRMS) as the instrumental approach assists in the accomplishment these goals. DART®-HRMS is an ambient ionization technique that allows for the direct analysis of samples, rapid screening and identification of compounds, and semi-automated quantification with the use of a linear rail system to produce consistent and reproducible results.

Representative kava and salvia samples were used to determine if DART®-HRMS could rapidly detect the relevant analytes of interest in these plants. The six major kavalactones and three flavokavains were detected in the kava products, and the compound salvinin A was detected in the salvia products. DART®-HRMS was then used to confirm that all 28 of these products originated from either kava or salvia plant material. Because yangonin and salvinin A are the major psychoactive components of kava and salvia plants respectively, standard curves developed using calibrators and internal standards of either yangonin-*d*<sub>3</sub> or cholesterol were used to quantify their presence in the various products. The ratio between the protonated yangonin and yangonin-*d*<sub>3</sub> isotope peaks was preserved in all calibrators, as was the ratio between the salvinin A [M+H]<sup>+</sup> and cholesterol [M+H-H<sub>2</sub>O]<sup>+</sup> peaks, and could therefore be used to develop standard curves to confirm their concentration in quality control samples. With the success of three runs for each of the psychoactive chemical standards, all validated according to the Food and Drug Administration (FDA) guidelines, the protocols were considered acceptable for application to commercial products with unknown yangonin or salvinin A content.

Eighteen kava products were purchased from eight vendors and consisted of powders, tinctures, capsules, roots, and pastes. Although two samples fell just below the validated curve range, the remaining 16 kava products contained yangonin concentrations that fell within the linear range of the standard curve. Tincture and liquid samples had yangonin concentrations that were between 1.03 and 4.59mg/mL, while the solid samples exhibited a range from 2.71 to 8.99mg/g. Eight salvia products were purchased from two vendors and included raw salvia leaf and enhanced leaf extracts of varying potencies. The salvia leaves had an average salvinin A concentration of 1.54mg/g, while the enhanced leaf extracts had concentrations ranging from 13.54 to 53.24mg/g depending on the reported strength of the extract (ranging from 5x to 60x). In addition, the concentration of salvinin A in the leaves and extracts were relatively consistent with previously reported salvinin A concentrations in *S. divinorum* products.

These results demonstrate the development of a protocol that can rapidly detect plant-based legal-high substances in a variety of complex plant matrices, in addition to enabling the quantification of the psychoactive components in the various sample types, and it circumvents many of the problems encountered during analysis of these plants by conventional methods.

### **B131 A Trace Elemental Analysis of Aluminum Flake Particles in Automotive Metallic Paints for Traffic Accident Investigation Using Synchrotron Radiation Micro X-Ray Fluorescence Spectrometry ( $\mu$ -SR-XRF)**

*Yoshinori Nishiwaki\*, Kochi-shi, JAPAN*

**Learning Overview:** The goal of this presentation is to establish a new method for forensic identification of automotive metallic paint fragments based on trace elements in the aluminum flake particles by  $\mu$ -SR-XRF.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by revealing that the trace elements in aluminum flake particles obtained by  $\mu$ -SR-XRF at SPring-8 became new indicators for the discrimination of automotive metallic paint fragments.

Automotive paint fragments are very important samples for traffic accident investigations. In forensic science laboratories in Japan, automotive paint fragments have been analyzed by the following four techniques: optical microscopic observation, microspectrophotometry, Fourier Transform Infrared (FTIR) spectroscopy, and Scanning Electron Microscopy/Energy Dispersive X-ray Spectrometry (SEM/EDS). However, there are cases in which the paint samples cannot be distinguished enough by these analytical methods. On the other hand, metallic pigments are widely used to enhance the designability of cars. It is known that aluminum flakes for automotive metallic pigments have a purity of 99.0% or higher and contain a large variety of trace elements. In this point of view, after shape observation and major element analysis of the aluminum flake particles in automotive paint fragments with SEM/EDS, the trace elemental analysis by  $\mu$ -SR-XRF was carried out using SPring-8, the world's largest synchrotron radiation facility. This study attempts to discriminate automotive paint fragments by the trace element composition of aluminum flake particles. The goal of this presentation is to establish a new method for forensic identification of automotive metallic paint fragments based on trace elements in the aluminum flake particles by  $\mu$ -SR-XRF.

Twelve metallic paints obtained from accident vehicles were collected for this research. For measurements of the paint fragment samples, three 0.4mm long by 0.4mm wide fragments, including metallic pigment layers, were separated individually with a scalpel blade. After carbon vapor deposition onto the separated fragments was conducted using carbon coater, SEM/EDS analysis was performed. The  $\mu$ -SR-XRF analysis was carried out at BL05SS of SPring-8. Since trace elements in the particles could be effectively excited, an incident X-ray beam of 20keV with a size of  $2\mu\text{m} \times 2\mu\text{m}$  was prepared by means of the Kirkpatrick-Baez (K-B) mirror system.

Based on the results of SEM/EDS analysis, aluminum (Al), silicon (Si), sulphur (S), and barium (Ba) were detected and the 12 samples were classified into 2 groups: Al-Si type (6 samples) and Al-Si-S-Ba type (6 samples). S and Ba are derived from a pigment dispersant ( $\text{BaSO}_4$ ), which can easily and finely disperse aluminum flake particles in reigns of car paints. Many elements, such as Al, Si, S, chlorine (Cl), calcium (Ca), Ba, iron (Fe), copper (Cu), zinc (Zn), gallium (Ga), lead (Pb), strontium (Sr), zirconium (Zr), and niobium (Nb) were detected in the aluminum flake particles by  $\mu$ -SR-XRF. Ga is generally contained in aluminum alloys because it is the same family element of Al. For that reason, Ga was detected in all aluminum flake particle samples. The aluminum flake particles could be identified with high accuracy by comparing the trace elements. It was found that the trace elements became new indicators for forensic discrimination of automotive metallic paint fragments.

#### **Aluminum Flake Particles, Automotive Metallic Paints, Synchrotron Radiation X-Rays**

### **B132 Optimization of the Forensic Identification of Blood Using Surface-Enhanced Raman Spectroscopy (SERS)**

*Miranda L. Shaine, BS\*, Allston, MA 02134; Richard S. Andino, PhD, Boston University, Photonics Center, Boston, MA 02215; Ranjith Premasiri, PhD, Boston University, Boston, MA 02215; Harrison Ingraham, BS, Boston University, Photonics Center, Boston, MA 02215; Amy N. Brodeur, MFS, Boston University School of Medicine, Boston, MA 02118; Lawrence Ziegler, PhD, Boston University, Boston, MA 02215*

**Learning Overview:** After attending this presentation, attendees will understand the principles of SERS, the characteristic spectroscopic features for blood identification, the wide variety of substrates on which SERS testing can be applied, and the ease of use and practical application for in-field sample analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a universal technique for the practical application of the identification of blood using SERS. It is recommended that crime scene investigators and detectives become familiar with this technique for the quick and easy use of on-scene sample analysis.

Blood is considered one of the most important forensic evidence found at a crime scene. The use of SERS provides a non-destructive and highly sensitive technique for the confirmation of blood for forensic relevance and can be applied on a portable Raman device for quick sample preparation and processing.

SERS is one of the few confirmatory techniques for blood and the only spectroscopic technique employed for the identification of blood at a crime scene or in the forensic laboratory. This method is able to distinguish between blood from other body fluids by collecting the SERS spectrum on a substrate surface that has been embedded with gold nanoparticles (AuNPs). The AuNPs create an electric field surface enhancement that produces an intense signal, leading to a SERS enhancement. The SERS enhancement allows for sensitive blood detection at dilutions down to 1:10,000, when dried bloodstains are not visible to the naked eye, mimicking a crime scene that has been previously cleaned. A stain transfer method to the SERS substrate was optimized by extracting dried bloodstains with water, saline, and 50% acetic acid solution. Acetic acid proved to be the most efficient in retaining the blood components and releasing the hemoglobin component of blood for detection.

The SERS spectrum of blood is a robust signature of hemoglobin that does not change over time. Characteristic peaks for the identification of blood are 754, 1513, and 1543  $\text{cm}^{-1}$ , attributed to a pyrrole ring breathing mode (Nu15) and two  $\text{C}_\beta\text{-C}_\beta$  stretches (Nu11, Nu38), respectively. These key SERS peaks, high sensitivity, and signal enhancement by a factor of ten are favorable when compared to normal Raman spectroscopy. A quick and easy procedure for in-field sample analysis for the detection of blood on different substrates has also been developed and applied on a portable Raman device. Various non-porous and porous substrates, including glass, ceramic tile, cotton, denim, fleece, nylon, acetate, wool, and polyester, have yielded strong results for the identification of bloodstains. In addition, testing different commercial and in-house SERS substrates has been effective in the identification of blood.

SERS identification of blood for forensic work is a non-destructive and portable tool that can be applied for quick and easy examination of evidence at a crime scene. The high sensitivity and selectivity of SERS provides a robust spectroscopic signature that aids in the confirmation of blood. It is a more favorable method when compared to alternative presumptive tests for blood and can be applied to stains on a variety of SERS substrates and sample surfaces for universal testing.

#### **SERS, Body Fluid Identification, Forensics**

### **B133 A Chemical Analysis of Gunshot Residues (GSRs) for Investigative Leads and Reconstruction of Firearm-Related Incidents**

*Courtney H. Vander Pyl, MS\*, Department of Forensic and Investigative Science, Morgantown, WV 26506; Oriana Ovide, Department of Forensic and Investigative Science, Morgantown, WV 26505; Colby E. Ott, MS, Shippensburg, PA 17257; Luis E. Arroyo, PhD, West Virginia University, Morgantown, WV 26506-6121; Tatiana Trejos, PhD, West Virginia University, Morgantown, WV 26506*

**Learning Overview:** After attending this presentation, attendees will have learned about the capabilities of Laser-Induced Breakdown Spectroscopy (LIBS) to offer rapid and reliable information in firearm-related investigations and to compliment other confirmatory chemical analyses (Scanning Electron Microscopy with Energy-Dispersive X-ray Spectroscopy [SEM/EDS] and Gas Chromatography/Mass Spectrometry [GC/MS]).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by proposing a practical, objective, and reliable method to modernize the analysis and interpretation of Firearm Discharge Residues (FDRs) in clothing and non-movable objects.

When a shooting incident occurs, materials and compounds originating from the ammunition are deposited on surrounding surfaces in the form of FDRs. These residues, which include Organic and Inorganic GSRs (OGSRs and IGSRs), can become essential pieces of evidence. For instance, when the question of suicide or murder arises, estimating the barrel-to-victim distance may play a critical role in the outcome of a case. Also, clothing, wounds, and other target materials are often inspected to determine an entrance or exit bullet orifice. Conventional methods used in the course of these investigations include colorimetric assays that react with organic compounds and heavy metal components present in the propellant and primer. However, these assays have severe drawbacks regarding reproducibility and selectivity; they are challenging to perform in non-movable objects and are partially destructive of the evidence. Bloody and dark-colored items can significantly diminish the efficacy of these assays. Furthermore, modernized ammunitions (non-toxic) have eliminated the use of the heavy metal compounds needed for some color reactions.

As a result, this study aimed to develop a novel approach that uses LIBS chemical mapping for shooting distance determination on blood-stained clothing, identification of FDR on substrates of interest, and identification of IGSR of standard and non-toxic ammunition. The central hypothesis of this research is that LIBS will provide an enhanced analytical technique for the detection of standard and non-toxic ammunition on target materials because of its ability to simultaneously detect multiple elements in the ultraviolet and infrared regions, in just a few minutes.

The LIBS methods were developed and validated for the analysis of GSRs on substrates commonly found during firearm-related crimes. Residues were analyzed off 133 fabrics, glass, drywall, and wooden samples. For the determination of shooting distance, a calibration curve was created using 15 white clothing samples (100% cotton) covered in human blood, shot at known distances of contact, 6 inches, 12 inches, 24 inches, and 36 inches. An additional ten samples, five pristine white and five samples covered in blood, were shot at unknown distances. Once data was collected, integration of peaks was performed on elements of interest, including antimony (Sb) (259.8nm), lead (Pb) (405.8nm), and barium (Ba) (493.4nm). Principal Component Analysis (PCA) and leave-one-out cross-validated Regularized Discriminant Analysis (RDA) were then performed on the elemental intensities and chemical profiles obtained from these integrations at 20 different locations from the bullet hole. For comparison purposes, the clothing samples were then subjected to conventional colorimetric testing. Color tests resulted in a misclassification of three out of ten shooting distances (30%), while the LIBS method correctly classified the distance range of all unknown testing samples.

For the identification of suspected bullet holes, a total of 21 substrates of different materials (glass, wood, and drywall) were shot from a close distance to simulate the scene of firearm-related crime. The GSR surrounding the bullet hole was transferred to an adhesive sheet to eliminate the need to transfer the substrates back to the laboratory. The adhesive samples were then analyzed by LIBS using a rapid spectral mapping method. Spatial distributions of IGSRs, including Pb and Ba, were used to determine if a bullet created the hole in the substrate. Furthermore, four standard ammunitions (Sellier & Bellot®, Winchester®, Remington®, and TulAmmo®), and four non-toxic ammunitions (Fiocchi®, CCI®, Syntech®, and Inceptor®) were shot into textiles in multiple replicates, then analyzed by LIBS, SEM/EDS, and GC/MS for characterization of their chemical profiles.

Overall, LIBS allowed for rapid and accurate chemical mapping of GSR patterns on pieces of evidence typically found at a crime scene. Chemical imaging of Pb, Ba, and Sb provided more objective approaches to the estimation of shooting distance and bullet hole identification, compared to color tests. Moreover, LIBS, GC/MS, and SEM/EDS provided enhanced detection of standard ammunitions and lead-free ammunition.

### B134 Silicone-Based, Cost-Effective Alternatives to Traditional Casting Material for Large-Scale Impressions

Ashley E. Haas, BS\*, Emporia State University, MSFS Program, Emporia, KS 66801; Mousa Alzubi, Emporia, KS 66801-3100; Ryan M. Rezzelle, MFS, Kansas City, MO 64151; Melissa M. Bailey, PhD, Emporia State University, Emporia, KS 66801

**Learning Overview:** The goal of this presentation is to present a method to create a new material for casting that will be a cost-effective, storable, and durable option for use in making large-scale impressions.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating that it is possible to create a cost-effective alternative to traditional casting materials for use on large-scale impressions, with considerations for in-field documentation and collection.

Traditional casting materials such as AccuTRANS™ and Microsil™ have been used successfully for many years to create casts of small impressions, such as those caused by tools. Larger impression evidence has been traditionally cast with products such as dental stone; however, its use is limited due to the weight and fragility of the resulting cast. In addition, storage and transport of a large cast can be problematic. While AccuTRANS™ and Microsil™ produce good-quality, fast-drying impressions that are lightweight, the cost of these materials may be prohibitively high if a large impression needs to be cast. Through the manipulation of different caulking compounds, in addition to various additives, it is possible to make a compound that is cost-effective, fast-drying, and retains a detailed cast without compromising the integrity of the impression substrate.

Three different types of caulking compounds were studied: 100% silicone-based compounds, acrylic latex-based compounds, and compounds comprised of a mixture of silicone and acrylic latex. Ten grams of each caulking compound were applied to a masonry brick with surface imperfections generated by a hammer and chisel. The caulking compounds were then allowed to dry completely and were then removed from the brick. Each caulking compound was evaluated on drying time, ease of removal, and impression quality.

After preliminary evaluations of the caulking compounds were completed, three classes of augmenting compounds were used in conjunction with each of the caulking compounds: spray-releasing agents, Monster Liquid Latex™, and Calcium Nitrate Tetrahydrate (CNT). The spray releasing agents were used to form a barrier between the casting compound being tested and the impression substrate in order to ease removal. It was determined that the use of spray-releasing agents greatly diminished the detail quality of the impression. The addition of Monster Liquid Latex™ at a ratio of 10:1 (caulk:liquid latex) increased the pliability of the casting compound; however, it also increased the drying time required. CNT was added to each of the caulk-liquid latex mixtures in an effort to reduce drying time while retaining the flexibility of the compound and quality of the cast.

To date, the best impressions have been obtained using a combination of 100% silicone caulk and liquid latex. It has been possible to obtain a detailed and reliable cast of the impression after a drying time of approximately three hours for the size of impressions used in the study. Research is ongoing to further reduce the drying time through the use of CNT while still producing a quality impression that retains integrity over time. Future research includes testing the optimized formula on a variety of substrates, temperature conditions, moisture conditions, drying time as a function of impression size, and assessing the scalability of the optimized compound.

#### Evidence Collection, Casting, Impression

### **B135 Integrating Undergraduate Mini-Research Project Exercises in Advanced Forensic Science Curriculum as a Course-Based Undergraduate Research Experience (CURE)**

*Sulekha Coticone, PhD\**, Florida Gulf Coast University, Fort Myers, FL 33965; *Lora Bailey Van Houten, MS\**, California Department of Justice, Fresno, CA 93740-0001

**Learning Overview:** The goal of this presentation is to discuss the utility of introducing students in forensic science programs to perform research, thereby enhancing their critical thinking skills and preparing them for a career in crime laboratories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing the community with future staff who have a better understanding of the fundamental knowledge of concepts involved in processing of evidence in crime laboratories.

One of the centerpieces of scientific education for undergraduate students with a science major is the incorporation of laboratory experiences.<sup>1</sup> The National Research Council (NRC) has emphasized the need for a revision in traditional laboratory courses to focus more on critical thinking skills and a deeper understanding and knowledge application.<sup>2</sup> More recently, original research and CUREs have gained a lot of attention as a high-impact strategy to improve learning outcomes resulting in improved student learning.<sup>3</sup> Additionally, several instructors have integrated research experiences into introductory science courses to improve undergraduate student interest and preparation for their science careers.<sup>4</sup> These research-based courses differ from expository (traditional) experiences since students are asked to develop procedures and outcomes for the experiments are not known. The benefits include learning important problem solving, critical thinking, communication skills, and gaining a deeper understanding of their field of study.

To improve student-learning outcomes in forensic science courses, this study has developed a research-based curriculum at the university. In the first seven weeks of the semester, students learn fundamental research techniques in a forensic biochemistry course that includes presumptive tests, DNA extraction, DNA quantitation, short tandem repeat-based polymerase chain reactions, and capillary electrophoresis. Using this fundamental knowledge, students develop a research problem/hypothesis, identify suitable protocols by a literature survey, plan and collect samples, determine variables, analyze data, and present their results as a formal laboratory report as well as an oral presentation. Students specifically design experiments dealing with changing variables (e.g., temperature, reaction conditions) in the collection, storage, and extraction of DNA for forensic DNA analysis. Data from Student Perception of Instruction (SPOI) and Student Assessment of Learning Gains (SALG) surveys administered at the end of the semester supported gains in student learning. Additionally, pre- versus post-survey data showed that students gained confidence in organizing and presenting their data, as well as a deeper understanding of the applications of biochemistry in forensic science. Incorporating research projects in other courses will help provide students with opportunities to be innovative and learn important critical thinking skills for their future careers.

### **B136 Bode Armor™: A Developmental Validation of a Robust Preservative Solution**

Allie Flores, BS\*, Bode Technology, Lorton, VA 22079-2626; Robert A. Bever, PhD, Bode Cellmark Forensics, Lorton, VA 22079; Daniel Watsula, MS, Bode Cellmark Forensics, Lorton, VA 22079

**Learning Overview:** After attending this presentation, attendees will gain an increased understanding of Bode Armor™, a preservative solution that can be applied to reference samples after collection to enhance sample stability.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing valuable data to laboratories that are looking to implement a solution to prevent degradation on their collected reference samples.

All 50 states in the United States collect DNA samples from convicted offenders and 31 states have legislation allowing for collection of DNA samples from qualifying arrestees.<sup>1</sup> The resulting DNA profiles may be entered into databases such as the Combined DNA Index System (CODIS). As of June 2019, the National DNA Index System (NDIS) contains more than 13.5 million offender profiles and more than 3.5 million arrestee profiles.<sup>2</sup>

When a hit or match is made in CODIS, the original reference sample taken from the individual is reanalyzed to confirm the genetic profile. This confirmation can occur soon after the sample is taken, or it can occur many years after the sample was originally collected and analyzed. As DNA is a biological material, cellular breakdown and degradation can occur over time if steps are not taken to preserve the sample. Degradation of the reference sample can cause interpretation issues if reprocessing needs to occur.

The adoption of any new method or technology requires careful consideration to ensure that it does not impact any downstream processing in the laboratory. This developmental validation evaluated Bode Armor™-treated reference samples and their ability to yield a complete DNA profile following both traditional processing (extraction, quantification, and amplification) and direct amplification procedures. This validation included the required studies for accuracy, artifacts, contamination, knowns, precision, repeatability, reproducibility, sensitivity, and stability. All experiments listed were performed using the THERMOFISHER™ GlobalFiler®/GlobalFiler™Express, Promega® PowerPlex® Fusion 6C, and QIAGEN® Investigator 24plex QS/24plex GO! amplification kits. Three amplification kits from three different manufacturers were chosen so that the resulting data would be valuable to most local, state, federal, or international agencies. All amplified samples were separated on an Applied Biosystems® 3500xL capillary electrophoresis instrument and analyzed utilizing appropriate analytical and stochastic thresholds for each amplification kit in GeneMapper® ID-X.

The resulting data showed that following manufacturer's recommendations, Bode Armor™ did not prevent the laboratory from obtaining accurate, reliable, and reproducible DNA profiling results. All DNA profile results obtained from Bode Armor™-treated samples were concordant with the previously obtained donor profiles.

The recommended application volume of Bode Armor™ is 100µl per reference sample. As expected, direct amplification procedures were impacted when the application volume was increased two- or three-fold. Traditional processing methods were not significantly impacted by the increased application volumes. Through this study, Bode Armor™ was shown to be a robust preservative solution that can enhance the stability of buccal reference samples while allowing for successful downstream analysis by DNA analysts.

### **B137 Fiber Sampling Effects on the Detection of Fluorinated Coatings Studied by Pyrolysis-Gas Chromatography-Plasma-Assisted Reaction Chemical Ionization-Mass Spectrometry (Py-GC-PARCI-MS)**

*Michael J. Dolan, Jr., MS\*, Georgetown University, Washington, DC 20057; Wanqing Li, Georgetown University, Washington, DC 20057; Kaveh Jorabchi, PhD, Georgetown University, Washington, DC 20057*

**Learning Overview:** The goal of this presentation is to provide information on the suitability of fluorinated fiber coatings for fiber classification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing attendees about the potential of fluorinated oil/water-repellant fiber coatings as differentiating characteristics for otherwise identical fibers.

**Introduction:** The value of fiber evidence is largely dependent upon commonality of fiber characteristics. Therefore, it is essential to utilize any differences possible, including fiber type, color, and chemical additives, to differentiate fibers. Fluorinated polymer coatings are a common chemical additive used to impart oil and water repellence for clothing. Previous work recently demonstrated that there are several classes of these chemicals that can be detected and distinguished using py-GC-PARCI-MS at a single fiber level.<sup>1</sup> In order to be useful in forensic analysis, it is necessary to also understand the variability and persistence of these coatings within sample collection. This work aims to address some of these forensically relevant questions.

**Methods:** Threads were pulled from commercial clothing items and single fibers were separated from the threads using tweezers. A single fiber was then transferred into a quartz tube for in-line pyrolysis. The pyrolysis products were separated by GC and fluorinated species were selectively converted to F<sup>-</sup> by the PARCI ion source for detection by a single quadrupole MS. Pyrograms were then compared pairwise by plotting the intensity of the peaks from one pyrogram vs. the intensity of the peaks from the other pyrogram. The correlation coefficients in the pairwise comparisons served as a similarity metric for the fibers.

**Results:** To examine location-dependent variability of coatings, a thread from five locations was sampled from two commercially coated clothing articles. The threads were analyzed in triplicate by testing three fibers from each thread. The fibers from various locations were examined for visual differences. Fibers analyzed from a multicolor shirt of uniform fiber type showed similar pyrograms, indicating that neither color nor sampling location had an impact on the detection of fiber coatings. Further, visually similar fibers from the second clothing item also supported the insensitivity of pyrograms to sampling location. However, for fibers from different locations that were also visually different, such as natural vs. synthetic fiber, differences in relative ratios of the pyrolysis products were observed. To further substantiate the utility of py-GC-PARCI-MS, this work will examine the persistence of fluorinated coatings in two experiments. First, determining whether contact between two clothing items can cause the coating to transfer from or to a fiber will be examined. Second, determining the effect of tape lifting, a common fiber collection technique, on the detection of fluorinated fiber coatings will be investigated.

**Conclusion:** This study has shown that the variability related to location in two different commercially coated clothing has minimal impact on fiber comparisons as long as only visually identical fibers are compared. Additional experiments are aimed at examining coating transfer between fibers and the potential impact of using tape lifts on fiber pyrograms. This information is critical in evaluating the potential forensic value of fiber coatings.

### **B138 Automated High-Throughput Potency Testing of Cannabis Samples Using Gas Chromatography/Mass Spectrometry (GC/MS) in a Forensic Lab**

*Kevin W.P. Miller, PhD\**, Hamilton Robotics, Reno, NV 89501; *Kaylee R. Mastrianni, PhD*, DPX Technologies, Columbia, SC 29203; *Melissa T. Horne, BS*, Richland County Sheriff's Department, Columbia, SC 29223; *Rachel Hardy, BS*, Richland County Sheriff's Department, Columbia, SC 29223; *Elissa Renneker, BS*, Richland County Sheriff's Department, Columbia, SC 29223

**Learning Overview:** After attending this presentation, attendees will be informed of a robust, automated approach to sample preparation for determination of total delta-9-Tetrahydrocannabinol (THC) in seized cannabis samples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an avenue for increasing cannabis testing throughput to reduce case backlog and an approach to discriminate illegal marijuana from legal hemp.

In the United States, federal law and many state laws differentiate between marijuana and industrial hemp through delta-9 THC levels, whereby the latter is defined as less than or equal to 0.3 percent THC on a dry weight basis. Many traditional cannabis identification methods employed by crime laboratories cannot accurately discriminate between illegal marijuana and industrial hemp. Most current methods for determining total THC content in accordance with federal and state regulations do so with increased time, labor, and risks of instrument damage and compromised sample integrity. In the case of Richland County Sheriff's Department Drug Identification Lab, it was paramount to decrease preparation and analysis time for the fastest case turnaround.

GC/MS systems are often used by crime labs to identify other illicit substances, such as heroin. However, several challenges should be addressed when using GC/MS systems as a method to identify and quantify total available THC levels. GC/MS methods cannot detect the acidic Tetrahydrocannabinol (THCA-A) without decarboxylation or derivatization. In order to avoid the increased time and cost associated with derivatization, decarboxylation was evaluated *in situ* during GC/MS injection.

A novel, automated Dispersive Pipette Extraction (DPX) method uses tip-based technology and an automated liquid handler to enable fast, hands-free selective isolation of THC and its precursors for robust downstream GC/MS analysis. The method simultaneously processes up to 24 samples from test tube post-sonication through extraction and into GC vials in less than 11 minutes with no human involvement.

The clean extracts provided by the DPX method reduce the need for instrument maintenance normally resulting from matrix build up. The method provided an average of 86% recovery of THC. THCA-A to THC conversion in the GC/MS injection was evaluated to have a consistent average of 65%. The average precision values were below 3% Coefficient of Variation (CV) and the average accuracy values were above 98%. A blind study of non-probative case samples, acquired hemp samples, and previous proficiency tests was performed. Each sample was accurately classified as a result of this method. It has been validated and implemented by the Richland County Sheriff's Department Drug Identification Lab in Columbia, SC.

#### **Automation, Cannabis, THC Testing**

### B139 Complex Mixtures Made Suitable for Interpretation Using Probabilistic Genotyping

Christina Hayes Nash, MS\*, Bode Technology, Lorton, VA 22079

**Learning Overview:** This presentation will benefit attendees by providing real case examples in which probabilistic genotyping benefited the interpretation of data that would have been considered too complex to interpret using manual interpretation

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by assisting attendees in understanding the use of probabilistic genotyping in cases of complex DNA mixtures.

The increased use of megaplex Polymerase Chain Reaction (PCR) amplification kits has increased the occurrence of complex mixtures due to their increased sensitivity and the additional loci detected. Substantial major profiles are not always present for deduction, and manual methods for interpretation of mixture profiles containing more than two individuals often waste data that is otherwise robust (above stochastic thresholds). STRmix™, a probabilistic genotyping software that uses a fully continuous modeling approach for profile interpretation, allows for increased use of data.<sup>1</sup> It is based on a biological model, statistical theory, and computer algorithms. STRmix™ interprets DNA profiles from both single-source and mixed-source samples using a two-step approach; interpretation of DNA profiles, including deconvolution of mixtures if applicable, and then a likelihood ratio calculation to provide a weight to the possible match between the interpreted and reference profiles.

Forensic casework samples were processed in accordance with standard operating procedures at Bode Technology. The samples discussed will include clothing, firearm swabs, interior vehicle swabs, and sexual assault kit body swabs. Bode evaluated six cases to compare the suitability for interpretation with and without STRmix™. Approximately 70% of the profiles developed (8 of 11), were interpretable using STRmix™ but otherwise would have been unsuitable for comparisons and/or uninterpretable. The statistics obtained from these complex mixtures, which would have otherwise not been of any probative value due to manual interpretation confines, could be the critical factor in a case.<sup>2</sup> The forensic DNA community is moving toward increased use of probabilistic genotyping as a reliable mixture interpretation tool.

### **B140 The Detection of Volatile Organic Compounds (VOCs) Released From Mass Storage Devices Utilizing Headspace/Solid-Phase Microextraction (HS/SPME) and Its Implications for Canine Training and Contraband Detection**

*Kelvin J. Frank, Jr., BS\*, Florida International University, Miami, FL 33174; Kenneth G. Furton, PhD, Florida International University, Miami, FL 33199*

---

**Learning Overview:** After attending this presentation, attendees will have more insight into the headspace analysis of various mass storage devices and the VOCs associated with them.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing recommendations for successfully training canines to detect mass storage devices.

Canines have been well known for their detection capabilities of illicit materials, such as explosives and narcotics. In recent years, canines have been trained to successfully recognize mass storage devices that may contain evidence of illegal activity. In cases of internet-based crimes, for example, evidence may be recovered as retrieved incriminating messages or files from the offender's mass storage device. These devices may be very small, as in the case of Secure Digital (SD) cards, and therefore very difficult to find as they may be hidden in areas not visible to the human eye. However, canines can be used to detect these clandestine devices by recognizing the odor (VOC) released by these devices. An example of this was observed in the home of former Subway® spokesperson, Jared Fogle, where a canine detected a hidden Universal Serial Bus (USB) drive containing incriminating pornographic material that was not previously found by investigators.

These canines have found regular usage within law enforcement correction facilities that employ them to find contraband devices being smuggled into the prisons. The method of training these canines for this purpose varies greatly, with limited scientific work done to validate the practice or determine the mechanism by which these canines detect these devices. As a result, theories as to the target material to be used for canine training are numerous, from training on entire devices for detection, such as a cellular phone, to training on only portions of the device, such as a lithium battery, creating even further variability and reliability in the detection capabilities of the canine.

The signature VOC and the specific odors that canines are alerting to in most of these devices remain to be scientifically determined. In addition, devices may produce different VOC profiles depending on the model, make, etc. This study analyzed a wide variety of cellular telephones, their components, such as batteries and Subscriber Identification Module (SIM) cards, as well as other commonly used mass storage devices. The results of this study will discuss the headspace VOC associated with these various devices and any common VOC that can potentially be used as a canine training aid to improve canine detection to a wider range of mass storage devices.

---

#### **Canine Detection, Mass Storage Devices, Volatile Organic Compounds**

### B141 Indole and Related Non-Volatile Compound Release From Decomposing Mammalian Liver Homogenate

Hayley K. Murphy, BS\*, University of New Haven, West Haven, CT 06516; Virginia M. Maxwell, DPhil, University of New Haven, West Haven, CT 06516; Robert H. Powers, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will have a greater understanding of the pattern of release of indole and some of the non-volatile compounds generated during decomposition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by clarifying the pattern of indole generation and release during the decomposition process. This knowledge could potentially be used in the determination of postmortem interval.

During the process of decomposition, biomolecules in the body are broken down via bacteria and other chemical reactions, most of which occur during the second and third stages, bloat and active decay, respectively. The transition period between these two stages is important because the release of the gaseous and liquid decomposition compounds from the body, or putrefaction, characterizes the end of the bloat stage and starts the active decay stage. The compounds produced throughout the process of decomposition include volatile, semi-volatile, and non-volatile species. Volatile compounds have been extensively studied and characterized using headspace Gas Chromatography/Mass Spectrometry (GC/MS), Liquid Chromatography/Tandem Mass Spectrometry (LC/MS/MS), and Time-Of-Flight (TOF) techniques.<sup>1</sup> The appearance of these compounds has been examined in relation to time, temperature, location, and other factors, with hundreds of unique volatile compounds having been identified over the course of numerous studies. However, an important issue regarding such volatile compounds is how long these compounds may remain or otherwise be detectable in the air surrounding the body, which is not only a question of time but also of weather conditions and other activity in the area. Relatively non-volatile or semi-volatile compounds, such as indole and similar species, in contrast, may be detectable near the body or gravesite longer, due to their lower volatility. Such compounds may therefore remain and be detectable to some extent, even after a body has fully decomposed.

Few studies have investigated the non-volatile compounds produced during decomposition. Prior studies on the non-volatile compounds of decomposition have noted the presence of fatty acids and cholesterol.<sup>2,3</sup> This study focuses on smaller, non-volatile compounds, specifically indole, that are produced by decomposition. Extracts of beef liver homogenate were utilized as the basis to analyze the non-volatile compounds obtained from these samples over a multi-day time course. GC/MS was used to analyze and qualify compounds extracted from the decomposing materials. Preliminary results confirm the presence of many fatty acids and cholesterol in the decomposed samples. However, also noted was the persistent appearance of indole in most of the decomposition samples, making it a prime candidate for future use as a marker compound for the decomposition process. Indole is an intermediate in the biosynthesis of tryptophan, as an intramolecular intermediate in the enzyme tryptophan synthase. Indole may be generated during the autolytic and putrefactive stages of decomposition by the action of bacterially generated tryptophanase. Indole, and related products from decomposition extracted from fluids, may provide information relating to the postmortem interval of decomposing bodies.

### **B142 A Simultaneous Chiral Analysis of Methamphetamine and Related Precursors and Screening of Methamphetamine-Related Organic Impurities in Seized Drugs by a Small Footprint Ultra High-Performance Liquid Chromatography-Photodiode Array/Mass Spectrometry (UHPLC-PDA/MS) System**

*Li Li, PhD\*, DEA, Dulles, VA 20166*

**Learning Overview:** The goal of this presentation is to present an efficient Ultra High-Performance Liquid Chromatography-Photodiode Array/Single Quadrupole Detection (UHPLC-PDA/SQD) method on methamphetamine profiling and chiral analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting an efficient UHPLC-PDA/SQD method on drug profiling and chiral analysis using a low-cost and small footprint system.

Methamphetamine (MA) is a widely abused stimulant of the central nervous system. MA can be synthesized by a number of routes starting from precursors of l-ephedrine/d-pseudoephedrine or 1-Phenyl-2-Propanone (P2P), which yield d-MA and racemic MA, respectively. Chemical profiling can be used to gather information about the manufacturing processes, emerging trends, cutting agents, and linkages between seizures. A number of analytical techniques are employed for the chemical profiling of MA samples. The detection of organic impurities and the determination of chirality for MA and its related precursors are essential to evaluate precursor chemicals and synthetic routes of clandestine MA production. Hence, dilute and shoot UHPLC-PDA/MS methods employing a small footprint and cost-efficient UHPLC-PDA/SQD systems are presented for the simultaneous chiral analysis of MA and related precursors (amphetamine, ephedrine, pseudoephedrine, norephedrine, norpseudoephedrine, methylephedrine, and methylpseudoephedrine), the targeted screening of MA manufacturing related organic impurities, and the untargeted screening of adulterants and emerging drugs.

Each pair of enantiomers was successfully separated in 9min by a LUX 3 $\mu$ m AMP chiral column with a mobile phase consisting of methanol and 0.2% cyclohexane. The Limit Of Detection (LOD) for MA by PDA, MS scan, and MS in Selected Ion Recording (SIR) mode, was 1 $\mu$ g/mL, 10 $\mu$ g/mL, and 10ng/mL, respectively. The chiral composition of MA was determined by using PDA data, even for samples with extremely skewed ratios of low enantiomer content. Route-specific compounds were separated in 8.5min by a BEH phenyl column with a gradient elution of acetonitrile and 0.1% formic acid. The SIR mode offered excellent selectivity and sensitivity (<25ng/mL) for the target impurities. Substances at a concentration of  $\geq$ 0.5 $\mu$ g/mL were detected by either PDA or MS scan. Using the developed methods, three sets of data (chirality, targeted, and non-targeted organic impurities) were generated from one sample set with two injections/separations of one sample preparation, which significantly improved the efficiency of MA chemical profiling. The developed method has been successfully applied to illicit MA samples, including tablets containing low doses of MA (<20%) and samples containing skewed ratios of d- and l-MA at trace levels.

## B143 The Differentiation Between Industrial Hemp and Marijuana Through Colorimetry, Spectroscopy, and Volatile Organic Compound (VOC) Profiles

Alexander Acosta\*, Florida International University, Miami, FL 33199; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will better understand three different approaches to differentiating between industrial hemp product (<0.3% THC) and marijuana.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by suggesting a three-pronged approach to differentiate between industrial hemp and marijuana easily, rapidly, and accurately.

The 2018 Farm Bill permits the cultivation and legal trade of Industrial Hemp in the United States. Hemp is defined as *Cannabis sativa* and any part or derivative of the plant, including seeds, that has a Tetrahydrocannabinol (THC) concentration below 0.3% (w/w). There is now an urgent need to differentiate hemp from marijuana (THC content >0.3%) with a fast and easy-to-use analytical method. A three-pronged approach was investigated in order to find a suitable method(s) for differentiating between hemp (<0.3% THC content) and marijuana.

The first approach was the development of a semi-quantitative color test for the Fast Blue BB (FBBB) reagent and THC reaction producing an easily discernable red color above the 0.3% THC threshold. An extraction procedure was developed that allowed the plant material to be placed in an extraction tube without the need for weighing. In addition, the extraction solvent was able to be placed onto a Capillary Microextraction of Volatiles (CMV) device that was preloaded with FBBB reagent. A deep red color indicated a positive result and the CMV was then desorbed into a Gas Chromatography/Mass Spectrometry (GC/MS) for confirmation and quantitation of the chromophore formed between FBBB and THC.

Recent studies have shown the capability for near-infrared spectroscopy to detect and quantify cannabinoids from *Cannabis sativa* directly from the plant samples.<sup>1,2</sup> Hemp and marijuana were also analyzed using an Infrared (IR) -Tracer 100 Fourier Transform Infrared Spectrophotometer (FTIR) with a Near IR kit attachment (Shimadzu® Corporation) and with the SCIO®. Chemometrics techniques (Principle Component Analysis [PCA], Partial Least Squares Discriminant Analysis [PLSDA]) were used to extract the data from the Near IR spectra obtained and the data sets from the IR-Tracer 100 and the SCIO® were compared to each other. This comparison displayed the ability for hemp and marijuana to be differentiated using the SCIO®.

The third and final method involved differentiating hemp and marijuana using their VOC profile. A previous study in the Almirall lab reported variations in the VOC profiles of hemp products and marijuana.<sup>3</sup> For this study, industrial hemp was purchased from various vendors, and marijuana samples were obtained from local law enforcement. Dynamic headspace sampling was optimized and performed on hemp and marijuana samples to collect and preconcentrate the VOCs onto the CMV. Multivariate analysis was then used to observe if industrial hemp and marijuana could be distinguished using their VOC profile. The results show that marijuana and hemp can be distinguished in this manner.

### **B144 An Analysis of Gaseous Mixture Adsorption by Nuclear Magnetic Resonance (NMR) Spectroscopy: Improving Our Understanding of Arson Debris Investigations**

*Christopher L. Suiter, PhD\**, National Institute of Standards and Technology, Boulder, CO 80305; *Jason A. Widegren, PhD*, Boulder, CO 80305; *Megan Harries, BS*, National Institute of Standards and Technology, Boulder, CO 80305; *Kavita M. Jeerage, PhD*, National Institute of Standards and Technology, Boulder, CO 80305; *Tara Lovestead, PhD*, National Institute of Standards and Technology, Boulder, CO 80305

**Learning Overview:** After attending this presentation, attendees will learn how gas-phase NMR spectroscopy can provide valuable insight about the adsorbent properties of activated carbon by monitoring the real-time composition of gases in a sealed sample tube containing a carbon strip. Using this method, multiple compounds of interest can be detected and quantified simultaneously. In contrast to traditional approaches in which analytical techniques are used to determine what is desorbed after a solvent extraction of the carbon strip, this approach measures changes in the gas-phase composition to determine what has been adsorbed onto the carbon strip.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing attendees with exposure to a new method that allows for monitoring the rate of compound adsorption, the impact of water vapor on adsorption, and the role, if any, of competitive adsorption effects between gas-phase mixtures and carbon strips. These findings have the potential to improve our understanding of gas-adsorbent interactions.

NMR spectroscopy is most often associated with investigations of molecules in the liquid-phase. While not common, NMR is occasionally applied for the study of gases.<sup>1</sup> Recently, the National Institute of Standards and Technology (Boulder, CO) research group developed a method for the quantitative analysis of low-pressure gas-phase mixtures by <sup>1</sup>H NMR spectroscopy.<sup>2</sup> With this method, low uncertainty composition determinations (<1%) can be made and data collected in a matter of minutes. Interestingly, during these experiments, unexpected adsorption between gas-phase mixtures and a Teflon<sup>®</sup> piston located inside of the sampling apparatus were observed. While inconvenient at the time, these findings led the research group to explore the possibility of measuring mixture adsorption for other systems of interest by NMR. Here, the original approach to measure gas-phase compositions in the presence of a carbon strip is extended in this work. Data for individual compounds and simple binary mixtures are presented that demonstrate the features of this technique and its potential impacts on the field of arson debris analysis; other problems of potential interest to the forensic community are discussed.

To conclude, NMR spectroscopy allows for low uncertainty composition determinations of gas-phase mixtures. Using this technique, questions related to the kinetics and competitive effects during gas-phase adsorption can be explored. This approach could improve our understanding of the underlying science of arson debris analysis and other topics in forensic science.

### **B145 The Validation of Gas Chromatography With Flame Ionization Detection (GC/FID) and Development of a Method to Quantitate $\Delta^9$ -Tetrahydrocannabinol (THC)**

Cara E. Paraska, BS\*, Marshall University, Huntington, WV 25703; Sandra Salido, PhD, Fairfax, VA 22033; Lauren L. Richards-Waugh, PhD, Marshall University Forensic Science Program, Huntington, WV 25701; Brandon P. Jones, MS, Washington, DC Department of Forensic Sciences FCU, Washington, DC 20024

**Learning Overview:** After attending this presentation, attendees will understand how to validate a GC/FID to detect and quantitate THC in marijuana samples. GC/FID is ideal for detecting THC due to its fast analysis and simple sample preparation. Currently, there is no method for quantitating THC at the District of Columbia Department of Forensic Sciences.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by furthering the methodology of quantifying THC using GC/FID.

Both hemp and marijuana originate from the plant, *Cannabis sativa*, differing only in the amount of THC contained within the plant.<sup>1</sup> Federally, marijuana is still a Schedule 1 controlled substance, whereas hemp has now been legalized.<sup>1</sup> Due to this distinction, quantifying the amount of THC in plant samples submitted to the laboratory is crucial.

Two GC/FIDs were validated following the procedures and validation process already in place at the District of Columbia Department of Forensic Sciences Forensic Chemistry Unit. Following instrument validation, liquid samples of various THC concentrations were analyzed using a quantitative method developed by the Forensic Chemistry Unit at the District of Columbia Department of Forensic Sciences. A calibration model was determined, then used to quantitate quality control samples prepared by fortifying oregano with known concentrations of THC. Extraction was performed by grinding the plant material with a mortar and pestle, using a sieve, then extracted with hexane. THC was successfully detected; however, the percent recovery was too low for quantification.

A marijuana sample was analyzed using the same method on the GC/FID using petroleum ether and hexane separately for the extraction. The GC/FID was able to detect THC without interference from other cannabinoids, but because the concentration of THC in the sample is unknown, the percent recovery could not be determined.

Future research will focus on obtaining quality control samples of marijuana with known amounts of  $\Delta^9$ -THC to quantify using the calibration model created in this study. Extraction methods should also be studied in order to increase percent recovery. Two different calibration curves should be developed so that one can be used for hemp samples and the other can be used for plant material with a higher concentration of THC.

### B146 The Easy Application of Chemometrics to Forensic Chemical Data: A Software Tool for Forensic Chemists

Tuomas Salonen, MS\*, National Bureau of Investigation Forensic Laboratory, Vantaa, Uusimaa 01350, FINLAND; Michael Bovens, PhD, Zurich Forensic Science Institute, Zurich, SWITZERLAND; Björn Ahrens, PhD, Federal Criminal Police Office, Wiesbaden 65173, GERMANY; Anders Nordgaard, PhD, Swedish Police Authority-National Forensic Centre, Linköping 58194, SWEDEN; Sami Huhtala, MS, National Bureau of Investigation, Vantaa 01370, FINLAND; Ivo Alberink, PhD, Netherlands Forensic Institute, The Hague, Zuid-Holland 2497 GB, NETHERLANDS

**Learning Overview:** The goal of this presentation is to inform attendees about a free specialized software being developed in Europe that facilitates easier application of chemometric methods in forensic chemistry casework, such as classification or profiling of drugs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a new software tool that allows easy application of the chemometric methods most commonly found in literature to real casework involving chemical data.

In recent years, chemometric methods have been explored to help analyze and extract useful information from forensic chemical data. While these methods have seen some success, their utilization usually requires rather advanced statistical and data analysis skills, such as deep theoretical understanding of statistics and statistical software. For this reason, the application of these methods can be intimidating for many forensic chemists, despite the clear benefits they could provide. To help resolve this issue, a specialized and free software called ChemoRe is being developed in Europe.

The work on ChemoRe was started in 2018 as the European Network of Forensic Science Institutes (ENFSI) project titled “Steps Towards European Forensic Area (STEFAs),” funded by the European Union. The software tool, based on popular statistical programming language R, is intended to provide a simple but powerful graphical user interface for forensic chemists to allow them to design and apply in practice the most common chemometric methods.

To determine the applicable methods, a literature survey was conducted as part of the project.<sup>1</sup> While not intended to be a comprehensive review, this survey was used to determine the most common use cases of chemometric methods in forensic chemistry literature, with a focus on illicit drugs. Based on these results, ChemoRe has been designed to be as intuitive as possible to apply to the typical workflow of forensic chemistry casework. This sets it apart from other similar software that also implement the same methods that tend to be more open-ended and require more statistical and computational expertise from their users.

ChemoRe acts as a bridge for its users to the powerful features of the statistical R-language through an interface, implemented with the Shiny framework that allows the user to design chemometric pipelines by a few clicks of the mouse.<sup>2,3</sup> This pipeline can be saved and validated within the software and subsequently converted to a ready method that can be applied to new case data. Additionally, the results obtained can be appropriately visualized to support interpretation and reporting of the results. This should make it attractive to forensic chemists who seek to make use of chemometric methods.

In this presentation, the ChemoRe software is introduced by presenting the relevant background on its development, including the results of the literature survey and main technical features. Furthermore, realistic example applications are introduced that show how chemometric methods can be applied to casework using ChemoRe.

## **B147 DNA Extraction and Profiling From Human Bone and Tooth Samples Exposed to High Temperatures: A Comparison of Current Techniques**

*Kadir Dastan, PhD\*, Istanbul Yeni Yuzyil University, Istanbul 34010, TURKEY; Melek O. Kulusayin, PhD, Istanbul University Cerrahpasa, Istanbul 34033, TURKEY; Gulden Rayimoglu, Istanbul University Institute of Forensic Sciences, Istanbul 34096, TURKEY; Ömer Karatas, Institute of Forensic Science Istanbul Türkiye, Istanbul 34303, TURKEY; Fatma Cavus Yonar, PhD, Istanbul University, Cerrahpasa, Istanbul 34500, TURKEY; Emel H. Yükseloglu, IstanbulUni-Cerrahpasa Forensic Medicine Institute, Istanbul, TURKEY*

**Learning Overview:** The goal of this presentation is to offer best-practice procedures for the isolation of DNA from burned human remains and to recover DNA useful for identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a predictive model to determine which incinerated human remains are likely to produce the best results for Short Tandem Repeat (STR) analysis.

In the identification of forensic cases, it is critical to obtain information on the victim's identity from burnt bone and tooth remains. When bone and teeth are burned, both their physical and chemical properties change significantly, which prevents anthropological evaluations and successful DNA profiling. Heat causes difficulties in the identification techniques in which bones and teeth are used, depending on the degree of temperature exposure.<sup>1</sup> Therefore, it is necessary to evaluate the results of observation and analysis, and the information obtained in a certain order, with the changes occurring in bone and teeth during the burning period. The identification of burnt or buried bones and teeth has always been a difficult process due to the diminished quality and quantity of DNA, and it is still a challenge.<sup>2</sup> Due to heterogeneity in DNA due to the heterogeneity within the bone, unfortunately, the only reliable method for obtaining DNA from highly degraded specimens, such as burnt bones and teeth, in the literature is still not available.

Because teeth and bones are the hardest tissues in the human body and known as the most abundant types of biological remains that are available in forensic cases, this study focused on the evaluation of the DNA extraction efficiency of burned bone and tooth samples and obtaining a DNA profile under different environmental conditions of exposure to temperature and time. In this study, 50 samples consisting of 25 bones and 25 teeth obtained from 22 females and 28 males aged between 18 and 71 years were used, and 50 samples of oral swabs belonging to the same persons were also used to compare current extraction methods, and the maximum temperatures at which DNA from bone and teeth can be obtained were determined. The collected tooth samples were healthy erupted third molars. All bone and tooth samples were divided into eight groups and exposed to certain temperatures, which were 100°C, 200°C, 300°C, 400°C, 500°C, 600°C, 700°C, and 800°C. Each group was treated at the determined temperature for 1, 5, 10, and 15 minutes. The control and burned samples were mechanically ground and subjected to DNA extraction and amplification. Based on the amplification data, it was not possible to obtain DNA from the teeth subjected to 400°C for 10 and 15 minutes, 500°C for 15 minutes, 600°C, 700°C, and 800°C for 5, 10, and 15 minutes. In the first temperatures and times, which were 100°C and 200°C, and one and five minutes, it was possible to obtain an amplification similar to that of the control samples; however, in most Short Tandem Repeats (STRs), the amplification was very low from 300°C for one or five minutes onward. These observations support earlier findings and indicate that even in teeth subjected to high temperatures and that were burned, it is possible to amplify the DNA; however, the data also show that it would be difficult to obtain an STR profile, which is probably due to the size of these regions that makes them more prone to degradation.<sup>3,4</sup> In this study, DNA extractions could be carried out in bone samples exposed to a maximum temperature of 190°C and tooth samples exposed to a maximum temperature of 400°C and a new modified extraction method was also proposed for increasing the effectiveness and efficiency in routine forensic genetic identification processes.

The results of this research provide a quantitative study in order to obtain a DNA profile from highly degraded bone and tooth samples and may increase the ability of forensic scientists to target the burned human bone and tooth remains to produce high yields of DNA, thereby increasing the probability of positive identification. Under the same or similar conditions, future research could extend these results by analyzing other potential regions of DNA for forensic identification.

### **B148 DNA Analysis From Human Skeletal and Tooth Remains: A Comparison of the Recent Isolation Methods for Removing Polymerase Chain Reaction (PCR) Inhibitors**

Kadir Dastan, PhD\*, Istanbul Yeni Yuzyl University, Istanbul 34010, TURKEY; Melek O. Kulusayin, PhD, Istanbul University Cerrahpasa, Istanbul 34033, TURKEY; Gulden Rayimoglu, Istanbul University Institute of Forensic Science, Istanbul 34096, TURKEY; Fatma Cavus Yonar, PhD, Istanbul University, Cerrahpasa, Istanbul 34500, TURKEY; Ömer Karatas, Institute of Forensic Science Istanbul Türkiye, Istanbul 34303, TURKEY; Emel H. Yükseloglu, Istanbul Uni-Cerrahpasa Forensic Medicine Institute, Istanbul, TURKEY

**Learning Overview:** The goal of this presentation is to offer best-practice procedures for the isolation of DNA and removal of PCR inhibitors from human burned remains and to recover DNA useful for identification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a predictive model to determine which incinerated human remains are likely to produce the best results for the removal of PCR inhibitors during extraction procedures.

DNA analysis of human bone remains is a crucial process for identifying missing persons and individuals in cases of mass disasters and wars. In this study, the ability of microbial DNA isolation kits to recover amplifiable bone DNA and remove PCR inhibitors was compared to other common extraction methods. The generation of a DNA profile from bone samples is an important part of the identification process, both in cases of mass disasters and in cases of unidentified persons.<sup>1</sup> As bones and teeth are often the only biological evidence remaining after exposure to challenging environmental conditions, intense heat, certain traumatic events, and in cases in which a significant amount of time has passed since the death of the individual, the ability to purify reasonable amounts of DNA from such hard tissues is always beneficial.<sup>2,3</sup>

Because sampling procedures from hard tissues for genetic analysis is a destructive process, it is important to understand the environmental and intrinsic factors that will contribute to the preservation of DNA.<sup>4</sup> DNA extraction systems consisted of several methods and kits, including a standard organic extraction and a QIAamp® DNA research kit. A preliminary study was conducted to determine whether the reagents contained in the kits were contaminated with human DNA. The standard protocol did not result in consistently amplifiable DNA. The protocol was optimized by altering the digestion step. In addition to DNA recovery, each extraction method was tested to determine its ability to remove the calcium, collagen, and humic acid PCR inhibitors associated with buried and burned skeletal remains. Since lack of DNA amplification is a common challenge encountered with bone debris, successful amplification of nuclear DNA for each extraction method was compared to see which amplifiable DNA was most frequently recovered. The five extraction methods were tested on several remains of human skeletons, including bones and teeth, that had previously shown inhibition of PCR during DNA analysis. After comparing the human DNA isolation kits with organic extraction and a standard DNA extraction kit for inhibitor removal, the amount of bone DNA recovered and the success of nuclear DNA amplification, the effectiveness of the DNA extraction kits for use in bone remains was determined, as well as the most convenient extraction method. Improving the ability to interpret DNA results from challenging samples will be an important aspect of the future of the field. Finding ways to reduce the cost of genetic analyses will reduce delays and allow more samples to be processed. Finally, adequate training and funding must be provided to recognize that sound research based on the scientific method is the key to advancement in any field of forensic sciences.

### B149 DNA Profiling of Rootless Hair Shafts Utilizing Massively Parallel Sequencing and Bi-Allelic Assays

*Ryan Gutierrez, BS\*, Alvin, TX 77511-4161; Bobby Larue, Jr., PhD, Sam Houston State University, Huntsville, TX 77341*

**Learning Overview:** After attending this presentation, attendees will understand the potential for rootless hair shafts to be used as genetic evidence for forensic purposes. Additionally, the utility of assays that include loci amplicons smaller than those found in traditional Short Tandem Repeat (STR)-based amplification assays will be discussed.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating the potential use of rootless hair shafts as discriminatory genetic evidence. With additional samples identified as viable sources of probative information, additional samples can be successfully processed during routine laboratory operations.

Shed hairs are often underutilized as genetic evidence. These hairs are often passively lost and do not contain a hair root, where intact DNA is usually found. However, with advances in genotyping techniques and instrument technologies, the remaining hair shaft may be more viable as evidence than previously thought. Using naturally shed hair samples, STR analysis often fails to provide profiles. However, there remains the possibility of DNA that is both low template and highly degraded by the keratinization process of hair formation remaining in or on a hair shaft. This remaining DNA, though unusable for STR analysis, may still be impactful in the forensic setting. Utilizing alternative methods for processing these sample types may provide information that can still be highly discriminatory.

Currently, complementing unsuccessful samples with mitochondrial genome sequencing is the best method for processing challenging rootless hair samples. Mitochondrial DNA is inherited maternally, with the lack of recombination in mitochondrial inheritance results in low discriminatory power for resulting genetic information. This makes exclusion or inclusion of possible donors difficult in cases where potential sources are related or share mitochondrial haplotypes by chance. The current limitations using the mitochondrial genome suggest a need for additional sample processing strategies. With current advances in available amplification chemistries and instrumentation, additional processing options are readily available. These novel options can be used in tandem with already established methods to increase the discriminatory power of DNA extracts obtained from rootless hairs.

This presentation will cover a preliminary investigation into alternative methods identified as promising for the genetic analysis of rootless hair shafts. In this research, samples of hairs were collected with informed consent. The rooted portion of hair samples was then removed before extraction with the InnoGenomics® Hair Extraction Kit. Sample extracts were amplified using three methods. As a control, STR analysis was attempted with the GlobalFiler® PCR Amplification Kit. Alternative sample processing strategies include amplification with the retrotransposon insertion polymorphism marker-based InnoTyper™ 21 chemistry, which was then analyzed using capillary electrophoresis. An additional test method applied massively parallel sequencing using the MiSeq® FGx. Samples were processed using the ForenSeq™ Signature DNA Prep kit with primer set B, which includes a number of bi-allelic single nucleotide polymorphisms that can be used for identification, ancestry estimation, or phenotyping.

### B150 Examining Various Methods to Extract and Amplify Degraded DNA

Emily Spack, BS\*, Lorton, VA 22079; Heather Sarik, MS, Bode Cellmark Forensics, Lorton, VA 22079; Jon Davoren, MS, Bode Technology, Lorton, VA 22079-2625; Kristen Naughton, BS, Bode Technology, Lorton, VA 22079

**Learning Overview:** After attending this presentation, attendees will have a better understanding of options available to improve profile results from forensic samples containing degraded DNA.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing results from an in-depth study of various DNA extraction methods and commercially available amplification chemistries for improved recovery and profile generation from degraded DNA.

In forensic casework, degraded DNA is encountered more frequently now that technologies have improved and allowed for increased detection of low-level DNA from decades-old cases. It can be difficult to generate full Short Tandem Repeat (STR) profiles from these cases due to DNA degradation. Traditionally, mitochondrial DNA (mtDNA) testing has been more common in cases of highly degraded DNA, especially when the evidence is a bone or rootless hair. However, mtDNA testing is a more lengthy and costly process and few labs have the capabilities to analyze mtDNA. For these reasons, it is important to examine whether nuclear DNA results can be improved by using these new methods.

In this study, hair (roots and shafts) were collected from multiple volunteer donors and extracted via four different methods: the QIAGEN® QIAamp® DNA Micro Kit, the InnoGenomics® Hair Extraction Kit, the MicroGEM forensicGEM™ Universal kit, and Protocol C from the Brandhagen et al. paper on nuclear DNA in hair shafts.<sup>1</sup> Samples were then quantified using Applied Biosystems® Quantifiler® Trio to determine quantity and level of degradation of DNA. Four different amplification kits were chosen to evaluate the DNA profiling method: Promega® PowerPlex® Fusion, Applied Biosystems® AmpFℓSTR® MiniFiler™, InnoGenomics® InnoTyper™ 21, and QIAGEN® Investigator® DIPplex. InnoTyper™ 21 and Investigator® DIPplex are not STR kits and were chosen due to their differences and possible improvements over the current STR systems. Both InnoTyper™ and DIPplex are biallelic and test for Retrotransposon Insertion Polymorphisms (RIPs) and Insertion/Deletion Polymorphisms (INDELs), respectively. The amplicon sizes in these two kits are smaller than the typical STR amplicons, increasing the chance that the primer target region will remain intact within degraded DNA and generate a profile where a traditional STR kit fails to do so. In addition to testing the kits' abilities to amplify the hair shafts and roots, other casework type samples were tested (bone, aged, inhibited, and degraded samples).

The sensitivity study in all four amplification kits resulted in optimal profiles with 0.25 to 0.5ng of DNA. In general, the hair roots had sufficient quantity and performed well in all amplification kits. While an improved quantity of DNA was obtained from hair shafts extracted with the Brandhagen et al. protocol over the other extraction methods, the amount of DNA was less than 5pg/μl and resulted in limited profile data with all amplification kits, including those with smaller amplicon size. However, the increased DNA yield will likely increase success rates from hair shafts for mtDNA testing. When sufficient DNA from degraded samples is available, the shorter amplicon kits have the potential to generate more complete profile results than STR kits, increasing the statistical power of degraded DNA evidence.

### **B151 The Benefits and Burdens of Implementing Probabilistic Genotyping (PG) Software**

*Roger Kahn, PhD\**, Harris County Institute of Forensic Sciences, Houston, TX 77054-2001; *Joseph Truppi, BS*, Harris County Institute of Forensic Sciences, Houston, TX 77021; *Priscilla A. Hill, MS*, Harris County Institute of Forensic Sciences, Houston, TX 77021; *Michael A. Donley, MS*, Houston, TX 77021; *Katherine Welch, MS*, Harris County Institute of Forensic Sciences, Houston, TX 77054

---

**Learning Overview:** The goal of this presentation is to relate challenges and rewards encountered when implementing and using PG software in DNA casework.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information to assist laboratories planning to implement PG software as a tool for DNA statistical calculations. Laboratories may encounter an unexpected negative impact on productivity after implementation.

PG methods are becoming widely used for DNA statistical analysis and this will continue as these statistical software tools provide more information in a more consistent and unbiased manner than previous methods. The Harris County Institute of Forensic Sciences implemented PG statistical software in February 2019 following validation and training DNA analysts over approximately 12 months. Since then, an increase in the number of informative results obtained per sample tested has been seen. Although the initial dip in productivity was attributed to analyst learning curve, it also became clear that as the sample success rate has increased, a commensurate increase in turnaround times was observed.

Low-level mixtures and mixtures exhibiting degradation become increasingly difficult to interpret manually as the number of contributors increases. This complexity is due to both potential missing information and an exponential increase in possible genotypes with each additional contributor. PG software allows an analyst to provide statistical calculations to samples that previously could not be evaluated through a binary method and were reported as inconclusive, uninterpretable, or having the potential for allele drop-out. While PG allows the laboratory to provide more information and do so more objectively, it does require more time to analyze samples. The additional information increases the detail in the report and the length and complexity of technical review.

To quantitate the increase in informative results, this study reviewed the percentage of samples that could be compared to a reference sample before and after implementing PG. Informative results increased from 18.8% to 34.2% with PG, almost doubling the reportable comparisons ( $n=1,451$  and 1,183 samples, respectively). Prior to PG, the average turnaround time of a sexual assault case (from submission to release of the report) was approximately 77 days and after implementation, it increased to approximately 98 days. This is approximately a 27.3% increase in time to complete analysis. To combat the increase in turnaround time, measures to limit the number of samples reported may be incorporated, such as a Y-screen for sexual assault samples or a stop at quantification procedure.

Using a PG statistical software can increase the number of informative results that a laboratory can report. Without additional changes to speed testing and reporting, the additional comparisons will increase the amount of time required to complete a case.

### **DNA, Probabilistic Genotyping, Productivity**

### **B152 The Use of Relationship Likelihood Ratios (LRs) as a Diagnostic for Probabilistic Genotyping: Validation and Casework Experience Through the Years**

*Samantha Orans Wandzek, MS\*, Coconut Creek, FL; Alicia M. Cadenas, MS, DNA Labs International, Deerfield Beach, FL 33441; Rachel H. Oefelein, MS, DNA Labs International, Deerfield Beach, FL 33441; Cristina L. Rentas, MFS, DNA Labs International, Deerfield Beach, FL 33441; Daniel I. Aguilar, MS, DNA Labs International, Deerfield Beach, FL 33441*

**Learning Overview:** The goal of this presentation is to illustrate how familial relationship LRs can be used as an additional diagnostic for probabilistic genotyping through validation and to highlight casework examples.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by helping to implement familial relationship diagnostics in individual labs.

Since 2016, DNA Labs International (DLI) has been online with STRmix™ expert forensic software. Validated for use with the Applied Biosystems® AmpFℓSTR® Identifiler® Plus on the Applied Biosystems® 3130xl Genetic Analyzer, and now with the Applied Biosystems® GlobalFiler® and Promega® PowerPlex® Fusion 6C on the Applied Biosystems® 3130xl and 3500xL Genetic Analyzers, thousands of casework samples have been evaluated.

At DLI, STRmix™ is used to aid the analyst in deconvoluting a DNA evidence sample and develop an LR. An LR is a ratio of two probabilities giving a numerical value that shows strength of support for one scenario over another. In the case of DNA, in the simplest of terms, it is saying whether it is more likely to observe the DNA profile if it originated from the individual of interest than from an unknown individual. The software also develops several types of relationship LRs, including sibling, parent/child, half siblings, uncle/aunt/niece/nephew, and first cousins where it addresses if it is more likely to observe the DNA profile obtained if a person of interest is part of an evidence sample versus a relative of the person of interest. This is of interest to both the prosecution and defense as members of a family share more alleles in common than unrelated individuals and can, therefore, lead to potential false inclusions or exclusions of individuals. It became clear from a few specific casework samples that the relative LR table provided in the STRmix™ report can be indicative of the inclusion of relatives into the mixture in question and can falsely inflate the LR for a person of interest.

As a result, additional validation studies were performed involving mixtures made from multiple family trees using different amplification kits and instruments. Diagnostic ranges were developed for comparison of the unified LR to the sibling LR as well as the unified LR to the parent/child LR, as these were shown to be the most affected. This diagnostic range, in conjunction with other diagnostics and the LR itself, may indicate when a relative LR should be of noted concern and would necessitate requesting standards of primary relatives of the person of interest for comparison. However, the LR value can be dependent on the quality of the profile and the overall presence of the applicable contributor in that profile as well.

Casework examples highlighting possible familial relationships and what was done to address them will be presented. Additionally, the diagnostic ranges that DNA Labs International employs for relative LRs that were developed during validation and how they were determined will be examined. This will benefit attendees by providing information on ways the familial LRs developed by STRmix™ can be explored during validation and how it relates to casework.

---

#### **Probabilistic Genotyping, Familial Relationships, Validation**

### **B153 Six Months to 30 Days in 24 Hours: A Laboratory's Journey to Meet Statutory Requirements Relative to Sexual Assault Evidence Collection Kit (SAECK) Processing**

*Lynn A. Schneeweis, MS\*, Massachusetts State Police Crime Laboratory, Maynard, MA 01754; Stefany E. Harman, MS, Maynard, MA 01754; Darina A. Griffin, JD, Massachusetts State Police Crime Laboratory, Maynard, MA 01754; Kristen Sullivan, MS, Massachusetts State Police Crime Lab, Maynard, MA 01754*

---

**Learning Overview:** After attending this presentation, attendees will better understand how legislative mandates relative to the forensic analysis of SAECKs may impact a laboratory's operations. Attendees will gain knowledge of the practical, operational, and financial considerations for implementing such mandates.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing insight that may assist laboratories with meeting statutory requirements relative to turnaround time on the analysis of SAECKs.

A national dialogue emerged several years ago as a result of the discovery of thousands of SAECKs sitting untested in law enforcement agencies' evidence storage facilities. This prompted demand for legislative reform by advocacy groups, scientific agencies, and law enforcement nationwide. The subsequent reaction of many jurisdictions has been one of action; identify the scope of the problem in their respective jurisdictions and implement measures to reform current practices with the goal of ensuring such a situation never repeats itself.

In April 2018, the Commonwealth of Massachusetts passed an Act Relative to Criminal Justice Reform (CJR) containing many initiatives designed to overhaul the Commonwealth's Criminal Justice System. Included in the reforms were sections that addressed topics directly applicable to forensic analysis providers within the Commonwealth. Specifically, one section directed the Commonwealth to identify and test previously unsubmitted SAECKs while another outlined requirements for testing current and future kits.

An Act Relative to Criminal Justice Reform, Chapter 69, Section 214, mandated law enforcement agencies to submit to the laboratory all previously unsubmitted investigatory kits to the crime laboratory. To accomplish this, each agency had to complete an inventory of SAECKs within their custody. Additionally, the section further prescribed that all identified previously unsubmitted investigatory SAECK must be tested within 180 days of submission.

Chapter 41 section 97B ½ addressed the processing of current and future kits by virtue of the following mandates: all investigatory kits would be submitted to the crime laboratory and tested within 30 days. Additionally, a SAECK tracking system would be implemented statewide between June 30, 2019, and December 1, 2019.

While well-intentioned, the CJR Act posed significant challenges to address before the mandates could be effectively met. Massachusetts has several hundred law enforcement agencies, including local, county, state, and academic institutions. By statute, all of these agencies were now required to complete the inventory, report on any SAECKs within their custody that fit the criteria for testing, and submit all identified kits to the laboratory. However, the statute did not specify the logistics or ultimate responsible party for ensuring this task was completed. Additionally, given that the number of potential kits subject to the new legislation was widely unknown, determining an appropriate facility to store what could be a significant number of kits posed another potential obstacle.

The 30-day turnaround time mandate for testing was progressive and likely intended to provide both expeditious justice for potential defendants as well as forensic answers for survivors. However, at the enactment of this bill, the Massachusetts State Police Crime Laboratory (MSPCL) lacked the adequate personnel, space, and equipment necessary to meet this mandate. Further compounding this, the statute was effective immediately, meaning no transition period was contemplated to achieve compliance.

Criminal justice reform is not unique to Massachusetts; many other jurisdictions have or may soon have mandates related to SAECK processing. This presentation will discuss the challenges associated with the reforms enacted within Massachusetts and the steps MSPCL has taken toward meeting these mandates. Specifically, the initial process for determining what kits fit the criteria of "previously unsubmitted," as well as the coordination of the inventory, collection, and testing of said kits, will be detailed. Additionally, the challenge to meet a 30-day turnaround time, including identification of resources needed and the data to support requests for these resources as well as optimization of current workflow, will be discussed. Lessons learned from the perspective of MSPCL will be shared, as well as suggestions for other agencies facing similar scenarios will be presented.

---

#### **Sexual Assault, Legislation, Testing**

## B154 An Exploration of EDTA Detection Within Forensically Relevant Blood Samples

Brittany C. Hudson, MS\*, Virginia Commonwealth University, Richmond, VA 23284; Matthew C. Rodriguez, BS, Virginia Commonwealth University, Richmond, VA 23284; Catherine Cupples Connon, PhD, Virginia Commonwealth University, Richmond, VA 23284

**Learning Overview:** After attending this presentation, attendees will be familiar with new presumptive and confirmatory techniques for the detection of disodium Ethylenediaminetetraacetic Acid (EDTA) within blood samples. Challenges encountered during the development of these methods will be discussed, as well as their limitations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing potential new methods for the presumptive and confirmatory detection of EDTA within blood samples, which can assist in the identification of “planted” blood evidence. Additional insight into possible techniques for the removal of hemoglobin from blood samples will be discussed as a side benefit to forensic biologists.

Detection of EDTA within blood samples has recently resurfaced in the forensic science community, especially as it pertains to “planted” evidence. Any method intended to distinguish authentic blood evidence from planted evidence requires the detection of exogenous component(s), such as EDTA, that would normally be absent in human blood. The ability of EDTA to form a stable complex with calcium, magnesium, and other metal ions enables its use during complexometric titrations to detect and quantify metal ions within a solution.<sup>1</sup> A colorimetric indicator, Eriochrome<sup>®</sup> Black T, was identified as a possible candidate for use in the detection of EDTA. This indicator changes color when free calcium and magnesium ions are present. If EDTA is present, it will preferentially bind these ions, preventing their interaction with the indicator. As visualization of a color change is inherently subjective and can preclude color-blind individuals from performing this protocol, use of UV/Visible (UV/Vis) spectroscopy could remove such subjectivity. It was hypothesized that the Eriochrome<sup>®</sup> Black T indicator, in conjunction with UV/Vis spectroscopy, could be used to presumptively detect the presence of EDTA. Furthermore, Attenuated Total Reflectance/Fourier Transform Infrared (ATR/FTIR) and Raman spectroscopy were also explored as possible confirmatory methods for the identification of EDTA. These rotational-vibrational techniques were selected given their high potential for compatibility with EDTA and to supplement previous reports using other instrumentation, primarily chromatographic, for EDTA detection.<sup>2-6</sup>

To establish proof of concept, sensitivity studies were performed based on expected levels of EDTA added to human blood, as well as expected levels of calcium and magnesium normally occurring in human blood, while also factoring in forensically relevant blood sample sizes. EDTA standards (0.003–3mg) were utilized for all four methods, whereas calcium and magnesium standards (1–30 $\mu$ g) were also necessary for the colorimetric indicator test and subsequent UV/Vis. For all EDTA amounts tested, Eriochrome<sup>®</sup> Black T correctly indicated whether EDTA was present or not, in combination with  $\geq 1\mu$ g of calcium and  $\geq 0.1\mu$ g of magnesium, as long as the EDTA:ion ratio was  $\geq 3$  for calcium and  $\geq 10$  for magnesium. Normally occurring EDTA to calcium or magnesium ratios well exceed these values. Furthermore, resulting UV/Vis spectra were different between samples that tested positive and negative for EDTA using Eriochrome<sup>®</sup> Black T. Positive samples (blue) yielded a peak around 200nm; all other regions of these spectra exhibited negligible absorbance. Negative samples (pink) exhibited a weak, broad peak from 500nm–700nm, with a point of inflection around 590nm. Unfortunately, robust baselines could not be established at any of these regions, thereby preventing the formation of reliable conclusions. Last, testing with ATR/FTIR and Raman spectroscopy proved challenging with the small sample sizes tested and need additional troubleshooting.

Following proof of concept, various areas were explored to adapt the Eriochrome<sup>®</sup> Black T indicator for use with forensically relevant blood samples. Sample size was a significant concern and quickly led to the need to remedy color interference from blood itself, even from dilutions as low as 1:400. Several products or reagents were evaluated: Microcon<sup>®</sup> filters, dryer sheets, HemogloBind<sup>™</sup>, sodium hydroxide, ethanol, and amidine latex beads. Though many of them proved successful at removing the interfering red color from blood, nearly all adversely interfered with the indicator reaction and resulted in either false positives or negatives. Unexpectedly, performing a 96% ethanol wash was effective and yielded the expected results; this process will be pursued further. Transitioning from liquid blood to dried stains was also problematic anytime a cellulose-based material was used (specifically, cotton swabs and cotton T-shirts); use of foam swabs remedied this issue.

These methods show varying degrees of promise for the development of a robust EDTA detection process. Future work will aim to further optimize and validate suitable methods.

## EDTA, Blood, Planted Evidence

### **B155 A Longevity Study on the Analysis of Sexual Lubricants When Stored in Different Environmental Conditions**

*Brooke R. Baumgarten, MS\*, Winter Park, FL 32792; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816; Mark Maric, PhD, Orlando, FL 32816; Nancy Flynn, BS, University of Central Florida, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will understand the effects of storage conditions on the analysis of sexual lubricants through Direct Analysis in Real Time-High Resolution Mass Spectrometry (DART<sup>®</sup>-HRMS), Gas Chromatography/Mass Spectrometry (GC/MS), and Fourier Transform Infrared Spectroscopy (FTIR).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information and preliminary patterns of the longevity of sexual lubricants when stored in sexual assault kits within different storage conditions over time. This may aid in providing knowledge of the viability of trace evidence (e.g., sexual lubricants) when analyzed at different time periods post-collection.

Unfortunately, sexual assaults are a reality in today's society. Due to the understanding that DNA from seminal fluid is one of the main forms of evidence being used to connect a suspect to a victim or crime scene, there has been an increase in the use of condoms in sexual assault cases. This dilemma has led the community to research other types of trace evidence (e.g., sexual lubricants). Previous research performed at the National Center for Forensic Science has led to the development of the Sexual Lubricant Database that aids in identification of discernable groups within lubricant manufacturing types, as well as the ability to separate lubricants from personal hygiene products. The classification and characterization of lubricants is a relatively new approach in analyzing trace lubricant residue in an operational setting.

Current research is being performed to determine the length and optimal conditions appropriate for storing trace lubricant residue before the samples begin to degrade and pattern becomes unrecognizable. Prior to conducting the study, it was necessary to determine how long the storage study samples could be stored in the event that the samples cannot be analyzed on the day of collection. Therefore, a two-week study was first performed to determine the longevity of extracted lubricants when stored within solvents at -20°C. Second, a preliminary cotton swab optimization study was completed to determine which swab yielded the most effective lubricant extraction and least background noise. After these studies were conducted, sexual lubricant from a condom and a personal bottled lubricant were deposited onto respective cotton swabs to be stored and evaluated under different conditions.

This research project used previously developed DART<sup>®</sup>-HRMS, GC/MS, and FTIR protocols to analyze the stored swabs containing sexual lubricants at time points: 0 hours, 24 hours, 7 days, and 1 month. At each time point, a blank swab, a personal lubricant swab, and a condom swab were stored in different storage conditions. These storage conditions were 35°C to simulate a hot environment, 22°C at approximately 100% humidity, 22°C at approximately 50% humidity, 22°C at approximately 0% humidity, 4°C to mimic samples stored within a refrigerator, and -20°C to imitate samples stored within a freezer. Storage of swabs at these conditions allowed for the determination of lubricant degraded and adversely affected the ability to recognize classification patterns at the simulated environmental conditions. Additionally, this study permitted the determination of optimal storage conditions for swabs containing trace lubricant evidence from sexual assault kits. The blank swab, personal lubricant swab, and condom swab were extracted into methanol and were analyzed in triplicate via the DART<sup>®</sup>-HRMS, as well as FTIR, and in duplicate by GC/MS. The resulting spectra from each instrument can be used to classify unknown lubricant samples and generate investigative leads. Multivariate statistical techniques were used to compare the stored samples to the neat samples to determine if chemical breakdown for each lubricant occurred and if the pattern changed significantly. Preliminary results suggest that the general profile of the lubricant does not change; however, the concentrations of the components may decrease over time.

Analysis of stored sexual lubricants within different environments over time via DART<sup>®</sup>-HRMS, GC/MS, and FTIR may be beneficial to the forensic community by allowing investigators and forensic examiners to identify the optimal condition for storage to prevent the degradation of lubricants when samples cannot be immediately analyzed. Additionally, the ability to understand the effects of environment and time to the analysis of sexual lubricants may offer helpful information when analyzing sexual assault kits and provide a link for investigators between a suspect and crime scene.

#### **Sexual Lubricants, Longevity Study, Mass Spectrometry**

### B156 Forensic Education Needs for Local and Federal Hiring Managers From Job Applicants

*Sandra B. Sachs, PhD\**, Oakland Police Department, Oakland, CA 94607; *Thomas M. Blackwell, BS\**, Drug Enforcement Agency, New York, NY 10011; *Scott R. Oulton, BS\**, Drug Enforcement Agency, Springfield, VA 22152

**Learning Overview:** The goal of this presentation is to educate academicians who teach in forensic programs what the needs are for the students they produce. Given the abundance of educational options available to students, guidance on what hiring managers are looking for is imperative for successful outcomes for both the applicant and the hiring laboratory.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by informing professors and students interested in forensic careers what skills will be necessary to hone in order to be successfully hired into a forensic laboratory and by providing data to inform the discussion surrounding what the current and future needs of local and federal employers really are, not what they are presumed to be, and to provide real examples of stellar and sub-par applications.

Forensic education programs have burgeoned in the past two decades. Some programs follow guidelines from Forensic Science Education Programs Accreditation Commission (FEPAC). There are also vast pools of educational institutions that adequately educate their students in fundamental sciences, such as chemistry, biology, and physics. Emphasis on specialization at colleges and universities has led institutions to tout more than 100 majors from which to choose.<sup>1</sup> Some newer majors have produced students with solid fundamental science grounding, but have left hiring managers with difficulties in assessing the adequacy of their skill set. Examples of degree programs that may cause forensic hiring managers to pause are majors such as “Applied Chemistry,” “Biotechnology,” “Environmental Toxicology,” “Pharmaceutical Chemistry,” and “Forensic Science,” to name a few. Degree programs often offer internships with real-world lab experience; the degree of relevancy to a forensic laboratory may only be explored during interviews or during a probation period.

In this joint session, representatives from different forensic science educational programs, local and federal hiring managers, as well as representatives of the legal profession and those who educate jurists will provide information and data to fuel discussion of “Are forensic science programs meeting the current and future needs of employers and the criminal justice system?” In this presentation specifically, hiring managers will discuss applicant pools for recent hiring cycles, the number of positions available, and the number of applicants and the number of individuals hired into the laboratory.

Examples from a local and federal laboratory will be thoroughly presented. As an example of job requirements, all entry-level and journey-level criminalists at one local laboratory are required to have graduated “from an accredited college or university with a bachelor’s degree in Criminalistics or a closely related physical or natural science which must include the successful completion of a minimum of seventeen semester (or equivalent quarter) units of chemistry course work. Chemistry coursework must include laboratory and cover general chemistry and organic chemistry.”

Many of the forensic disciplines have specific education requirements. These requirements can be found in various scientific working group recommendations and forensic standards. Applicants need to be cognizant of these requirements to even be considered for positions. Hiring managers will discuss these various specific requirements and examples will be provided.

To fill one vacancy for a journey-level Criminalist II DNA position at a local laboratory, a recruitment produced 17 applications, 14 of which made it from Human Resources (HR) to the laboratory; when reviewing transcripts and experience only 8 were determined to meet minimum qualifications. A separate Criminalist II firearms recruitment to fill four vacancies produced too few candidates at the Criminalist II experience level, thus an entry-level Criminalist I recruitment will be considered.

As another example, a federal laboratory system had 30 forensic chemist vacancies to fill. There were a total of 434 applicants. Of those, only 100 were deemed qualified by HR. After the interview and testing phase, only 15 applicants were chosen.

The education does not stop after making it beyond the interview. A clean background check is required. Accreditation agencies have requirements obliging laboratories to train their scientists on the job to learn the skills and methods in the laboratory. Accreditation requirements state that court testimony training, testing, and monitoring shall occur, emphasizing the important nexus between forensic science and the legal system.<sup>2</sup> Additionally, forensic standards exist that provide specific requirements for forensic science practitioner training, continuing education, and professional development (e.g., American Society for Testing and Materials [ASTM] E2917). Hiring managers will describe these standards and provide examples.

In order to span the gap between what forensic programs produce, what hiring managers require, and the knowledge scientists must have of courtroom procedures, dialog is imperative so that institutions are aware of the gaps that exist and to appropriately course-correct to produce employable and articulate forensic scientists.

#### Forensic Education, Hiring Requirements, Forensic Skills

### **B157 Expert Forensic Testimony Training for Non-Analysts**

*David Jackson, MSc\*, Washoe County Sheriff's Office, Reno, NV 89512*

---

**Learning Overview:** The goal of this presentation is to inform attendees about non-conventional training opportunities and methods to best serve the criminal justice system and to provide details of such opportunities.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by enthusing, educating, and informing attendees in the importance of delivering forensic testimony training to a wide range of end-users and through diverse methods.

This presentation regards the forensic scientist's responsibility to be equipped and seek opportunities to adequately and appropriately inform and train all members of the criminal justice system, especially those who have a vested interest in the expert witnesses testimony. During the course of a forensic scientist's training program, which can often be very lengthy, much emphasis is rightly given over to the practical aspects of bench work, data interpretation, report writing, and review.

While the aforementioned topics are extremely necessary portions of the training program, this presentation will encompass the opinion that an area of training that could be much improved upon concerns expert witness testimony. Not only are the testifying scientists in need of robust and realistic training for such an occasion that can often be out of their comfort zone, but so too are all other end users of the forensic testimony to be given before the court. Often neglected within training programs are the needs of all people within the courtroom and justice system to understand the intent behind the presentation of potentially complex results, interpretations, and opinions being offered by the highly skilled and technically trained scientist. This presentation will address the shortfalls inherent when the forensic science provider conducts their own internal witness training program that, within government laboratories, is generally tailored to prosecution lines of questioning. This is especially important during a time when the recent emphasis on attempting to minimize bias within the field is at the forefront of forensic conversation.

A universal training or teaching course is inadequate to fulfill the very different needs of the analyst, Law Enforcement Agency (LEA) officer, prosecution attorney, defense attorney, judge, and the general public (jury pool). The analyst may well be among the best equipped to assist the understanding of each of these contributors to justice, and this presentation will give examples and suggestions of how a crucial understanding may be instilled upon all stakeholders with clarity, succinctness, and even a touch of levity.

A unique position within the courtroom is held by the judge whose role within that arena and the judicial system is critical to the fair outcome of any legal hearing or trial proceeding. With such a burden comes the expectation by the court for a judge to make well-informed and just decisions during the admission of testimony. This presentation will additionally focus on the opportunities that exist for laboratory personnel to input in the continuous education of judges. Participation at this level of education is extremely beneficial to the individual judges, scientists, and the wider justice system. However, this opportunity is seldom taken; therefore, much encouragement will be given during this presentation toward greater involvement at this level.

---

### **Court Testimony, Education, Training**

### **B158 Crime Scene Transformation: Helping Evidence Tell Its Story**

*Kaitlin Main, MA\*, Pearland, TX 77584; Peter R. Stout, PhD, Houston Forensic Science Center, Houston, TX 77002; Jerry Pena, CPA, Houston Forensic Science Center, Houston, TX 77002*

---

**Learning Overview:** After attending this presentation, attendees will have learned how to transition a crime scene unit from a classified operation to a civilian unit and the downstream benefits to the crime laboratory's forensic analysis.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by serving as a rubric for how to make the transition to and understand what efforts best serve the community, police department, inter-agency relationships, and other stakeholders. The discussion will include information about how the concept of a civilian and independent crime scene unit began, the efforts the City of Houston, the Houston Police Department, and other key stakeholders employed to make it a reality, and the belief that crime scene investigation is the face of forensics in the field and at the core of successful subsequent testing. The Houston Forensic Science Center (HFSC) has been nationally recognized for innovation and transparency in other forensic areas, but the crime scene unit's transformation has gone largely unnoticed. This presentation is aimed at sharing that unit's success and at educating others about the pros and cons of this transition.

Crime scene investigators are often those among the first, if not the first, to encounter evidence and the scene. As such, a unit's standard operating procedures impact not only what is identified as evidence, but how those items are collected, the level of potential contamination and/or loss, and whether the evidence is collected, preserved, handled, packaged, and identified in a manner that can potentially be used to further a criminal investigation. It is also where forensics comes into the most direct contact with law enforcement at a time when emotions are highest, a crime scene. As a result, transitioning from a classified to a civilian crime scene unit comes with trials and tribulations, and all aspects and phases must be considered, from the slow introduction of civilians into a unit that still has classified personnel, transferring those officers back to their law enforcement duties, and continuing to offer quality work while overcoming the obstacles.

The HFSC navigated all of this and more as it transitioned to a civilian crime scene unit. HFSC's successes, failures, and numerous challenges can now serve as an educational tool for others in the forensic community looking for ways to become more efficient and offer higher quality services to stakeholders. HFSC's Crime Scene Unit (CSU), like all other forensic disciplines in the agency, is now accredited by the American National Standards Institute (ANSI) National Accreditation Board (ANAB) to International Organization for Standardization/International Electrotechnical Commission (ISO/IEC) 17025 standard. This unit has changed the perception of Crime Scene Investigators (CSIs) from mere "technicians" or "garbage collectors," as they were called before HFSC took over, to colleagues with skills and critical thought processes that are crucial to an investigation.

### **B159 Are Forensic Science Programs Meeting the Current and Future Needs of Prospective Employers?**

*Ruth Waddell Smith, PhD\*, Michigan State University, East Lansing, MI 48824; Glen P. Jackson, PhD\*, West Virginia University, Morgantown, WV 26506-6121*

---

**Learning Overview:** After attending this presentation, attendees will be familiar with forensic science educational programs in the United States, the skill sets gained by students in these programs, and the subsequent placement of graduates into forensic science laboratories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing data to inform the discussion surrounding forensic science educational programs meeting the current and future needs of employers.

Over the past decade, there has been an increase in the number of forensic science educational programs offered in the United States at both the undergraduate and graduate levels. In the early 2000s, the American Academy of Forensic Sciences established the Forensic Science Education Programs Accreditation Commission (FEPAC), with the aim of developing and implementing education standards to ensure the high quality of forensic science education programs. The FEPAC standards stipulate that forensic science degree programs must include core courses in forensic science topics and specialized science topics, as well as a capstone/research experience, which should culminate in a scholarly product, such as a presentation or publication. Further, programs must demonstrate interactions with forensic science laboratories that may include internships and collaborative research opportunities. Accreditation is granted for five-year cycles, and programs must undergo a rigorous reassessment process to be granted reaccreditation. As of July 2019, there are more than 25 undergraduate and 20 graduate programs currently accredited, meaning that each program has demonstrated implementation of and compliance with the standards.

In this joint session, representatives from different forensic science educational programs, local and federal hiring managers, as well as representatives of the legal profession and those who educate jurists, will provide information and data to fuel discussion regarding the question “Are forensic science programs meeting the current and future needs of employers and the criminal justice system?” In this presentation specifically, ways in which various forensic science educational programs implement FEPAC accreditation standards at both the undergraduate and the graduate level will be discussed. In one example, recent program changes that have been made to enhance the skill set of students will be presented, including additional required courses, a more formal research proposal presentation, and the incorporation of professional development opportunities. This presentation will also provide data on job placement of recent graduates and lessons learned from post-graduation surveys. In addition to FEPAC-accredited BS and MS programs, this presentation will also discuss the recent creation of two PhD programs in forensic science in the United States. This aspect of the presentation will describe the motivations and considerations for the PhD programs, the requirements of the programs, and some lessons learned following the first few years of operation of each program. Throughout the presentation, specific examples will be given to contribute to the discussion of “Are we meeting the current and future needs of employers and the criminal justice system?”

---

#### **Forensic Science Education, FEPAC, Employer Needs**

### B160 Ridge Drift: The Relevance of a Not-So-Rare Fingermark Aging Phenomenon

Josep De Alcaraz-Fossoul, PhD\*, University of New Haven, West Haven, CT 06516; Katherine A. Roberts, PhD, Hertzberg-Davis Forensic Science Center, Los Angeles, CA 90032-4210; Cathy Johnson, MS, California State University, Los Angeles, Los Angeles, CA 90032-8530; Carme Barrot, PhD, University of Barcelona, Barcelona 08036, SPAIN; Ryan Tully-Doyle, PhD, University of New Haven, Arts & Sciences, West Haven, CT 06516; Brooke W. Kammrath, PhD, University of New Haven, West Haven, CT 06516

**Learning Overview:** After attending this presentation, attendees will understand that ridge drift is not an uncommon event in processed latent fingermarks and will recognize the variables that correlate to higher incidences of this phenomenon.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing the practical implications when detecting ridge drift in processed latent fingermarks. Knowledge of the variables that affect ridge drift will inform attendees as to best practices when processing, comparing, and identifying fingermark evidence to prevent ridge drift from contributing to false negative conclusions.

Latent fingermarks recovered from crime scenes are compared with reference fingerprints to provide circumstantial evidence of the presence of an individual at a location. A limitation of this source attribution approach is the quality and quantity of the friction ridge characteristics, which can contribute potential sources of error to a comparison analysis. Further, the timeframe from occurrence to recovery may account for degradation effects that preclude a true contemporaneous comparison.<sup>1</sup>

A previous study by De Alcaraz-Fossoul et al. described a phenomenon, referred to as fingermark ridge drift, which was characterized as a random modification of aged fingermark patterns at a ridge scale.<sup>2</sup> This event was proven to alter key elements used for identifications, such as the physical appearance of minutiae. Little is currently known of the underlying cause or factors contributing to the occurrence of ridge drift. Currently, the Organization of Scientific Area Committees (OSAC) Friction Ridge Subcommittee documents do not consider fingermark ridge drift in order to account for possible dissimilarities during a comparison process. As a result, an examiner who compares an aged latent fingermark to a reference print (i.e., inked or scanned) without considering ridge drift may erroneously report an inconclusive result where a positive identification may be justified.

The present study was designed to both replicate and expand the variables of the previous ridge drift study by including 672 fingermarks from male and female subjects of similar age; two substrates (tile and plastic); two distinct color powders (carbon black and titanium dioxide–white); three light conditions (direct natural light, shade, and darkness) indoors; and two secretion types (sebaceous- and eccrine-rich). Fingermarks were simultaneously deposited, aged over a period of 2 to 72 days, and powdered for visualization. All developed prints (aged) were compared relative to fresh (day 0) latents to locate ridge drift. For the purpose of the study, ridge drift is collectively defined as either true drift (attributed to ridge movement) or selective degradation (visual modification of ridge patterns). Each processed fingermark was independently examined by three people for the presence of ridge drift. A conservative examination approach was adopted in identifying incidences of drift in that unanimous agreement was required among all three examiners. The number of prints containing drifts was considered rather than the individual counts per print. An inconclusive result was reported when discrepancies occurred among examiners. Further, fingermark images of poor quality (due to degradation effects or artifact inclusions) were also reported as inconclusive results.

Ridge drift was observed in 42 of 672 prints, while 168 prints were reported as inconclusive results. While incidences of ridge drift were detected in multiple fingermark samples across all independent variables, statistical analysis using a multinomial logistics model showed that only powder type, secretion type, and the substrate indicated a significant correlation with increased incidences of ridge drift. There was no significant correlation in the incidence of ridge drift with respect to the subject, time since deposition, or the environmental lighting conditions used. The incidence of ridge drift was significantly higher when black powder was used on plastic. Of note, although the focus of the study was detection of ridge drift, the number of inconclusive samples reported was higher for prints processed with black powder and found to be statistically significant.

The average observation of ridge drift in approximately 6% of samples processed in this study supports that ridge drift is not a rare event, particularly in light of the conservative analysis approach implemented. This is of even greater concern if a fingerprint examiner follows the International Criminal Police Organization (INTERPOL) European Expert Group on Fingerprint Identification II (IEEGFI II) recommendation that single minutiae differences are significant to the conclusion of an identification. Logically, this approach will increase the number of false negative conclusions. Ridge drift can provide useful information that can help reduce misidentifications.

## B161 Accelerated Development of Latent Prints on Thermal Papers

Brent M. Allred, PhD\*, Defense Forensic Science Center, Forest Park, GA 30297; Emily Brisson, BS, Army Educational Outreach Program, Forest Park, GA 30297; Anthony Koertner, MS, U.S. Army Criminal Investigation Laboratory, Forest Park, GA 30297; Kalisha Gill, BS, Defense Forensic Science Center, Forest Park, GA 30297

**Learning Overview:** The goal of this presentation is to demonstrate how heat and humidity can be judiciously applied to accelerate the development of latent prints on thermal papers without sacrificing print quality.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by debunking commonly practiced traditions that any application of heat or humidity will negatively affect thermal papers and thus enable forensic examiners to more expeditiously develop latent prints.

Latent print development on thermal paper is a time-consuming task for latent print examiners. Development methods applied to non-thermal papers have historically been modified for thermal papers. The addition of heat on thermal papers has been widely discouraged because the dyes in the active layer of thermal paper (commonly leuco dyes) change color in the presence of heat, acids, and electron-accepting compounds.<sup>1</sup>

Generally, latent prints on thermal papers are developed over 24 hours in the dark under laboratory environmental conditions.<sup>2-4</sup> However, some research has promoted the use of heat to preferentially develop a latent print on thermal paper using various tools, including a hairdryer, a metal press called the Hot Print System, and heated solid chemicals (i.e., 1,2-indanedione and zinc-chloride).<sup>5,6</sup> Consequently, it may be concluded that heat above ambient laboratory temperatures can aid in developing latent prints on thermal papers.

The goal of this work was to determine whether the use of heat and humidity via a humidity chamber can be used to accelerate the development of latent prints on thermal papers similar to how non-thermal papers are treated. The application of heat and humidity was evaluated for the accelerated development of prints using common porous substrate staining solutions, including 1,2-indanedione, ninhydrin, and 2-isononylninhydrin (i.e., Thermanin).

Fingerprints from multiple donors ( $n=20$ ) on a comprehensive range of thermal papers ( $n=13$ ) were developed using 1,2-indanedione, ninhydrin, and Thermanin. The quality of prints were measured using Universal Latent Workstation's (ULW's) LQ Metrics overall clarity score as well as scoring by five trained latent print examiners using unenhanced grayscale images. It was determined that heat (50°C) and humidity (60%RH) could be applied to thermal paper without inducing discoloration. Additionally, the prints developed using the aforementioned accelerated method (20min) were generally equal to or higher in quality than those produced over 24hrs under ambient conditions. These same findings held true for prints aged and tested out to 30 days post-deposition. Additionally, a thermal probe was developed to more accurately categorize the thermal sensitivity of thermal papers and thus screen new evidence for method compatibility. In summary, this technique successfully accelerated the development of latent prints on thermal papers from 24hrs to 20mins, thereby expediting evidence processing for any of the three processes without compromising the overall quality of the developed prints.

## B162 A Microfluidic Device for the Identification of Biological Sex by Analysis of Fingermarks

Jamila S. Marshall Roberts, MS\*, University of Virginia, Charlottesville, VA 22903; James P. Landers, PhD, University of Virginia, Charlottesville, VA 22904

**Learning Overview:** As a result of attending this presentation, attendees will have introductory knowledge about a novel microfluidic technique for colorimetric determination of biological sex from the biochemical analysis of fingermarks.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a non-enzymatic, cost-efficient, microfluidic colorimetric assay that was developed to measure the arginine content in fingermarks. Rapid and objective determination of the biological sex of unknown individuals was accomplished using inexpensive instrumentation. Notably, the assay described herein is unaffected by the presence of magnetic, dual-use powder; this compatibility is imperative as this powder is commonly used to visualize latent fingermarks at a crime scene prior to further analysis.

Current fingerprint analysis techniques are largely visual and exclusionary, and therefore inherently require a reference for comparison. However, biochemical analysis of fingermarks is becoming more common and provides the opportunity to obtain unique donor identifiers without comparison to a reference. Fingermarks contain metabolites from several hormone-regulated metabolic mechanisms, which can serve as biomarkers or indicators of physiological attributes of the donor, such as age, ethnicity, health status, and gender.<sup>1-3</sup> For instance, in most cases, amino acid concentrations in fingermarks from a female donor are approximately two-fold higher than those deposited by a male.<sup>1</sup> Determination of amino acid concentration in fingermark deposits can thus be used to indicate the biological sex of the donor.

To date, most research regarding amino acid detection and quantification in fingermarks relies on spectrometric methods, including Raman and infrared spectroscopy. A significant disadvantage of such methods is the requirement for the use of sophisticated and expensive instrumentation by trained personnel. Consequently, on-site, chemical analysis of fingermarks is not commonly implemented. Notwithstanding, Brunelle et al. report a colorimetric method for the determination of the biological sex of a fingermark originator using Ultraviolet/Visible (UV/Vis) spectroscopy.<sup>4</sup> Though this represents progress toward minimizing assay cost, the instrumentation required is still quite expensive and necessitates non-trivial user training. Consequently, there is still a need for a rapid, inexpensive, and automated method of analysis that diminishes the need for significant user training for on-site use. Biometric data obtained onsite would facilitate accelerated determination and/or elimination of suspects, thereby increasing the efficiency of time-sensitive investigations.

In this research, the Sakaguchi colorimetric test was adapted to a rotationally driven microfluidic platform and used to detect and quantify arginine in fingermarks deposited by male and female donors. Observation of a red color following the reaction is indicative of the presence of arginine in a given sample. The intensity of this color is linearly proportional to the concentration of arginine in fingermark samples. Objective detection and quantification of arginine was accomplished using open-access image analysis software based on this colorimetric result. The mean concentration obtained experimentally for samples from female donors, 79.60 $\mu$ M, was not statistically different from the theoretical value, 94.8 $\mu$ M ( $p=0.2562$ ).<sup>5</sup> For males, the experimental value obtained was 42.2 $\mu$ M, which was not statistically different from the theoretical value, 54.0 $\mu$ M ( $p=0.3666$ ).<sup>5</sup> Conversely, the experimental means from male and female samples were found to be statistically different from each other with  $p < 0.0001$ . This indicates that the microfluidic protocol could reliably be used to differentiate between male and female fingermarks.

Following initial chemical optimization, compatibility of the assay with magnetic, dual-use powder was evaluated by including a powder-dusting step prior to further analysis. The application of magnetic powder was included as a means of approximating “real world” conditions at a standard crime scene. The magnetic particles were removed following hydrolysis of the fingermark samples. It was observed that despite the inclusion of the magnetic powder, minor modifications of experimental conditions resulted in the expected development of color and intensity.

The novel microfluidic assay for determination of biological sex from fingermark deposits described herein can not only be used to reproducibly differentiate between male and female donors, but is also portable and automatable, making it conducive to use onsite by untrained personnel.

### B163 Analyzing Latent Print Chemistry Using 2D Gas Chromatography

Jessica H. Kindell, BS\*, National Center for Forensic Science, Orlando, FL 32826; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816

**Learning Overview:** After attending this presentation, attendees will have learned of another way of analyzing latent prints based on the chemistry in addition to evaluating the quality of the print and how different correlation statistical methods, such as Pearson's correlation, aids in inter- and intra-variability based on the participant's chemical composition.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting a new instrumental technique in analyzing latent print chemistry that would be a supplement to traditional latent print examination.

Latent print evidence when received from a crime scene are analyzed and compared by examiners using the Analysis, Comparison, Evaluation-Verification (ACE-V) protocol. This accounts for the analysis of the questioned print using Type 1, 2, and 3 minutia details, comparing it to a known exemplar print either obtained from the Automated Fingerprint Identification System (AFIS) or any potential suspects. However, there may be benefit to the community to evaluate the chemistry of the latent print in addition to the analysis of physical minutiae because the chemistry of the naturally secreted sweat and oils is relatively consistent, aside from illnesses and the use of personal hygiene products (e.g., lotions, hair oils, etc.).

Over the years, researchers have evaluated the use of various instrumental techniques in analyzing latent prints, such as Gas Chromatography/Mass Spectrometry (GC/MS), matrix-assisted laser desorption/ionization, and Raman and infrared spectroscopy. GC/MS has been used in latent print studies in identifying lipids and amino acids observed in different volunteer groups based on age, gender, and ethnicity, along with determining the age of the print from deposition to collection; however, there are areas where co-eluting compounds were present within the chromatograms that could decrease the potential of accurate associations or discrimination between unknown and known comparison latent prints.

In this research, 2D GC/MS was used to determine if latent prints could be linked to a source. Statistical techniques, such as Pearson's correlation coefficient, was used to determine the inter- and intra-correlation values between latent prints deposited by various volunteers. In a second study, it was determined latent prints could be classified into either age, gender, or race/ethnicity groups based on chemical composition. Latent print samples collected from volunteers were deposited onto a microscope slide and a microfiber filter, which were extracted using dichloromethane or hexane, and evaporated under nitrogen. To afford for better chromatographic separation and detection along with decreasing volatility, the samples were derivatized before GC analysis. Boron Trifluoride in Methanol (BF<sub>3</sub>-MeOH) and n-Methyl-n-(trimethylsilyl)Trifluoroacetamide (MSTFA) was used for sample derivatization, and the reagent that displayed the better peak identification based on percent quality match, abundance, and reproducibility was used for the duration of the study.

The results of the latent print samples were subjected to compound identification and compared visually for similar/dissimilar peaks between volunteers. The latent print samples were either linked back to a source using Pearson's correlation values or categorized into a class (i.e., race, gender, or race/ethnicity) using principal component analysis and k-nearest neighbors. Error rates were determined to test the validity of the statistical methods described for the samples obtained from the 2D GC/MS.

### B164 Lessons Learned From Conducting Black-Box Evaluations in Multiple Disciplines

R. Austin Hicklin, PhD\*, Noblis, Reston, VA 20191; JoAnn Buscaglia, PhD\*, FBI Laboratory, Counterterrorism and Forensic Science Research Unit, Quantico, VA 22135

**Learning Overview:** The goal of this presentation is to help attendees understand the issues involved in designing and conducting black-box evaluations of the accuracy and reliability of forensic examiners, across several forensic disciplines.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing approaches to assess potential areas of strength and weakness in multiple areas of forensic science.

**Hypothesis Statement:** Lessons learned from black-box evaluations in a forensic discipline can identify issues for consideration in the design of studies assessing the accuracy and reliability of examiners in other forensic disciplines.

The 2016 President's Council of Advisors on Science and Technology (PCAST) Report on forensic science stated that black-box evaluations are necessary to establish the validity of forensic examination methods that rely on human judgment and provided some guidance on what criteria PCAST required for such testing to be considered rigorous and suitable for court admissibility.<sup>1</sup> The accuracy, reproducibility, and repeatability of conclusions in a number of forensic science disciplines have not yet been assessed using such black-box studies. The results of such studies would assist in supporting the scientific basis of these forensic disciplines and provide insights into improved operational procedures and training.

The forensic science community is currently engaged in a variety of efforts to evaluate the accuracy and reliability of forensic conclusions in the pattern evidence disciplines. This presentation will discuss the issues involved and lessons learned from designing and conducting black-box evaluations in five forensic disciplines, including completed studies of latent print examination and studies in progress of handwriting examination, footwear examination, bullet examination, and bloodstain pattern analysis. This presentation will discuss what aspects of study design and data collection have commonalities that apply to multiple disciplines and the aspects that are specific to individual disciplines.

This presentation will discuss topics that should be considered in the design of black-box evaluations, including: (1) controlled collection of samples to simulate operational casework; (2) accounting for different conclusion scales; (3) quality assurance; (4) analysis methods; (5) distribution of physical vs. electronic samples; and (6) evaluation based on classification of individual samples (e.g., bloodstain pattern analysis) vs. comparison of multiple samples.

These studies are designed to evaluate and/or demonstrate the validity of each discipline, as well as providing essential information to laboratory managers and practitioners that may be used to improve or enhance practices in the laboratory. This presentation will also discuss how the results of black-box studies provide data for subsequent "white-box" evaluations and present lessons learned from designing and conducting white-box testing.

### **B165 Using a Smart Phone Special Gadget to Find and Collect Latent Fingerprints: Simplifying the Process**

*Maryah E.M. Haertel\**, Florianópolis, Santa Catarina 88036-635, BRAZIL; *Eduardo J. Linhares*, Jaraguá do Sul, Santa Catarina, BRAZIL; *André L. Melo*, Lages, Santa Catarina, BRAZIL

**Learning Overview:** After attending this presentation, attendees will have learned about an innovative use of a smart phone, equipped with a special and simple gadget, to acquire latent fingerprints in crime scenes with a low-cost, non-destructive method.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by demonstrating the possibility of using a smart phone, with a low-cost gadget and without any chemical substances, to highlight and acquire latent fingerprints in crime scenes, improving the productivity and cost of forensic examination, especially in developing countries.

Latent digital prints are important vestiges in crime sites, due to their high incidence and possibility of author identification. However, their acquisition usually depends on the personal experience of the forensic examiner regarding knowledge of classical methodologies and the correct use of reagents.

Although there are new technological tools commercially available for use in the search and acquisition of fragments, such resources are still restrictive to Brazilian professionals because of their high cost. As a consequence, the registration of papillary fragments ends up depending on classical methods, which involves the use of chemical reagents, causing modifications that destroy the vestige as originally conceived. Most of these chemical reagents also have high toxicity, which can impair the health of the examiners.

This research proposes the development of a simple and low-cost device, designed to adapt to a smart phone, allowing the enhancement of latent papillary fragments and their capture through the smart phone camera using optical methods. The built prototype is simple, lightweight, and enables the proposal of a non-destructive and low-cost methodology, without any chemical interaction with the evidence, preserving the vestige as originally conceived, and allowing its use in other methodologies, such as spectrophotometry and touch DNA.

The prototype was tested with a medium technology smart phone in laboratory and under external conditions. Latent fingerprints were acquired from non-porous surfaces, frequent in crime scenes, such as glass, metal, and plastic. Tests were also performed focusing on other possible applications of the method, such as using mass and oil to analyze the results of modeled and stamped fingerprints.

The results were confronted with known fragments, and the comparisons demonstrated sufficient quality for at least 12 matching points (Brazilian standards). Both the device and the developed methodology showed an excellent performance for the acquisition of latent papillary fragments on different surfaces and conditions. The results obtained with the gadget allows a new step for the research, which would be tests in crime scenes.

### **B166 A Cyanoacrylate Chamber for Vehicles: Innovation and Astonishing Results in Brazilian Casuistry**

Angela T. Oliveira, MS\*, Civil Police of Federal District, Brasília, Distrito Federal 70610-907, BRAZIL; Arthur P. Vidal, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Ayeska E. Maia, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Cecília V. Jacintho, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Débora H. Kist, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Diana W. Moraes, Civil Police of Federal District, Brasília 70610-907, BRAZIL; João G. Souza Neto, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Kenio W. Tida, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Laura P. Macedo, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Leandro S. Faria, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Luana D. Batista, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Osmar S. Oliveira Neto, MS, Civil Police of Federal District, Brasília 70610-907, BRAZIL; Marco A. Paulino, Civil Police of Federal District, Brasília 70610-907, BRAZIL

**Learning Overview:** The goal of this presentation is to show the possibility of increasing the number and quality of developed latent fingermarks in vehicles with the use of a cyanoacrylate chamber for vehicles, especially when the powder method would exhibit limitations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining an exclusive project developed by fingerprint experts from Brazil, the cyanoacrylate fuming chamber for vehicles, that is fully automated, which guarantees scalability in the amount of material to be processed and safety for the experts and to the environment. This processing allows revealing latent fingermarks in a high-quality standard and on uncommon surfaces when compared to other conventional methods.

The analysis of latent fingermarks stands at the forefront of criminal investigations, especially in crime scene casework. Their detection on smooth surfaces, like metals, plastics, or glass by Cyanoacrylate Ester (CA) fuming is a commonly used technique worldwide.<sup>1</sup> In fuming chambers, the CA is vaporized and polymerizes as a white solid residue on the surfaces of the potentially manipulated objects. In Brasília, Brazil, vehicles commonly used to be analyzed by visual inspection and treated with the black fingerprint powder/lift technique. Considering that the CA method is capable of enhancing the quantity of ridge detail as well as better quality fingermarks being developed when compared to the powder methods, fingerprint experts from Brasília projected, installed, and validated a CA Chamber for Vehicles (CCV), which is considered the largest in the world (6.2×4.0×3.1m). This was the result of an exclusive project developed by fingerprint experts that work in the Laboratory of Fingerprint Enhancement Methods of the Civil Police of the Federal District. Usually, the CVV is used to process vehicles related to homicides, large thefts, and robberies and allows processing a vehicle as large as a pickup truck. There is an internal division isolating one-third of its volume for daily use to process small- and medium-sized objects recovered from crime scenes and two-thirds of its volume is designated to the vehicle. The operating cycle was tested and automated in three steps: (1) pre-humidification to about 80% by water evaporation using a boiler; (2) CA fuming using 16 electric heaters (180–200°C) distributed inside and outside the vehicle for 40min; and (3) CA fume exhaustion for 40min. The equipment also includes an air circulation device to homogenize humidity and a CA fume inside the chamber.

Vehicle processing in CCV enables visualization of fingermarks on surfaces that would rarely be appropriate for the application of other techniques. Positive results were obtained on the turn signal, windshield wiper handle, central panel, glove compartment, driver's seat regulation handle, emergency brake button, ignition, steering wheel, motor compartment, gear shift, headrest stand, inside door handle, and seatbelt buckle. Since the inauguration of CVV (approximately ten months), 26 vehicles have been processed and 17 suspects were identified based on the fingermarks developed on vehicle structures. Six of these suspects have previously been criminally identified and one of them was identified in two different vehicles. For vehicles treated by the black powder method and subsequently processed in the CVV, an increase in the number of developed fingermarks was observed. In addition to an increase in the number, the new equipment allowed an increase in the quality of fingerprint evidence, especially when the powder method would show limitations. The acquisition of CVV represented a significant improvement in the expert routine of the Identification Institute of the Civil Police of the Federal District and should be encouraged for other forensic laboratories around the world. The results have helped to solve several criminal cases in the Federal District.

### B167 Fingerprints and Ancestry: Is It in the Details?

Jessica R. Ford\*, Oklahoma City Police Department, Oklahoma City, OK 73135

**Learning Overview:** This presentation will discuss the plausibility of using Galton features, specifically the certain types of Galton features to determine a person's ancestry.<sup>1</sup> Such research could aid law enforcement in shortening an otherwise lengthy suspect list or even aid in the exoneration of those wrongfully convicted.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by creating a greater understanding of criminalistics, specifically as it relates to the viability of fingerprints left at a crime scene and new tools that could be used to determine a fingerprint's origin.

Over the years, Sir Francis Galton, and more recently, Fournier and Ross have explored this concept of ancestry determined from fingerprint minutiae.<sup>1,2</sup> Galton studied and compared the fingerprints of English pure Welsh, Hebrew, Black, and some Basques from Cambo in the French Pyrenees to look for differences in patterns and minutiae characteristics.<sup>1</sup> His study had a sample size of more than 100 individuals. While his study did not yield significant scientific results, Galton claimed to be able to tell a difference in fingerprint minutiae between the different ancestries. Fournier and Ross conducted a similar study with the purpose of exploring the influence of sex, ancestry, and pattern type on minutiae in African descent and European descent males and females.<sup>2</sup> Overall, 243 right index fingerprints were chosen, including 61 African American females and 61 African American males for a total of 122 African Americans, as well as 60 European American males and 61 European American females for a total of 121 European Americans. Based on this study, fingerprint minutiae, specifically the total number of bifurcations, shows promise as a method to predict the ancestry of an individual to some degree of certainty.

Researchers at the University of Central Oklahoma conducted a study made up of 250 participants, 25 Hispanic-descendant males, 25 Hispanic-descendant females, 25 Asian-descendant males, 25 Asian-descendant females, 25 Native American-descendant males, 25 Native American-descendant females, 25 African-descendant males, 25 African-descendant females, 25 European-descendant males, and 25 European-descendant females. The sex and ancestry of each participant was ascertained based on self-identification and demographic information. In order to collect the prints, each participant had their right index finger rolled on an index card using fingerprint ink. Each print shows a complete nail-to-nail roll recorded for later analysis of friction ridge detail. Because of the statistical likelihood that the right index finger is the print most often encountered at crime scenes, those prints were used for analysis. With assistance of AFIX Tracker® technology, each print was analyzed and marked by the researcher for each of the five main fingerprint minutiae characteristics: bifurcations, enclosures, dots, ending ridges, and short ridges. It has been found that the amount of bifurcations in one's fingerprint yields significant results as it relates to ancestry. Interestingly, it has been found that African American descendants have slightly more bifurcations than European American descendants.

Significant results in the above research highlights new possibilities for law enforcement personnel. Deriving someone's ancestry from their fingerprints can serve as corroborative evidence that could aid in the conviction of criminals who could otherwise walk free. Additionally, this forensic tool could also aid in the exoneration of those wrongfully convicted. This presentation could greatly impact the forensic science community by shedding light on innovative ways that fingerprints can be used in the application of criminalistics to crime scenes.

### **B168 The Formation and Examination of Bloody Friction Ridge Patterns on Common Textile Materials Using Different Enhancement Techniques**

*Kaitlyn Chetney\*, Shorewood, IL 60404; Ralph R. Ristenbatt III, MS, Pennsylvania State University, University Park, PA 16802*

---

**Learning Overview:** After attending this presentation, attendees will better understand which chemical and dye enhancement techniques can be used to enhance latent (blood) friction ridge patterns on various fabrics.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing criminalists with information as to which techniques are best suited for the enhancement of fingerprints composed of blood on fabrics that may be found at crime scenes.

The presence of fingerprints at a crime scene has proven to be useful during an investigation due to the great variability of ridge features. Finding and analyzing fingerprints may provide criminalists with information allowing an individual to be linked to an incident. It is common to find fingerprints, along with other friction ridge patterns, at crime scenes on a multitude of surfaces. For example, textiles of various types and complexity are often present at crime scenes. If a textile contains differentiating pieces of evidence, such as fingerprints composed of blood, it could be instrumental in the resolution of the investigation. However, bloody fingerprints on textiles may often be difficult to observe or locate, causing them to remain undetected or be deemed unsuitable for comparison. The enhancement of bloody fingerprints on fabrics could be crucial in increasing their probative value in an investigation.

There are several techniques that may be used to enhance fingerprints generated by blood-contaminated friction ridge skin. Criminalists must first characterize the fabric containing the pattern. Composition, structure, color, and textile porosity must be considered before selecting an appropriate chemical or dye. Three different classes of compounds that can be used to enhance fingerprints made primarily of blood are protein dyes, heme-reactive compounds, and amino-reactive compounds.

A series of five bloody fingerprints created with a blood-covered finger were deposited onto a variety of textiles. This was accomplished by depositing 20 $\mu$ L of defibrinated ovine blood onto the fingertip of the index finger (palmar surface of the distal phalange) and redistributing the blood with a Teflon<sup>®</sup> spatula, followed by placement of the fingertip onto the substrate. Four subsequent fingerprints were deposited onto the substrate without applying additional blood. The fingerprints were deposited onto both washed and unwashed fabric swatches of different colors with different backing materials.

The fabric swatches were allowed to dry for a specific amount of time (1 hour, 5 hours, 10 hours, or 24 hours), then fixed and/or enhanced using a variety of different dyes and chemicals (Amido black, Coomassie blue, Leucocrystal Violet, DFO, Hungarian Red, or Acid Yellow 7). After enhancement, a Nikon<sup>®</sup> D810 Digital Single-Lens Reflex (DSLR) camera was used to record the results of each trial. Different optical techniques were employed in an attempt to provide further enhancement.

The enhancement of patterns of friction ridge skin composed of blood on different fabrics may be important in forensic investigations. If better understood, criminalists may be able to decide which technique would provide optimal results for the enhancement patterns of blood on fabric.

---

## B169 Fingerprint Error Rate on Close Non-Matches (CNMs)

*Jonathan J. Koehler, PhD\*, Chicago, IL 60611; Shiquan Liu, PhD, China University of Political Science and Law, Beijing 100000, CHINA*

**Learning Overview:** The goal of this presentation is to provide attendees with information about the risk of false fingerprint identification in cases in which prints from different sources have many common features and few dissimilar features.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by making attendees aware of data related to how often expert fingerprint examiners err in difficult cases.

The accuracy of fingerprint analyses is critically important to the administration of criminal justice. However, a 2016 Report by The President's Council of Advisors on Science and Technology (PCAST) indicated that there were only two well-designed empirical studies that directly examined the accuracy of fingerprint examiners' identification conclusions.<sup>1</sup> These two studies reported very low false positive error rates on print pairs that the authors described as "challenging" and "representative of case work."<sup>2,3</sup>

Though encouraging, it is not clear whether similarly low error rates would be observed for CNMs in which the latent and exemplar prints have many common features and few dissimilar features. It is important to learn more about CNM error rates because CNMs are more likely to arise in casework as database searches become more common and as the size of the searched databases increases.

In the present study, high-level fingerprint examiners from 125 Chinese fingerprint agencies completed a mandatory online proficiency test using Picture Annotation Software 4 (PiAnoS4) fingerprint software that included two CNMs. PiAnoS4 enables participants to conduct a detailed, annotated, step-by-step examination of print pairs using the standard fingerprint method. Examiners viewed eight consistent points of comparison (minutiae) between the prints followed by an inconsistent point. Examiners were instructed to provide one of three conclusions for each latent-exemplar print pair: identification, exclusion, or inconclusive. In keeping with casework practices in China, the instructions discouraged reliance on the inconclusive conclusion. Examiners were also encouraged to provide written comments that document their thoughts at various decision points. Each agency received a unique user name and code. Agencies had five days to complete the test and submit results.

The false identification rates on the CNMs were 15.9% (17 out of 107, 95% Confidence Interval (CI): 9.5%, 24.2%) and 28.1% (27 out of 96, 95% CI: 19.4%, 38.2%), yielding a combined false identification rate of 21.7% (44 out of 203, 95% CI: 16.2%, 28.0%). These false positive error rates are higher than those observed by Ulery et al. and Pacheco et al., but they are roughly in line with error rates observed elsewhere on difficult CNMs.<sup>1,2</sup> Written comments from examiners who committed identification errors suggest that those examiners frequently failed to note any important points of difference between the latent and exemplar prints. A smaller percentage of examiners who committed identification errors observed dissimilarities, but they often rationalized them away as unimportant artifacts.

This presentation concludes that the false identification rate on CNMs may be substantially higher than the error rate identified in the two well-designed studies singled out in the PCAST Report. If so, then the probative value of reported identifications may be lower than widely believed in cases where the risk of encountering a CNM is amplified.

### Error Rate, Close Non-Match, Fingerprint

### B170 Testing the Accuracy and Reliability of Palmar Friction Ridge Comparisons: A Black Box Study

Heidi Eldridge, MS\*, RTI International, Research Triangle Park, NC 27709; Marco De Donno, University of Lausanne, Lausanne 1015, SWITZERLAND; Christophe Champod, PhD\*, University of Lausanne, School of Criminal Science, Lausanne-Dorigny, Vaud 1015, SWITZERLAND

**Learning Overview:** After attending this presentation, attendees will be aware of the results of a recent large-scale black box study that measured the performance of expert friction ridge examiners to establish a discipline error rate estimate for the comparison of palmar impressions. This is the first study to specifically measure performance on the palmar comparison task.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an error rate estimate that can be used by examiners in court when testifying to the results of palm comparisons. These results provide the first step in establishing the foundational validity of palmar comparisons, as defined by the recent President's Council of Advisors on Science and Technology (PCAST) Report.<sup>1</sup>

In 2011, a team of researchers from the Federal Bureau of Investigation (FBI) and Noblis published in the Proceedings of the National Academy of Sciences the first large-scale black box study measuring the accuracy of fingerprint examiners.<sup>2</sup> They reported a low rate of false positives (0.1%) and a rather high rate of false negatives (about 7.5%). The FBI/Noblis study dealt only with marks and prints originating from the distal phalanges of fingers (fingerprints). However, anecdotally it is estimated that approximately 30% of comparison cases involve palm impressions. It has been unknown up to now whether examiners are equally accurate at both tasks. This presentation provides the results of a recent large-scale black box study that measured examiners' accuracy when conducting exclusively palm comparisons.

This presentation reports on the results recorded both during the Analysis phase and the Comparison phase by a total of 226 fingerprint examiners who carried out a total of 12,279 determinations in Analysis and 9,460 decisions following Comparison. The pool of cases was composed of 526 cases (questioned and known palm impressions) of known ground truth (i.e., the source of the unknown impressions was known to the researchers before conducting the study). Both known mated pairs and known non-mated pairs were presented. Participants first performed a suitability analysis on unknown mark; thus, not all unknown marks proceeded to comparison (those deemed by the examiner to be unsuitable were not presented with a known exemplar to compare). Unknown marks and known exemplars varied in quantity and quality of features to reflect the complexity of casework.

Two online Shiny applications will also be presented for exploring the results of the study and the data's associated confidence and credible intervals. The implications of these results on the reporting of "error rates" associated with palm print examinations will be discussed along with the implications and incidence of "questionable" conclusions that may not be supported by a consensus panel.

### **B171 Unusual Fingerprint Patterns in a North Indian Population—Implications in Forensic Casework and Fingerprint Research**

*Neha Baryah, MS\*, Panjab University, Anthropology Department, Chandigarh 160014, INDIA; Kewal Krishan, PhD, Panjab University, Chandigarh 160 014, INDIA*

**Learning Overview:** After attending this presentation, attendees will understand the usefulness, importance, variability, and implications of the unusual fingerprint patterns in forensic casework and fingerprint research, especially while classifying the fingerprint patterns into defined categories.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community regarding new information on unusual fingerprint patterns. Moreover, this presentation is also expected to further help forensic scientists and fingerprint researchers acquire profound understanding of the fingerprint pattern in the identification process and in making population standards pertaining to different types of fingerprints in various population groups.

Fingerprinting remains one of the most popular methods of identification since the denouement of 19<sup>th</sup> century. Fingerprints serve as a powerful and most widely used characteristic tool in various issues pertaining to identification. The science of fingerprints has been employed for business transactions in Babylon up to the present day biometric, security system, and fingerprint sensing for locking of smart phones to secure the privacy of the user. The presence of definitive patterns and a large number of combinations of their occurrences form the basis of its use in forensics for identification purposes. The tenacity of fingerprint evidence for the identification of criminals has been well documented, but none of the research work focused on unusual fingerprints; therefore, the present study attempted to define such rarely encountered fingerprints in a population. The objective of the present study was to explore the unusual pattern types on the finger balls and their comparison with the commonly occurring and classifiable pattern types. Further, this presentation discusses the occurrence of unusual fingerprints in both the sexes with reference to the finger digits.

The research was conducted on 512 participants aged between 18 and 35 years from two ethnic groups residing in Districts Solan and Shimla in Himachal Pradesh State of North India. A total of 5,120 fingerprints from each digit of the 512 individuals were obtained. The fingerprints were analyzed for the pattern types based on Henry's classification. The patterns that did not fall in the prescribed category as per the definition of the finger pattern types were identified as unusual fingerprints.

A total of 11 unusual fingerprints were reported in both the sexes and two different ethnic groups studied, thus accounting for ~0.21% of the unusual fingerprints. These fingerprints were thoroughly analyzed and compared with the general pattern types according to Henry's classification. Furthermore, this study attempted to define these unusual fingerprints to formulate a category that may aid in the individualization process. The suggestive definition and naming of these new fingerprint patterns stands as a central pocket whorl (two patterns), a single spiral whorl enclosing mesh, a central pocket loop with a diminutive loop, and a lateral pocket loop with triradii (left) in the center. The proposed new nomenclature of these unusual fingerprints is expected to assist the forensic scientists and fingerprint examiners in better understanding and labeling of similar patterns in forensic cases.

### **B172 Do We Understand the Factors That Influence Fingermark Detection?**

*Sebastien Moret, PhD\**, University of Technology Sydney, Sydney 2007, AUSTRALIA; *Xanthe Spindler, PhD*, University of Technology Sydney, Sydney 2007, AUSTRALIA; *Scott Chadwick, PhD*, University of Technology Sydney, Broadway, NSW 2007, AUSTRALIA; *Christopher J. Lennard, PhD*, University of Western Sydney, Richmond, NSW 2753, AUSTRALIA; *Claude Roux, PhD*, University of Technology Sydney, Broadway, NSW 2007, AUSTRALIA

**Learning Overview:** After attending this presentation, attendees will have an improved understanding of the variety of factors that affect the detection of a latent fingermark. The goal of this presentation is to provide an up-to-date review of the factors influencing fingermark detection and how these can be determined and studied.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information to address a current knowledge gap and by encouraging the community to appreciate the complexity of this area. This presentation will: (1) assist researchers in fingermark detection to undertake more robust research; and (2) assist practitioners to be more proficient through a better understanding of the fundamentals of latent fingermarks when implementing detection methods in casework.

The primary aims of fingermark detection research are to improve the quality and number of recovered fingermarks. This is usually performed through the development of new methods and technologies to provide alternatives to or improve current procedures. While research of this nature is important to pursue, it fails to address the underlying question related to the factors that affect the detection of a latent fingermark. There has been significant research that has examined the differences between techniques, donors, and fingermark age, as well as the composition of latent fingermarks. However, previous research tends not to focus on determining how these factors influence the quality of the developed mark.

A previously published study found that substrate characteristics and fingermark donor inter- and intra-variability play major roles in the number and quality of marks developed.<sup>1</sup> Based on the findings of this initial study, there is still more research required to understand the fundamentals of latent fingermarks and their detection. This presentation will provide an update on the continuing investigations being performed to better understand the factors that influence fingermark detection, focusing on the second phase of the study using a larger donor population under more realistic conditions. The discussion will cover a number of related areas, including: (1) the influence of substrate chemical and physical characteristics on the development of fingermarks, and (2) the influence of the donor on the detection process, particularly cyanoacrylate fuming on plastic substrates. In both phases of the study, a greater donor dependency was observed for cyanoacrylate fuming than for indanedione-zinc.

It is argued that such research provides much-needed information to address the current knowledge gap. It also encourages the forensic science community to appreciate the complexity of this area. The findings from this study assist researchers in fingermark detection to undertake more robust research. For example, these findings provide guidance when developing experimental design by taking donor/fingermark composition and substrate characteristics into consideration, in particular for positive early studies. These findings also assist practitioners to be more proficient through better understanding the fundamentals of latent fingermark detection processes when implementing these methods in casework, including validation and refinement of Standard Operating Procedures (SOPs).

## B173 A Comparison of 2D Footwear Images Using Maximum Clique (MC) and Speeded-Up Robust Features (SURFs)

Soyoung Park, MS, Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011; Alicia L. Carriquiry, PhD\*, Center for Statistics and Applications in Forensic Evidence, Iowa State University, Ames, IA 50011

**Learning Overview:** The goal of this presentation is to introduce an objective, accurate, and reliable approach to quantify the similarity between two outsole impressions.

**Impact on the Forensic Science Community:** Footwear impressions are commonly found in crime scenes, but examiners lack objective approaches to analyze and interpret the evidence. This presentation will impact the forensic science community by presenting an algorithm to quantify the similarity between two impressions and enable calculation of the probative value of footwear impressions in real casework that would have a big impact among footwear examiners.

Footwear examiners are tasked with determining whether the suspect's shoe could have left the print at the crime scene. Current practice relies on the visual comparison of the two impressions and a subjective assessment of their similarity, perhaps with the aid of a catalog of outsole patterns with brand and model information.

Footwear evidence are found in about a third of all crime scenes.<sup>1</sup> However, footwear impressions are rarely introduced as evidence in criminal proceedings. This may be because accurate, reliable, and validated methods to quantify the similarity between two outsole impressions have yet to be proposed, and therefore, examiners are limited in the type of conclusions they can make.

A new method called Maximum Clique, Comparison, Speeded-Up Robust Features (MC-COMP-SURF) that quantifies the similarity between two outsole impressions is proposed. The method compares a full or partial image of a shoe impression (Q) from an unknown source to an impression (K) from a known reference shoe, using 2D images of the impressions. MC-COMP-SURF relies on robust features on each impression and aligns them using MC.<sup>2</sup> MC arises from graph theory and can be used to assess the property of geometrical congruence in the outsole patterns. An advantage of the MC method is its invariance to rotation and translation. A disadvantage is that for large images, the method can be computationally intensive and time consuming. After aligning features in Q and K, it is possible to define multiple similarity features and combine them into a univariate similarity score using a Random Forest (RF). The approach that outputs an RF score from MC-COMP-SURF is denoted RF-SURF.

A large experimental database of 2D outsole images was built by researchers in the Center for Statistics and Applications in Forensic Evidence (CSAFE). One hundred sixty participants were allocated a new pair of athletic shoes of one of two brands and sizes 8, 8.5, 10, 10.5. Each shoe from each pair was imaged four times right after purchase and about every eight weeks on three additional occasions, during which time study participants wore the shoes. The algorithms discussed in this presentation were constructed and tested using a subset of the data consisting of shoes with the same class characteristics and similar degree of wear that are difficult to tell apart. RF-SURF outperformed other methods in the literature, including Phase-Only Correlation (POC) and MC-COMP-edge in the sense of minimizing classification error into the same or different shoe classes.<sup>3,4</sup>

The algorithm was also tested in more realistic scenarios with partial, degraded, and smudged images from the questioned impression. Images obtained from Q were degraded sequentially, resulting in images of decreasing clarity. The same algorithms were used to quantify the similarity between degraded images from Q and a high-quality image of K. Results suggested that the comparison algorithm based on SURF is robust to some forms of image degradation; at all levels of degradation, MC-COMP-SURF outperformed all other methods in terms of classification accuracy.

*This work was partially funded by the Center for Statistics and Applications in Forensic Evidence (CSAFE) through Cooperative Agreement 70NANB15H176 between the National Institute of Standards and Technology (NIST) and Iowa State University, which includes activities carried out at Carnegie Mellon University, University of California Irvine, and University of Virginia.*

### Footwear Impressions, Similarity Score, Source

### B174 Estimating the Probability of Randomly Acquired Characteristics (RACs) Locations on a Shoe Sole

Naomi Kaplan-Damary, PhD\*, University of California, Irvine, Sunnyvale, CA 94087; Micha Mandel, PhD, Hebrew University of Jerusalem, Jerusalem 91905, ISRAEL; Yoram Yekutieli, PhD, Hadassah Academic College, Jerusalem 9101001, ISRAEL; Sarena Weisner, MS, Division of Identification and Forensic Science, Jerusalem 91906, ISRAEL; Yaron Shor, MS, Division of Identification and Forensic Science, Jerusalem, ISRAEL

**Learning Overview:** After attending this presentation, attendees will better understand the process of comparing the shoes of a suspect with prints left at a crime scene and the importance of faults on the shoe sole, known as RACs—especially their spatial distribution—in determining the findings' evidential value. Novel methods for estimating the probability of a RAC appearing at a given location on a shoe sole will be explained, as well as the impact of this information on the likelihood of a match.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by developing a greater expectation that forensic evidence have a solid scientific basis.

In recent years, forensic methods have been criticized for their shortcomings in providing courts with objective and quantitative answers to the question of whether a sample from a suspect matches a sample found at the crime scene. Unlike DNA that is used routinely to link suspects to crime scenes because of its scientific objectivity and accessible documentation, the evaluation of other types of evidence, such as shoeprints, tire tracks, tool marks, and the like, has not reached this gold standard. Both the 2009 National Research Council (NRC) Report, *Strengthening Forensic Science in the United States: A Path Forward*,<sup>1</sup> and the 2016 President's Council of Advisors on Science and Technology (PCAST) Report to President Obama, *Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods*, have called for the strengthening of the scientific basis of forensic procedures.<sup>1,2</sup>

Here, shoeprint comparison is considered. The identification of footwear impressions is based on the comparison of a print found at the crime scene with a print made from a suspect's shoe. The analysis of shoeprints by experts is done in two broad stages. First, the pattern, size, and wear of the shoe sole are compared to the crime scene print. If these do not fit, the analysis is stopped, and the pair is classified as a non-match. In the second stage, the forensic expert examines whether RACs on the shoe sole, such as scratches or holes, match the RACs on the print from the crime scene. These RACs may have various characteristics; for example, location, shape, and orientation. However, the distribution of RAC characteristics has not been investigated thoroughly. New statistical methods are presented for estimating the probability of a RAC at a given location on the shoe sole. RACs are assumed to follow a 2D point process, the intensity function of which governs the probability of their appearance at different locations. A smooth intensity function based on pixel data is first estimated using a logistic regression and natural cubic splines. This approach fully exploits the data, but may be problematic as the definition of location is ambiguous. An alternative approach is presented, which uses a piece-wise constant intensity function in regions defined by forensic experts. It is shown that RACs are likely to appear at certain locations, corresponding to the foot's morphology.

The findings of this study take us a step forward in assessing the evidential value of shoeprint comparison. As RACs in certain locations are rarer than in others, they carry more weight in determining the rarity of the shoe sole, or in other words, the probability of a match between the crime scene print and the suspect's shoe.

#### Footwear Impression, Randomly Acquired Characteristics, Shoeprints

### B175 The Effects of Elevated Temperatures and Substrates on the Weathering of Ignitable Liquids

*Caitlyn Wensel, BS\*, West Virginia University, Morgantown, WV 26505; Isaac Willis, BS, Michigan State University, East Lansing, MI 48823-8325; Zilin Fan, PhD, Tianjin Fire Research Institute of MPS, Morgantown, WV 26506; J. Tyler Davidson, MS, West Virginia University, Morgantown, WV 26505; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV 26506-6121*

**Learning Overview:** After attending this presentation, attendees will better understand how elevated temperatures, the type of substrate, and the penetration of the ignitable liquid into each substrate affect the relative evaporation rates of different components of the ignitable liquid. Attendees will better understand the different phenomena that lead to the observed weathering of ignitable liquids in fire debris.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of how the volatiles within a mixture evaporate at different rates when they are spiked onto different common household substrates and evaporated at elevated temperatures that mimic casework. Such understanding will assist analysts in making more reliable inferences on the presence and identification of ignitable liquids in authentic casework samples.

**Hypothesis:** Two central hypotheses are that the temperature at which weathering occurs and the penetration depth of an ignitable liquid into a porous substrate will both affect the relative evaporation rates of the components in the mixture. An additional hypothesis is that the surface chemistry of a non-porous substrate will not influence the weathering of an ignitable liquid.

**Methods/Results:** Analyses involved the development of a synthetic gasoline sample and a variety of sample treatments and weathering conditions. A simplified, synthetic form of gasoline was created using nine compounds that represent a wide range of volatilities and chemical classes in fresh gasoline, including alkanes, substituted aromatics, an indane, and a polyaromatic. To achieve the desired weathering, an aluminum block with an aluminum weight boat in the center was preheated to the desired temperature in a vacuum oven, while a second aluminum block was cooled to -20°C in a freezer. Once the heating block and weight boat reached the appropriate temperature, a measured aliquot of the synthetic gasoline was spiked into the weight boat and weathered at the desired temperature to the desired extent, at which time the weight boat was transferred to the cold block to prevent additional evaporation.

The five substrates included a hard wood, a soft wood, nylon carpet, olefin carpet, and cotton. To simulate the expected conditions of casework samples, different delay times were studied between when the ignitable liquid was spiked on each substrate and when the weathering was initiated. Penetration times ranged from 30 seconds to 30 minutes.

Preliminary results corroborate this evaporation model, which is based on equilibrium theory, in which the temperature of evaporation plays a major role in the relative distribution of the residues in weathered ignitable liquids. For example, when a synthetic gasoline sample is weathered 90% at 30°C, the molar fraction of toluene—the most volatile component in the mixture—decreases from the original value of ~35% to a value that is below the threshold for detection on the Gas Chromatography/Mass Spectrometry (GC/MS). However, when the same mixture is weathered to the same extent at 210°C, toluene is readily observed at a molar ratio of ~1% after weathering. The model shows that compounds of disparate boiling points have a narrower range of vapor pressures at elevated temperatures, which explains why the disparate compounds evaporate at more similar rates at elevated temperatures than at room temperature.

Experiments regarding the effect of substrate are still ongoing, but preliminary results show that short (e.g., 30 seconds) penetration times on different surfaces do not significantly influence the weathering pattern of the gasoline simulant. The effects of longer penetration times are currently undetermined.

#### **Ignitable Liquids, Weathering, Household Substrates**

### **B176 The Utilization of Portable Gas Chromatographic (GC) Systems Coupled With Capillary Microextraction of Volatiles (CMV) for On-Site Detection of Ignitable Liquid Residues (ILRs)**

Michelle N. Torres, BS\*, Florida International University, Miami, FL 33199; Nicole Valdes, BA, Florida International University, Miami, FL 33199; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199

**Learning Overview:** After attending this presentation, attendees will be familiar with the performance capabilities of current generation portable Gas Chromatograph/Mass Spectrometers (GC/MS) as applied to fire investigations.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the advantages and disadvantages of the systems and the extraction techniques presented here, which would be particularly helpful to fire scene investigators and fire debris analysts.

Laboratory methodologies for the detection and analysis of ILRs in fire debris are well-established; however, methodologies pertaining to on-scene detection and identification are less defined. Instrumentation, such as hydrocarbon “noses,” have not been widely utilized due to a lack of specificity and have instead been surpassed by ILR-trained canines. Thanks to recent advancements in miniaturized hyphenated systems, the potential for rapid and more accurate on-site detection of ILRs exists. With the growing availability of these portable systems on the market, there is now a need to evaluate their effectiveness in the field relative to traditional laboratory methods.<sup>1</sup>

In this study, two portable GC/MS systems, the TRIDION™-9 and the Griffin™ G510, are applied to the analysis of ignitable liquid residues recovered from fire debris. Both systems are low thermal mass GCs; the TRIDION™-9 utilizes a toroidal ion trap as its detector while the Griffin™ utilizes a linear quadrupole. The instrument inlets are configured to allow Solid Phase Microextraction (SPME) sampling in addition to other sampling techniques. Other commercially available accessories available from both instrument companies also allow for the coupling of the CMV device. The CMV is a dynamic headspace sampling device which consists of a dual open-ended capillary tube filled with glass microfiber strips that are coated in a Polydimethylsiloxane (PDMS) -incorporated sol-gel polymer. The CMV can be thermally desorbed by direct insertion into a GC/MS inlet and has had successful applications to several materials of forensic interest.<sup>2-4</sup>

The two instruments are evaluated using several points of comparison. Chromatographic resolution, software identification capabilities, overall time of analysis, and ease of use are evaluated. The figures of merit for each system are also compared to those of a benchtop GC/MS system. Method development and optimization is carried out using standardized accelerant mixtures. Simulated debris sampling is carried out in three scenarios: closed-system using 1L steel paint cans or paper cups with various charred substrates, and open-system using a calibrated vapor source. The techniques used for sampling include SPME fibers and the CMV with their recovery capabilities compared across all three systems. Finally, both systems have been utilized onsite at an accelerated live-burn exercise, and the results of this exercise are also presented.

### B177 The Benefits of High-Resolution Mass Spectrometry for the Identification of Ignitable Liquids

Haylea Debolt\*, State College, PA 16801; Frank Dorman, PhD, University Park, PA 16802-4500

**Learning Overview:** After attending this presentation, attendees will see that through the use of high-resolution mass spectrometry, ignitable liquids may be more readily identified as well as the estimation of the degree of weathering (or loss) as compared to traditional methodologies employing nominal-mass mass spectrometry.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing forensic scientists with a more precise method of identifying specific ignitable liquids.

The current method used to identify ignitable liquids consists primarily of pattern matching either the gas chromatogram or extracted-mass chromatograms of the unknown sample to the gas chromatogram or extracted-mass chromatograms of a reference sample. This is performed by computer software in conjunction with the analyst and is subject to possible bias, which may impact the results. The samples are also likely to undergo significant degradation and experience interferences due to evaporation, microorganism activity, matrix effects, or from the actual combustion. The potential degradation and interferences can remove or add compounds, which may further impact the identification ability. These missing or additional compounds can negatively impact the ability to properly match the obtained pattern to that of the reference sample.

Additionally, when comparing the mass spectra between the unknown and reference samples using common analytical approaches, only nominal mass (integer mass) is observed. Fractional mass differences can be utilized to correctly distinguish between the fragments in a sample, which in turn can be used to better identify the compounds in the questioned ignitable liquid. These identified compounds can then be used to classify the ignitable liquids by American Society for Testing and Materials (ASTM) standard practices. Having a method that can identify specific compounds gives more validity to identifying ignitable liquid samples than the standard pattern-matching practices. A quantitative element is gained, and the possibility of bias and misidentification by the analyst is reduced. The goal of this project is to demonstrate that high-resolution mass spectrometry can be used to better identify ignitable liquids based upon fragments fractional-mass values.

Known ignitable liquid samples were analyzed using a LECO® Pegasus® GC-HRT+ 4D High Resolution Time-Of-Flight/Mass Spectrometry (TOF/MS). Reference samples were used to construct an accurate-mass library. The data collected underwent statistical analysis in order to group together relevant fragments that could be useful in identification. Then, the statistical data along with the library were used to identify unknown ignitable liquid samples. These unknown samples included both neat and weathered samples. Preliminary results showed that this technique would prove useful in the identification of ignitable liquids.

### **B178 A Foundational Study of Fire Debris Interpretation Using Quantitative Measures of Chromatographic Features**

*Brenda B. Christy, MS\*, Virginia Department of Forensic Science, Norfolk, VA 23510; Reta Newman, MA, Pinellas County Forensic Lab, Largo, FL 33778; Kelsey R. Winters, MSFS, Virginia Department of Forensic Science, Norfolk, VA 23510; Alexandria Rossheim, MS, Virginia Department of Forensic Science, Norfolk, VA 23510*

**Learning Overview:** The goal of this presentation is to introduce a validated method that quantifies the data supportive of a gasoline identification using a sufficiency chart and to introduce documentation software that allows for a more transparent inferential process and is capable of verification.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a quantitative sufficiency chart and a computerized pattern-comparison documentation program that also facilitates verification that will make the fire debris experts' inferential process standardized, objective, and visible.

This presentation will discuss an interpretation method for fire debris Gas Chromatography/Mass Spectrometry (GC/MS) data using quantitative measures based on key chromatographic features, which were used to establish the sufficiency of the data for a conclusion. The analysis of the key chromatographic features is highlighted, as well as the process by which a graphical display of the sufficiency of the data was created. This novel approach to data interpretation is the first step toward a validated analysis method for ignitable liquids, starting with gasoline, in the presence of complex matrices. Ultimately, this research aims to make the fire debris analysis process more standard, objective, and transparent by establishing a validated method with quantitative measures that includes the implementation of intuitive documentation software and verification, all of which is based on robust data evaluation.

Ignitable liquid identification is based on pattern recognition techniques using chromatographic data. While the analytical processes associated with the analysis of fire debris for the presence of ignitable liquids are based on fundamental chemical properties, the interpretation process is entirely subjective. The degree of subjectivity is directly related to the abundance and type of interferences from volatile compounds produced by the matrix (including inherent, pyrolysis, and combustion products), as well as the concentration of any ignitable liquid residues present in the sample. Currently, there are no published, validated methods for the interpretation of these complex samples, which can, and does, lead to a lack of consistency in interpretation and reporting within the field. Therefore, this study was designed to establish a novel quantitative measure of assessing the chromatographic features of gasoline generated during analysis by applying statistical measures to create sufficiency parameters for use in interpreting data and rendering conclusions.

A methodology for establishing and measuring variables associated with quantity, quality, and confidence is being optimized and applied to neat gasoline samples, gasoline samples evaporated at 25%, 50%, 75%, and 90% levels, negative matrix samples, and real-world samples composed of mixtures of matrix and gasoline. Key chromatographic features in 150 gasoline samples were evaluated and 64 chromatographic peak height ratios determined for comparison. Statistical analysis was conducted to determine the variation observed for each of these ratios in the known gasoline samples and to determine the presence of these key chromatographic features in the negative matrix samples. This information was evaluated to determine the relative scores for each of these features. The scores were used to create a sufficiency chart, which is a graphical display detailing the totality of data supporting a potential gasoline identification. The sufficiency chart will also identify the "gray area" where analysts are more likely to form differing opinions. A discussion of this "gray area," its implications, and the proposed solutions under development will be presented.

The final results of this study will be a foundational validation with essential quality assurance measures for the purpose of identifying gasoline in fire debris samples. The investigators plan to use methodologies similar to Analysis/Comparison/Evaluation/Verification (ACE-V) for documenting the examination process, thereby ensuring greater transparency in fire debris examination and comparisons. However, this documentation process that will be introduced is currently under development. The end-goal of the proposed project is to generate a quantitative sufficiency chart for reliable data interpretation with the adaptation and utilization of a computerized pattern-comparison documentation program that also facilitates verification.

### **B179 Human Scent Biometrics: Paving a Path Toward Improved Data Analysis**

*Vidia A. Gokool, BS\*, Miami, FL 33157; Howard K. Holness, PhD, Miami, FL 33199; Kenneth G. Furton, PhD, Florida International University, Miami, FL 33199*

---

**Learning Overview:** After attending this presentation, attendees will understand the hurdles facing the use of human scent as a biometric and the Gas Chromatography/Mass Spectrometry (GC/MS) data processing approaches being implemented toward the systemization of scent profile comparisons.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by equipping attendees with approaches for extrapolating the influential features of their GC/MS data, assessing the appropriateness of statistical tests, and venturing into exploratory data analysis as presented through the lens of human scent profiling.

Human scent is a complex mixture of Volatile Organic Compounds (VOCs) detected in the headspace above a scent sample. These VOCs are the culmination of oils, sweat, and other skin secretions enduring microbial action at the skin's surface. With genetic and environmental influences each playing a role in its characteristics, human odor is a product of diverse factors that allow it to be viewed as a biometric that can be used to identify a person.

There is a seeming agreement arising in regard to best practices for human scent collection with multiple reported uses of Headspace/Solid Phase Microextraction (HS/SPME) and wide utilization of Gas Chromatography/Mass Spectrometry (GC/MS) to identify the VOCs extracted from human scent samples. Despite convergences in approaches toward the collection and instrumental analysis, there is no commonly accepted practice for interpreting the resulting GC/MS profile data.

Utilizing hand odor profiles retrieved by HS/SPME-GC/MS efforts to develop a robust systematic approach for human scent profile discrimination will be examined. With regard to previously implemented statistical tests, such as Spearman Rank Correlation, Linear Discriminant Analysis (LDA), and Principal Component Analysis (PCA), additional considerations also have to be evaluated for their utility in defining class barriers and making determinations of association between profiles. Inherent to the improvement of existing approaches, an expanded evaluation of chromatographic feature relevancy has been conducted. Namely, elution time, peak height, and peak area were compared in relation to mass spectral compound identifications to assess the influence of each parameter on profile comparison. The resulting methods for performing human hand odor profile discrimination are presented in conjunction with paths for reducing data complexity and conducting an exploratory investigation of the processed data; with topics including multivariate analysis and clustering methods.

Data analysis continues to be a roadblock between the academic endeavor of human scent profiling and the casework application of this technique. Through further developing the presented methods, a path will continue to be paved between this novel method and the crime laboratory where it may be utilized.

#### **SPME-GC/MS, Human Scent, Data Analysis**

### **B180 The Practical Application of a Kinetic Model to Generate Predicted Reference Collection for the Identification of Ignitable Liquids in Fire Debris Samples**

*Briana A Capistran, BA\*, Michigan State University, East Lansing, MI 48824; Victoria L. McGuffin, PhD, Michigan State University, East Lansing, MI 48824-1322; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI 48824*

**Learning Overview:** The goal of this presentation is to demonstrate the practical application of a kinetic model to generate a reference collection of predicted chromatograms used to identify ignitable liquids in fire debris samples.

**Impact on the Forensic Science Community:** After attending this presentation, attendees will understand how the kinetic model can be applied to the chromatogram of an unevaporated liquid to predict chromatograms corresponding to a range of evaporation levels. These predicted chromatograms form the basis of an extensive reference collection which, in this work, is used to identify ignitable liquids in samples collected from large-scale burns.

Fire debris samples are analyzed by Gas Chromatography/Mass Spectrometry (GC/MS) to determine the presence of ignitable liquids based on comparisons to a suitable reference collection. Identifications can be challenging due to evaporation of the ignitable liquid and the presence of interferences arising from substrates in the fire debris samples. These challenges can be overcome by including evaporated liquids in the reference collection and by using extracted ion profiles to minimize or eliminate substrate effects. However, experimental evaporations can be time consuming, with the result that not all liquids in the reference collection will be evaporated to different levels.

A first-order kinetic model was previously developed in the Michigan State University laboratory to predict evaporation rate constants for compounds in ignitable liquids as a function of retention index, which is related to boiling point. The evaporation rate constants are used to calculate the fraction remaining of each compound in a liquid, from which chromatograms corresponding to evaporated liquids can be predicted. Previous work in this laboratory demonstrated the predictive accuracy of the model for petroleum distillates, whereas recent work highlighted improvements in accuracy for gasoline. In this work, practical application of the model is demonstrated.

The kinetic model was applied to generate a reference collection of ignitable liquids from five different chemical classes defined in American Society for Testing and Materials (ASTM) 1618 (isoparaffinic, aromatic, naphthenic-paraffinic, petroleum distillate, and gasoline). Unevaporated liquids from each class were analyzed by GC/MS to generate Total Ion Chromatograms (TICs) and Extracted Ion Profiles (EIPs) of the major compound classes. The kinetic model was applied to the TICs to predict chromatograms corresponding to total fraction remaining ( $F_{Total}$ ) levels of 0.9–0.1 (evaporation levels of 10%–90%) for each liquid. Predicted reference collections corresponding to the EIP for major compound classes were generated in a similar manner.

The liquids were also experimentally evaporated to different  $F_{Total}$  levels and analyzed by GC/MS. The TICs and EIPs of the experimentally evaporated liquids were then compared to the corresponding predicted reference collection, using Pearson Product-Moment Correlation (PPMC) coefficients as a measure of similarity. For example, for the TIC of paint thinner experimentally evaporated to  $F_{Total}=0.50$ , strongest correlation was observed for comparisons to predicted TICs of paint thinner, with a maximum PPMC of 0.942. Conversely, the PPMC coefficients for comparisons of the experimentally evaporated paint thinner to other liquids in the predicted reference collection were generally less than 0.500, indicating weak correlation.

To demonstrate practical application of the model, three burn cells (8ft x 16ft) furnished with carpeting and other household items were prepared. Gasoline was poured in two of the cells and paint thinner in the third cell. Each cell was ignited and allowed to burn for 8min or just past flashover. The fires were extinguished, and samples were collected and analyzed by GC/MS. The resulting TICs and EIPs were compared to the predicted reference collections.

For burn samples containing paint thinner, the maximum PPMC coefficient for comparison to the TIC reference collection was 0.862, which corresponded to the predicted TIC of paint thinner with  $F_{Total}=0.80$ . Higher correlation was observed when the EIPs were considered. For example, the maximum PPMC coefficient of 0.935 was observed for comparison to the cycloalkanes/alkenes EIP with  $F_{Total}=0.90$ . Only weak correlation was observed for comparisons to all other liquids in the TIC and EIP reference collections, with PPMC coefficients less than 0.500.

This presentation will describe the development of the predicted reference collection in more detail and application to data collected from large-scale burns. Overall, this work will demonstrate the utility of the kinetic model combined with EIPs to more accurately predict the presence of ignitable liquids in fire debris samples.

#### **Fire Debris, GC/MS, Extracted Ion Profile**

### **B181 Expert System for Characterization Using AMDIS Plus Excel® (Escape): Connecting Cultural Heritage Research to Trace Evidence Analysis by Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS)**

*Michael R. Schilling, MS\*, The Getty Conservation Institute, Los Angeles, CA 90049-1684; Kristina Fritz, BS\*, Los Angeles County Sheriff's Department, Los Angeles, CA 90032-4210; Steven D. Phillips, BS, Los Angeles County Sheriff's Department, Los Angeles, CA 90032*

**Learning Overview:** After attending this presentation, attendees will be aware of the technology and expert database used by cultural heritage scientists.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing details about the automated system for evaluating complex Py-GC/MS data, resulting in a more detailed classification of paint-binding media.

Cultural heritage research shares several things in common with the field of trace evidence analysis. Both are interested in learning as much as possible about the major, minor, and trace components present in tiny samples originating from a diverse range of materials. Sample characterization typically involves Fourier-transform infrared spectrometry, Raman spectroscopy, scanning electron microscopy with energy-dispersive X-ray spectrometry, and polarized light microscopy. For in-depth compositional information about paints, coatings, adhesives, plastics, and a range of other organic materials used by artists—and to learn how the materials have changed over time—cultural heritage scientists routinely turn to Py-GC/MS. Microfurnace pyrolyzers possess many advantages over other pyrolyzer types, including an ambient temperature sample introduction area purged with helium, a deactivated quartz furnace tube, a reproducible pyrolysis event ensured by sample cups dropping into a pre-heated zone, and mounting the furnace directly onto the GC inlet to minimize problems of cold spots.

New practitioners of Py-GC/MS face a number of daunting challenges: locating relevant information scattered throughout disparate literature, selecting an optimum analytical method, recognizing material types that require derivatization, processing hundreds of GC peaks, accurate compound identification when mass spectral libraries are incomplete, recognizing characteristic patterns of marker compounds that relate to specific materials, proper characterizing material mixtures, and the need for data presentation that is meaningful to non-scientists. As interpretation of Py-GC/MS data requires considerable expertise, many potential users in both disciplines avoid learning the technique.

The Expert System for Characterization using Automated Mass spectral Deconvolution and Identification System (AMDIS) Plus Excel® (ESCAPE) was developed at the Getty Conservation Institute (GCI) as a two-step Py-GC/MS data processing tool to identify compositions of decorative lacquers, coatings, and paints. AMDIS (from the National Institute of Standards and Technology [NIST]) is used with a specialized 1,500 compound library to identify marker compounds in sample data. Specialized Excel® reports sort the AMDIS marker compound report by material type and provide users with expert knowledge needed for confirming the presence of materials in the sample. Expert knowledge in ESCAPE originates from interviews of Py-GC/MS experts in material characterization and from publications. Excel® reports present the analytical results in various ways—marker compound tables, diagnostic bar graphs, pie charts of composition, and correlation coefficient tables of marker compounds—to best convey the results to both practitioners and non-scientists. Shared databases of the final analytical results provide benefit to the entire cultural heritage community.

In order to evaluate the accuracy of ESCAPE and its applicability to forensic paint samples, Collaborative Testing Services (CTS) samples were tested at the GCI in a collaboration with trace evidence examiners from the Los Angeles County Sheriff's Department. The results were fully consistent with the known compositions, and compositional differences between Q and K specimens were clearly illustrated by bar graphs of key markers in the binding media. Additional studies of the diverse types of paints used in the creation of art—tube colors, house paints, industrial paints, and spray paints—illustrated best practices for clear presentation of compositional data for acrylic, vinyl, alkyd, epoxy, and urethane binding media.

ESCAPE could be considered as a common platform for sharing paint composition data between the forensic and cultural heritage research communities. It can be customized to meet the unique needs of the forensic community, especially in regard to developing meaningful formats for presenting analytical results in court. Interested researchers learn ESCAPE in workshops conducted by the GCI, so that researchers with Py-GC/MS instrumentation can immediately start applying ESCAPE in their work. For laboratories without a Py-GC/MS, ESCAPE provides justification for equipment purchase as the expert knowledge in the system overcomes the steep learning curve for new users. Collaboration with experts in toxicology, arson, tapes, and fibers can extend the utility of ESCAPE beyond paints and coatings. One desired outcome is the development of a shared paint composition database that would benefit the cultural heritage and forensic communities on both a national and an international level.

---

#### **Py-GC/MS, Paint Analysis, Shared Database**

### **B182 A Comparison of Direct Analysis in Real-Time High Resolution Mass Spectrometry (DART®-HRMS) and Pyrolysis-Gas Chromatography/Mass Spectrometry (Py-GC/MS) in Automotive Paint Analysis**

*Kaitlin Jones, BS\*, National Center for Forensic Science, University of Central Florida, Orlando, FL 32826; Mark Maric, PhD, Orlando, FL 32816; Candice Bridge, PhD, National Center for Forensic Science, University of Central Florida, Orlando, FL 32816*

**Learning Overview:** After attending this presentation, attendees will understand the benefits of using DART®-HRMS in comparison to Py-GC/MS when analyzing automotive paint evidence.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by introducing a rapid ionization technique for the analysis of automotive paint evidence. Furthermore, a comparison of the discriminatory capabilities of both techniques will be demonstrated.

Currently, there are three common analytical techniques used for the analysis of automotive paint: microscopy, infrared spectroscopy, and Py-GC/MS. Py-GC/MS is the gold standard when it comes to automotive paint analysis due to its ability to differentiate between paint samples that are indistinguishable by infrared spectroscopy. The reason for the high discriminatory capability of Py-GC/MS is the technique's sensitivity to binders, additives, and cross-linking agents. However, a disadvantage of Py-GC/MS is that the technique is time consuming and destructive to actual case samples.

A preliminary study determined that DART®-HRMS could discriminate black car paint samples and provided comparable results to Py-GC/MS.<sup>1</sup> Therefore, a larger study was conducted to determine if DART®-HRMS provides better or comparable discriminatory results to Py-GC/MS while also having the advantage of analyzing samples in a fraction of the time. DART®-HRMS is a rapid screening technique that uses soft ionization. The technique requires little sample preparation and rapidly analyzes samples in four minutes under ambient conditions. Moreover, DART®-HRMS has the capability to measure the mass of large and high-weight molecules, such as polymers commonly found in automotive paints. Both techniques were compared to assess how the data obtained from DART®-HRMS related to that of Py-GC/MS.

A cross-section of the paint was cut with a scalpel from 100 samples that were obtained from automotive body shops around the Orlando, FL, area and from a junkyard in Pembroke Pines, FL. A VHX 6000 Keyence digital microscope was utilized to visualize the cross sections and determine layer systems of each sample. The clear coat and base coat of the 100 samples were analyzed using DART®-HRMS in positive ionization mode. Several samples were analyzed, in triplicate, in negative ionization mode on the DART®-HRMS; however, no additional information was obtained. The clear coats of the set of 100 samples were also analyzed in duplicate with Py-GC/MS for comparative purposes. Principal Component Analysis (PCA), Hierarchical Cluster Analysis (HCA), and Linear Discriminant Analysis (LDA), were performed on the data to determine the classification potential of each instrumental technique. HCA was performed to identify unsupervised clusters within the data. Then, PCA was utilized to reduce the dimensionality of the data set to make it easier to visualize the patterns in each dataset. Last, LDA was performed to determine the accuracy of the models. The multivariate statistics performed on the data demonstrated that DART®-HRMS can be as discriminating as Py-GC/MS. DART®-HRMS has the potential to be a great addition to the analytical techniques currently used for the analysis of automotive paint due to the method's rapid analysis time.

*This research was supported by the 2017 Forensic Science Foundation's Lucas Grant.*

### **B183 Barking Up the Wrong Tree: Detection and Identification of Illegally Traded Endangered Species of Wood Using Mass Spectral Techniques**

*Meghan Fogerty, MS\*, Ilion, NY 13357; Rabi A. Musah, PhD, State University of New York at Albany, Albany, NY 12222*

**Learning Overview:** The goals of this presentation are to introduce attendees to: (1) field-optimal sample collection for detecting and identifying illegally traded endangered species of wood; (2) classification of wood species using multivariate statistical analysis processing of mass spectral data; and (3) identification of diagnostic molecules for the identification of illegally traded wood species.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on a technique that enables law enforcement to distinguish and recognize endangered wood species in open spaces, such as shipping containers or at crime scenes.

Illegal logging and related trade occur when timber is harvested, transported, processed, bought, or sold in violation of national or sub-national laws. Globally, the act of illegal logging nets billions of dollars annually and accounts for 70% of all timber exports for some countries.<sup>1</sup> Organized crime networks in conjunction with corrupt government officials contribute to these sobering statistics. The illegally traded logs are difficult to distinguish visually from legally traded wood, and conventional identification techniques, including DNA profiling, morphological feature characterization, and stable isotope analysis, are time-consuming, costly, and require specialized expertise. These challenges make it more difficult for law enforcement to detect and identify illegally traded woods at points of entry into the United States. Therefore, a technique that is more readily amenable to field sampling is needed that will allow for the rapid detection and identification of illegally traded endangered woods. This study demonstrates that species-level identification can be achieved through the use of species-specific chemical signatures revealed by Direct Analysis in Real Time High Resolution Mass Spectrometry (DART®-HRMS) along with Gas Chromatography/Mass Spectrometry (GC/MS). The results demonstrate proof-of-concept that if a database of species-specific chemical signatures of endangered woods could be created, samples collected in the field can be screened against it to enable rapid species identification.

To develop the approach, multiple different species of wood representing a range of genera were shredded into a fine powder. The headspace volatiles of each were concentrated onto conditioned Solid Phase Microextraction (SPME) fibers for 30 minutes. The fibers were then analyzed using DART®-HRMS by suspending the fiber directly in the DART® gas stream for 30 seconds. The powdered woods were also analyzed directly by placing the closed end of a melting point capillary tube into the material, then suspending the coated surface of the tube in the DART® gas stream. The DART® mass spectra consistently showed inter-species differences and intra-species similarities and, therefore, the data were subjected to multivariate statistical analysis processing in order to perform classification. A set of feature masses were selected as species-specific diagnostic  $m/z$  values for each set of results, and these were used to perform kernel discriminant analysis. The statistical analysis processing showed that classification of wood species could be achieved from the chemical fingerprints produced from the direct analysis of the bulk material as well as the headspace of wood samples. In order to identify the molecules responsible for the ability to discriminate between species, the samples were analyzed using Thermal Desorption-Gas Chromatography/Mass Spectrometry (TD-GC/MS). The results revealed the identities of several  $m/z$  values whose presence was diagnostic of species, including 107.0492, 133.0663, and 137.0619 for the headspace samples and 255.1016, 285.1100, and 375.1097 for the bulk material samples. Tentative identification could be made in some cases and revealed the presence of benzaldehyde, cinnamaldehyde, and 4-methoxybenzaldehyde in the headspace and dalbergichromene, 3,4-dimethoxydalbergione, and caviunin in the bulk material. These results indicate proof-of-concept that the mass spectral analysis of wood samples can be used to create a database available to border patrol agents that can be used for the efficient identification of illegally traded wood species.

### **B184 The Contamination of Homes With Methamphetamine: Are Current Assessment and Remediation Approaches Adequate?**

Stewart Walker, PhD\*, Flinders University, Adelaide, South Australia 5001, AUSTRALIA; Kirstin Ross, PhD, Flinders University, Adelaide 5042, AUSTRALIA; Jackie Wright, PhD, Environmental Risk Sciences Pty Ltd, Sydney, NSW 2118, AUSTRALIA

**Learning Overview:** The goal of this presentation is to inform attendees on the effectiveness of the current assessment of risk from living in homes contaminated with methamphetamine and the effectiveness of different remediation processes over time.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by improving understanding of the effectiveness of different remediation processes for removing, or covering up, methamphetamine contamination in a variety of materials found in domestic homes, including walls, ceilings, soft fabrics, blinds, and toys.

Contamination of domestic dwellings from methamphetamine cooking or smoking is an increasing public health problem in many countries.<sup>1,2</sup> To evaluate the extent of contamination, sampling generally focuses on collection of surface-wipe samples from walls and other surfaces of a potentially contaminated home and analysis by established methods. However, the concentration of methamphetamine on surfaces may not give a true representation of the extent of contamination. The contamination levels of many household materials may depend on the material, the porosity, absorptivity, and the room in which the material was located with respect to the room where the drugs were synthesized or smoked. Results in this presentation come from a long-term study of contamination in a home (Rural Victoria, Australia) that had been used to cook methamphetamine, then sold, lived in for 18 months by the new owners until it was deemed to be unfit for human habitation, then left unattended (since March 2015).<sup>3</sup> Although the time since the cooking had taken place was significant (more than six years), the levels of contamination were still extremely high in items that were part of the house when the cooking of drugs was taking place (blinds, carpets, walls). In addition, levels were also high in articles brought to the house post-cooking (rugs, toys, beds, etc.). Both wipe sampling and analysis of bulk samples indicate that the methamphetamine is not breaking down or being removed and is being transferred from contaminated to non-contaminated objects.

Furthermore, the concentration of methamphetamine inside the boards (plasterboard—a building material made from calcium sulfate dehydrate sandwiched between paper) of the ceiling were found, in places, to be around three times higher than the concentration on the external surface, indicating that the methamphetamine had soaked in.

A study of several remediation processes was also carried out in this property with “fogging,” “ozone,” “washing,” and painting over with oil-based and water-based paints applied to large sections of the wall. Initial results indicated a reduction in the level of methamphetamine detected; however, in all cases, methamphetamine was still detected over time in subsequent analysis. If the level of methamphetamine inside the wall is not reduced by these surface remediation treatments, then it may seep out over time, leading to “recontamination” and exposure to people living in the “treated” house. The same applies to methamphetamine absorbed into materials, rugs, toys, beds, etc.

These results raise questions about the adequacy of characterizing contamination and making decisions about the extent of remediation required, based just on surface-wipe samples. Without fully understanding the extent of contamination that is present, not only on surfaces, but within the building materials, it is difficult to ensure that the correct and most effective remedial approaches are taken to appropriately address the risks to inhabitants.

### **B185 Multivariate Statistics for the Masses: A Novel, User-Friendly Method for Positional Isomer Differentiation Using Mass Spectral Data**

*Jennifer Bonetti, MS\*, Virginia Department of Forensic Science, Norfolk, VA 23510*

**Learning Overview:** After attending this presentation, attendees will be aware of a novel method of positional isomer differentiation using only mass spectral data that is commonly generated during the analytical scheme of controlled substances. Additionally, attendees will be introduced to an easy-to-use user interface that has been developed with the typical forensic scientist in mind.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by showing an alternative method of positional isomer differentiation using multivariate statistical analysis of mass spectral data rather than other, more time-consuming methods, such as additional chemical or instrumental analysis.

Mass spectral analysis is the confirmatory method of choice for seized drug analysis in forensic laboratories. However, spectra of positional isomers are often too visually similar to allow for differentiation, which leads to identification challenges for forensic laboratories that are inundated with novel psychoactive substances. Scientists now find themselves in a position to make a choice between reporting an ambiguous conclusion that does not identify the specific isomer or resorting to additional chemical or instrumental analysis.

This presentation builds on previously published work that used multivariate statistical analysis of Fluoromethcathinone (FMC) and fluorofentanyl to offer a feasible alternative means of differentiating between electron ionization mass spectra of positional isomers, saving laboratory resources while still resulting in specific compound identification.<sup>1</sup>

Mass spectral data was collected from the four state regional laboratories across the Commonwealth of Virginia. Data from the past two to three years for any primary standards of commonly encountered positional isomers was requested. Isomer groups included pseudoephedrine/ephedrine, novel cathinone isomers, and several fentalogs. All data was collected on instruments that were tuned daily using either an autotune or etune procedure. A starting library of more than 950 spectra was collected from more than ten different Gas Chromatography/Mass Spectrometry (GC/MS) instruments.

The isomer groups were analyzed using the proposed method of spectral comparison which utilizes Principal Component Analysis (PCA) for dimension reduction, followed by Linear Discriminant Analysis (LDA) for isomer classification. For PCA, the original variables were the individual  $m/z$  ratios, and the data for each sample was its normalized abundance at each particular  $m/z$  ratio. The variables that were used to derive the LDA discriminant functions are the scores that resulted from projecting the original  $m/z$  variables onto the first several principal component axes. A user interface was developed that allows the user to dictate the number of principal components to utilize for LDA. Once selected, a Leave-One-Sample-Out Cross Validation (LOOCV) error rate can be calculated that shows how accurately the method can classify an unknown sample based on the available library.

Once the library is shown to be robust by resulting in a LOOCV error rate below a chosen threshold, the user interface allows a chemist to upload an unknown spectrum as a text file for comparison to the chosen group of isomers, and the program will use the above method to classify the compound based on the posterior probability. A blind study was conducted to show the accuracy of this classification method.

The results indicate multivariate statistical analysis, especially when combined with an easy-to-use user interface, is a promising addition to the analytical scheme of the identification of positional isomers. This would allow for higher confidence in the final identification of a compound without the need for additional chemical or instrumental analysis, saving laboratories both time and money.

### B186 On-Scene Detection of Low-Dose Fentanyl Tablets

*Pauline E. Leary, PhD\*, Federal Resources, Stanfordville, NY 12581; Sarah M. Davis, BS, University of New Haven, West Haven, CT 06516; M. Isabel Sanchez-Melo, MS, West Haven, CT 06516; Leah Rynearson, BS, University of New Haven, West Haven, CT 06516; Lauren Vallee, BS, Bristol, CT 06010; Emily Langlois, Quinebaug, CT 06262; Zachary Lawton, MS, PerkinElmer, Inc, Shelton, CT 06484-4794; Koby Kizzire, PhD, University of New Haven, West Haven, CT 06516; Brooke W. Kamrath, PhD, University of New Haven, West Haven, CT 06516*

**Learning Overview:** After attending this presentation, attendees will understand the capabilities and limitations of field detection and identification of fentanyl in low-dose tablets using commercially available portable instruments.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science and law enforcement community by establishing the best methods for field detection and identification of fentanyl in low-dosage forms.

Concerns about the illegal trafficking of fentanyl into the United States have largely been centered on its addition, in relatively pure powder form, to heroin and other illicit street drugs. These street drugs are dangerous to the end user, emergency responders, and the public at large. Due to the high potency of fentanyl (100 times that of morphine), a new trend is emerging in the illicit drug trade with the manufacture, smuggling, and distribution of relatively low concentrations of fentanyl dosage forms, including low-dose fentanyl tablets. The United States Drug Enforcement Administration (DEA) started a Fentanyl Signature Profiling Program (FSPP), analyzing samples from fentanyl seizures to help identify the international and domestic trafficking networks responsible for many of the drugs fueling the opioid crisis. In 2017, the FSPP analyzed 520 fentanyl powder samples from seizures totaling 960kg of fentanyl. While the average purity was 5%, the DEA has indicated that fentanyl shipped directly from China often has purity levels above 90%, while fentanyl trafficked over the Southwest border from Mexico often has purity levels below 10%. For low-dose fentanyl tablets, the concentration has been estimated to be closer to 1%. These low-dose fentanyl tablets can pose a significant analytical challenge for the on-scene detection and identification of the fentanyl by law enforcement due to interference by other components of the tablet with the fentanyl chemical signature. In some instances, particularly with Infrared (IR) and Raman analytical methods, the spectral features of fentanyl become hidden behind the spectral features of the tablet's other components. This effectively masks the fentanyl signature and prevents the identification of the fentanyl when spectra are compared against library databases. In other cases, as with ion mobility spectrometry and high-pressure mass spectrometry, the fentanyl signature may be suppressed by the presence of the other components of the tablet. Additionally, there have been instances where the low concentration of fentanyl-doped tablets has been assumed to be lower than portable instruments routinely deployed to field users are capable of detecting. To date, there has not been research that compared the detection capabilities for fentanyl when this substance is dispersed in typical pharmaceutical matrices across portable-instrument platforms.

This research analyzed fentanyl-doped acetaminophen samples using various commercially available portable instruments including IR spectrometers, Raman spectrometers, Surface-Enhanced Raman Spectrometers (SERS), mass spectrometers, gas chromatography/mass spectrometers, ion mobility spectrometers, and field-based color tests. Each technique's utility for the detection and identification of fentanyl was compared, with a focus on determining limits of detection when the fentanyl is dispersed at low concentrations within complex matrices. It was concluded that neither field-based color tests nor portable vibrational spectrometers have the limit of detection capabilities to positively identify fentanyl in these low-dose tablets. Analysis using SERS lowered detection limits. Additionally, ion mobility and mass spectrometers (with and without gas chromatography) were able to detect and identify fentanyl at concentrations less than those routinely found in the low-dose tablets (1%); however, each of these portable instrumental technologies have their own challenges that must be considered when completing this analysis.

**WITHDRAWN**

## B188 On the Fragmentation Behavior of Fentanyl and Its Analogs in Electrospray Ionization-Tandem Mass Spectrometry (ESI-MS/MS)

J. Tyler Davidson, MS\*, West Virginia University, Morgantown, WV 26505; Zachary J. Sasiene, BS, West Virginia University, Morgantown, WV 26506; Younis F. Abiedalla, PhD, Auburn University, Auburn, AL 36830; Randall Clark, PhD, Auburn University, Auburn, AL 36849; Jack DeRuiter, PhD, Auburn University School of Pharmacy, Auburn, AL 36849; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will better understand the structures and mechanisms of formation of at least three distinct isomeric/isobaric fentanyl product ions observed at nominal mass  $m/z$  188 in ESI-MS/MS. Attendees will learn about the concepts of multistage Mass Spectrometry ( $MS^n$ ), accurate mass measurements with High Resolution Mass Spectrometry (HRMS), and isotopic labeling for structural elucidation of fentanyl and Fentanyl-Related Compounds (FRCs).

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a better understanding of the fragmentation pathways of fentanyl and FRCs. Specifically, the identification of a novel isobaric fentanyl product ion at  $m/z$  188 with ESI-MS/MS will enlighten this community about potential issues with the use of the  $m/z$  188 fentanyl product ion for quantification with Multiple Reaction Monitoring (MRM).

**Hypothesis:** The central hypothesis is that the combination of  $MS^n$ , isotope labeling, and accurate mass measurements with HRMS will result in a deeper understanding of the fragmentation behavior of fentanyl and its analogs. Another hypothesis postulates that isomers having identical masses and different constitutional arrangements of atoms will provide measurable differences in their fragmentation patterns. A final hypothesis is that isotopic labeling (e.g., D for H and  $^{13}C$  for  $^{12}C$ ) does not alter the fragmentation behavior of an ion in a meaningful way, other than by changing the  $m/z$  value(s) of the product ions that contain the isotope(s).

**Methods/Results:** Analyses involve the characterization of fragmentation pathways of fentanyl and FRCs using  $MS^n$ , accurate mass measurements with HRMS, and isotopic labeling. Specifically, the identification of isobaric fentanyl product ions of the base peak at  $m/z$  188 with ESI-MS/MS was accomplished through the analysis of fentanyl, fentanyl-d5, and two  $^{15}N$ -fentanyl analogs. All compounds were analyzed using a Thermo Scientific™ LTQ™ Velos Pro™ with Heated Electrospray Ionization (HESI) ionization source and an Agilent® Technologies 6538 UHD Accurate-Mass quadrupole Time-Of-Flight (qTOF) with a dual Electrospray Ionization (ESI) source.

Wichitnithad et al.<sup>1</sup> have shown that when the protonated precursor ion of fentanyl at  $m/z$  337 is exposed to collisional activation, two distinct constitutional isomers of the product ion at  $m/z$  188 are formed. The two constitutional isomers are formed via the intermediate at  $m/z$  281. However,  $MS^n$  experiments in this work demonstrate another isobar at nominal mass  $m/z$  188 that has a distinct elemental composition from the other structures based on accurate mass measurements. This third ion forms via the intermediate fragment at  $m/z$  216 and is of interest because the abundance of  $m/z$  188 is commonly used for quantification with Multiple Reaction Monitoring (MRM)<sup>1</sup>, and one should be confident in the ions' identity and relative abundance.

$MS^n$  data on the linear ion trap mass spectrometer reveals that there are three pathways of formation for the nominal mass of  $m/z$  188, but that the isolation and  $MS^n$  fragmentation of  $m/z$  188 from different precursors provides distinct fragment ions. For example, the pathway  $m/z$  337→281→188→ provides a range of product ions consistent with the two distinct isomers at  $m/z$  188 that were first described by Wichitnithad et al.<sup>1</sup>. However, the current work shows that the pathway  $m/z$  337→216→188→ results in an exclusive fragment at  $m/z$  132 and that fragmentation through the pathway  $m/z$  337→244→188→ results in fragments at  $m/z$  134 and  $m/z$  120.

The proposed mechanism for the formation of the novel isobaric product ion involves the opening of the piperidine ring from the  $[M+H]^+$  fentanyl precursor followed by a 4-center-elimination of the saturated alkyl chain. The combination of  $MS^n$ , accurate mass measurements with HRMS, isotopic labeling, and differences in the  $MS^3$  product ion spectra allow for the identification of this novel fentanyl product ion and an enhanced understanding of the fragmentation behavior of fentanyl and FRCs.

### **B189 The Detection and Identification of Synthetic Cannabinoids by Portable Nanoflow Liquid Chromatography-Ultraviolet (LC-UV) Detection**

*David C. Pavone, BS\*, Washington, DC 20008-3413; Marisa C. May, BS, Alexandria, VA 22304; Ira S. Lurie, PhD, George Washington University, Washington, DC 20007*

**Learning Overview:** After attending this presentation, attendees will understand how synthetic cannabinoids can be screened for and/or positively identified using portable nanoflow LC-UV detection instrumentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by presenting the first truly portable method of nanoflow LC with UV detection as a method for reliable detection and identification of synthetic cannabinoids. This methodology is not only applicable for field testing of these emerging drugs but presents a relatively low-cost alternative (Category A tests not available) to meeting the Scientific Working Group for Seized Drugs (SWGDRUG) requirements for drug identification.

Within the United States, drug abuse has been at an all-time high and has no indication of slowing down. In fact, cases involving drug overdose deaths have more than tripled since 1990. Many different factors have contributed to this rise in drug abuse, one of these being a sharp and steady increase of “emerging” drugs. These emerging drugs are defined as the variances of controlled substance analogs that are synthesized to circumvent existing drug laws. For this study, the type of emerging drug being investigated is synthetic cannabinoids. Synthetic cannabinoids are defined by being able to affect the same receptors in the brain as  $\Delta$ -9 Tetrahydrocannabinol ( $\Delta$ 9-THC). Commonly known as “Spice” or “K2,” synthetic cannabinoids are used as an alternative to marijuana because of their similar psychoactive effects. General drug screening techniques struggle to identify synthetic cannabinoids, compounded by the multitude of analogs that are continuing to be made every day.

As a complementary separation technique to Gas Chromatography (GC), various forms of LC have emerged for drug analysis. These forms of LC not only can be applicable to most if not all drugs, without the need for liquid-liquid extraction and/or derivatization, but also they can increase the reliability of retention time measurements to assist in compound identification. Ultraviolet (UV) detection, a complementary technique to electron ionization mass spectrometric detection for GC, is commonly employed for LC.

For field test purposes, the most common methods for synthetic cannabinoids include color and spectroscopic techniques. Color tests are highly susceptible to false positives. Other techniques, such as portable Raman and Fourier Transform Infrared (FTIR) spectroscopy, have proven to be effective in screening for drugs at remote sites, but struggle when trying to perform the analysis of mixtures. Not only is a portable nanoflow LC able to be used at remote sites, but it has also proven to be a reliable method for screening and/or identification of drugs in a mixture.

This presentation describes the use of a portable nanoflow LC instrument, which provides for specificity in detection of synthetic cannabinoids, applicable to mixtures. Drug detection is accomplished by employing tandem capillary columns in series with dual UV wavelength on-column detection, resulting in very low solvent usage, all in an instrument that weighs only about 16 pounds. The instrument generates dual uncorrelated retention times and peak area or peak height ratios, which are proportional to a compound’s extinction coefficient at both wavelengths. Two capillary columns in series (e.g., C8 and biphenyl) and dual UV LED detectors (e.g., 255nm and 275nm) are employed. Specificity in analysis arises from the unique ratios of dual relative retention times and peak area or peak height ratios from dual UV wavelength detection. The applicability for the screening and/or identification of these emerging drugs in various plant material matrices is presented. In regard to drug identification, the proposed instrumentation has the capability of adhering to the SWGDRUG guidelines by providing laboratories for which a Category A test is not available with two Category B tests (dual complementary retention times) and at least one Category C test (dual UV wavelength detection).

#### **Portable Nanoflow LC, Emerging Drugs, Synthetic Cannabinoids**

### **B190 2020 Update From the Scientific Working Group for the Analysis of Seized Drugs (SWGDRUG)**

*Sandra E. Rodriguez-Cruz, PhD\*, Drug Enforcement Administration, Dulles, VA 20166*

**Learning Overview:** The goal of this presentation is to provide attendees with a summary of the most recent activities and work products developed by SWGDRUG.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing and discussing information and resources for the analysis of seized drugs.

SWGDRUG was formed in 1997 in a joint effort between the United States Drug Enforcement Administration (DEA) Office of Forensic Sciences and the Office of National Drug Control Policy (ONDCP). SWGDRUG works to improve the quality of the forensic examination of seized drugs and to respond to the needs of the forensic community by supporting the development of internationally accepted minimum standards, identifying best practices within the international community, and providing resources to help laboratories meet these standards. This presentation will provide attendees with information on SWGDRUG activities during the past year.

During the summer of 2019, core committee members approved the most recent version of the SWGDRUG Recommendations, version 8.0, which includes revisions to PART IIIB, Methods of Analysis/Drug Identification. A reliable and scientifically supported identification of a drug or chemical depends on the use of an appropriate analytical scheme by competent analysts in a quality-controlled process. The purpose of PART III B is to recommend minimum requirements for the forensic identification of such materials. PART III B addresses the overall selection of techniques, the rationale behind their categorization, and emphasizes the need to develop robust analytical schemes dependent on the scenario at hand or jurisdictional application.

A new supplemental document, SD-7 (Construction of an Analytical Scheme), was also approved during 2019. The objective of this supplemental document is to provide guidance to practitioners on the design and implementation of appropriate analytical schemes, as required by SWGDRUG Recommendations PART IIIB. It includes more than a dozen examples of analytical schemes applicable to many jurisdictions. During this presentation, some of these examples, their rationale, limitations, and applicability will be discussed.

SWGDRUG committee members are also working on revisions to PART IVA (Quality Assurance/General Practices) and PART IVB (Quality Assurance/Validation of Analytical Methods) of the Recommendations. Revisions include additional background information and clarifications on the performance characteristics to be evaluated during the validation of both qualitative and quantitative methods. Furthermore, the currently existing Supplemental Document SD-2 (Validation of Analytical Methods) is also being revised and expanded to better assist seized-drug practitioners during method validation activities. Additions include examples of how to perform and document validations for a color test, a Gas Chromatography/Mass Spectrometry (GC/MS) method, and an Infrared (IR) spectroscopy method.

This presentation will also summarize recent updates on multiple SWGDRUG resources, such as the MS library, IR library, and Drug Monographs.

The SWGDRUG core committee includes representatives from regional, national, and international forensic organizations; educators, practitioner and scientists from the United States; and representatives from the European Network of Forensic Science Institutes (ENFSI), the Academia Iberoamericana de Criminalística y Estudios Forenses (AICEF), the Asian Forensic Science Network (AFSN), and the United Nations Office on Drugs and Crime (UNODC).

---

### **Criminalistics, Drug Analysis, SWGDRUG**

### **B191 Qualitative and Quantitative Characterization of Complex Samples Containing Fentanyl From Supervised Consumption Sites Using Quantitative Nuclear Magnetic Resonance (qNMR) and a Multi-Component Multiple Resonance Post-Processing Quantitative Algorithm**

*Richard R. Laing, MS\*, Health Canada, Burnaby, BC V5G 4P2, CANADA*

**Learning Overview:** After attending this presentation, attendees will be familiar with the capabilities of the NMRQUANT algorithm and quantitative and qualitative trends derived from more than 600 samples collected at supervised consumption sites in British Columbia, Canada, as part of a “Drug Checking” project.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on a new and innovative method for multi-component analysis allowing for complete characterization of street drugs using qNMR and a post-processing algorithm. Every component of a street drug mixture can be simultaneously quantitated, providing they possess a proton (1H) and are soluble in the analysis solvent (Deuterium Oxide [D<sub>2</sub>O]). Complex Controlled Substance (CS) mixtures are routinely characterized using this technique to provide trends of diverse mixtures, including diluents and adulterants. These trends will be presented along with the typical opioids and other CS mixtures found in supervised consumption sites in British Columbia, Canada.

According to the United States Centers for Disease Control and Prevention, 70,237 drug Overdose (OD) deaths occurred in the United States in 2017 of which 47,600, or 67.8%, involved a synthetic opioid.<sup>1</sup> The highest rate of OD deaths in 2016 was observed in West Virginia at >50 deaths per 100,000 population. Unfortunately, this trend is not unique to the United States. In Canada, on April 14, 2016, the province of British Columbia proclaimed a “Public Health Emergency” to alert policy makers, the public, and the media as to the impact synthetic opioids were having on local communities. In 2016, a total of 668 OD deaths, in which fentanyl was detected, rose to 1,229 in 2017 and to 1,334 in 2018 for all of British Columbia.<sup>2</sup> In the city of Vancouver, these annual figures rose from 152 to 306 to 337, respectively, in the same period.<sup>3</sup> To put this into perspective, for Vancouver in 2018, the OD death rate in which fentanyl was detected was 53 per 100,000, a number similar to West Virginia; however, this was in a small area of only 115km<sup>2</sup>.

In response to this crisis, all levels of government have contributed to numerous initiatives. One initiative, based on harm-reduction principals, is the extension of access to drug checking at supervised consumption sites where users can have their drugs tested for fentanyl using Fourier Transform Infrared (FTIR) and an immunoassay test strip prior to use. The premise of drug checking is that with the provision of knowledge of the drug composition, the user can make an informed decision about its usage. Because of Canada’s Federal Action on Opioids, Health Canada’s Drug Analysis Service (DAS), a network of forensic drug analysis laboratories, took on new activities in support of harm-reduction initiatives for health authorities and Non-Governmental Organizations (NGO). In 2018, DAS, through its Vancouver lab, piloted a project where “drug checked” samples could be submitted and undergo more rigorous testing. Using a 400MHz Bruker® Ascend™ Nuclear Magnetic Resonance (NMR) equipped with a CryoProbe™ Prodigy, the NMRQUANT algorithm can identify and quantitate more than 30 controlled substances and common adulterants or diluents in a 10mg sample to the 1% level. The algorithm, based on the programming language Julia, uses a chemical shift and integral library calculations against the response of an internal standard so that individual components of a mixture can be identified and quantified during the same experiment without the requirement for chromatographic separation. As of August 2019, approximately 600 samples have been submitted for analysis where the principal components have been quantitated, size permitting. Approximately 70% of all samples contained fentanyl at varying concentrations. Fentanyl was found as the primary, secondary, or tertiary controlled substance, and common mixtures of heroin and fentanyl or fentanyl and methamphetamine have been characterized as well. Nearly 80% of all samples contain caffeine, with mannitol being the preferred cutting agent. An overview of the qNMR experiment, NMRQUANT method, and trend results will be presented and discussed.

### B192 Examination of Fentanyl and Fentanyl Analog Samples in Canada: Trends and Strategies for Analysis

*Michelle Boileau, PhD\*, Drug Analysis Service, Health Canada, Toronto, ON M1P 4R7, CANADA*

**Learning Overview:** After attending this presentation, attendees will understand the trends in fentanyl and fentanyl analog samples submitted for analysis to the Drug Analysis Service Laboratories over the past several years. Additionally, attendees will be introduced to liquid chromatography-based methods for the identification and quantitation of fentanyl and fentanyl analogs.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing information on the recent trends of fentanyl and fentanyl analog samples submitted for analysis in Canada. Additionally, this presentation will impact the forensic science community by providing an introduction to Liquid Chromatography coupled with Triple Quadrupole Mass Spectrometry (LC/TQMS) and Liquid Chromatography coupled with quadrupole Time Of Flight Mass Spectrometry (LC-qTOF/MS) for the identification and quantitation of fentanyl and fentanyl analog samples.

Fentanyl and fentanyl analogs have become a major concern in Canada. Since 2012, there has been an almost 4,100% increase in the number of fentanyl and fentanyl analog samples being submitted to the Drug Analysis Service Laboratories for analysis. Not only has the number of samples increased, but the composition and type of samples have also changed dramatically over this same time period. The changes in sample type and composition have necessitated a change in the type of analysis performed. The fentanyl and fentanyl analog samples tend to be low-dose/high-potency samples and traditional methods of analysis, such as Gas Chromatography coupled with Flame Ionization Detector (GC/FID) and Gas Chromatography coupled with Mass Spectrometry (GC/MS), may not be sufficient on their own to identify these compounds. As a result, the Drug Analysis Service Laboratories have incorporated the use of LC/TQMS and LC/qTOF for the identification and quantitation of these samples.

The low concentration of the fentanyl and/or fentanyl analogs present in the samples submitted provided challenges to their analysis. The increase in sample preparation concentration needed to obtain a positive result also increased the risk to the analysts themselves during sample handling. The high sensitivity of the LC/TQMS allowed for lower concentration samples to be effectively analyzed, thereby reducing the risk to the analyst during sample preparation. The new LC/MS/MS method allowed for the identification of 27 fentanyl and fentanyl analogs. These compounds are fentanyl, acetylfentanyl, butyrylfentanyl,  $\beta$ -hydroxythiofentanyl, furanylfentanyl, carfentanil, 4-ANPP, meta-fluorofentanyl, para-fluoroisobutyrylfentanyl, para-fluorobutyrylfentanyl, alpha-methylfentanyl, isobutyrylfentanyl, cis-3-methylfentanyl, trans-3-methylfentanyl, W-18, cyclopropyl fentanyl, crotonyl fentanyl, methoxyacetylfentanyl, acrylfentanyl, para-chlorofentanyl, para-chloroisobutyrylfentanyl, 4-methoxybutyrylfentanyl, ocfentanil, valerylfentanyl, alpha-methylbutyrylfentanyl, W-15, and U-47700.

As a result of the high volume of quantitation requests, discussed below, a method was developed using LC/qTOF to assist the LC/TQMS with the identification of these types of samples. The method developed on the LC/qTOF is able to identify approximately 36 different fentanyl and fentanyl analogs. With the exception of 4-ANPP, this method is able to identify all the fentanyl compounds identified by the LC/TQMS identification method plus 4-APP, benzoylfentanyl, benzylacrylfentanyl, benzylcarfentanil, benzylfentanyl, ortho-methylfuranylfentanyl, para-chlorofuranylfentanyl, U-48800, U-49900, and U-5174.

Due to the increase in overdose deaths, more and more law enforcement agencies inquired as to whether it would be possible to determine the concentration or amount of fentanyl and/or fentanyl analog present in the samples submitted for analysis. Consequently, a quantitation method was developed on the LC/TQMS that is currently capable of quantifying five different fentanyl and fentanyl analogs. These compounds include fentanyl, acetylfentanyl, carfentanil, furanylfentanyl, and cis-3-methylfentanyl. The five compounds selected for inclusion in this method were based on the samples submitted for analysis. Additional fentanyl analogs can be added should the need arise.

The nature of the samples submitted to the Drug Analysis Service Laboratories for analysis have changed over the years. This is especially true for those samples containing fentanyl-related compounds. The high sensitivity of LC/TQMS and LC/qTOF provides the forensic drug chemist additional tools in the identification and quantitation of these types of samples.

#### **Fentanyl, LC/TQMS, LC-qTOF**

### **B193 Using Silica-Hydrate-Based Stationary Phases for Dual-Mode Ultra High Performance Liquid Chromatography (UHPLC) Separation of Synthetic Cathinone Positional Isomers**

*Carly Ploumen, BS\*, Alexandria, VA 22302; Ioan Marginean, PhD, The George Washington University, Washington, DC 20007; Ira S. Lurie, PhD, The George Washington University, Washington, DC 20007*

**Learning Overview:** After attending this presentation, attendees will understand the great utility of silica-hydrate-based LC columns for the separation of synthetic cathinone positional isomers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing methodology that will enhance the separation power of traditional LC technology employed for the separation of positional isomers of emerging drugs by involving the use of silica-hydrate-based stationary phases, allowing for more accurate identification of these compounds.

Synthetic cathinones are a class of “emerging drug” commonly referred to and marketed as “bath salts.” Synthetic cathinones provide users similar psychostimulant and hallucinogenic effects as amphetamine, cocaine, and MDMA, but at a much cheaper price and with possibly lower legal liability. Like many other classes of emerging drugs (fentanyl, synthetic cannabinoids, and phenethylamines), many positional isomeric forms of synthetic cathinones exist, making identification of these drugs difficult for forensic laboratories.

Tandem techniques, such as Gas Chromatography/Mass Spectrometry (GC/MS) and LC/MS are employed for the analysis of emerging drugs. The identification of positional isomers using MS detection can be difficult, especially when substitution occurs on the benzene ring. Photo Diode Array Ultraviolet (PDA UV), vacuum-UV, and Fourier Transform Infrared (FTIR) detection for GC and LC have proved to be capable of distinguishing between some or all isomeric forms of these compounds. Due to the high degree of structural similarity between positional isomers, separation is often difficult. GC is commonly employed by laboratories to analyze synthetic cathinones, but derivatization and/or liquid-liquid extraction is normally required. LC (either characterized as High-Performance Liquid Chromatography [HPLC] or UHPLC) uses Reversed Phase Chromatography (RPC) or Hydrophilic Interaction Chromatography (HILIC) that allows for the direct analysis of these compounds. Due to the presence of a water layer formed during the chromatographic process, equilibration and repeatability in HILIC is challenging.

For Silica-Hydrate (SiH) -based stationary phases, under Aqueous Normal Phase (ANP) conditions, a negligible water layer exists surrounding the stationary phase. ANP chromatography, similar to HILIC, employs an aqueous mobile phase with high organic content. Unlike HILIC, equilibration times are shorter and run times exhibit good repeatability. Another favorable aspect of SiH columns is that they can be operated under both RP and ANP modes. This dual-mode capability is highly advantageous in that a single sample can be run under both chromatographic modes using the same solvent reservoir solutions without the need to change columns. This methodology yields orthogonal retention times and dual UV wavelength detection, thereby significantly increasing the reliability of compound identification.

A mixture of eight synthetic cathinone positional isomers was analyzed by UHPLC-PDA/MS. Several SiH columns (C18, Phenyl Hydride, UDC Cholesterol, Diamond Hydride, and Silica-C) were run under RP and ANP conditions. Results were compared to the use of classical RPC and HILIC columns: C18, Silica, and Pentafluorophenyl (PFP). The PFP column also exhibits dual mode capability. “Optimum” separation conditions were determined for each column, and column selectivity, reversibility, and repeatability were explored.

Significant selectivity differences were observed using bi-modal columns and between different stationary phases. The SiH Silica-C column, which contains no derivatized ligands attached to the silica-hydrate backbone, not only gave the most orthogonal separations of the bi-modal columns, but provided a unique separation of all 8 positional isomers (resolution>1) using ANP. Although the combination of RPC and HILIC columns gave the most orthogonal separations (with slightly greater selectivity than Silica-C stationary phase), allowing for a separation of all the positional isomers, poor repeatability was obtained using HILIC. In contrast, the Silica-C column, under ANP conditions, produced great separation and repeatability. The ability to use a single column to perform two types of orthogonal chromatographic separations with good repeatability would be beneficial for the separation of positional isomers of emerging drugs.

#### **Silica-Hydrate Stationary Phases, Emerging Drugs, Positional Isomers**

### **B194 An Analysis of Emerging Benzodiazepines by Thermal Desorption/Direct Analysis in Real Time-Mass Spectrometry (TD/DART®-MS)**

*Sydney Jones, BS\*, Baltimore, MD 21209; Edward Sisco, PhD, NIST, Gaithersburg, MD 20899; Ioan Marginean, PhD, The George Washington University, Washington, DC 20007*

**Learning Overview:** After attending this presentation, attendees will better understand the capabilities of TD/DART®-MS to detect and identify benzodiazepines in pure form as well as in binary mixtures, complex matrices, and real case samples. Attendees will also gain an understanding of the capabilities and weaknesses of this technology and sampling strategies for presumptive screening.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing an optimized method for the use of an emerging technology, TD/DART®-MS, for the detection and analysis of the rising number of benzodiazepine analogs.

Novel Psychoactive Substances (NPSs) represent a prominent and increasing concern for forensic laboratories across the country. Benzodiazepines belong to one class of NPSs that has seen a growing presence in the United States. The rise of benzodiazepines, driven predominantly through the increased production and prevalence of counterfeit pharmaceutical tablets, may lead to another drug epidemic. The development of new techniques, or new methods for existing techniques, allowing for rapid detection and identification of these compounds is required for laboratories to rapidly respond to this emerging concern.

There is an increasing need for rapid, reproducible, and precise identification of NPSs such as benzodiazepines to assist presumptive and confirmatory analyses. As drug units across the country are facing overwhelming backlogs, the ability to rapidly characterize a drug sample, from a field collection, a swipe, or an extract, with a highly specific and reproducible screening technique could provide substantial progress in both reducing case backlog and lowering turnaround time. TD/DART®-MS was investigated in this work as a technology that can face these challenges. TD/DART®-MS, which is a modification of DART®-MS that incorporates a thermal desorption unit, has been shown to provide increased reproducibility, sensitivity, and analyst safety compared to traditional analyses. This modification also allows for analysis via swipes, instead of glass capillary tubes, which has been demonstrated to be an effective way to screen evidence or evidence packaging. This project aimed to develop and understand the capabilities to detect benzodiazepines using TD/DART®-MS.

The initial component of this study used a design of experiments approach to determine the key instrumental parameters and led to the creation of an optimized method. Parameters that were optimized included: DART® ionization gas, Vapor flow rate, thermal desorber temperature, and DART® exit grid voltage. The optimized method was then used to collect representative spectra and create a library at different fragmentation voltages for a suite of 19 different benzodiazepines. Sensitivity of the method was then determined by calculating the limit of detection for a select number of compounds and was found to be on the order of single nanograms per swipe. Studies were also completed to identify the effect common cutting agents, such as stearic acid, mannitol, lactose, and caffeine, and additional drugs, such as heroin, had on the ability to detect the benzodiazepines in mixtures. Additionally, the incorporation of three complex background matrices for swipe-based collection (fingerprints, dirt, and plasticizers) to the samples was completed to test potential ion suppression. Real case samples were also analyzed to demonstrate the utility of the technique for a practicing forensic laboratory.

This work demonstrates that rapid detection of benzodiazepines with nanogram sensitivity is achievable using TD/DART®-MS with minimal issues caused by complex matrixes and mixtures. The detection of low sample quantities can be advantageous to forensic scientists as it provides a sensitive and rapid analysis of target analytes using swipes of evidence packaging, evidence itself, or extracts.

### **B195 A Comparison of Expected Drug and Confirmed Findings in Samples Submitted by Clients of Supervised Consumption Sites in British Columbia**

*Aaron M. Shapiro, PhD\**, British Columbia Provincial Toxicology Centre, Vancouver, BC V5Z 4R4, CANADA; *Kenneth Tupper, PhD*, University of British Columbia, Vancouver, BC V6T 1Z3, CANADA; *Christopher Mill, MS*, Public Health Agency of Canada, Ottawa, ON K1A 0K9, CANADA; *Samuel Tobias, MS*, British Columbia Centre on Substance Use, Vancouver, BC V6Z 2A9, CANADA; *Olanrewaju Kayode, BS*, British Columbia Provincial Toxicology Centre, Vancouver, BC V5Z 4R4, CANADA; *Priya Patel, MPH*, British Columbia Centre on Substance Use, Vancouver, BC V6Z 2A9, CANADA; *Lianping Ti, PhD*, British Columbia Centre on Substance Use, Vancouver, BC V6Z 2A9, CANADA

**Learning Overview:** After attending this presentation, attendees will understand the nature of the illicit drug supply in British Columbia, Canada, as it pertains to adulteration, contamination, and misrepresentation.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by addressing some common misconceptions about the nature of the illicit drug supply

**Background/Introduction:** Opioid-related deaths have increased dramatically in the past five years in British Columbia, which have mainly been driven by fentanyl and its analogs in the illicit drug supply. While there is speculation that fentanyl can be present in all types of illicit drugs, there is a paucity of literature that directly compares the expected drugs that are purchased illicitly with confirmed drug identification. Counterfeit tablets that resemble pharmaceutical opioids or benzodiazepines have been adulterated with fentanyl. Clinical and postmortem testing of biological samples often show co-occurrences of fentanyl and stimulants, which has led to speculation that stimulant drugs may also be adulterated with fentanyl. Identification of drug samples seized by border and police services in British Columbia has shown a co-occurrence of opioids and stimulants (such as cocaine and methamphetamine) of approximately 10%. However, it is not clear if seized drugs and toxicology results are representative of the local illicit drug supply. A better understanding of the drug supply is needed in order for policy makers, health care professionals, and harm reduction workers to assist in providing a less risky environment for people who use illicit drugs.

**Objective:** To characterize the illicit drug supply by comparing expected drug identity with results obtained from laboratory analysis.

**Method:** Clients at select supervised consumption sites in British Columbia, Canada, who utilize on-site drug checking services provided staff with information on the expected identity of their purchased street drug and approximately 5mg of sample. Powdered samples were submitted to the Provincial Toxicology Centre for analysis using Gas Chromatography with Mass Spectrometry (GC/MS) in full scan mode and compared to commercial libraries and in-house verified standards.

**Results:** In total, 223 samples were submitted for this study; 163 (73%) were primarily expected to be opioids, and 31 (14%) were expected to be cocaine or methamphetamine; the remaining 29 (13%) samples were not expected to contain opioids, cocaine, or methamphetamine. Among all expected opioids, 125 (77%) had fentanyl detected, 20 (12%) had methamphetamine detected, and 7 (4%) had cocaine detected. Fentanyl was the expected substance in 48% of submitted samples. Of those expected to contain fentanyl by clients ( $n=107$ ), 83% contained fentanyl. Expected fentanyl samples that did not contain fentanyl had at least one of: diacetylmorphine (i.e., heroin), a fentanyl analog, or a synthetic cannabinoid. One expected fentanyl sample contained only methamphetamine. Heroin was expected in 23% of submitted drugs. Among the 30 samples that were purchased as heroin, 73% had heroin detected and 50% had fentanyl detected. Expected stimulants were generally in good agreement with detected substances. However, two expected cocaine samples contained fentanyl but did not contain any stimulants. Of the five counterfeit “Xanax” tablets that were submitted, none contained alprazolam but did contain other central nervous system depressants, including fentanyl analogs, etizolam, and antihistamines.

**Conclusion/Discussion:** Illicit opioids and benzodiazepines often contain fentanyl or its analogs, regardless of expected substance. Stimulants are generally not adulterated with opioids or other depressants. However, two cases were identified in which fentanyl but not cocaine was present in expected cocaine samples. This may be due to a number of reasons, including mislabeling, accidental misclassification, or intentional adulteration. Efforts to increase sample size for expected stimulants are underway.

#### **Drug Identification, GC/MS, Illicit Drug Supply**

### **B196 Identifying Powdered Illicit Drugs Using Magneto-Archimedes Levitation (MagLev), Signal Processing, and Digital Finger Printing**

*Christoffer K. Abrahamsson, PhD\*, Harvard University, Cambridge, MA 02138; Markus P. Nemitz, PhD, Harvard University, Cambridge, MA 02138; Michael J. Fink, PhD, Harvard University, Cambridge, MA 02138; Daniel J. Preston, PhD, Rice University, Houston, TX 77005; Joe Bozenko, MSc\*, Dulles, VA 20166-9509; George Whitesides, PhD, Harvard University, Cambridge, MA 02138*

**Learning Overview:** After attending this presentation, attendees will have learned how MagLev can be used to separate and determine the composition of powdered mixtures. This presentation will focus on how signal processing of the MagLev data is used to generate digital fingerprints that are used for automated identification and attribution of illicit drugs (e.g., fentanyl and its analogs, heroin, methamphetamine, and cocaine) in powdered mixtures with adulterants and diluents.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by illustrating how the use of density-based analysis techniques and signal processing methods can simplify and accelerate the analysis of complex mixtures found in forensics. The digitalization of the MagLev data enables comparison with previously characterized samples, and this could aid forensic chemists in achieving attribution of their samples.

**Methods:** Dry and powdered samples are suspended in a solution of a non-polar paramagnetic gadolinium(III) chelate in a non-polar solvent inside a cuvette (polar compounds do not dissolve as they separate in the paramagnetic solution). The cuvette is placed between two magnets with like poles facing each other. The balance of forces (magnetic, buoyancy, and gravity) form a linear density gradient along the vertical axis of the cuvette, in which the individual components of the powder equilibrate at their characteristic density, forming a levitation profile. By photography, image analysis and digital classification (Dynamic Time Warping [DTW] and DTW Barycenter Averaging), the sample is automatically attributed to a class (a digital fingerprint), such as mixtures of “lidocaine-HCl” or “caffeine,” and entered into a database of class representations of mixtures of powdered drugs. Unknown mixtures are compared to the class representations to determine their maximum likelihood-classification.<sup>1</sup>

**Results:** MagLev and signal processing techniques were applied to three problems relevant to the testing of illicit drugs: (1) identification of individual components (fractions) in powdered mixtures using automated signal processing of levitation profiles. In addition, classification techniques are used for the identification of components in mixtures of unknown composition (e.g., an unknown fraction of lidocaine HCl is identified in a powdered mixture from multiple different class representations, including fentanyl-HCl, heroin-HCl, acetaminophen, levamisole HCl, lactose, mannitol, and sucrose); (2) the abundance of lidocaine-HCl and caffeine in binary mixtures of different compositions were determined; and (3) classification techniques were used for the attribution of powdered samples identifying potential matches (batch and formulation) between previously characterized samples in a laboratory database.

**Conclusions:** MagLev is a rapid and portable method for screening of drugs. It separates mixtures into their individual components and reduces the time for identification of illicit drugs. This method establishes and uses a database of digital fingerprints of powdered mixtures of illicit drugs. In the future, the database could be combined with data about the point of seizure and a time stamp map drug trafficking patterns. The device and analysis methods are adaptable to other applications, such as powdered chemicals, food products, or explosives.

## B197 Machine-Learning (ML) Approaches for Source Attribution of Forensic-Relevant Materials

Josh Dettman, PhD\*, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02420; Amanda M. Casale, Massachusetts Institute of Technology Lincoln Laboratory, Lexington, MA 02421

**Learning Overview:** After attending this presentation, attendees will better understand how Artificial Intelligence (AI) ML algorithms are enabling new applications requiring the classification of large data sets, including extracting conclusions on the source of materials using chemical and physical signature data.

**Impact on the Forensic Science Community:** Applications of AI and ML techniques are growing rapidly, including in forensic science. This presentation will impact the forensic science community by increasing competence in ML by introducing potential ML approaches and disseminating methods for material source attribution to the operational community and other researchers.

Source attribution of materials involved in a crime using chemical and physical signatures can be an important technique for generating investigative leads on the origination location (source) of the material and potential association with a suspect. Proof-of-concept studies of this type have been performed for a variety of materials of forensic and commercial importance. Chemometric or, more generally, ML techniques can be used to extract conclusions from the relatively high-dimensional data collected and estimate the probability that a sample originated from a specific source. This presentation will describe the development of a composite ML sourcing algorithm utilizing multiple tiers of supervised ML classification methods, data conditioning, bootstrap supplementation of reference data, and probability-weighted results fusion to estimate the probability of source membership of fertilizer samples based on chemical and physical signature data.

Reference samples of fertilizer were obtained from known commercial and industrial sources. For most sources, only single samples were available (single-lot sources); however, nine to ten samples were collected over a period of five months from two sources (multi-lot sources) to estimate signature variance over time. After evaluation of many potential signature types, the final set of signatures collected from the reference samples was comprised of reflectance spectra (color), particle morphology (size/shape), and trace element composition. This data was subjected to limited conditioning (e.g., conversion from intensity to element concentration by a calibration curve, calculation of color, and shape summary variables). Additional bootstrapped reference data for algorithm training was performed based on the signature means (by source) and largest experimentally measured variance for each signature (by source and lot). Increasing the signature variance above what was empirically measured incorporates an estimate of source variance (not otherwise possible with the largely single-lot source sample set) and provides a more conservative and, notionally, realistic estimate of operational classification performance.

The relative probability that the unknown sample arose from one of the reference sources (or from a previously measured unknown source) is determined using a composite ML algorithm consisting of three parts: (1) elimination of the least likely sources using a  $k$ -Nearest Neighbors ( $k$ -NN) classifier for each of the three signature types; (2) a Multinomial logistic Regression (MNR) classifier to aid the examiner in assessing if a reference sample matching the unknown sample is present in the reference database or not; and (3) three random forest classifiers (one for each signature type) for final estimates of the relative match probability for the unknown sample to each of the remaining sources from the reference database. The source probabilities from the random forest classifier for each signature type are weighted by  $z$ -score across all of the source probabilities, then averaged and normalized to give “fusion scores” that are relative weighted probabilities. The individual signature and fused relative probabilities, as well as the raw signature data, are presented to the examiner in a user-focused web interface for further analysis and a source assignment decision.

To estimate the algorithm performance conservatively and as realistically as possible given inherent sample collection limitations, cross-validation testing was done by holding out signature data from entire lots (rather than a random subset of single samples) during training and using the entire held-out lots for subsequent testing. For the samples from 23 fertilizer sources that were tested, the correct source is chosen in cross-validation as the most likely source 87% of the time and is an average of 2.3 times as likely as the most probable incorrect source. These relatively accurate and confident sourcing results, even under conservative performance estimate conditions, indicate the promise of the signatures and composite ML sourcing algorithm for determining the source of unknown fertilizer samples.

### Machine Learning, Artificial Intelligence, Attribution

### B198 A Regression-Based Algorithm to Maximize the Confidence in Mass Spectral Identifications

Samantha A. Mehnert\*, West Virginia University, Morgantown, WV 26506; Brandon D. Lowe, St. Vincent College, Latrobe, PA 15650; Emily Ruiz, West Virginia University, Morgantown, WV 26505; J. Tyler Davidson, MS, West Virginia University, Morgantown, WV 26505; Glen P. Jackson, PhD, West Virginia University, Morgantown, WV 26506-6121

**Learning Overview:** After attending this presentation, attendees will have learned the major sources of random and non-random variance in mass spectrometric analyses and the value of ion correlation analysis. Attendees will also know how to use the correlation that exists between ion abundances in replicate spectra to make compound identifications that are more confident and more accurate than existing algorithms.

**Impact on the Forensic Science Community:** This presentation will provide the forensic science community with a mathematical model for compound identification from mass spectrometric data that is more accurate and more precise than current static/discrete methods. The application of a more selective algorithm will decrease the incidence of false positives and further assist with the identification of unknown compounds in casework.

**Hypothesis:** It was hypothesized that a mathematical model that takes into account the covariance between ion abundances will provide better discrimination between true positives and true negatives than an algorithm that does not take into account the covariance between ion abundances, and for the model to work, several other hypotheses about the data must be also be true, one of which is the expectation that the residuals in the predictions should be normality distributed.

**Methods/Results:** Current mass spectrometric methods of substance identification use a “static” algorithm to determine the identity of a substance. The “static” approach assumes that there is one “best” or average exemplar of a substance in a library against which unknowns are compared. However, the variance in ion abundances for replicate spectra is around  $\pm 20\%$  (95% Confidence Level [CL]), which can result in false positives in substance identifications. Instead, the algorithm uses a multivariate general regression model between ion abundances to make ion abundance predictions within a measured spectrum.

A mixture containing five drug standards was analyzed several times a day for approximately two weeks. From the approximate two dozen Gas Chromatography/Electron Ionization/Mass Spectrometry (GC/EI/MS) data files, hundreds of unaveraged mass spectra of each drug were extracted and split into a training set and an external validation set. The ion abundances were normalized to the base peak for each drug, and the 15 most abundant ions were selected iteratively to be the dependent variables within the general linear models. The model predicted ion abundances at each  $m/z$  value, and these predicted abundances were then compared to the measured spectra using Pearson Product-Moment Correlations (PPMCs) or Root Mean Squared Errors Of Predictions (RMSEP). The PPMC values for known positives and known negatives are then compared to a range of different threshold PPMC values to assess the True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) rate at each threshold. These assessments were used to construct Receiver-Operator Characteristic (ROC) curves, which provided Areas Under the Curve (AUC) of 1, or errorless classification. A separate test was conducted to assess the number of spectra necessary to create an accurate model for a certain compound. Varying numbers of spectra were used to create general linear models, and the PPMC values and Root Mean Square Errors (RMSEs) were compared.

Whereas the AUC of ROC curves for the prediction of external validation spectra was 1 for each drug model, the PPMC threshold at which no mistakes were made varied slightly for each drug. For example, diacetylmorphine and fentanyl required PPMC thresholds between  $\sim 0.5$ – $0.625$  to distinguish TPs from TNs, but cocaine, ecgonine methyl ester, and 6-monoacetylmorphine required PPMC thresholds of  $\sim 0.88$ – $0.95$  to achieve the same errorless identifications. When changing the number of spectra used to make a  $\Delta^9$ -tetrahydrocannabinol model, a model constructed from as few as 30 spectra performed just as well as a model built with 200 spectra.

The opinions, findings, and conclusions or recommendations expressed in this publication/program/exhibition are those of the authors and do not necessarily reflect the views of the Department of Justice.*

#### Dynamic Algorithm, Mass Spectrometry, Ion Correlations

### **B199 Detection and Differentiation of Derivatized Controlled Substances by Gas Chromatography-Vacuum Ultraviolet (GC-VUV) Spectrophotometry**

*Zackery Ray Roberson, BS\*, Indiana University Purdue University Indianapolis, Indianapolis, IN 46202; Heather C. Gordon, Indiana University Purdue University Indianapolis, Indianapolis, IN 46202; John V. Goodpaster, PhD, FIS Program, Indianapolis, IN 46202*

**Learning Overview:** The goal of this presentation is to bring an understanding of GC-VUV spectrophotometry as applied to derivatized controlled substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by highlighting the capabilities of GC-VUV spectrophotometry to detect and differentiate derivatized controlled substances.

GC-VUV is a technique with the ability to differentiate isomers based on their spectra and is complimentary to Mass Spectrometry (MS). By probing sigma bonds and high energy pi bonds in the region of light from 120–430nm, every molecule aside from diatomic hydrogen can be detected. As interest in the technique grows, questions arise such as how various derivatization reactions change the spectrum of a molecule. To answer this question, the change in spectra by silylation and acylation of drugs, including methamphetamine, methcathinone, ephedrine, pseudoephedrine, fentanyl, and carfentanil, were analyzed by GC-VUV.

Derivatization is performed when working with analytes having low volatility, thermal instability, or when functional groups known to adversely affect the chromatographic performance of the analyte are present. By exchanging polar or active groups with more non-polar or inactive groups, increased volatility and improved chromatographic performance on polydimethylsiloxane columns can be obtained. Derivatization also improves the thermal stability of compounds such as methcathinone, which is known to degrade with time, temperature, and light exposure. When analyzed by GC/MS, derivatized compounds experience a shift in retention time and fragment ions with increased mass based upon the added functional group(s). Using GC-VUV, the retention time shift is maintained, but the difference is seen in absorptivity. Acylating reagents such as Trifluoroacetic Anhydride (TFAA) add a new pi-bond to the molecule that is detected in the VUV spectrum, alkylating and silylating reagents will adjust the sigma-bond regions. Vibronic coupling of the molecules will result in altered spectra based on distance of the functional groups to VUV absorptive groups within the molecule. Compounds with no active hydrogens, such as fentanyl and several of its analogs, require a different derivatization reagent, such as Pentafluorobenzyl-Hydroxylamine (PFBHA), an acylation reagent, to react with the ketone group.

Results indicate improved response in the pi-bond region of the spectra for acylation derivatization of most compounds. Improved response leads to increased peak area, which produces lower limits of detection and quantitation than for non-derivatized forms of the same drug. Peak shape in the form of asymmetry also improves for compounds with active functional groups (i.e., methamphetamine). Several de-identified “street” samples were analyzed to show “real world” performance.

It should be noted that VUV has difficulties differentiating small alkanes and should be considered as complimentary to GC/MS rather than as a replacement. Overall, GC-VUV continues to show promise for future use in forensic drug analyses as a technique complimentary to GC/MS.

*This work was funded by a grant from the National Institute of Justice and does not necessarily reflect the opinions of the National Institute of Justice.*

#### **GC-VUV, Derivatization, VUV Detection**

### **B200 An Evaluation of Four Fentanyl Colorimetric Testing Options for Field Use**

*Michelle Cerreta, PhD\*, Drug Enforcement Administration, New York, NY 10011; Brian A. Green, BS, Drug Enforcement Administration, New York, NY 10011; Maolin Li, Drug Enforcement Administration, New York, NY 10011*

**Learning Overview:** After attending this presentation, attendees will be familiar with multiple, available, on-site colorimetric test kits for fentanyl and the most effective choice for field work in terms of accuracy. Attendees will see the challenges encountered when field testing fentanyl analogs and mixtures with colorimetric test kits.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by providing a side-by-side comparison of four available fentanyl field test kits evaluating accuracy, reliability, and ease of use. Determining the best method for on-site fentanyl detection will allow for safer handling and securement of fentanyl for law enforcement personnel.

Over the past several years, the country has experienced a surge of opioid use, specifically a rise in the synthetic opioid, fentanyl. The rise of fentanyl use has led to many concerns. Most alarming are the dangers associated with its potency, as well as the risk of accidental exposure as the drug is a known inhalation and contact threat. These facts have led law enforcement personnel to improve on-site protocols looking for efficient, safe, and accurate field detection methods for the detection of fentanyl. The purpose of this research was to evaluate four colorimetric fentanyl field tests to determine the most accurate and reliable method for fentanyl field detection, taking into account ease of use for untrained personnel to easily evaluate a scene when unknown powders are present. Early detection could allow other law enforcement personnel responding to the incident to upgrade their Personal Protection Equipment (PPE) and keep the area contained for the safety of bystanders. Field detection of fentanyl could also contribute to safer handling, packaging, transporting, or shipping of evidence for analysis or court-related proceedings. Additionally, chemists or those further handling the evidence could be alerted to the potential risks of the exhibit.

This evaluation focused on the colorimetric tests' ability to detect known fentanyl and some of its common analogs and fentanyl in mixtures, such as in a mixture with heroin. One hundred case samples were evaluated using four field colorimetric tests: the Presumptive Drug Test (PDT) Fentanyl Reagent Box, the Narcotic Analysis Reagent Kit (NARK II), the MDT Fentanyl, and the MMC Fentanyl/Oxycodone, Heroin/Morphine, Codeine Test Kit. When assessing whether each of the four colorimetric tests would correctly identify the primary controlled substance present in each case sample, the NARK II correctly presumptively indicated fentanyl 77% of the time. As for correctly identifying fentanyl samples and mixtures containing fentanyl or fentanyl-related compounds, the NARK II colorimetric test presumptively indicated fentanyl correctly 50% of the time, while the PDT colorimetric test correctly presumptively indicated fentanyl 75% of the time. The results indicated that NARK II indicates heroin instead of fentanyl in mixtures where both heroin and fentanyl are present. While the PDT color test outperformed the NARK II in terms of fentanyl detection, the PDT test also had the most false positives than the other tests evaluated. Based on the colorimetric test results coupled with the preliminary observations, the NARK II colorimetric test had a higher presumptive indication rate for fentanyl/heroin identification in the field out of the four colorimetric tests evaluated.

### B201 Investigating the Robustness of a Statistical Method to Compare Mass Spectra of Fentanyl Analogs

Hannah Clause, BS\*, Michigan State University, Holt, MI 48824-2926; Victoria L. McGuffin, PhD, Michigan State University, East Lansing, MI 48824-1322; Ruth Waddell Smith, PhD, Michigan State University, East Lansing, MI 48824

**Learning Overview:** After attending this presentation, attendees will be familiar with a method for the statistical comparison of mass spectra that can be used as a tool to increase confidence in identifications. Positional isomers of Fluorobutyryl Fentanyl (FBF) and Fluoroisobutyryl Fentanyl (FIBF) will be used to demonstrate application of the method, taking into account the effect of concentration and mass spectral tune conditions on the association and discrimination of the isomers.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by describing a method by which two mass spectra can be compared statistically to increase confidence in controlled substance identification, which is especially useful for positional isomers and other structurally similar compounds.

The typical method for the identification of controlled substances is to analyze samples using Gas Chromatography/Mass Spectrometry (GC/MS) and to perform a visual comparison of the resulting mass spectrum to a suitable reference spectrum. However, for spectra of structurally similar compounds, visual comparison of spectra for identification can be challenging. Previous work in the Michigan State University laboratory focused on the development of a statistical method to compare the mass spectrum of an unknown sample to a suitable reference spectrum using an unequal variance *t*-test. In this approach, *t*-tests are used to statistically compare the mean abundances at every corresponding *m/z* value in the scan range for the two spectra at a user-defined confidence level. The null hypothesis ( $H_0$ ) being tested is that the difference between the mean abundances of a given *m/z* value is equal to zero. The alternative hypothesis ( $H_a$ ) states that the difference between the mean abundances of a given *m/z* value is not equal to zero. If  $H_0$  is accepted at each *m/z* value, the two spectra are statistically indistinguishable and a random-match probability is calculated to estimate the probability that the fragmentation pattern occurred by random chance alone. However, if  $H_a$  is accepted at any *m/z* value in the scan range, the two spectra are statistically distinguishable, and the ions responsible for discrimination are identified.

The statistical comparison method has been applied to differentiate amphetamine-type stimulants as well as positional isomers of ethylmethcathinone and fluoromethamphetamine. While the method has shown potential for differentiation of isomers, in the current work, the robustness of the method is tested by investigating the effect of analyte concentration and the effect of mass spectral tuning on the ability to associate and discriminate isomers.

In this work, GC/MS was used to analyze two sets of fentanyl isomers, which included the *ortho*-, *meta*-, and *para*- forms of FBF and the *ortho*-, *meta*-, and *para*- forms of FIBF. Compounds within each set were initially analyzed under equivalent conditions over several days, and the resulting spectra were statistically compared to assess association of corresponding isomers with discrimination from the others.

Initial results indicate the potential of the method for differentiation of these isomers. For example, spectra of corresponding isomers of FBF were statistically associated at the 99.9% confidence level with discrimination from the other FBF isomers. More specifically, *ortho*-FBF was discriminated from *para*-FBF and *meta*-FBF at the 99% confidence level with nine ions responsible for discrimination in each case, including common ions of *m/z* 44, 71, 102, 118, 144, 164, and 171. Similarly, *para*-FBF was discriminated from *meta*-FBF at the 99% confidence level, with three ions responsible for discrimination, *m/z* 44, 176, and 234. A long-term study is currently being conducted to investigate the effect of concentration and the effect of mass spectral tune conditions on the association and discrimination of these isomers.

In this presentation, the statistical method and ions responsible for discrimination will be described in more detail. Further, the results of the long-term concentration and tune studies will be presented to demonstrate the robustness of the method.

#### Mass Spectral Comparison, Fentanyl Analogs, GC/MS

### **B202 The Differentiation and Identification of Fentanyl Analogs Using Gas Chromatography Interfaced With an Infrared Detector (GC/IRD)**

*Agnes D. Winokur, MS, Drug Enforcement Agency, Southeast Laboratory, Miami, FL 33182; Lindsay M. Kaufman, BS\*, Drug Enforcement Administration, Miami, FL 33182; Jose R. Almirall, PhD, Florida International University, Miami, FL 33199*

**Learning Overview:** The goals of this presentation are for attendees to : (1) obtain a better understanding of the analytical challenges associated with fentanyl-related substances; and (2) obtain knowledge and understanding of how to apply GC/IRD methodologies for the separation and identification of fentanyl-related substances.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by explaining how GC/IRD methodologies can be optimized to rapidly detect and identify structurally similar fentanyl-related substances in complex mixtures when conventional analytical techniques yield limited information.

The United States declared a national public health emergency in October of 2017 in response to the Opioids Crisis. Since 2014, there has been a significant increase of drug-related deaths attributed to the abuse of opioids, with more than 60,000 deaths in 2017. Fentanyl and related substances are among the opioids having the most impact on drug overdose deaths. Following the trend of fentanyl-related overdoses, there has been a dramatic increase of fentanyl-related, seized drugs being submitted and analyzed in crime laboratories. The structure of these drugs continues to be manipulated to generate new structurally similar substances challenging the rapid detection, identification, and reporting of these novel fentanyl substances, which is vital to the assessment and understanding of the illicit drug markets in specific locations.

Forensic scientists routinely utilize Electron Impact/Gas Chromatography/Mass-Spectrometry (EI/GC/MS) for the separation and identification of substances in drug samples; however, the use of GC/MS for the analysis of fentanyl samples comes with analytical challenges and limitations. Fentanyl analogs and their positional isomers have similar chemical structural configurations, making them difficult to detect and identify. GC/IRD is a useful and powerful tool in separating and identifying many of these compounds, for which traditional analytical techniques offer limited differentiations between them. In this study, it has been shown that similar fentanyl analogs (2- and 3- furanylfentanyl, 2-furanylbenzylfentanyl, crotonylfentanyl, cyclopropylfentanyl, methoxyacetylfentanyl, meta-fluoroisobutyryl fentanyl, and ortho-fluoroisobutyryl fentanyl) can be detected and identified using GC/IRD and optimization of GC/IRD parameters can enhance the resolution and detection of these substances. In particular, the effects of light pipe temperatures, resolution, and programmed temperature vaporizing have been studied.

### B203 Data Mining the War on Drugs From Incarceration to Rehabilitation in Oklahoma

Ruthie O. Kennedy\*, Cameron University, Lawton, OK 73505; Kathleen E. Brown, University of Central Oklahoma, Edmond, OK 73034; Joselina Cheng, PhD, University of Central Oklahoma, Edmond, OK 73034; Rhonda C. Williams, PhD, Oklahoma State Bureau of Investigation, Edmond, OK 73034

**Learning Overview:** The goal of this presentation is to correlate changes in the law and incarceration trends over the past four decades in Oklahoma.

**Impact on the Forensic Science Community:** This presentation will impact the forensic science community by relaying the effect of new drug laws on the addicted population of Oklahoma.

The war-on-drugs era began in the 1980s and progressed through the 1990s and even through today. This era was remarkable due to courts giving harsher sentences for drug possession and distribution, which caused the prison population to grow from approximately 300,000 to 800,000 in only a decade.<sup>1</sup> The 2017 Bureau of Justice Statistics report showed there were more than 1,439,808 incarcerated individuals. The number of people incarcerated for drug offenses was 40,900 in 1980 and 452,964 in 2017.<sup>1</sup> This increase has caused overpopulation in the prisons and very little hope for rehabilitation. In 2017, the State of Oklahoma passed legislation reducing possession drug charges to misdemeanors in an effort to rehabilitate through drug treatment programs instead of prison time. The theory is that fewer individuals would be incarcerated on drug charges and that some may even receive help that could reduce recidivism and crime escalation. The fees for their misdemeanor charges were to be used to help with rehabilitation programs. The data mining study started with a sample size of 50 randomly selected individuals from Oklahoma that was selected from each of the decades of the 1980s, 1990s, 2000s, and 2010s. There was also an additional data group selected from 2017 to 2019, when possession of drugs was reduced to a misdemeanor. In addition to gender and ethnicity, data were broken down into the most common crime categories: Assault & Battery, Possession/Distribution of Controlled Drug Substances (CDS), Larceny, Burglary, Robbery, and Homicide/Manslaughter. Data were compiled and used to report the highest crimes from each category. There were also data on drug charges and the typical incarceration time seen over the decades. The uniform crime report provided by the Oklahoma State Bureau of Investigation showed a 7.5% decrease in drug arrests from 2016 to 2017.<sup>2</sup> Sample-sized data over the 1980–1990 periods suggested that Burglary and Possession of CDS had the highest frequency/count and may be linked, and this pattern continued over the decades. Newer data from 2017 did not show as significant a decrease in drug charges as expected, probably due to the lagging court system. However, data from 2018 is slowly showing a decrease in drug charges in comparison to previous years. As 2019 data are still being collected, it seems that drug charges may actually be slightly decreasing, especially when referring to possession charges. Tracking the changes over time may determine the effectiveness of the newly instituted misdemeanor drug laws in Oklahoma: 2018 total drug arrests—35,596; 2017 total drug arrests—38,996; 2016 total drug arrests—42,182; 2010 total drug arrests—37,398; 2006 total drug arrests—41,164; and 2002 total drug arrests—40,662.
